Recruits have been coming in rather slowly but at present the battalion is about two-thirds strength in enlisted men and one-third in officers. Training conditions are unsatisfactory, due to the numerous Division details and schools.

Maj. R. G. MOSES left the organization at Del Rio, being transferred to the 318th Engineers at Camp Grant, Illinois.

Capt. R. F. FOWLER joined the column at Comstock and assumed command at Del Rio, on the departure of Major Moses.

Lieutenants MARLOW and GREEN left on June 10th to attend school at the Boston Tech. This leaves the battalion without any lieutenants.

ENGINEER TROOPS IN GERMANY.

Lt. Col. B. A. MILLER, *Chief Engineer.*

The activities of the Chief Engineer's Section, American Forces in Germany, consist in general, of carrying forward the projects in construction, renovation of existing installations, barracks, buildings, procurement of articles and materials for construction and equipment and the furtherance of the Public Utilities.

Vocational schools are conducted with satisfactory results.

Employment of Engineer troops.—Engineer troops are engaged in construction, operation of depots and dumps and infantry exercises. The latter included a review by the Commanding General, American Forces in Germany, at Ransbach, 15 kilometers northeast of Coblenz, on March 5th, followed by field maneuvers March 6th-9th, inclusive.

Approximately 40 per cent of A Co. engaged during March in construction, in making necessary repairs and alterations in the target ranges of the First Brigade, in infantry exercises and in duties of engineers, including normal engineer instruction in bridges, reconnaissance, and pioneering. In addition, a course in musketry was inaugurated in preparation for the coming target practice season.

During the maneuver period, this organization engaged in problems comprising:

1st. Rail movement to review field at Ransbach with review and march to billets at Elgendorf.

2nd. Infantry action involving repulse of an army after a "break-through."

3rd. Organization and consolidation of position, including accessory defenses.

4th. Withdrawal problem—one platoon being assigned to each battalion of infantry for demolition of bridges, destruction of roads and ferries.

5th. Concentration of troops and a return to quarters by brigade march.

Co. "B," organized as a special railway operating unit, continued its training in railway operation activities. The officers and enlisted men in this organization not so engaged received instruction and training in infantry work. This organization is at present armed with rifles, and future extensive training is to be undertaken with this arm to secure maximum efficiency in its use. The problems undertaken by this organization during the field maneuvers consisted entirely of those dealing with the railways of the bridgehead in relation to capacity and movement of troops, transportation, and supplies over such railway lines.

D Co. continues to furnish the personnel for the operation of the Engineer dump at Andernach and has charge of construction, alterations and repairs in the Second Brigade area. In general terms, the problems assigned to this company during the field maneuvers differed but slightly from those assigned to Co. A, though the organization was attached to the Second Brigade while A Co. was attached to the First Brigade.

Operation of public utilities.—Strikes and revolutionary disturbances at various times caused considerable annoyance, it having been necessary at one time to commandeer coal in order to continue in operation the Coblenz gas generating plant. The trolley service was interrupted frequently, due to a lack of fuel and industrial plants at Maven and Nieder Mendig were forced to close for nearly a week. Coal is moving more freely now from the Ruhr Basin, but the supply is still considerably short of the amount needed.

The water supply at Ehrenbreitstein has been increased by the addition of two wells.

Enlistment in the Regular Army.—Enlistments in the Army now average about 1,600 a week. There is a noticeable reduction in reenlistments, which thus far have not responded to the increase in pay. As an inducement to former service men, they are offered, in addition to the two months' leave, an assign-

THE PEASE PEERLESS

AUTOMATIC—CONTINUOUS—ELECTRIC

BLUE PRINTING EQUIPMENT

The Only Real One on The Market

PRINTS, washes and dries in one continuous operation. Can be installed in one end of drafting room, constantly under supervision of chief draftsman—occupies only 5½×6½ feet of floor space.

Made in four sizes—printing widths being 30″, 42″, 54″ and 66″, respectively.

No open wash trays. No wet floors. No lines of dripping prints. No waste of sensitized paper. No noisy and unreliable friction disks.

All speeds electrically controlled. Exposed paper or cloth is thoroughly washed, evenly dried, and delivered free from distortion or wrinkles, three operations in one.

Printer may be used (also purchased) independently from washer and drier, if desired.

MAXIMUM output with one operator, 100 linear yards per hour. This obtained with a consumption of but 7 kw. electric energy, 50 cubic feet of gas and 60 to 70 gallons of water. If preferred, electricity instead of gas may be used for drying.

PEASE Peerless Blue Printing Equipment is used in all U. S. Government departments; in every navy yard and station; by all leading ship builders; railways, automobile, aeroplane and other manufacturers and by all important Commercial Blue Printers of the country—over 1200 in use in all. They are also to be found in successful operation in twenty foreign countries.

Write now for new catalog "B-26" which fully illustrates and describes these machines, and let us send you the names of some large firms in your neighborhood who have a Peerless installation.

ment to any branch of the service they may desire, and to any station, provided the particular service they wish has not been filled. This feature is also offered to any man enlisting for a three-year period, the only exceptions being the air service and the motor transport corps, assignments to which are covered by special regulations. Recruiting officers are instructed to report specially the effect of this liberal offer, and whether it acts as a deterrent to re-enlistments for home stations.

APPLICATIONS FOR APPOINTMENT IN THE REGULAR ARMY.

1. The War Department has on file a large number of approved applications, submitted during demobilization, of officers who served during the emergency and who desire permanent appointment in the Army under the provisions of Army reorganization legislation. No further action on the part of such applicants is necessary to insure consideration of their application at the proper time.

2. Emergency officers or former emergency officers who have not now approved applications on file in the War Department and who desire to make application should do so without delay.

3. Applications will be submitted on Form No. 739, A. G. O., and for persons now in the military service will be forwarded to The Adjutant General of the Army through military channels with recommendations. Applications of persons not in the military service will be mailed direct to The Adjutant General of the Army.

4. Application blanks, Form No. 739, A. G. O., may be obtained, upon request, at the headquarters of any divisional camp, at the headquarters of each military department or from The Adjutant General of the Army.

R.O.T.C.

ENGINEER UNIT AT MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

Maj. H. F. CLARK, *Engineers.*

This academic year is the first one in which the unit has been established, and there are three advanced students enrolled. The compulsory first two years of training has to be given by the technical officers on duty, and the Engineer Officer has given thirty lectures on engineer duties, etc., to the Sophomore class of 620 students.

Attendance at an Institute Summer Survey Camp makes a good supplement to the six weeks at Camp Humphreys, and engineer students of the lower classes can attend both and have no surplus time to spend during the summer.

Charts have been prepared from the various A. E. F. notes and data, and lantern slides, which are used to illustrate the lectures given. Considerable interest has been taken in the charts and many questions asked by the students. Since all the sophomore military science work is theoretical, some novelty, in a few lectures, has been improvised in order to break the monotony.

A small model of a piece of artillery was camouflaged and discharged before one class to demonstrate flat-tops, trap-door cover to piece, etc. A section of double-apron wire entanglement was erected on the platform before another class, using tape for the wire and setting the screw pickets in cast-iron standards.

The lecture on explosives was amplified by timing various kinds of fuse and exploding an electric cap by the exploder box. This lecture, and its details, seemed to be more appreciated by the students than any other.

A class of about 25 advanced engineers is expected to be enrolled next year. The summer camp this year will have about 25 men from Tech.

ENGINEER UNIT AT WEST VIRGINIA UNIVERSITY.

Capt. H. SWENHOLT, *Engineers.*

The Engineer Unit West Virginia University R.O.T.C. really started work on October 20, 1919. The number of students enrolled in the unit is 78, of which 17 are contract men taking the Advanced Course, 27 are enrolled in the Basic 2 course and 34 in the Basic 1 course.

The amount of time allowed by the University authorities for military instruction amounts to four hours per week. In order to fulfill the requirements of five hours' military instruction per week specified by Special Regulations, No. 44, it is necessary to hold military periods Saturday afternoons during the early spring. This fits in nicely, as more and better work is accomplished in one four-hour period than could be accomplished in four one-hour periods. Especially is this true of the course in Military Map Making, and in the tracing of field fortifications.

The Engineer Unit is organized into a separate Engineer Company, and all the officers are members of the Advanced Class. It is a particularly well-drilled company, due to the fact that the cadet officers are excellent, and also to the fact that the material comprising the Engineer Company consists of exceptionally high-class men. Only those men were enrolled in the Engineer Unit who expressed a preference for that branch of the service. For that reason we were assured that a good spirit would prevail in the organization. A very large percentage also of the men now enrolled in the unit and not in the Advance Class will sign the contract and will become eligible for Reserve Commissions in the Corps of Engineers. This supposition is warranted because of the fact that of the 17 men of the entire corps that signed the contract at the beginning of the present semester, 8 were members of the Engineer Unit.

While it is true that the situation described above tends to make a better Engineer Unit, it is a question as to whether it should be continued. The Corps of Engineers is not benefited as much as it would be if more men received the Engineer Instruction, even though they did not eventually sign the contract. At the present time a plan is being considered whereby every man entering the University and taking an Engineering course will be automatically assigned to the Engineer Unit and transferred to the Infantry Unit only if he specifically makes a request for such transfer. Heretofore the reverse has been the case, and it has been found difficult to interest students who already have an assignment and perhaps N. C. O. rank in the Infantry Unit.

The Engineering Faculty of the University co-operates in every way possible with the Military Department. Every request made by the Military Department has received courteous consideration and has been granted. Credit for a summer course has been granted to students who attend a Basic Summer Camp. The Engineering Courses, however, are very rigid, and students have no opportunity to elect different subjects, as in the Letters and Science Courses. The military work is compulsory for all physically fit students during the Freshman and Sophomore years. Students in Engineering, however, who elect to take military work during the last two years and sign the contract, can not substitute this military work for some other course. It is additional work for the student concerned. No effort has been made as yet to change this situation, as it is not considered desirable to have the student drop any course, which might greatly handicap him in his civilian occupation. Besides it would appear that the Military Department would be more successful and more efficiently fulfill the purposes of the R.O.T.C. as the quality of the men in the R.O.T.C. is raised, if these men can be drawn into the Corps in sufficient numbers.

THE R.O.T.C. AT THE UNIVERSITY OF ALABAMA.

Maj. CHARLES W. COCHRAN, *Engineers,* P. M. S. and T.

The University of Alabama is rich in historical interest. December 18, 1820, one year and four days after ratifying the Constitution, the General Assembly passed an act establishing the University.

The site for the erection of the buildings was selected 1¼ miles east of the courthouse of Tuscaloosa. The University was opened for the admission of students on April 12, 1831.

On April 4, 1865, Federal cavalry set fire to and completely destroyed all the buildings except the astronomical observatory. The erection of new buidings was begun in January, 1867, and the University was again opened for instruction April, 1869. The institution has grown steadily under the able management of its various presidents until today it ranks as one of, if not the leading, university of the South.

The military feature is no new experiment, as the school was for a number of years a noted military college.

The campus is not excelled for beauty by any in the United States, and the facilities for drill are excellent, while the grounds surrounding the University afford the best of opportunity for tactical and topographical training.

Three units have been organized here, viz., Engineer, Infantry and Coast Artillery, with a total enrollment of about 400. The course is compulsory for freshmen and sophomores and open to other students who desire to enroll. Total credits for a degree required by the University are 60, of which 6, or ten per cent, are allowed the student taking the four-year military training. Three officers, one for each unit, and six enlisted men are detailed for instructions.

The training has been carried on in compliance with S. R. 44.

A rifle team of 20 members has been organized to compete for the championship of the Southeastern Department R.O.T.C. Arrangements are under way for a big military field day, consisting of mass athletics and competitive drills. The program to be arranged so as to give every man an opportunity to show what he can do.

Prizes will be offered in the following events: Company baseball team, company track team, relay race, high jump, broad jump, boxing, tug-of-war, company having best rifle team, best-drilled company, company having fewest absences during year, company showing up best at inspection, best-drilled cadet, best-drilled squad. The business houses of Tuscaloosa have offered the prizes. Perfect harmony exists between the University and the R.O.T.C., and a live, progressive unit is the result.

Personals

Changes in personnel.—The following changes in the commissioned personnel of the Corps of Engineers have occured since the last issue of THE MILITARY ENGINEER:

Maj. Gen. LANSING H. BEACH has been appointed a member of the Board of Ordnance and Fortification, relieving Maj. Gen. William M. Black, U. S. A., retired, of that duty.

Brig. Gen. WILLIAM D. CONNOR has been assigned to the command of Camp A. A. Humphreys, Va., and the Engineer School, relieving Col. Clement A. F. Flagler.

Col. E. EVELETH WINSLOW has been appointed Division Engineer of the Pacific Division, relieving Col. Charles L. Potter. In addition to the above duty, Colonel Winslow has been detailed in the 18th Lighthouse District, relieving Colonel Potter.

Col. CHARLES L. POTTER has been appointed Division Engineer of the Western Division, and detailed in the 15th Lighthouse District, relieving Col. Curtis McD. Townsend, retired.

Col. HARRY TAYLOR has been appointed a member of the Anchorage Board, representing the War Department, relieving Maj. Gen. Lansing H. Beach.

Col. CLEMENT A. F. FLAGLER has been appointed Department Engineer, Hawaiian Department; District Engineer, Honolulu; and Commanding Officer, 3rd Engineers, Hawaii. In addition he has been detailed in the 19th Lighthouse District, relieving Col. Henry C. Newcomer, who is ordered to return to the United States and report to the Adjutant General for instructions.

Col. JAMES C. SANFORD has been appointed Division Engineer of the Northeastern Division, and detailed for duty in connection with lighthouses in the 3rd and 9th Lighthouse Districts, relieving Col. William C. Langfitt.

Col. SPENCER COSBY has been appointed Division Engineer, Southeastern Division, relieving Lieut. Col. William J. Barden. Prior to this detail Colonel Cosby was District Engineer at Galveston, Texas. His present station is Savannah, Ga.

Col. JAMES P. JERVEY has been appointed Division Engineer of the Eastern Division (at Baltimore, Md.), relieving Jol. James C. Sanford.

Lieut. Col. CURTIS W. OTWELL has been appointed District Engineer of the Wheeling, W. Va., Engineer District.

Lieut. Col. GEORGE P. HOWELL has been appointed Department Engineer, Southeastern Department, relieving Lt. Col. G. R. Lukesh.

Lieut. Col. HERBERT DEAKYNE has been appointed Division Engineer of the Gulf Division, relieving Col. Mason M. Patrick.

Lieut. Col. LEWIS H. RAND has been relieved from station and duty in San Francisco, Cal., and assigned to the command of the 4th Engineers, Camp Dodge, Iowa.

Lieut. Col. MERIWETHER L. WALKER has been appointed Division Engineer of the Central Division, relieving Maj Gen. Lansing H. Beach.

Maj. ARTHUR R. EHRNBECK has reported his arrival in Honolulu, T. H., where he was ordered for duty as Assistant to the Department Engineer. Major Ehrnbeck, prior to this detail, was on duty in the Office of the Zone Finance Officer, New York City.

Maj. WILLIAM P. STOKEY has been detailed as Superintendent of Lighthouses in the 14th Lighthouse District, relieving Maj. Gen. Lansing H. Beach.

Col. T. H. JACKSON has been appointed Department Engineer for the Northeastern Department. His headquarters are at Boston.

Col. R. G. ALEXANDER has been ordered to West Point as professor of drawing to succeed the late Col. E. R. Stuart.

Col. JAMES G. STEESE has been relieved from duty as a member of the General Staff Corps and directed to report to the Commanding General, Western Department for temporary duty in connection with commissioned personnel of the army. Upon completion of this duty Colonel Steese will proceed to Juneau, Alaska, for duty as President of the Board of Road Commissioners for Alaska, relieving Lieut. Col. John C. Gotwals of that duty. Lieut. Col. Gotwals will remain on duty in Alaska as Secretary and Disbursing Officer for the Board.

Maj. EARL J. ATKISSON, who has been engineer instructor at Camp Benning, has been assigned to the command of Edgewood Arsenal.

Maj. WILDURR WILLING has been assigned to duty as District Engineer at Boston, Mass., and detailed for consultation or to superintend the construction of any aid to navigation in the 1st and 2nd Lighthouse Districts, relieving Maj. Gilbert Van B. Wilkes.

Maj. ROGER G. POWELL, until recently on duty overseas as Engineer Purchasing Officer with station in London, Eng., has returned to the United States and has been assigned to duty as assistant to the Engineer Commissioner, District of Columbia.

Maj. EDWARD N. JOHNSTON has been assigned to duty as District Engineer at Wilmington, Del., relieving Col. James P. Jervey. Maj. W. F. Beyer, Chemical Warfare Service, has been detailed as assistant to Major Johnston.

Maj. CHARLES J. TAYLOR has been relieved from duty at Portland, Ore., and assigned to duty as Engineer Officer, Coast Artillery Training Center, Fort Monroe, Va., and as assistant to the District Engineer, Norfolk, Va.

Maj. CHARLES L. HALL has been relieved from duty as assistant to the District Engineer, Galveston, Tex., and ordered to duty in the Office of the Chief of Engineers.

Maj. LEWIS M. ADAMS has been assigned to duty as District Engineer, Galveston, Tex., relieving Col. Spencer Cosby.

Maj. ROBERT P. HOWELL has been relieved from duty as District Engineer at Nashville, Tenn., and assigned to duty as District Engineer, Vicksburg, Miss., and the 3rd Mississippi River District, relieving Capt. John W. Stewart.

Maj. RAYMOND G. MOSES has been relieved from duty with the 9th Engineers (Mtd.) and assigned to the 318th Engineers, Camp Grant, Ill.

Majs. RALPH T. WARD and LEWIS H. WATKINS have been assigned to duty as instructors at the General Service Schools, Fort Leavenworth, Kans.

Maj. RAYMOND F. FOWLER has been relieved from duty at West Point and assigned to the 9th Engineers (Mtd.), El Paso, Tex.

Capt JOHN W. STEWART has been directed to report at United States General Hospital No. 19, Oteen, N. C., for observation and treatment.

The following-named officers have been assigned to temporary duty as students at the Engineer School, Camp A. A. Humphreys, Va.:

Capt. William H. Holcombe,
Capt. John S. Bragdon,
Capt. Earl E. Gesler,
Capt. Alfred L. Ganahl,
Capt. John P. Conklin,
Capt. Mason J. Young,
Capt. Dabney O. Elliott,
Capt. Edwin A. Bethel.

Capt. PAUL A. HODGSON has been relieved from duty as assistant to the District Engineer at Philadelphia, Pa., and ordered to Manila, Philippine Islands, for duty with the 3rd Engineers.

Capt. ALBERT K. B. LYMAN has been relieved from Camp A. A. Humphreys, Va., and directed to St. Louis, Mo., as Secretary and Disbursing Officer, Mississippi River Commission.

Capt. JOHN E. HARRIS has been discharged from the Letterman General Hospital, San Francisco, Cal., and ordered to Camp A. A. Humphreys, Va.

Capt. THOMAS B. LARKIN has been relieved from duty at Camp A. A. Humphreys, Va., and assigned to the Office of the Chief of Engineers.

Capt. GERALD A. COUNTS has been relieved from duty with the 6th Engineers, Camp Pike, Ark., and assigned to the 9th Engineers (Mtd.), El Paso, Tex.

Capt. RAYMOND A. WHEELER has been relieved from duty as assistant to the District Engineer, Providence, R. I., and ordered to the Infantry School, Camp Benning, Ga.

Capt. HOWARD S. BENNION has been relieved from duty in the Office of the Chief of Engineers and assigned to the Office of the Assistant Chief of Staff, Director of Purchase, Storage and Traffic.

The provisional appointments of Lieutenants Walter L. Medding, Roy M. McCutcheon, Bennet H. Bowley and Geo. M. Steese have been made permanent, they having been found duly qualified by a Board of Officers. These officers have since been promoted to the grade of captain.

Maj. VIRGIL L. PETERSON has been relieved from duty at Camp A. A .Humphreys, Va., and assigned as Assistant to the District Engineer, Maj. Wildurr Willing, at Boston, Mass.

Capt. ROBERT M. FOX has been relieved from duty at Fort Bayard, N. M., and assigned to the 8th Engineers (Mtd.), Fort Bliss, Tex.

Lieut. WALTER S. OLSON, Chemical Warfare Service, recently discharged, has been appointed engineer on the Drainage and Waters Commission of Minnesota

Lieut. Col. E. B. MORDEN, recently provisional appointee, has been appointed permanent chief of the Bureau of Street Cleaning of Philadelphia. During the war Colonel Morden was constructing quartermaster at Camp Custer, Battle Creek, Mich., and subsequently constructing quartermaster of the Philadelphia Army Supply Base.

The resignations of the following-named officers of the Corps of Engineers have been accepted:

Capt. William B. Wilson,
Capt. Freeman Clarkson,
Capt. James B. Cress,
Capt. W. Morris Chubb,
Capt. Clifford H. Springer,
Capt. Rudolph C. Kuldell,
Capt. Edward P. Morton,
1st Lieut. Bernard E. Baer,
1st Lieut. William M. Howe,
1st Lieut. Robert A. Love.

The following-named officers of the Corps of Engineers have been ordered to Boston, Mass., for a course of instruction at the Massachusetts Institute of Technology:

Captains—
Holland H. Robb,
George J. Richards,
Raymond G. Moses,
William A. Snow,
Thomas D. Finley,
Wilburn H. Henderson,
Ludson D. Worsham,
Ralph G. Barrows,
Robert R. Neyland, Jr.,
Stanley L. Scott,
Daniel Noce,
Henry Hutchings, Jr.,
Herman H. Pohl,
Gerald A. Counts,
Hiram B. Ely,
Kenneth M. Moore,
Thomas D. Stamps,
Girard B. Troland,
Llewellyn B. Griffith,
John P. Dean,
Patrick H. Timothy, Jr.,
Leland H. Hewitt,
Preston W. Smith,
Charles F. Baish,
James M. Young,
Thomas H. Nixon,

First Lieutenant—
Lemuel Pope, 3rd.

The following-named officers of the Corps of Engineers have been relieved from the Engineer School, Camp A. A. Humphreys, Va., and ordered to report for duty at the educational institutions indicated after their names (R. O. T. C.):

Capt. Earl E. Gesler—Iowa State College, A. & M. A., Ames, Iowa.
Capt. Donald A. Davison—Yale University, Sheffield Scientific School, New Haven, Conn.
Capt. Layson E. Atkins—University of Illinois, Urbana, Ill.
Capt. Patrick H. Tansey—Oregon Agricultural College, Corvallis, Ore.
Capt. Michael C. Grenata—University of Kansas, Lawrence, Kans.
Capt. Lucius DuB. Clay—Alabama Polytechnic Institute, Auburn, Ala.
1st Lieut. Harry A. Montgomery—Rose Polytechnic Institute, Terre Haute, Ind.
1st Lieut. Howard L. Peckham—University of Tennessee, Knoxville, Tenn.
1st Lieut. Edwin P. Lock, Jr.—Missouri School of Mines, Rolla, Mo.
1st Lieut. Albert Riani—State University of Iowa, Iowa City, Iowa.

The following-named officers have been relieved from duty at Camp A. A. Humphreys, Va., and ordered to report for duty to the commanding officers of the organizations indicated after their respeitive names:

Maj. Harold G. Smith, 4th Engineers, Camp Dodge, Iowa.
Maj. Charles E. Perry, 1st Engineers, Camp Taylor, Ky.
Capt. Hugh Miller, 2nd Engineers, Camp Travis, Tex.
Capt. Frank N. Smith, 5th Engineers, Camp A. A. Humphreys, Va.
Capt. Horace H. Braun, 318th Engineers, Camp Grant, Ill.
Capt. Mason J. Young, 7th Engineers, Camp Gordon, Ga.
Capt. Hubert W. Collins, 1st Engineers, Camp Grant, Ill.
Capt. Frank B. Hastie, 318th Engineers, Camp Taylor, Ky.
Capt. Arthur P. von Deesten, 4th Engineers, Camp Dodge, Iowa.
Capt. Tattnall D. Simkins, 9th Engineers, Camp Travis, Tex.
Capt. Frank M. S. Johnson, 4th Engineers, Camp Dodge, Iowa.
Capt. Aubrey H. Bond, 7th Engineers, Camp Gordon, Ga.
Capt. Frederick S. H. Smith, 2nd Engineers, Camp Travis, Tex.
Capt. Robert D. Ingalls, 6th Engineers, Camp Pike, Ark.
Capt. Eugene F. Gaebler, 318th Engineers, Camp Grant, Ill.
Capt. William C. Atwater, 5th Engineers, Camp A. A. Humphreys, Va.
Capt. Anderson T. W. Moore, 8th Engineers, Fort Bliss, Tex.
1st Lieut. John H. Veale, 1st Engineers, Camp Taylor, Ky.
1st Lieut. Henry C. Wolfe, 6th Engineers, Camp Pike, Ark.
1st Lieut. Henry Berbert, 6th Engineers, Camp Pike Ark.
1st Lieut. John M. Harman, 1st Engineers, Camp Taylor, Ky.
1st Lieut. David W. Griffiths, 2nd Engineers, Camp Travis, Tex.
1st Lieut. Bernard S. Stearns, 1st Engineers, Camp Taylor, Ky.
1st Lieut. Leslie L. Groves, Jr., 7th Engineers, Camp Gordon, Ga.
1st Lieut. Frederic B. Butler, 5th Engineers, Camp A. A. Humphreys, Va.
1st Lieut. Wilson G. Saville, 5th Engineers, Camp A. A. Humphreys, Va.
1st Lieut. Frederick A. Platte, 4th Engineers, Camp Dodge, Iowa.
1st Lieut. Karl B. Schilling, 6th Engineers, Camp Pike, Ark.
1st Lieut. John H. Elleman, 1st Engineers, Camp Taylor, Ky.
1st Lieut. William D. Wanamaker, 318th Engineers, Camp Grant, Ill.
1st Lieut. Beverly C. Snow, 7th Engineers, Camp Gordon, Ga.
1st Lieut. Otto Praeger, Jr., 7th Engineers, Camp Gordon, Ga.
1st Lieut. Newell L. Hemenway, 6th Engineers, Camp Pike, Ark.
1st Lieut. Chester K. Harding, 318th Engineers, Camp Grant, Ill.
1st Lieut. William V. Hesp, 4th Engineers, Camp Dodge, Iowa.
1st Lieut. William C. Bennett, Jr., 9th Engineers, Camp Travis, Tex.
1st Lieut. Claude H. Chorpening, 6th Engineers, Camp Pike, Ark.
1st Lieut. James P. Jervey, Jr., 5th Engineers, Camp A. A. Humphreys, Va.
1st Lieut. George S. Witters, 4th Engineers, Camp Dodge, Iowa.
1st Lieut. Harvey D. Dana, 5th Engineers, Camp A. A. Humphreys, Va.
1st Lieut. John P. Dietrich, 2nd Engineers, Camp Travis, Tex.
1st Lieut. William A. Callaway, 318th Engineers, Camp Grant, Ill.
1st Lieut. Howard V. Canan, 4th Engineers, Camp Dodge, Iowa.
1st Lieut. Vere A. Beers, 7th Engineers, Camp Gordon, Ga.
1st Lieut. John B. Hughes, 5th Engineers, Camp A. A. Humphreys, Va.

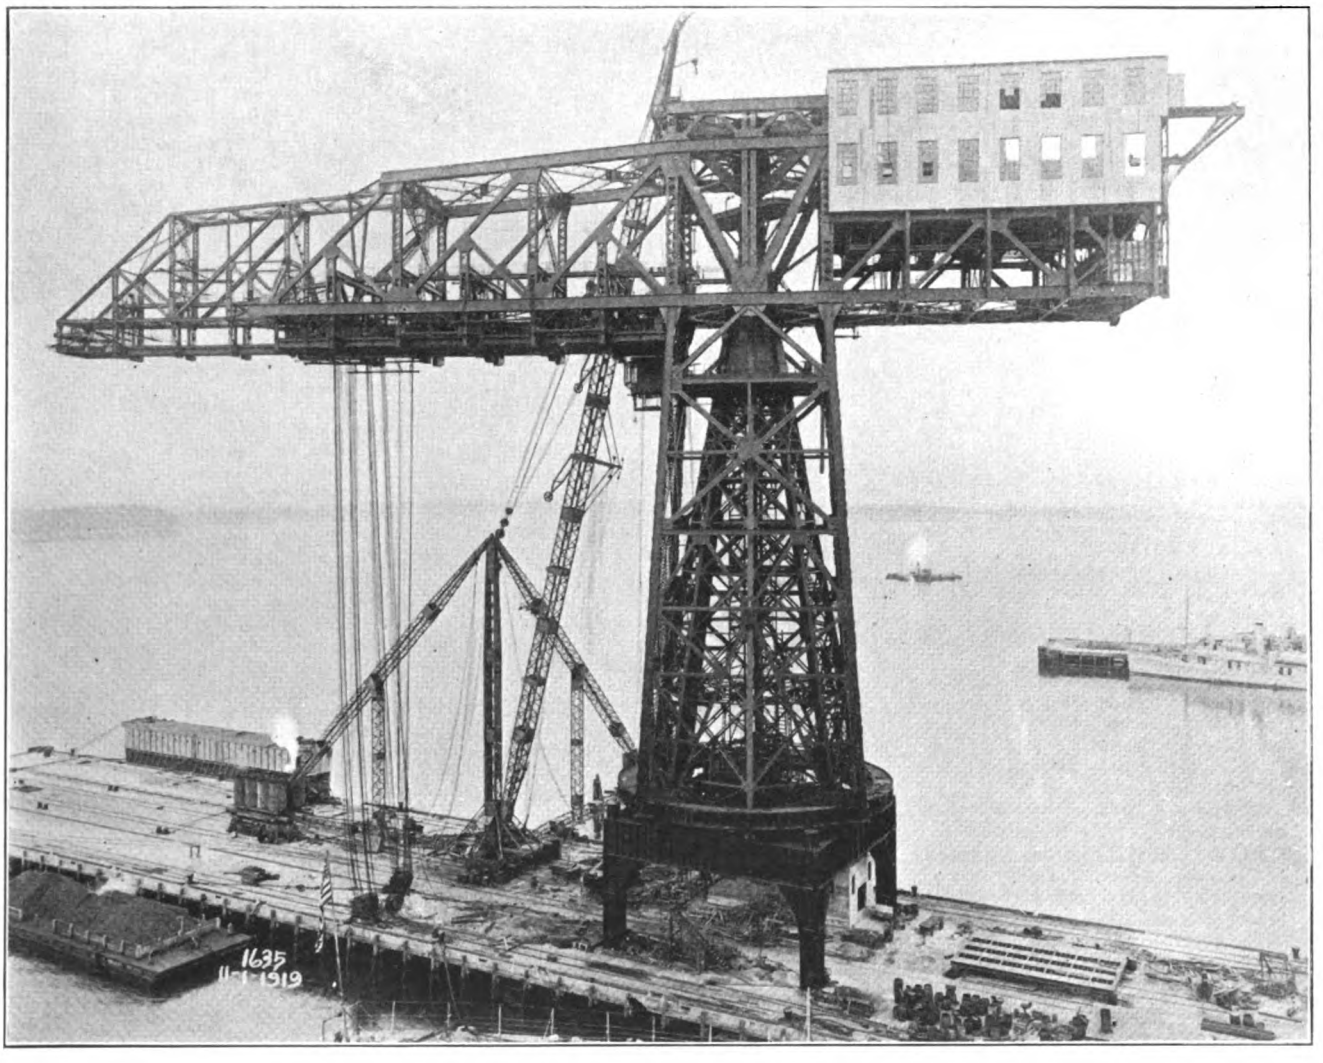
The following-named officers of the Corps of Engineers, having been examined as required by law and found qualified, were promoted to the ranks indicated:

To be Brigadier General, U. S. A.—
Col. Henry Jervey.

To be Colonels:
Lieutenant Colonels—
Herbert Deakyne,
Spencer Cosby,
Jay J. Morrow,
James P. Jervey,
James B. Cavanaugh,
George P. Howell,
Charles W. Kutz.

To be Lieutenant Colonels:
Majors—
George B. Pillsbury,
Gustave R. Lukesh,
John R. Slattery,
Curtis W. Otwell,
Albert E. Waldron,
Francis A. Pope,
Gilbert A. Youngberg.

To be Majors:
Captains—
John R. D. Matheson,
Charles J. Taylor,
Edwin H. Marks,
Earl North,
Gilbert Van B. Wilkes,
John C. H. Lee,
Frank S. Besson,
Albert K. B. Lyman,
Creswell Garlington,
Daniel D. Pullen,
Carey H. Brown,
Oscar N. Solbert,
Beverly C. Dunn,
Donald H. Connolly,
Raymond F. Fowler.



To be Captains:
1st Lieutenants—
Hans Kramer,
Albert G. Matthews,
Amos B. Shattuck, Jr.,
Leland H. Hewitt,
Michael C. Grenata,
Preston W. Smith,
Thomas F. Kern,
Ralph E. Cruse,
Lewis T. Ross,
Charles F. Baish,
Clarence L. Adcock,
Keryn ap Rice,
Charles S. Ward,
Henry M. Underwood,
James B. Newman,
James M. Young,
James C. Marshall,
Walter E. Lorence,
Bennett H. Bowley, Jr.,
Robert D. Ingalls,
Walter L. Medding,
Warren A. Lyon,
Albert C. Lieber, Jr.,
Robert K. Munroe,
Eugene F. Gaebler,

THE McMYLER INTERSTATE CO.
CLEVELAND OHIO

THE LARGEST CRANE AND THE LARGEST STIFF-LEG DERRICK

The crane shown, which lifted 505 tons at one time, is in operation in the Philadelphia Navy Yard, where it was erected by the aid of the largest stiff-leg derrick ever constructed.
The height of the crane is 235 feet, while the derrick is equipped with a boom 252 feet long.
Both the crane and the derrick were designed and built by THE McMYLER INTERSTATE CO.
By those who are uninformed, this crane installation may be accepted as an index to our possibilities.

The appointments of the following-named officers of the Corps of Engineers have, by order of the President, been honorably terminated:

Capt. Simon Medine,
1st Lieut. Philip N. Cristal.

The following named emergency officers of Engineers have been honorably discharged the service, their services being no longer required:

Capt. Victor Willits,
Capt. James M. Ranck, Sr.,
1st Lieut. Clark B. Carpenter,
1st Lieut. Ralph G. Shankland,
1st Lieut. Morgan H. Patten.

HAL M. SCOTT, former captain of Infantry, 32nd Division, U. S. A., has been elected chief engineer, and John P. Bonner, former captain of Trench Mortars, 2nd Division, U. S. A., has been elected resident engineer, of the Greenbrier & Eastern R. R. Co., with headquarters at McClungs, Greenbrier County, W. Va. Construction has just been begun on this railroad, which will connect with the Sewell Valley R. R. at Rainelle, W. Va., and will be about 12 miles in length.

LEWIS E. KNERR, former captain of Engineers, U. S. A., has resigned his position in the Tacoma (Wash.) city engineer's office to become constructing engineer of the Seattle (Wash.) Hemlock Mills, Ltd.

Maj. RAY W. BERDEAU, formerly with the U. S. Engineers, on New York harbor improvements, has left for Hong Kong, China, in the employ of the Vacuum Oil Co.

HENRY WELLS DURHAM, formerly Major, Engineers, with the American Expeditionary Forces, has received from the French Government the *Mérite Agricole*, a decoration conferred in recognition of his work on road construction and maintnance during his service abroad with the Division of Construction and Forestry.

L. FRED PATSTONE, recently Major, 217th Engineers, U. S. Army, has resigned as city engineer of Manila, P. I., to accept the managership of the China Development Co., with offices at 34 Nanking Road, Shanghai.

Lieut. Col. GEORGE D. SNYDER has been commissioned Colonel, commanding the 22nd Regiment, Engineers, New York Guard. He joined the regiment in 1915, serving with it on the Mexican Border in 1916, and when it was reorganized for the World War as the 102nd Engineers he served with it in all the actions with the 27th Division in Belgium and France. Colonel Snyder is a member of the firm of Jacobs & Davies, Inc., consulting engineers, builders of the Hudson tunnels.

Brig. Gen. WILLIAM L. MARSHALL, formerly Chief of Engineers, U. S. Army, for the past ten years consulting engineer to the Secretary of the Interior, has tendered his resignation on account of ill health. As we go to press the death of General Marshall at Walter Reed Hospital is announced. Notice later.

Capt. GEORGE M. SHEPARD, Engineers, recently discharged from the Army, has accepted a position with L. P. Wolff, Consulting Engineer, St. Paul, Minn.

Col. GEORGE A. JOHNSON of the Construction Division of the Army, has resigned his commission to assume his duties as the directing head of the engineering firm, Johnson & Benham, with offices in New York City and in Kansas City, Mo. The specialty of the organization whose general direction Colonel Johnson will assume, is the design, construction, supervision and management of water supply and sewerage plants and other public utilities.

Capt. BILLINGS WILSON, Corps of Engineers, U. S. Army, has resigned from the service, effective April 1, to take a position with Francis Lee Stuart, consulting engineer, New York City.

Capt. JAMES N. GLADDING, recently returned from overseas service, has received the appointment of city manager of Albuquerque, N. M., taking the position made vacant by the resignation of A. R. Hebenstreit. Captain Gladding was formerly city engineer of Albuquerque.

Capt. WILLIS G. WHITTEN, Engineers, U. S. A., (1st Lieut., Corps of Engineers, Regular Army), died at Coblenz, Germany, March 13, 1920. He was born in Nebraska, Oct. 10, 1892, and was apponted a second lieutenant in the Engineer O. R. C., June 11, 1917. He was commissioned a second lieutenant, Corps of Engineers, in the Regular Army July 7, 1918, and was appointed a temporary captain the same date.

E. A. MORITZ, office engineer, U. S. Reclamation Service, Denver, Colo., has been appointed project manager of the Flathead Project, with headquarters at St. Ignatius, Mont.

G. R. SOLOMON, recently colonel U. S. A., officer in charge of engineering branch Construction Division of the Army and formerly of Solomon-Norcross Co., consulting engineers, Atlanta, Ga., has resumed engineering practice as vice-president of the Fuller Industrial Engineering Corp., 949 Broadway, New York City.

C. F. LEWIS has resigned his position with the U. S. Bureau of Public Roads to open offices in Greensboro, N. C., under the firm name of Spoon & Lewis, consulting engineers. The firm will render general consulting service, giving particular attention to highway and municipal work.

Maj. ROBERT C. WHEELER, chief of water supply section, Construction Division, U. S. Army, recently discharged, and at the time of leaving associated with Capt. Harry Barker, New York City, in the general practice of engineering, sailed March 16 for Athens, Greece, with a party of engineers organized by Ford, Bacon & Davis to prepare plans and estimates for the water supply and sewerage of Athens. Major Wheeler will be in charge of the work on water distribution, sewage collection in that city and methods of sewage disposal. The work will require about six months and on its completion he will return to New York and resume active participation in the work of his firm.

W. G. CALDWELL, formerly captain, Engineers, U. S. A., has been appointed highway engineer of Waukesha County, Wis., with offices in Waukesha.

Col. THOMAS MANN RANDOLPH TALCOTT, civil engineer, died at Richmond, Va., May 7, aged 82 years. He was born in Philadelphia, in 1838, one of the sons of Capt. Andrew Talcott, formerly of the Corps of Engineers, U. S. Army.

During the Civil War Colonel Talcott served as Lieutenant of Engineers in the Confederate Army. His professional career was devoted to railroad engineering and administration.

U. S. ENGINEER OFFICE, First District, New York City, Room 710, Army Building, 39 Whitehall Street, New York City.—*To whom it may concern:* Whereas navigation is obstructed and endangered by wreck of a wooden boat, name unknown, sunk in the Hudson River between Hazards Landing and Dupont Dock, N. J.: Notice is hereby given, that unless said vessel is removed by the owner within thirty days from July 8, 1920, it will be removed by the United States under authority of law. Sealed proposals will be received here until 12 M., August 9, 1920, and then opened, for removing said wreck. Information on application.

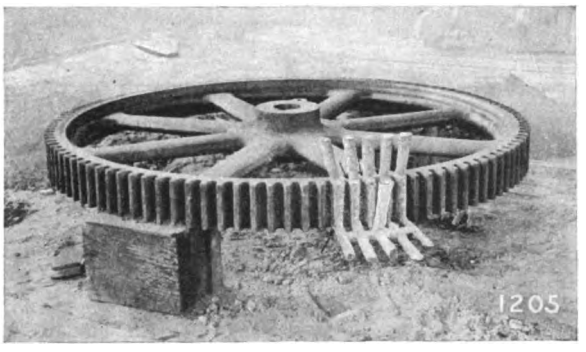
Discharge of Regular Army officers from emergency commissions.—Under authority of a General Order, issued June 5, 1920, all officers of the Regular Army holding advanced rank, who have not been discharged from their emergency commissions, are discharged therefrom effective June 30, 1920.

Value of top soil for highways.—Top soil should be used for foundation wherever possible. It is claimed that this is proven advantageous by observation in the State of Ohio. Shallow side ditches for quick drainage entirely away from the road into the fields are preferable to deep side ditches and the holding of water contiguous to the road for long periods. Stability of berms is increased by shallow ditches. Soils and drainage need study in conjunction with highway building. Railroad grading methods have had too much influence in highway construction.—*Eng News-Record.*

A comparison of steam and electric motive power.—Mr. A. H. Armstrong, of the General Electric Co., recently delivered an address with the above title before the Schenectady section of the American Institute of Electrical Engineers, from which the following is taken:

During the winter of 1917-18 our railways fell down badly when the need was the greatest in their history. It is true that the cold weather conditions were unprecedented and the volume of traffic abnormal, but the weakness of steam-engine haulage was disclosed in a startling manner.

In marked contrast to adjoining steam-engine divisions, the 440 miles of electrified section of the Chicago, Milwaukee and St. Paul R. R. continued to do business as usual throughout the trying winter of 1917-18. Freight and passenger trains were brought over the electrified tracks on schedule time or better; in fact, it was customary to make up on the 440-mile electric run fully two hours of the time lost by passenger trains on adjoining steam-engine divisions.



The author, in discussing other advantages of electrification, points out that a large reduction in non-revenue producing ton mileage would be made by eliminating locomotive tenders and locomotive coal, and also in the reduction of railway coal, by reason of the great savings that could be made burning fuel in large modern power stations under the most efficient conditions possible, rather than under the boilers of 63,000 locomotives now in service throughout the country.

Without considering water power as a means for generating electricity, he estimates that the electrification of our railroads would in 1918 have saved more than two-thirds of the consumed by the railroads that year.—*Eng. and Cont.*

Graduation exercises, Engineer School.—Graduation exercises were held in the open-air ampitheater near Harris Hall on June 16, 1920. Gen. W. D. Connor, the Commandant of the School, gave a talk to the graduating class. He was followed by Secretary of War, Newton D. Baker, who gave the address of the day. Music was furnished by the Fifth Engineer Band. Practically the entire Post attended.

A large number of officers, students and instructors, have received orders relieving them from the school. Almost all will go to duty with troops.

THERMIT WELDS ON LARGE GEAR WHEEL

THERMIT

is the only reliable process for Welding Heavy Steel Sections

SUCH AS BROKEN

Crankshafts, Locomotive Frames, Steel Plant Equipment, Sternframes of Ships and Many other Heavy Steel Sections.

The steel required to make a Thermit Weld is produced in bulk at a temperature of 5000° F. instead of drop by drop, as in other welding methods. It therefore makes a perfect amalgamation with the adjacent metal and secures a Homogeneous Weld free from shrinkage strains, unattainable in any other way.

Professional Notes

of Military and Engineering Interest

Heights of vessels and clearance of bridges.—An investigation has recently been conducted by the Port Facilities Commission, United States Shipping Board, to ascertain the maximum height of seagoing vessels above light and load water line, the results of which are of interest in connection with the vertical clearance of bridges, and cable lines across navigable waters.

Data were received as to 53 vessels ranging in gross tonnage from 4,170 to 54,281 and in height above water line from 96.8 to 217 feet.

Fifteen of the 53 vessels have a maximum height above light-water line greater than 150 feet, as follows:

Fifteen vessels of maximum height (in feet)

Name	Built	Gross tonnage	Height Light	Height Loaded.
Aquitania	1914	45,647	217.0	205.0
Leviathan	1914	54,281	192.8	186.5
Stavangerfjord	1917	13,600	191.0	183.0
Carmania	1905	19,524	181.0	173.0
Caronia	1905	19,687	181.0	173.0
Mauretania	1907	30,704	173.0	170.0
Nestor	1918	14,501	168.5	153.0
Henderson	1917	7,493	164.4	157.0
Rotterdam	1908	24,149	162.3	149.0
Geo. Washington	1908	25,569	159.7	154.0
Von Steuben	1901	14,908	154.8	151.0
Noordam	1902	12,531	153.5	135.8
Ryndam	1901	12,527	152.5	135.8
Aeneas	1910	10,049	151.0	136.0
Ascanius	1910	10,048	151.0	136.0
Average (15)	1909	21,014	170.0	159.9

The following table contains data on the more important bridges under which ocean-going vessels pass.

Clearances of important bridges.

Name of bridge.	Type.	Waterway.	Maximum horizontal span in feet.	Vertical clearance in feet.
Poughkeepsie	Cantilever	Hudson River	547	160
Firth of Forth	Cantilever	Firth of Forth	1,700	157
Quebec	Cantilever	St. Lawrence River	1,800	150
Vancouver	Vertical lift	Columbia River	250	150
Glisan Street, Portland, Oreg.	Vertical lift	Willamette River	205	144
Tower Bridge, London	Double bascule with overhead footway	Thames River	280	141
Brooklyn	Cable suspension	East River	1,546	135
Manhattan	Cable suspension	East River	1,470	135
Williamsburg	Cable suspension	East River	1,536	139
Hell Gate	Fixed arch	East River	1,017	135
Queensboro	Cantilever	East River: East span	947	135.6
		West span	1,153	133.6

Of the 53 vessels reported on, 32 have a height above light-water line greater than 135 feet and are therefore unable to pass under the East River bridges.

Of 19 vessels whose gross tonnage ranges from 12,527 to 54,281, 12 exceed 150 feet and 16 exceed 135 feet in height.

Of 18 vessels whose gross tonnage ranges from 10,048 to 11,850, 2 exceed 150 feet and 9 exceed 135 feet in height.

Of 16 vessels whose gross tonnage ranges from 4,170 to 9,996, 1 exceeds 150 feet and 7 exceed 135 feet in height.

Of the 53 vessels, only one, the *Powhatan*, gross tonnage 10,531, is less than 100 feet in height. Its height above light-water line is 96.8 feet.

The vessels built during the war for the Emergency Fleet Corporation, ranging in gross tonnage from 2,020 to 7,898, all have heights less than 100 feet. This is due, however, to the fact that the height of these vessels was, prior to the signing of the armistice, kept as low as possible. Restrictions upon the allowable height of vessels of the Emergency Fleet Corporation have now been removed.

In view of the constant tendency to give deep water access from the sea to important cities at moderate and even considerable distances from the ocean, the restricted heights of bridges are a serious problem.

Facts and figures about pulp and paper.—The annual newsprint requirements of city daily papers vary from about 2,500 tons in the smaller cities to 160,000 tons in the case of the New York Journal, the paper having the largest circulation in the country.

A few of the newspaper companies, such as the New York World, have their own paper mills. The New York Times makes most of its newsprint at its mill in Brooklyn, using pulp from Canada. However, the company recently bought 2,500 tons from the Powell River Company in Vancouver. The cost of this paper delivered in New York, including freight charges amounting to $24, was $125 a ton, which was cheap compared to spot market prices of $140 to $160.

The present abnormal consumption of newsprint is, of course, the result of the unusual amount of advertising. Newspaper advertising in the 16 leading cities of the United States increased from 56,000,000 agate lines in January, 1919, to 80,000,000 in October, 1919.

Whether justified or not there is a general feeling among publishers that there is at least an understanding between the manufacturers. Almost every publisher was reduced on his 1920 contract, with the result that he will have to buy the balance of his requirements on the spot market. With spot sales of $8 to $10 per hundred pounds it is, of course, to the advantage of the manufacturer to sell as much as possible in that way, and still retain his regular customers.

Reports from Canada indicate that the yearly production of newsprint is over 800,000 tons, and that only 120,000 tons are consumed in the country. The mill capacity of Canada is being considerably increased.—*Forest Service Bulletin.*

Aerial photography in map making in France.—During the war, aerial photography was one of the most efficient means of investigation placed at the disposal of the Command. But in addition to general information secured by photographs from airplanes, this method was more specially utilized to complete the existing maps.

The *Plans Directeurs* on scales: 1/5,000, 1/10,000, 1/20,000, were prepared from accurate instrumental surveys or compilation of cadastral maps. Photographs from the air allowed the addition to these maps of all emergency features of the ground (allied and enemy organizations) as well as every change in the prewar cultural features (new roads, trails, demolitions, etc.).

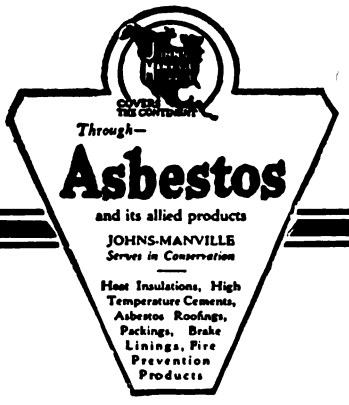
After the armistice, the co-ordination of the results obtained during the war by the employment of aerial photography was contemplated, as well as their utilisation for the needs of peace time.

The use of photographs from the air was chiefly considered as a means of making a new cadastral map or bringing it up to date, and also for the preparation of maps on a larger scale.

The value of these new methods remain to be demonstrated.

As a rule, it may be said, that from the viewpoint of planimetry, photographic surveys give a representation of the details as exact and precise as that obtained with the regular methods of surveying. The efficiency is particularly valuable in case of terrain exhibiting complicated features.

Furthermore, the momentous advantages in economy of personnel and working facilities are obvious. Nevertheless, it must not be forgotten that some difficulties have to be overcome, especially the distortions of the photographs. Further investigations must therefore be made.



As far as relief is concerned, the use of aerial photographs has not as yet given any great promise of usefulness.

During the war, the duties of the Air Service and the *"Service geographique"* were always distinct.

The personnel of the Air Service was responsible for the taking of photographs (special airplanes, observers) and laboratory work in the development of negatives and printing.

The personnel of the "Service geographique" (working in the "groupes de canevas de tir d'Armee") was responsible for the utilization of photographs from the air for map purposes, restitution of photographs, determination of the location of the various details, siting of these details in the "Plans directeurs," etc.).

But it may be presumed that in the peace-time organization, in view of the execution of the topographic works necessary for surveying or correcting the maps, the duties of the "Service geographique" will be extended to include all photographic work.—Report from the French War Dept.

Pile and concrete piers for Missouri River bridge.—Timber pile piers constitute a notable feature of the new Missouri River bridge for the Chicago, Milwaukee and St. Paul Railway, at Chamberlain, S. D. The original bridge, built at this site in 1905, was a 1,500-foot pile trestle with a ponton draw span. In 1916, the ponton, which had become old and leaky, was replaced by a temporary 75-foot plate girder swing span on pile piers. To provide for the great quantity of ice and the excessive scour in the 20-foot blanket of sand and silt forming the river bed, the present design was adopted as providing a practically permanent structure within the practicable limits of war-period financing. A portion of the old trestle is replaced by two 300-foot steel trusses on pile and concrete piers, with a 262-foot ponton draw at the east end of the trusses.

The piers are of uniform design, including a main pier and an ice breaker nose. The main pier is about 30 feet above the river bottom, 14 feet wide at the top and 36 feet long, with a wedge-shaped vertical tail. The ice breaker, of similar height and width, and a total length of about 58 feet, has a wedge-shaped nose inclined at an angle of about 30 degrees. As protection against scour the whole pier is surrounded by a willow brush mattress which was woven on scows and, after launching, was sunk by loose rock thrown from barges. In addition riprap was deposited around the pier.

Each main pier contains 7 rows of piles, with 12 piles in each row, capped about 8 feet above high water, the outer piles being battered. Cedar piles 70 to 80 feet long were used, and all were driven to refusal with a penetration of 30 to 50 feet. 12 x 12 inch longitudinal timbers, 3 inches apart, were bolted to the batter piles of the pier, to form a heavy sheathing, while plank sheathing was spiked to the five piles driven to form the wedge-shaped tail. To hold the riprap protection in place, a row of 40-foot piles was driven just outside of the pier, and another row of 30-foot piles, about 4 feet away. Both of these rows of piles were cut off below low water and covered with the stone fill around the pier. Midway between high and low water levels is a 30-inch concrete slab thickened to 66 inches at the upstream edge to afford bearing for the crib-work of the ice breaker. It is reinforced, top and bottom, with longitudinal and transverse bars, the latter being looped around the piles of the outer rows. The slab is also tied to the piles by 12-inch spikes partly driven into the piles and partly embedded in the slab. A timber grillage forms the deck of the pier and supports the shoe castings for the truss spans. A concrete deck slab was originally contemplated, but the grillage was substituted in the interest of speed. The top of the pier is covered with galvanized steel sheeting as protection against cinders and sparks.

The ice breaker, which is built integrally with the pier, contains seven 4-pile transverse bents, spaced 8 feet c. to c. and of varying heights, 5 piles in the wedge-shaped nose and 2 compact groups of 5 piles each behind and against each of the bents. Each bent is capped, and longitudinal struts between the piles of the two inner rows stiffen the entire structure. The horizontal sheathing and the riprap anchor piles of the main pier are extended along the ice breaker. The crib is filled with stone, and riprap is placed along the outside.

Reinforcing bars were laid along the timbering at the slope of the nose of the ice breaker, and concrete was filled over the timbers and bars to a minimum depth of 12 inches At the ridge it is faced by a line of old rails embedded flush with the concrete and anchored by U-bars passing through holes in the web of the rail. To prevent scour at the nose, the concrete is carried vertically downward in the form of a toe wall for 5 feet, and the rail extends to the bottom of this wall.

The substructure of this bridge was commenced in July, 1918, and in January it was ready for the steel erection, which was completed in March, 1919. The new ponton was launched and installed when the ice went out in April.—*Eng. News-Record.*

Commercial traffic on the Panama Canal.—There has been a steady and very satisfactory increase of traffic through the canal, as shown by the following table:

Year (calendar).	Number Vessels.	Tons of cargo.
1915	1,149	4,894,134
1916	1,222	4,83_,496
1917	1,960	7,427,680
1918	2,072	7,294,502
1919	2,134	7,468,167

In the first four months of 1920 the total cargo passing was 3,425,195 tons.

If the capital cost of the canal be placed at $450,000,000, and interest on this sum at 5 per cent, the annual interest charge (not including operating expenses and maintenance) is $22,500,000. For the year 1919 this meant about $3 per ton of cargo.

Safety an important factor in commercial operation of aeroplanes.—After being in operation for nearly a century, neither railroads nor ocean steamers are immune from accidents, and it is probably useless to expect that travel by the air can be rendered more secure than these older methods of travel by land and sea. But it is reasonable to hope that the frequency of accidents may be reduced, thus providing aviation with a relative security, at least equal to that of other methods of locomotion.

For the public safety, and especially in order to give confidence to the passengers, it is necessary henceforth to study devices for absolutely avoiding fires and all dangers of impact on landing.

As a matter of fact, the landing chassis of the large airplanes have received little attention up to the present time. For the war plans we have certain fixed rules, and landing chassis with V struts, joined axles and rubber shock-absorbers have been generally adopted. But with such devices, if the pilot makes an abrupt landing, the fuselage receives a considerable shaking up.

It has been assumed that the shocks are practically deadened in the following proportions:

30 per cent for the pneumatic tires.
15 per cent by the flexion of the nonjointed axles.
55 per cent for the shock-absorbers.

For the war airplanes, nearly all the builders have placed the center of the wheels in front of the center of gravity at a distance about equal to one-quarter of the height of the center of gravity from the ground, corresponding to about 13 or 14 degrees. This gives a device which practically avoids the danger of overturning, but which in certain cases subjects the tail skid to rather severe strains, especially if the fuselage is short.

For the airplanes intended to carry heavy loads, the question of tail skid shock absorbers is an important one, as there is little use of easing the landing if, at the moment when the tail skid touches the ground, all of the passengers are to be rudely jostled about in their seats.—*War Department News Bureau.*

Service pay increase.—After many months of delay Congress on May 14 passed the act granting increased pay to the united services, and the act became law when signed by the President on May 18.

The increases, which are very small, ranging from 10 to 23 per cent of officers' compensation, are in the form of a temporary bonus, effective until June 30, 1922.

The monthly increases for the Army and for corresponding grades in other services are as follows:

Second lieutenant	$35.00
First lieutenant	$50.00
Captain	$60.00
Major	$70.00
Lieutenant colonel	$50.00
Colonel	$50.00

No increases are allowed in the higher grades, and none for retired officers.

The most satisfactory portion of this act is that which provides transportation in kind for the families of officers making a change of station.

The expense of estimating.—When ten contractors make ten separate quantity estimates on a piece of work, the cost is ten times as great as if an accurate quantity estimate had been furnished the contractors when bids were invited. It is commonly supposed that this burden is borne by the contractors. But the contractor must "pass it on" to the public, and it thus becomes a waste—an unnecessary charge against the community.

If the owner goes to the trouble to prepare the plans, it is logical for him to go further and prepare a bill of materials. If there be a mistake in the bill of material, this is easily adjusted in the light of the facts.

This will not eliminate all the contractors' estimating expenses, but it would tend to eliminate chances of mistakes and the additional charges to cover them, and to acknowledge bids. The great variation in bids is often due to variation in quantity estimates quite as much as to variation in unit prices. It is to be remembered also that a contractor must often bid on ten jobs to get one.—*Eng. and Cont.*

Note.—The practice of preparing quantity estimates for the benefit of bidders, and as a uniform basis for canvassing bids, has long been the universal custom of the U. S. Engineer Dept.—Ed.

The roads of France—a summary.—Maj. H. W. Durham, Engrs., in *Good Roads*, gives a most thorough and entertaining account, based on accurate personal observation, of the roads of France, from which the following is taken:

The many routes of France, connecting the principal cities, are generally well aligned—straight. They were not spoiled by too much consideration for local topography and property rights. They were intelligently located in the beginning to meet the needs of the country.

A department of public works exercises complete control of the national routes under

Digitized by Google

a comprehensive and continuous plan for development, construction and maintenance. Minor routes are administered by departments and communes. The mileage is, national routes, 24,000; departmental, 18,500; all others, 375,000. The same methods of maintenance are in force on all classes, and all are supervised by the national organization.

The general plan or layout is like that of a spider web, the radiating lines being the national and the connecting lines the departmental routes.

Grades generally do not exceed 3 per cent, and very long tangents, often several miles, are characteristic, greatly facilitating motor traffic. All bridges and culverts are of permanent construction. In the mountains, tunnels, lighted by electricity, are often encountered. The width of the national routes, including berms, varies from 20 to 30 feet.

Drainage is by means of cross ditches through the grassy berms to the side ditches or main drains. Lines of trees grow on the berms, forming the most characteristically striking feature of the French national routes.

All routes are thoroughly marked by signposts at each intersection, with metal arms indicating distances to adjacent towns, both the small towns next in order, and the larger towns on the same route. These signs were evidently designed in the days of horse transport, as the lettering is too small to be satisfactory from the motorist's point of view. During the war it was found necessary to supplement these really attractive markers with large, ugly signboards bearing large painted letters which could be read without slacking speed, even in the dusk.

The minor routes resemble the national roads, as to surface, general construction, signposting, etc. They are generally of less width and not so heavily metalled.

The national routes formerly all ran through the towns, merging into the streets and being often difficult to follow, especially for the foreign motorist passing through at night. Occasionally the modern national routes pass outside the smaller towns lying upon them.

The system of maintenance is perhaps the best feature of the French road system. It is simple, like all good things, but very efficiently administered. It consists in keeping the ditches open and all water off the road, patching pot-holes as soon as they develop, scraping off mud and dust, and respreading binder. When the old surface becomes too worn for minor repairs, a new layer of 2 to 3 inches of macadam is added, and thoroughly compacted with road rollers.

Formerly some of the principal routes, especially in the vicinity of Paris, were paved with Belgian block. These are being gradually replaced by macadam or telford-macadam. As rock is found close to the surface almost everywhere in the country, the supply of road metal is a simple problem—the cantonniers can find it for themselves if necessary. But as this rock is rather soft and of indifferent wearing quality, the labor of maintenance is heavy and continuous. For many of the important routes better grades of rock have been transported from the localities where they are found.

The advent of the motor vehicle, which was earlier in France than in the U. S., brought the French engineers their troubles. The problem was not, as with us, to provide new routes, as there were ample numbers in existence. But the high-speed motor soon proved destructive to the wearing surface of simple, water-bound macadam. Before the war road maintenance was barely able to keep pace with the destruction wrought by the motor vehicle, and experiments with bituminous binders were in progress.

In its general plan and efficient maintenance the French road system is a model for the world. But the French roads will not stand up under heavy motor traffic without unduly heavy maintenance, and at best they are dusty in summer, which is not only a nuisance, but involves the waste of enormous quantities of material. A better wearing surface must be found for the principal routes at least.

In three important respects the French roads are superior to those of any other country:

(1) In the national system of control, with its splendid organization, independent of politics.

(2) In a complete original plan and layout, and good design and construction, making extensive new work unnecessary.

(3) In continuous and systematic maintenance on a simple and effective plan.

With such a foundation it may be expected that French road engineers will successfully meet the grave problems of motor traffic which now confront them.

The best French roads are not equal to the best American roads. But the French road system, as a whole, is greatly superior to that of America, in layout, design, construction, administration and especially maintenance.

Water power in Canada.—Practically every great industrial center in Canada is now provided with hydro-electric power, and the system is being rapidly extended. A great variety of industries are served.

The water-power resources of Canada are estimated as easily 20,000,000 horsepower, of which 3,385,000 will be usefully developed when plants now under construction are completed. The tendency is toward the installation of large units, 76.3 per cent being contributed by units of 2,000 horsepower or more.

The total capital now invested in central stations is $370,000,000, an average of $210 per primary horsepower.

With a development of 274 horsepower per thousand of population, Canada is surpassed in this development only by Norway. The enormous reserves still untouched are a guarantee of continuous industrial expansion and prosperity.—*Jour. West. Soc. of Engrs.*

Public hearings on Great Lakes-St. Lawrence River deep waterway.—Hearings on the proposal to construct a deep waterway from the Great Lakes to the sea via the St. Lawrence River were held in a number of American and Canadian cities in May and June by the international joint commission of the United States and Canada.

The commission's itinerary, announced recently, included hearings at North Bay, May 7; Marquette, May 10 and 11; Fort William, 13 and 14; Winnipeg, 15 and 17; Grand Forks, 18; Regina, 20; Calgary, 22 and 24; Billings, 26 and 27; Boise, 31; Cheyenne, June 2; Denver, June 3; Omaha, 5 and 7; Des Moines, 8; Aberdeen, 9; Minneapolis, 11 and 12; Duluth, 14 and 15; Superior, 16; Ashland, 17; Milwaukee, 18 and 19; Toledo, 21; Lansing, 22; Windsor, Ontario, 23; London, Ontario, 24; St. Catherine's Ontario, 25; Hamilton, Ontario, 26; Buffalo, 28 and 29.

Permanent type of check dam in Southern California.—Check dams of a permanent type of reinforced concrete construction have been successfully used to control storm waters out of the foothills in Ventura county and to prevent expensive erosion, which in the past has ruined many acres of valuable tableland.

In places where the fall is 3 or 4 per cent and greater, the storm waters have cut narrow channels as deep as 50 feet in the valuable flat lands, and if not controlled they become deeper and wider every year. The banks and side walls of the channels are all soil, and there are few bowlders or rocks of any kind in the bottoms.

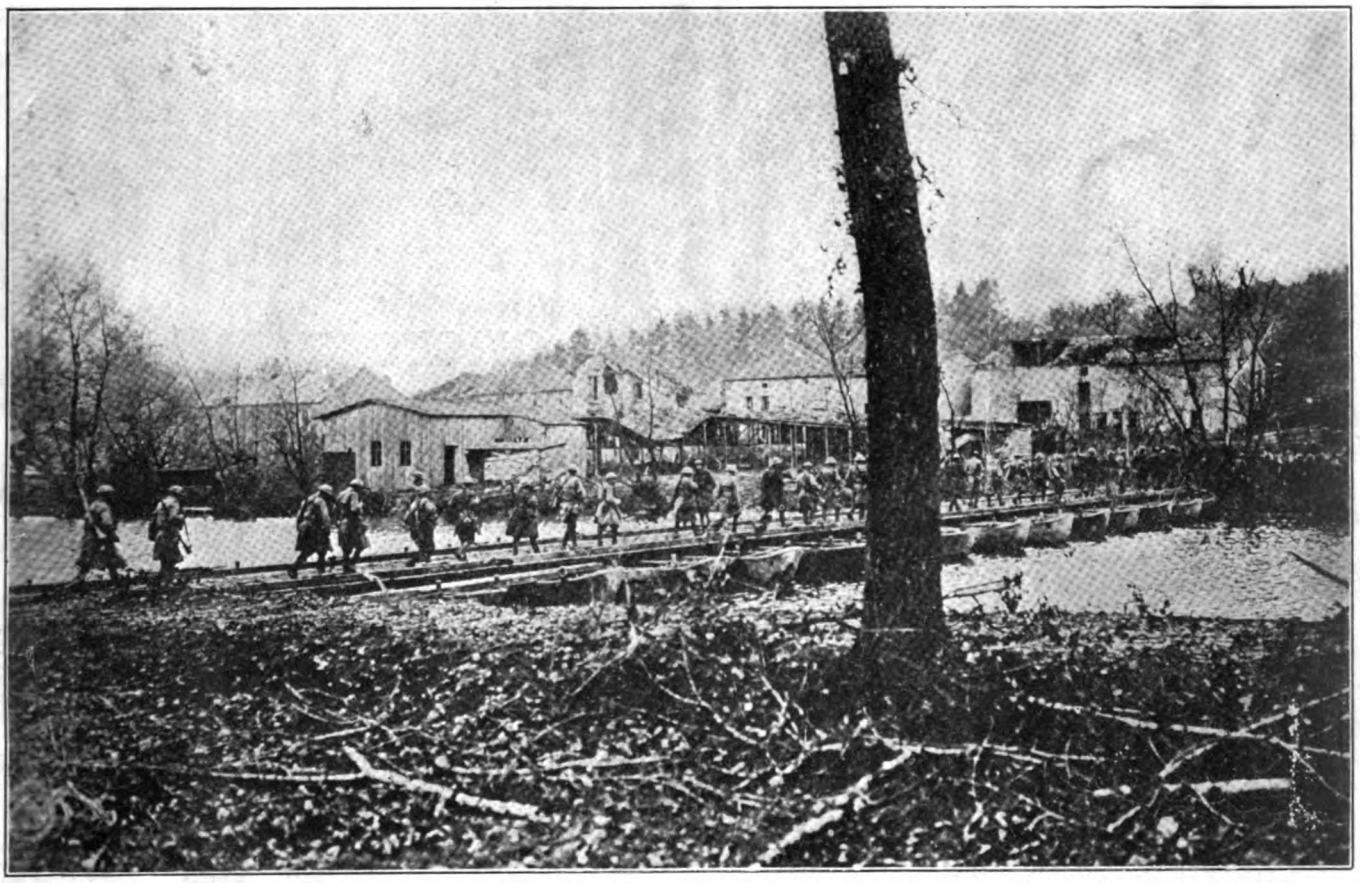
The design of the dams which have been constructed is the result of study of local conditions. They are of reinforced concrete and open, box-like construction, the sides of which are thin panels supported by cut-off walls, which penetrate 5 feet into the solid sidewalls of the channel. The excavations for these cut-off walls are just wide enough to receive the concrete, so there is no back-filling, and the chances of percolation around the cut-off walls are reduced to a minimum.

The water falls over a semicircular spillway into a pool, or water cushion, formed by a baffle wall between the sides. Where it is desired to raise the bed of the channel 25 feet at once, it is the practice to have the first water cushion 8 feet deep and a second below, 3 feet deep. The result of placing one of these dams in a channel is the filling up of the channel above the dam with silt and, while this is taking place, a cutting or lowering of the bed below. After the channel is filled above and a sufficient grade established for the water to carry silt, the portion below will fill again. The outlet must be so designed that the structure will not be endangered by this lowering of the channel.—*S. W. Builder and Contractor.*

U. S. ENGINEER OFFICE, Room 710, Army Building, 39 Whitehall Street, New York City.—Complaint having been made regarding delays to southbound trains on the Third Avenue elevatel line, New York City, at certain hours of the day through the opening of the Harlem River drawbridge, a public hearing to consider the matter will be held before the undersigned at Room 512, Army Building, 39 Whitehall Street, New York City, at 10 a. m., July 27, 1920. Interested parties are invited to be present.—EDW. BURR, Colonel, Engrs.

Naval strength and programs of leading nations, May, 1920.—The following is the displacement tonnage of all war vessels built and projected (including all now building) for the navies of the world:

Nation.	Built.	Projected.	Total.	Per cent of total projected.
Great Britain	2,457,777	141,370	2,599,147	6
United States	1,126,637	900,515	2,027,152	39
Japan	555,821	811,020	1,366,841	36
France	524,209	154,168	678,377	7
Italy	285,021	146,922	431,943	6
All others	628,158	130,780	758,938	6
	5,577,623	2,284,775	7,862,398	100



Of the tonnage projected or under construction by the United States almost half is battleships of the big-gun (dreadnaught) type.

Peace on earth, but perhaps not on the water.

Cube Mixed Concrete Guarantees a Sound Structure

There are many Austins in this world but only one

AUSTIN
"MOVES THE EARTH"
MIXES THE CONCRETE

TRADE MARK

This Trade Mark stands for strength and reliability in contractors' machinery.

Whether your concrete is overhead where it may be seen, or underground in your foundation, the mixture is always perfect. Every batch is uniform.

The "Cube" principle is indisputably correct. Look at the drum. Imagine it to be revolving. Follow the zig-zag line the materials must necessarily follow. The sides of the cube fold the upper portion of the mass over upon itself, always past the center. The action is "kneading"—not alternate combination and separation. Every particle of the mix gets its share of water. Incorporation of air is reduced to the minimum.

The "Cube" is a long-life mixer—**it's the only Mixer made with renewable inside wearing plates,** of blue annealed steel.

And in addition the "Cube" has all the labor and time-saving devices demanded by the contractor. It's a money-maker from the word go—steady—consistent—dependable.

The Austin Catalog No. 25 picturing many typical jobs, sent on request.

Regulation of the Level of Lake Superior

and the Development of Water Power at Its Outlet

By

L. C. Sabin

U. S. Assistant Engineer

THE usual water-power development requires natural or artificial reservoirs which may be drawn upon in the months of low supply, such use resulting in considerable changes in elevation of the water surface of the reservoir. In the development of power at the outlets of the Great Lakes this condition is materially modified. The reservoirs are already provided, and are of such size, compared with the drainage areas and consequent volumes of discharge, that the flow is unusually well distributed throughout the year; but on account of the paramount importance of navigation, the reservoirs may not be drawn upon to an extent which would increase the fluctuations in the level of lake surface, lest the depth of water available for navigation in the channels and harbors be unduly reduced.

Within the past few years a system of regulation of the outflow of Lake Superior has been evolved, which is of interest because of the size of the reservoir and the success of the undertaking. A brief description of the development of the water power at the outlet of Lake Superior, and the works constructed to maintain the elevation of the lake surface within narrower limits of variation than those obtaining under natural conditions, forms the subject of this paper.

Hydraulic conditions

Lake Superior has a surface area of 32,060 square miles, and drains a basin 76,134 square miles in extent. Its maximum depth being in excess of 1,000 feet, it is the largest single volume of fresh water on the globe. The St. Marys River, which forms the outlet, connecting it with Lake Huron, is about 64 miles in length, having a total fall of from 18.3 feet to 23.6 feet, according to the relative stages of the two lakes. The discharge from the lake under natural conditions varied from 52,000 to 122,000 cubic feet per second, with an average discharge of about 82,000 cubic feet per second.

The greater part of the slope in the river is concentrated at the St. Marys Rapids, where, in a distance of less than a mile, the fall under natural conditions varied from 15 to 19 feet; but since the improvement of certain portions of the river by dredging new and enlarged channels, the fall at the rapids has varied from 18 to 21 feet. The possibility of developing about a hundred thousand horse power at this point was early appreciated, but its accomplishment is not yet complete.

The St. Marys Rapids cut through a Potsdam sandstone formation creating a natural regulating weir. The controlling cross-section at the head of the Rapids under natural conditions had a total area of about 16,000 square feet. Of this about 2,000 square feet was between the islands, while the area of the main channel was about 14,000 square feet, with mean depth of about 6 feet. The area of the lake surface bears so great a ratio to the area of the drainage basin that with no inflow the mean discharge for three months would lower the lake surface only 9 inches, while the increment of discharge for 1-foot rise in stage is approximately 25 per cent of the mean flow. Due to these conditions, the elevation of the lake surface, as indicated by monthly mean gauge readings, was maintained within a range of about 3.3 feet, the recorded monthly mean stages showing a minimum of 600.8 and maximum of 604.1 feet above mean tide at New York.

Encroachments on the cross-section of the outlet channel by the construction, in 1887, of the international railroad bridge, crossing the rapids at about the critical section, and the closing of portions of the channel in connection with the early water-power developments, reduced the area and discharge of the outlet and the natural increment of discharge per foot rise in lake level. On the other hand, the flow through the power canals introduced the possibility of drawing down the lake surface by reason of the use of a greater volume of water than would have been discharged under natural conditions. Attention was therefore drawn to the need of compensation for the water withdrawn for power purposes, and of artificial works and restrictions to replace the regulation offered by the natural conditions which were being interfered with.

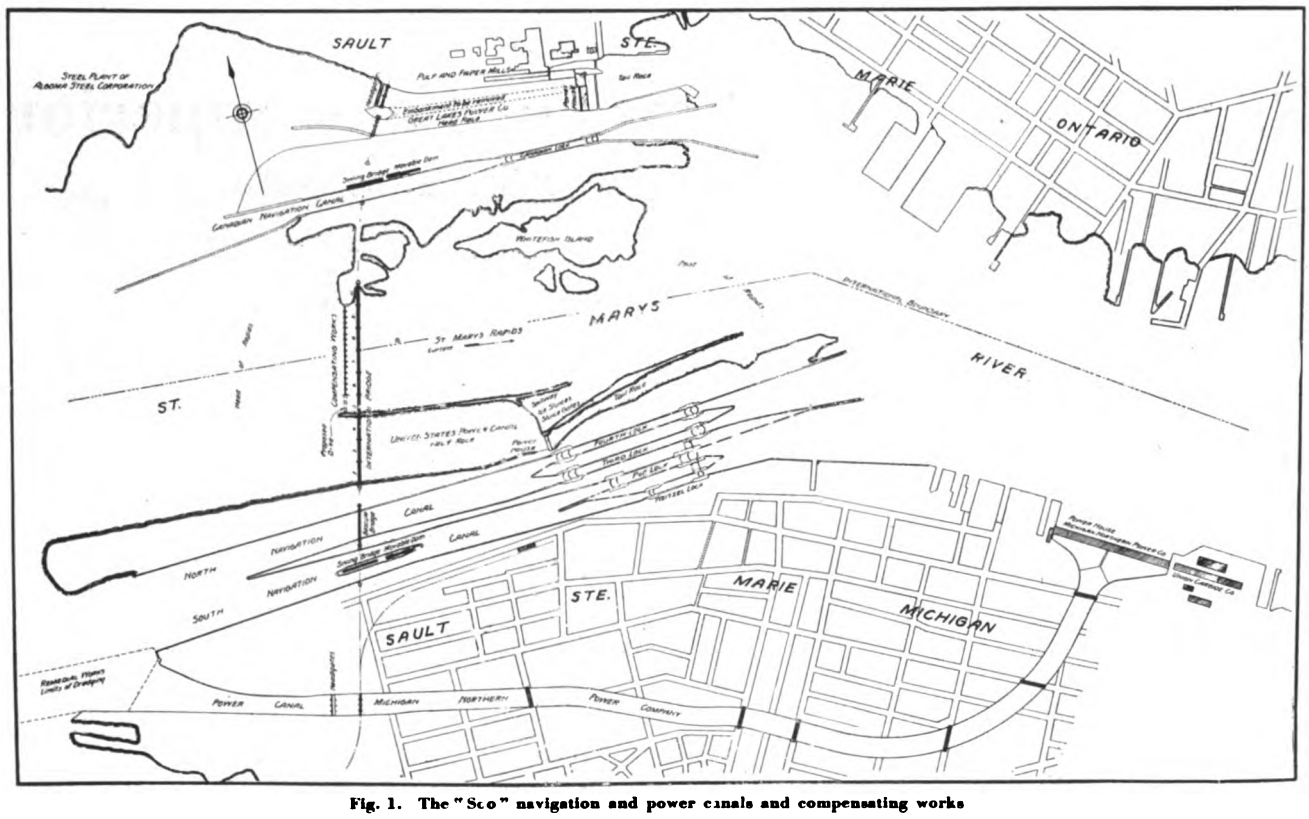

Fig. 1. The "Soo" navigation and power canals and compensating works

Improvements for navigation

The works that have been carried out for the benefit of navigation may be briefly outlined as follows:

The Northwest Fur Company built a small lock on the Canadian side of the rapids in 1797-98, to facilitate the passing of the rapids by canoes engaged in the fur trade. This lock was destroyed in 1814 by United States troops. The first canal for the passage of ships was built by the State of Michigan in 1853-55. The tandem locks of this canal were destroyed in 1888, by excavation for the Poe lock. In 1881 the Weitzel lock, built between the State locks and the American shore, was completed, and in 1896 the Poe lock was opened, being constructed on the site of the old State locks. The present ship lock on the Canadian side was opened in 1895.

None of the above works for the benefit of navigation appreciably obstructed the flow in the rapids at the critical section. Two new locks have recently been opened, one in 1914 and one in 1919; their construction would have obstructed, to some extent, the flow in the river if no power development had been made, but as the power canal extended farther into the rapids, the obstruction is considered under that head.

The present lockage system comprises one lock on the Canadian side, 900 feet long, 60 feet wide, with 18-foot depth, and on the American side one lock 515 feet long by 80 feet wide, with 13-foot depth; one lock 800 feet long, 100 feet wide and 18-foot depth, and two locks 1,350 feet long, 80 feet wide and 24½-foot depth.

Artificial obstructions in outlet

The first encroachment on the cross-section at the rapids was due as stated, to the building of the international bridge in 1887. This bridge originally had ten spans, numbered from south to north, with nine piers in the rapids, and its construction cut off about 14 per cent of the original cross-section area of the rapids, and about 8 per cent of the flow.

Power development was initiated in 1887, when the Edison Sault Light & Power Company was organized, and the following year built a canal through a strip of land lying between the ship canal and the river bank, along the upper part of the rapids. The interests of this company were divided later between two allied companies—the Chandler-Dunbar Water Power Company and the Edison Sault Electric Company. In 1892 a permit was granted to the latter to build a dike extending downstream from the international bridge to its power house. The construction of this dike cut off the free flow, in a section about 500 feet in width, through the two southerly spans of the international bridge, the obstruction being estimated to be about 9 per cent of the mean flow.

On the Canadian side, the Ontario Light & Power Co., whose works were purchased later by the Lake Superior Power Co., built a canal in 1889, partially obstructing a small stream between the islands, and this obstruction was later made complete. This company, in connection with the construction of compensating works in the rapids in 1901, also closed the area under the tenth, or northerly, span of the bridge.

Digitized by Google

The effect of these various works, exclusive of the compensating works above span 9, to be referred to later, was to confine the natural flow to bridge spans 3 to 9, inclusive, reducing the cross sectional area of the rapids at or near the critical section by about 42 per cent, and the discharge at mean stage by about 23 per cent.

No measurements of discharge had been taken prior to the placing of a part of these artificial obstructions, and the observations made shortly afterward were somewhat fragmentary. It appears, however, that after the placing of the obstructions the increment of discharge of the stream per foot rise in stage was about 18,000 c. f. s., and that the obstructions had cut off about 19,000 c. f. s. If no water had been used through the power canals to offset this obstruction, the effect would have been to raise the mean lake level of Lake Superior by about 1 foot.

Present power development

Great Lakes Power Company. The company which began the construction of a power canal on the Canadian side in 1889 became financially embarrassed, and its property and franchises were taken over in 1895 by the Lake Superior Power Co., which completed the canal and began the use of water in December of that year. Since that time the canal and power plant have been enlarged, and the use of water has increased from about 2,000 c. f. s. in 1896 to nearly 14,000 c. f. s. at present. The plant, which is now owned by the Great Lakes Power Company, is still in process of enlargement.

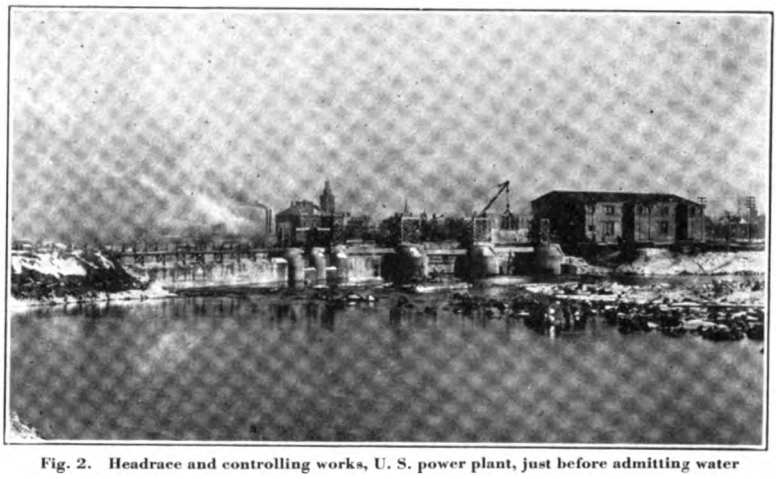

Fig. 2. Headrace and controlling works, U. S. power plant, just before admitting water

The headrace is about 3,000 feet long, and when completed will have a width of about 400 feet and depth of 13 feet. The plant is intended to utilize a flow of about 23,000 c. f. s. The power installation is divided between a ground wood mill, the old power station, and the new power station. The ground wood mill equipment consists of 12 horizontal units of 5 runners each, direct connected to wood grinders, the turbines being 34-inch new American type, with rating of 240 horsepower, each at 18-foot head. In the old power station there are four 51-inch vertical McCormick turbines, having a rating of 350 horsepower at 18-foot head, but not now used to full capacity. The shafts are connected through gearing to horizontal generators. In the new power station the equipment consists of 24 units of 53-inch Allis-Chalmers wheels, rated at 950 horsepower at 18½-foot head. At present about 14,000 c. f. s. is used in the plant, but with full flow a development of about 35,000 horsepower would be possible.

United States Power Plant. The construction of a power plant adjoining the rapids on the American side, carried out in 1888 by the Edison Sault Light and Power Company (later the Edison Sault Electric Company), and the extension of this plant under War Deparment permit of 1892, has been referred to above. Under another permit, granted in 1903, the company built, in 1906, a new power house farther out in the rapids, and extended its headrace and tailrace accordingly. The new power plant comprised four units, 72-inch vertical Leffel turbines, with generators mounted on the same shaft.

The rivers and harbors act approved March 3, 1909, directed the Secretary of War to acquire all lands and property lying between the St. Marys Falls Canal and the international boundary line, and provided that any excess of water in the St. Marys River not required for navigation be leased for power purposes by the Secretary of War upon such terms as he might consider best calculated to insure the development thereof. The lands and property so acquired included the canal and power plant of the Edison Sault Electric Company. The power plant, with a limited amount of power, was then leased to the company for a period of thirty years. This lease provides for the payment by the company of $12.00 per year for each horsepower that can be delivered on the switchboard of the plant.

Since the power canal interfered with the construction of the new navigation canal leading to the third and fourth locks, the United States extended the headrace of the power plant by constructing a dike leading downstream from the fourth pier of the international bridge to join the plant, thus shutting off the natural flow under spans 3 and 4 of the bridge, and including this area in the headrace. At the same time the first span of the bridge was removed and replaced by a fill so that the new headrace included the area under spans 2, 3 and 4, and this new headrace was deepened to minimum of 5½ feet for width of 200 feet, to provide for the desired flow with less loss in head. (See Figs. 1 and 2.)

Digitized by Google

In order to compensate for thus cutting off the natural flow under two additional spans, the United States constructed, at the lower end of the headrace or forebay, and just north of the power house, controlling works, consisting of three sluice-gates, each 15 feet high and 34 feet 4 inches long, between centers of end bearings, giving 33 feet clear opening. In case of high water in Lake Superior these sluice-gates may be opened and will pass a greater volume of water than passed spans 3 and 4 under natural conditions.

The works installed at the lower end of the headrace also include two ice passages of 16-foot clear opening, and about 5-foot depth, closed by stop logs between concrete piers 8 feet wide, and a concrete weir 150 feet in length, with crest near mean high water level. The purpose of the weir is not to assist in regulation of flow, but to relieve excessive high water caused by unusual weather conditions or fluctuations in the use of water.

The sluice-gates are of the Stoney type, being constructed of steel and composed of three horizontal girders with upstream sheathing. The gates are 4 feet thick throughout the center 21 feet of the length, decreasing to 2 feet 4 inches at the bearings. They are provided with end thrust rollers to keep them in position, and the roller nests of the main bearings operate against vertical cast steel bearing plates, secured in recesses in the piers. On the upstream side of the gate at the bearing are two vertical angles, with but slight clearance between them and the vertical face of the pier recess. When the gates are closed, this joint soon fills with débris, or may be calked, if desired, to make the joint practically watertight. At the ends of the gates watertight steaming chambers are provided to thaw the ice forming at the junction of the gate and pier in case winter operation is required. A timber cushion is attached to the bottom of the gate, designed to bear on the timber sill.

The spacing of the piers is the same as the penstocks in the power house, 49 feet, so that in case it is decided to extend the power plant the extension may be built directly below the gates, and the piers will form a part of the permanent construction, while the gates will serve to close individual penstocks when needed.

The piers for the gates are of concrete, 16 feet wide, 28 feet long, and about 28 feet high. The upstream starling is protected from ice by sheathing of 60-pound rails. The piers are founded on Potsdam sandstone bedrock.

The sills are made of two pieces of 12 by 12 inch oak timber, set side by side in concrete and flush with the floor of the apron, which is paved with vitrified brick. The excavation for the sill concrete was also carried to rock, but for a portion of the aprons above and below the sill a layer of concrete 4 feet thick was placed on the compact sand filling overlying the rock and protected from wash below the gates. Each pier was designed to be anchored to the rock near the upstream end with nine 1-inch square twisted bars, extending 5 feet into the rock and 5 feet embedded in the concrete. In drilling for these anchor rods in the first, or south, pier, a water-bearing seam was encountered. This seam was filled with grout under pressure, the number of rods was increased to 24, and the length in the rock increased to 12 feet to guard against sliding of the upper layer of rock in case of excavation downstream from the pier. The rock was also drillel and grouted in the first gateway and anchor rods placed under the first concrete sill.

As already stated, the plant as purchased by the United States had an installation of four 72-inch vertical Leffel turbines, with generators on the same shaft capable of developing a total of about 2,000 horsepower at 15-foot head. After the execution of the lease the company desired additional power, and the United States therefore extended the power-house southward to cover an additional penstock that had already been provided, and installed one additional unit. This unit consists of one Allis-Chalmers 60-inch, single, vertical turbine, rated 925 horsepower at 17-foot head, with a General Electric 625 K. W. generator, mounted on same shaft. The present capacity of the plant is about 3,200 horsepower at 17-foot head.

Michigan Northern Power Company. The construction of a power canal on the American side was begun in 1887 by the St. Marys Falls Water Power Company. A canal about 3 miles in length was projected to run through the city of Sault Ste. Marie from above the ship canal to connect with the river 2 miles below the locks, and since the transmission of electricity had not then been perfected, it was proposed to supply each manufacturing plant with separate turbines.

This company failed, and its right-of-way was purchased by the Michigan Lake Superior Power Company, which in 1898-1901 constructed a canal extending from just above the upper entrance of St. Marys Falls ship canal to a point about a mile below the locks, where the power house is located. The present owner of the plant is the Michigan Northern Power Company.

The canal, or headrace, is about 2 miles in length and has a cross-sectional area of about 4,400 square feet. Near the upper end of the canal are located head gates, capable of shutting off the flow and permitting unwatering the canal. At the lower end the canal expands into a forebay leading to the power house, which is about a quarter mile in length with 81 open penstocks and tail pits, three of which are used for spillway purposes to dispose of ice and trash.

The company operated from 1903 to 1914 under a War Department permit issued in accordance with the terms of the rivers and harbors act of June 13, 1902,

Digitized by Google

the use of water increasing from about 8,500 c. f. s. in 1904-5 to about 11,000 c. f. s. in 1906-14. The use of water under this permit being made subject to water-level conditions, the company was restricted in its operations, the permitted flow being reduced in low water.

On account of the character of the foundations of the power house, the full head could not be utilized at first, and only about half of the total number of units was installed. The plant was purchased by the Michigan Northern Power Company in 1913, and under the terms of a lease from the United States, to be referred to later, the power house was strengthened, the remaining penstocks supplied with turbines, and the use of water increased to about 30,000 c. f. s. in 1917. With this flow the loss of head in the canal is about 3 feet, and the power developed is about 40,000 horsepower on switchboard.

Fig. 3. Compensating works in rapids, from Span 7 of International Bridge First four gates, Canadian side

The plant installation consists of 78 units, each composed of 4 turbine runners on the same horizontal shaft, the runners being arranged in pairs, each pair having a separate draft chest and draft tube. The turbine units in use are 41 McCormick type, installed in 1901-2, 22 S. Morgan Smith units, installed in 1915-16, and 15 Wellman-Seaver-Morgan units, installed in 1916. The electrical equipment consists of 95 direct-connected generators, of which 4 are exciters. Seventeen generators and exciters are on extended shafts.

Restrictions regarding the use of water

Under the rivers and harbors act of March 3, 1909, which made provision for the acquisition by the United States of all lands and property lying north of the St. Marys Falls Canal to the international boundary line, and also empowered the Secretary of War to lease the surplus water for power purposes, the Michigan Lake Superior Power Company made application in 1911 for a lease of water according to certain plans for compensating and remedial works, and certain restrictions that were subsequently approved by the Secretary of War. After the purchase of the plant by the Michigan Northern Power Company, the name of the applicant was changed accordingly. A similar application, including the above plans, was, in 1913, submitted to the International Joint Commission created by the treaty of January 11, 1909, between the United States and Great Britain, and having right of review of proposed works in boundary waters that might affect the natural levels thereof. At about the same time the Algoma Steel Corporation, Ltd., of Canada, made a similar application to the International Joint Commission.

Under date of May 26, 1914, the Commission approved the obstruction, diversion and use of water under certain conditions, which included the construction of compensating works at the head of the rapids, to consist of sixteen Stoney sluice gates of 52-foot clear opening, located above and parallel to the international bridge, and a dike about 200 feet long, extending from the south end of the gates to the headrace dike of the United States Government headrace. Four of these sixteen gates had been constructed in 1902, and title to them secured by the Algoma Steel Corporation, Ltd., subsequently passing to the Great Lakes Power Company, now operating the canal on the Canadian side. The Canadian Company was directed to place four additional gates, and the American company was to place eight gates and the dike on the American side of the boundry.

The power companies were to operate the compensating works gates under the direction of a "board of control" of two members, the American member being the officer of the Corps of Engineers in charge of the improvement of the falls of the St. Marys River. The conditions of the order of approval also provided that should currents caused by operation of the works unduly interfere with navigation, the power company operating the works should take necessary steps to remedy this condition.

The rules laid down for lake regulation require the level of Lake Superior, as measured by monthly mean readings, to be maintained as nearly as may be between the levels of 602.1 and 603.6 above mean tide at New York, giving a range of 1.5 feet. The natural levels (prior to 1887) had a range of 3.33 feet, or from 600.75 to 604.08, and it is known that with the degree of flexibility given by the proposed additional outlets, or canals, and obstructions, or compensating works, it will not be possible to reduce this range to 1.5 feet under all the variations in rate of supply that have obtained in the past.

To guard against unduly high stages of water in Lake Superior, however, it is provided that the rules formulated for the operation of the compensating works, when tested by the physical conditions prevailing in any year of extreme high water in Lake

Digitized by Google

Superior under natural conditions, shall give no monthly mean level of the lake greater than the maximum monthly mean actually experienced in said year; in other words, with the recurrence of the amount and distribution of supply in any prior year of extreme high water, the lake must not be permitted to attain a higher level under regulation than it actually did attain under the natural conditions of discharge during that year. To guard against unduly low stages in Lake Superior it is provided that whenever the monthly mean level of the lake is less than 602.1 feet the total discharge permitted shall be no greater than would have obtained at the prevailing stage and under the discharge conditions which existed prior to the placing of any obstructions; that is, prior to 1887.

The conditions regarding construction of compensating works referred to above were incorporated in a lease made by the Secretary of War to the Michigan Northern Power Co. for the use of 25,000 c. f. s. "primary water," with provision that at such times as the flow of river will permit, the United States will allow the use of 5,000 c. f. s. additional flow, to be known as "secondary water." The price fixed for primary water, expected to be continuously available, was $2 per cubic foot year, and the price of secondary water, intermittently available, $1 per cubic foot year.

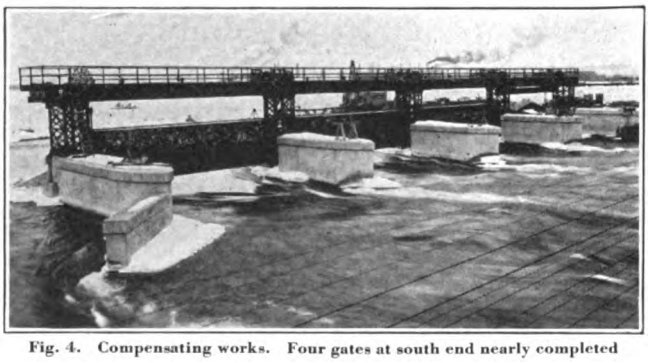

Fig. 4. Compensating works. Four gates at south end nearly completed

Under the terms of this lease the company deepened the entrance to its power canal to reduce cross-currents in the adjoining navigation canal, repaired and strengthened the foundations of the powerhouse to withstand full head of water, and constructed the eight gates of the compensating works required on the American side of the international boundary for regulating the level of Lake Superior.

The company bore the expense of all improvements in the first instance, but retain rentals until the cost of the compensating works and the excavation outside of harbor line at the canal entrance have been repaid, the compensating works remaining the property of the United States.

Compensating works

The compensating works as now built consist of 16 Stoney sluice gates between masonry piers, and are located on a line parallel to, and 150 feet above, the bridge. The structure is continuous and the gates are of such length that a set of four exactly correspond to the length of one bridge span. The section of the stream above span 10 is now occupied by a fill, and a dike will be built to shut off the cross section above span 5, thus giving complete control of all flow in the rapids. The international line is at the pier between spans 7 and 8 of the bridge. (See Figs. 1 and 5.)

The four gates on the Canadian side, first built, were designed under the direction of the late Alfred Noble, and the remaining gates are similar, plans for the eight American gates having been prepared for the Michigan Northern Power Co. by the firm of Noble and Woodward.

The north and south abutments have wing walls for confining the adjoining fills or dikes. The three gate

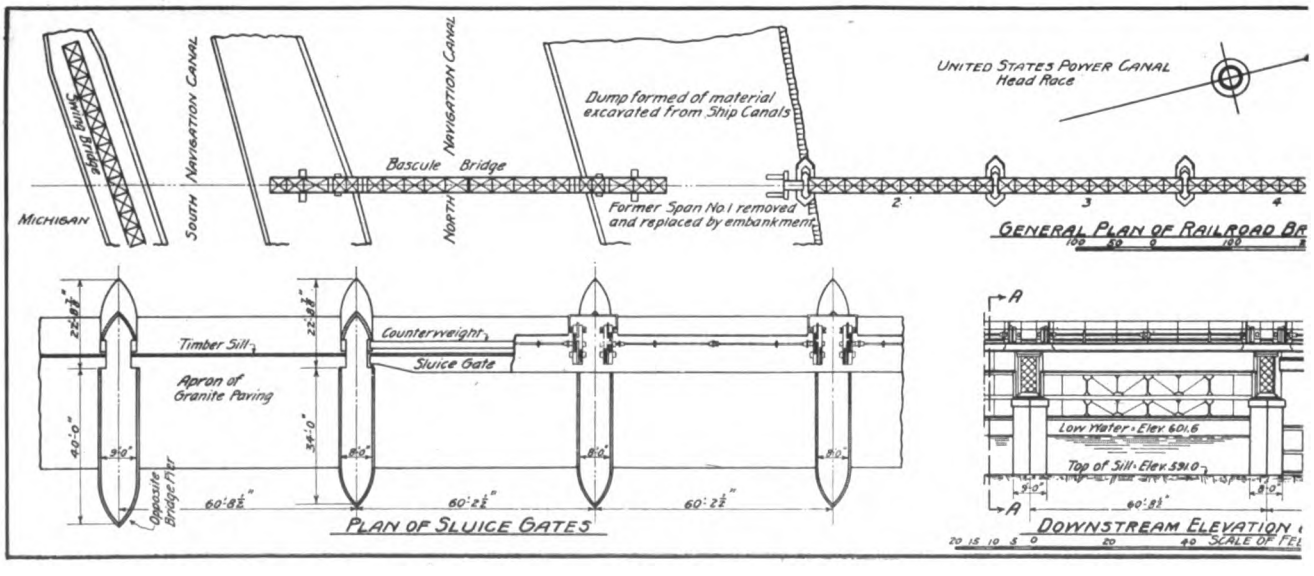

Fig. 5. Compensating works.

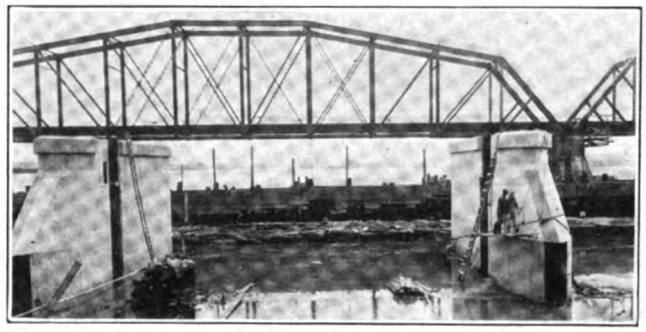
Digitized by Google

piers that are immediately upstream from the bridge piers are 9 feet wide and 62 feet 9 inches long, while the twelve intermediate piers are 8 feet wide and 56 feet 9 inches long. The piers are recessed on the sides forming quoins to receive the gates, which have a clear opening of 52 feet 2½ inches each.

The gates are of steel, about 13 feet high and 54 feet 6½ inches in length. The four Canadian gates above span 8, built last, have sill elevation 1 foot lower, and consequently these gates are 1 foot higher. The members carrying the main stresses are three horizontal plate girders 5 feet wide for 32 feet of the central portion, reducing to 2 feet 8 inches at the ends. The upstream face has ⅜-inch sheathing, and girders are connected by vertical end frames, 3 cross frames and adequate diagonal bracing. Bearing plates on the back of the end frames run on the rollers of the roller trains, which in turn bear on cast steel tracks bolted to quoins of the piers. A 6 by 12 inch oak cushion extends across the gate at the bottom next the sheathing, forming contact with the oak sill when in place. The weight of the gate is nearly balanced by a counterweight consisting of an open steel box, carrying cast-iron weights and extending across the entire length of the gate. Hand-operated machinery for raising and lowering the gates is located on an overhead platform, supported by steel towers on the piers.



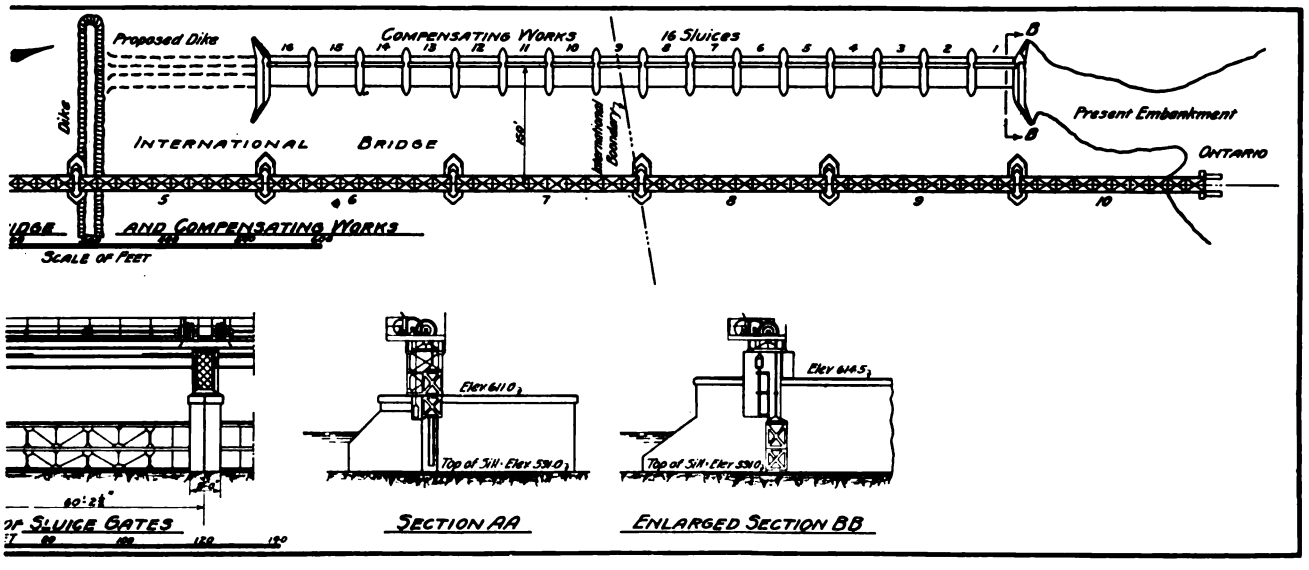


Fig. 6. Compensating works, details of view of piers

The piers are mainly of concrete; the five northerly piers, those built in connection with the first four gates, have the upstream starling, the recesses or quoins, the downstream nose stones and the coping, of cut stone, the starling and the lower quoin facing being of granite, while the remainder is limestone. The bodies of these piers are faced with granite paving blocks, and the aprons between the piers are paved with granite blocks for a length of 39 feet. The other twelve piers were built later and are entirely of concrete. On these piers the upstream nose is protected at the point by steel plate. (See Fig. 6.)

The following details of construction relate only to the eight gates on the American side. The site being at the head of the rapids, where a strong current existed, the Potsdam sandstone rock was practically clear of overburden. As it was necessary to obstruct as little of the discharge cross-section as practicable during construction, the gates were built in sets of 4 the northerly 4 being built first. Each set was constructed within a cofferdam. A breakwater of loose broken rock was first placed above the site of the cofferdam to break the current, and below this the dam was constructed by building 30 by 16 ft. corn-cob cribs of square timber and sinking them by filling with gravel. The bottoms of the cribs were scribed to approximately fit the rock surface. To increase the watertightness of the dam, sheathing was placed along the outside and about 6 ins. from the cribs, and the intervening space filled with cinders. The pumping required was about 4,000 gallons per minute for each cofferdam.

The elevation of original rock surface varied from 590 to 595. With elevation of 591 for gate sills and sluice floors, or aprons, it was proposed to excavate under the piers and sills to grade 589 and under the

St. Mary's River, above Falls

Digitized by Google

apron to grade 589.5. At these grades, however, the rock in general was not sound and was underlaid with mud seams so that actual excavation was carried to from 586 to 589 under the piers and for 10-foot width under the sills, and from 587 to 589 under the apron. Grout was also forced under pressure in 2½-inch holes, 2 to 8 feet deep, spaced about 10 feet apart under the sills and piers, and other places where water-bearing seams were encountered. Piers were molded monolithic in wooden forms, the concrete being composed of a rich mixture of cement, sand, screenings and broken igneous rock. Concrete was mixed on floating plant lying just above the dam,

Fig. 7. Compensating works. Inside of cofferdam. Abutment of Pier 17 in foreground

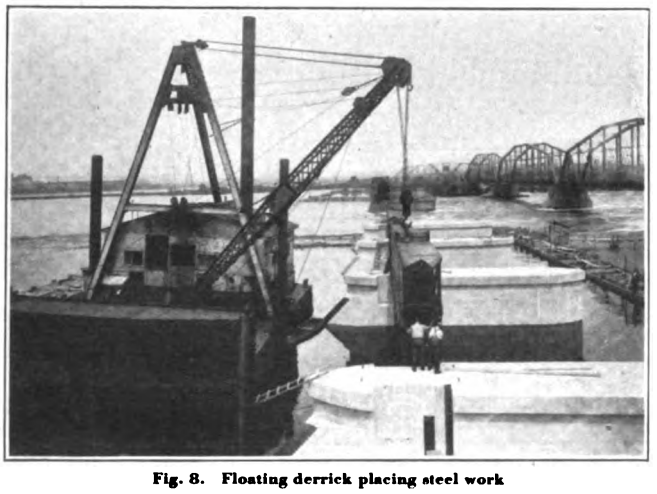

Fig. 8. Floating derrick placing steel work

transported to the pier sites by cars running on an elevated trestle within the cofferdam, and deposited through chutes. The piers were given a rubbed sand finish.

On the completion of one section the cofferdam inclosure was flooded and the cribs used in building the other section. The sluice gates were assembled on land, and, when completed, were hoisted, transported to site, and set in place by floating derrick, the weight of each gate being about 30 tons. The structural work of towers and footbridges and the machinery were also placed by floating derrick. (See Fig. 8.)

The eight American gates of the compensating works were completed, tested and accepted August 28, 1916, and the last four Canadian gates were built in 1918, completing the works as planned, except for the construction of dike above span 5 of the bridge, which has been left open until such time as the power canals on the Canadian side should be completed, and some material just downstream from the gates excavated to allow full flow through the gates.

Operation of compensating works

Water levels have been observed on Lake Superior from 1860 to date. The earlier results were from daily or tri-daily readings of staff gauges, and all depend on the maintenance of proper elevations of bench marks and gauges. Some doubt exists concerning the accuracy of some of the earlier levels, especially prior to 1872. Discharge measurements in the outlet of Lake Superior have been taken at various times since 1896. At that time the bridge piers were already in place, and certain other physical changes had been made, modifying the rate of discharge, but the effect of these

Fig. 9. Compensating works at head of rapids, sluices completed Looking northwest from International Bridge

changes has been evaluated so that the quantity of mean discharge for each month for the past sixty years is fairly well known. The lake levels give the rise or fall for each month; that is, the storage, either positive or negative.

These two factors permit the determination of the supply to the lake. The discharge or outflow, expressed in feet depth on lake surface, plus the storage, with proper sign, gives the supply. This has been determined for each month and may be used in the test of any plan of operation of canals and compensating works that may be proposed. Starting with a certain level on the first of a given month, adding the supply for that month, and subtracting the discharge that is proposed under the scheme of regulation, gives the resulting level on the first of the succeeding month.

In making such tests the earlier the mean level is assumed to be known the more closely can regulation be effected. It should be possible to know the mean level for any month by the first of the next month. In making such tests it is assumed that the gates are

Digitized by Google

set on the first of the month and not disturbed until the first of the following month, though it would be possible to operate somewhat more closely by permitting a change each half month.

Before the present works were authorized, such a test was made to show how successful they would prove under the conditions of supply that have obtained in the past. Should the conditions of supply be more extreme in the future the levels can not be retained between limits as narrow as proposed. For any assumed or actual conditions as to discharge capacity, various rules of operation may be worked out, such that certain desired results as to regulation shall be attained or approached.

Under the present conditions the extra cross-section to give additional flow through side outlets—that is, the power canals—has not been provided to the full extent contemplated in the plans, and there is still uncontrolled flow through a small part of the rapids channel, but a rule has been deduced for the operations under these conditions which gives a degree of regulation not far inferior to that which will be possible when the proposed works are entirely completed. Such a rule is shown in the table.

REGULATION OF LAKE SUPERIOR

CONDITION XI

Rule Curve "C" for Operation of Gates of Compensating Works

Month to which gate opening applies	Preceding month.	All gates closed when mean elev. for preceding mo. is below—	4 gates open when mean elev. for preceding mo. is equal or above—	8 gates open when mean elev. for preceding mo. is equal or above	12 gates open when mean elev. for preceding mo. is equal to or above	16 gates open when mean elev. for preceding mo. is equal or above	All gates open, including 2 sluice gates in U. S. Govt. headrace, when mean elev. for preceding mo. is equal or above
February	January	602.64				602.64	
March	February	602.44				602.44	
April	March	602.36				602.36	
May	April	602.32				602.43	602.55
June	May	602.27	602.27	602.37	602.46	602.55	602.55
July	June	602.43	602.43	602.52	602.61	602.70	602.80
August	July	602.65	602.65	602.74	602.82	602.90	603.00
September	August	602.87	602.87	602.95	603.02	603.10	603.20
October	September	603.09	603.09	603.16	603.24	603.30	603.40
November	October	603.20	603.20	603.24	603.27	603.30	603.50
December	November	603.10				603.10	603.50
January	December	602.84				602.84	
Assumed use of water in canals, cu. ft. sec.		43,000	50,000	50,000	50,000	54,500	59,000

Applying this rule to the supply that existed in the past sixty years, 1860 to 1919, inclusive—that is, assuming that the present artificial works had been in place in 1860 and this rule curve were used to regulate the discharge—the level of Lake Superior would have gone below 602.1 during thirty-two months, the lowest level being 601.5 in April, 1911; but the low water would have occurred usually before the opening of navigation, and the level would have been always above 602.1 by the middle of June. The level would have risen above the desired upper limit of 603.6 in only two years—1869 and 1876—and then would not have exceeded the level which existed under natural conditions in those years. In 1869 the water levels indicate a supply to the lake of 3.87 feet in six months, and in 1876 a supply of 3.24 feet in five months. Under such conditions it is impracticable to prevent an extreme rise in level with any reasonable discharge capacity.

Had the supply of 1908 to 1911 occurred under natural conditions of discharge, the level would have gone 0.4 foot below any prior monthly mean and 1.2 feet lower than the computed stage under regulation. This is shown graphically in Fig. 10. The curves for the past four years, 1916 to 1919, inclusive, are also shown. Had the works been completed to the present degree in 1916 the maximum level under regulation would not have reached 603.5, and the low level in April, 1918, which was actually below 601.5, and which under natural conditions of outflow would have reached 601.1, would have been held up to about 602.0.

With the rates of supply to the lake that have prevailed in the past and the natural conditions of discharge of the outlet, the elevation of the lake surface as measured by the monthly mean levels would have fluctuated between limits of 604.1 and 600.3, a range of 3.8 feet. Under the same conditions of sup-

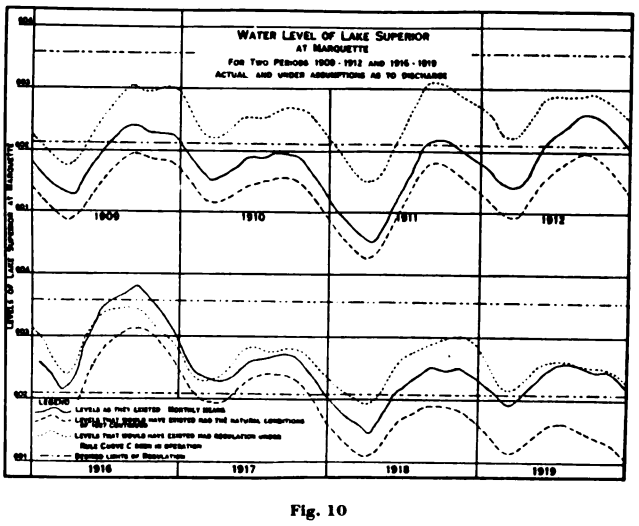

Fig. 10

Digitized by Google

ply and the present controlled outflow the range would have been between 604.1 and 601.5, or 2.6 feet. It thus appears that while the outlet of the lake gave naturally a high degree of regulation, it is possible to improve it by avoiding periods of extreme low water and, at the same time, permit the use of the minimum flow for power purposes.

When the works are entirely completed the flexibility of the system will be increased, since the entire flow will be under control; the degree of regulation will not be materially improved, however, but a greater use of water for power will be permissible. What will be accomplished, then, is the continuous use of the natural minimum flow, equal to about 75 per cent of the mean discharge of the river, and a reduction of the fluctuation in monthly mean levels from a range of 3.8 feet to a range of about 2.6 feet. The economic advantage of power development to the extent of some 80,000 horsepower is thus combined with improvement of navigation conditions.

Surveying in France during the War

An entertaining article on "Survey in France during the War," by Lt. Col. E. M. Jack, C. M. G., D. S.O., R. E., appears in *The Royal Engineers Journal* for July, 1919.

The British Field Survey Battalions were charged with the preparation of maps in the field and by compilation, and with sound and flash ranging and map issue. Map publication in quantity was at first carried out in England but was later done by forces in the field.

Among our American forces the opinion is held in some quarters that the *plans directeurs* in France had been prepared prior to the war and in other quarters that they were prepared entirely by field survey. Both ideas are erroneous.

"Belgium was covered with a very fair topographical map, published on 1/40,000 and 1/20,000 scales.

"In France no large scale maps had been published. The Fortress *Plans Directeurs* had been prepared in peace time, for the areas around fortresses and along the frontier, as a secret map. These were topographical maps on the 1/20,000 scale, of good quality but not always up-to-date. For the rest of the area with which we were concerned no maps were readily available except the French General Staff map on 1/80,000 scale.

"A cadastral survey of France had, however, been carried out early in the nineteenth century, but it was never published. . . . This survey is mostly of good quality, but each commune was done independently, and there was no trigonometrical framework. The documents consist of an enormous number of small drawings on 1/2,500 scale.

"An attempt was made to use photographic enlargements (to 1/20,000 scale) of the 1/80,000 map. This was almost immediately found to be useless: . . . An effort was then made to revise the map and correct its errors, using as a basis the photographic enlargement. This proved equally useless. It was therefore decided to start a topographical survey *ab initio.*"

Subsequent efforts led to most careful methods of map preparation.

An interesting sidelight upon the initial mistakes of the British is contained in the final report of our American G.2.C. "The first and most important thing, both from point of view of the Artillery and of the Topographical services, is the establishment of a uniform system of control. This is clearly shown on a report of British 'Maps,' which never recovered, even after four years of war, from initial mistakes, and instead of a comprehensive and complete geodetic system were compelled, up to the end of the war, to submit to the annoyance, confusion and error of a patch-work system devised by various irresponsible surveyors for their immediate needs. The geodetic systems of the different German groups of armies also were different and unrelated, which must have been a source of trouble and confusion. During the period when a unified system of geodetic control is being established, the artillery has in its own hands rough means of sufficient accuracy for bridging over the gap."

The British writer himself decides: "The conclusion is evident, that it always pays in the long run to make your map as accurate as you can in the first instance, as it is then a reliable basis for all subsequent work." This sentence appears to contain the very essence of sound advice in mapping.

In work in the forward or enemy areas use was made of aerial photographs when there was existing sufficient data in the way of old triangulation, cadastral surveys, railway and canal plans or new triangulation established by intersection, to tie in the aerial photographs. Air photos in themselves were unreliable, owing to the errors and distortions to which they were subject. By these methods maps reliable in plan were secured but the problem of contouring remained difficult. Railway and canal plans, the hachured 1/80,000 maps and other available data was used, but the contouring of necessity remained the weak part of the maps.

Some of the difficulties of the surveyors are amusing. "The first surveyor who appeared with a theodolite was arrested as a spy, on the ground that no one but a German would be likely to use such an instrument in our area. These difficulties were enhanced when our men were working in or near an area occupied by French troops, and it became a common experience for topographers to be taken into custody. Eventually, we had to provide every man with an elaborate passport, bearing as many signatures and office stamps as it was possible to crowd on the sheet; after which they were able to do their work with less interruption. It has been said with some truth that in this, as in other services, the difficulties of contending with the enemy were insignificant compared with the obstacles placed in the way by our own friends. One Field Survey Battalion Commander stated that his three chief enemies were rumors, British tanks and Australians. The first caused unnecessary movements, the second picked up and carried away all telephone cables, and the third took anything they saw. In one area the greatest difficulty was experienced in preserving any kind of trigonometrical signal or picket. It was found that there was only one kind of monument that was respected, and thereafter every trigonometrical point was made secure by marking it "*Grave of an unknown soldier of the —th Field Survey Battalion.*"

Light Railway Practice in the A.E.F.

By

V. R. Irvine

Captain, 14th Engineers (Ry.), A. E. F.

[NOTE. Captain Irvine's regiment was engaged in light railway work in the 3rd British Army North, from August 18, 1917, to May 20, 1918, in the vicinity of Arras. This regiment participated in the Cambrai battle of 1917 and the great offensive of March 21 to April 6, 1918. In the latter battle they lost about one-half of their trackage but saved all of their locomotives, cars and tools. After this drive the regiment constructed and operated about 65 kilometers of new line in addition to the remaining line.

After leaving the British 3rd Army North the regiment constructed standard and meter-gauge tracks for the British 1st Army in the vicinity of Calais until the latter part of July, 1918, when they went to the American 3rd Corps as corps troops, between the Marne and the Vesle. The regiment later went back to Verdun, dividing up on operation, construction and shop work.—ED.]

DURING the war with Germany, in order to relieve the highways of their enormous burden of traffic, it became necessary to develop a supplementary means of transportation. At the end of the war this consisted of a network of narrow-gauge railways along the entire Western front. The gauge of these combat light railways was in most cases 60 centimeter (23⅝ in.). This gauge was adopted by the American, British, French and German armies. The weight of rail used as a standard by the Americans was 25 pounds per yard, the other armies using a somewhat lighter rail which averaged about 20 pounds per yard. The motive power consisted of steam and gasoline locomotives.

The primary function of combat light railways is to deliver ammunition, troops, rations, supplies and engineer material from railheads to points near the front. Troops were taken to and from the trenches, thereby bringing them to the front in a fresh condition and shortening the necessary period of recuperation at the rest camps. During periods of combat inactivity important salvage operations were carried on.

At the rail heads or canal heads the work of the light railways began. Up to these points material was brought by standard gauge or by boat. Material was then transferred to light railways, motor trucks or wagons, either directly or after storage, and carried by them to distributing points in the forward area, such as ammunition, engineer and ration dumps. Railway yards at rail heads should be designed to permit assembly of cars into trains, of direct transfer from standard gauge to narrow gauge, motor trucks, horse-drawn wagons or storage yards. The storage yards should in turn be accessible to these various kinds of transportation.

The field of construction and operation of light railways is within the enemy's field of fire. In their simplest forms these light railways ran perpendicular to the front line, connecting rail heads with forwarding distributing points. Ordinarily these lines were connected by lateral lines at a safe distance from the front, thereby forming a series of loops. These lines were rarely double-tracked as the loops served the same purpose. These loops also had the advantage of providing alternative routes to critical positions in case the line was broken by shell fire at any point.

Experience in the late war has shown that approximately 10 miles of light railway was necessary to each mile of front line, and that one balanced company of trained operating, mechanical and maintenance men would take care of approximately 25 miles of track.

The loads carried on light railways gradually increased in size and weight; in some cases guns 9½ feet over hubs were carried, and the loads reached 3 tons per axle. As a result of the increased loads greater care was necessary in the location and construction of these railways, and it was found that even in locating what was thought to be a temporary track, grades and curves should be kept down to a minimum, as these temporary tracks usually became more or less permanent.

The location of a line of light railway must be determined by the relation of the broad-gauge rail heads to the front-line operation, and by its possible availability for the distribution of ammunition and all classes of army material and the evacuation of salvage material. Also there should be considered its possible means of access to objectives within the enemy's lines, and connection with the enemy's light-railway system in case of an advance. In the event of such an advance the broad-gauge lines would necessarily be brought forward and supersede the light railway until the operation became stable, and the location of the light railway should be made with the idea that the broad-gauge lines of railway could be placed upon the location of the light railway with a minimum effort.

As the reconnaissance is completed and the data plotted on the map the line should be staked out instrumentally on the ground, the same as would be done in standard-gauge practice, and levels run over the center line in such manner that a profile may be compiled and grade lines laid on the profile. One of the principal causes of the breaking down of the light railways in the late war was that the locations were hastily and improperly made and that gradient and curvature were subordinated to speed in location and construction. Any carelessness in location will be paid for in difficulties of operation.

The principles of actual mechanical and physical location differ very little from those laid down for broad-gauge lines. Speed in the location and construction is very important, and some of the refinements that would be used in locating a broad-gauge line would not apply in the location of a light railway, but basically the mathematical problems are the same.

The location of a light railway resolves itself into three general parts:

1. Preliminary location.
2. Map location.
3. Staking the final location on the ground.

It is very essential that, wherever possible, light railway tracks should be concealed from direct observation by the enemy. This may be accomplished by judicious use of slopes of hills, defiles, artificial screens, the rear of large woods,

Digitized by Google

or by going through a large wood. Tracks should not ordinarily be located parallel to a road or trench and should not cross at the intersection of two main highways. They should never be located so that the track will be laid along a highway, as they are not only more liable to be destroyed by shell fire but reduce the space for wheel traffic, thereby causing congestion, and they themselves are damaged by that same traffic. Nevertheless they often were laid parallel to the roads.

Grades should not exceed 3 per cent. A level or descending grade toward the front is to be desired, as the movement of the heaviest traffic is in that direction. Grade lines should be laid as close to the natural surface as possible, keeping within the maximum limits, allowing shallow cuts and low fills, as during a severe bombardment the line is liable to be broken in several places at the same time. One night during the German drive in March, 1918, the system of light railway operated by the 14th Engineers for the British 3rd Army North, south of Arras, was broken eighteen times by enemy shell fire. The breaks were all repaired and operations resumed.

In laying grade lines on the profile it is desirable to have the minimum number of fills, for the bulk of grading will be done by hand, which means that fills constructed by this method that are over 1 foot in height will shrink from 10 to 20 per cent and will be soft for a considerable period of time; whereas shallow cuts may be rapidly taken out and the track used as fast as it is laid.

Because of the added frictional resistance of rolling stock on curved track, it was found necessary to compensate the grades on curves. The compensation of curves was allowed at the rate of 0.02 per cent per degree of curve; *i. e.*, a 3 per cent grade on a 5-degree curve is equal to 3.10 per cent on a straight track.

The same principles and formulæ that are used for curves for standard-gauge roads apply on light railways. Curves should not have a radius of less than 50 meters, or 165 feet. Vertical curves should be placed at the meeting points of grades where there is a difference of 0.5 per cent or more.

One of the most important economic elements entering into the operation of light railways is the ballasting of the track, for after the new track had been laid and before extensive operations could take place, it was often found necessary to place some kind of ballast under the track. The material used in order of desirability was crushed rock, slag, gravel, brick bats, cinders, chalk and sand. The kind of ballast used is ordinarily that which can be obtained locally. Chalk ballast was used very extensively by all of the belligerents in France, and this made a very good road bed in dry weather, but it was objectionable, owing to the fact that when it rained the ballast became very slippery and soft, allowing the track to get out of line and surface and making it very hard to rerail engines or cars when they got off. Another objection to chalk is that it shows up very prominently in air photographs, thereby offering an excellent target for artillery fire and bombing.

It was considered that a minimum of 6 inches of ballast should be placed under the ties, extending at least 6 inches beyond their ends, so crushed stone or gravel was used. When chalk was used the slopes were generally banked with clay or earth to prevent waste due to the action of wind or water.

The accessibility of the ballast, the haul and method of loading will determine the rate of ballasting, but it was estimated that the following was a fair average for the work done: For a 6-inch raise under ties, 1,026 cubic yards per mile, or .20 cubic yards per foot of track; 205 man days to loosen and load ballast for 1 mile of track, or one man to 25 feet; 580 man days to unload and place a mile of ballast, or approximately 9.2 feet per man per day. This, of course, is contingent upon train service and other unforeseen circumstances.

The speed at which track laying may be done varies with the local conditions. The French have found that the amount of work which they can do in a day will not under favorable circumstances exceed 3,300 feet, provided the materials used in construction are transported on the line itself. French experience shows 2,150 man days of labor is required per mile of track. This is equivalent to 2.46 track-feet per man per day. British experience shows 1,760 to 2,400 man days is required per mile of track. This is equivalent to from 2.20 feet to 3 feet per man day. It was estimated that American track forces would construct an average of 4 track-feet per man per day.

Narrow-gauge track came in two forms, the rail and ties separately, and the fabricated section. The fabricated sections were in lengths of 5, 2.50 and 1.25 meter lengths. The loose rail came in 30-foot lengths and shorter, and when loose was assembled in sections in material yards.

It is contended by some that the fabricated sections should not be used in future operations, and that all light railway track should be constructed of rail of 30-foot lengths and with wooden ties. This contention is questioned, as the writer maintains that the fabricated sections are absolutely essential in the forward areas where the track is broken repeatedly by enemy shell fire, as making repairs at night where it is impossible to use lights, the method using the longer rails and ties would be absolutely inadequate. As has been stated before, on the night of March 21, 1918, the 14th Engineers had eighteen breaks in their main-line track, in each case the sections were removed and new sections installed without the aid of lights and with a minimum amount of confusion and noise. This would not have been possible if track had been torn out, wooden ties laid and new rail spiked into place, though it would be ideal to have this form of track on a salvage or back line that was not continually subject to enemy shell fire. The same argument is put forth with regard to the metal ties and the wooden ties, as it is an established fact that the wooden ties are far superior to metal ties, once they are in place, but the metal ties are more easily transported and more adaptable.

There have been a number of arguments brought forward advocating the adoption of a guage of 28, 30 and 36 inches for light railways, but the writer believes that only two gauges of track should be used—the standard gauge (4 feet 8½ inches) and the narrow gauge (23⅝ inches), as the primary object of using the light railway is the rapidity of construction and mobility of the system. If the gauge is widened to 30 or 36 inches, no heavier power would be used, and the cost of initial construction would be almost as much as a temporary standard-gauge railway. It should be borne in mind that the light railway is only a temporary expedient, and with an advance or retirement of any magnitude the light railway would immediately be replaced by standard gauge. Therefore, if conditions would warrant laying 30 or 36 inch gauge track, the same conditions would warrant laying standard-gauge track.

The operation of light railways was similar to that of standard railways with the exception that the light railways were operated by telephone-dispatching system of verbal orders and a positive manual block.

In dispatching trains it is essential to have simplicity and flexibility; after various experiments in the war with Germany, an adaptation of the simple Manual Block Sys-

Digitized by Google

tem was found most satisfactory. By this system the interval between trains was measured by distance instead of time. The road should be divided into sections or blocks into which only one train with full rights would be allowed at any one time, but others going in the same direction may be admitted but will be limited by the presence of the train ahead.

For example:

A———B———C———D———E

A to E represents a main track divided into four blocks or sections, with operators at each of these points. "A" represents the railhead where the dispatcher is located. The dispatcher wishing to start a train "A" to "E" calls up control at "B" and ascertains whether block "A" to "B" is clear. If clear, train leaves terminal, dispatcher notifying "B" train has left and at what time, recording time on his train sheet. On train sheet is also recorded make-up of train, name of conductor, engine number, number of cars and tonnage. After train has left terminal, or control at "B" has been notified that train is on the way, "B" calls up "C" and ascertains if block "B" to "C" is clear. If clear, "B" displays signal "block clear" and train need not stop at "B." If block "B" to "C" is occupied by train coming in opposite direction, "B" displays stop signal, and all trains approaching must stop before reaching signal. As soon as trains pass "B," operator there notifies all operators interested and movement continues. When any train passes any block, operator at that point immediately notifies dispatcher at "A" giving time of arrival or departure, also notifies control next ahead. This method may employ either telegraph or telephone, the latter being preferable for light railways. For example: Extra 1728 with ammunition and Extra 2196 light, en route from "A" to "E." Extra 1824 with salvage en route from "E" to "A." The dispatcher decides that Extra 1824 would meet Extra 1728 at "D" and Extra 2196 at "C." He calls operator at "E" before Extra 1824 leaves there and gives him the order: Extra 1824 will meet Extra 1728 at "D" and Extra 2196 at "C"; the order being given to the conductor verbally. A similar order would be given to Extra 1728 at "C" and 2196 at "B." Extra 1728 being a movement *outward* would occupy the main line. Extra 2196 being light, although outward bound, would take passing track at "C."

This method was quite safe, flexible, easy of operation and a saver of time. The greatest advantage was the ease with which meeting points could be changed. Trains were forbidden to pass any station where an operator was located without a "proceed" signal. Due to the slow speed maintained over the system it was not necessary to give the meet order at the station in advance of the actual meeting place, but it may quite often be given at the station where the meeting would take place.

During the war it was the experience of one American light-railway unit that due to the excess tonnage handled and the shortage of cars (never more than 120 to a division and averaging 75 to 80) there was an average daily car loading, for a period of five months, of 3.6 times per car and a maximum of 6.1 times per car.

The tonnage was classified and moved in order of priority according to the following schedule:

A—Ambulance
  Engineer reinforcements
  Personnel
B—Ammunition
  Engineer stores
  Rations and other supplies
  Road metal.
  Canteen stores.
C—Empty cars required for immediate movements.
D—Other empties.

Because of the lack of facilities for weighing the loaded cars, each commodity was classified and given a tonnage rating as follows:

	Tons.
Ammunition	10
Coal	10
Engineer material:	
Camouflage	4
Elephant iron	4
Trench-boards	4
Lumber	6
Wood	6
Logs	6
Cement	9
Miscellaneous	4
Forage	5
Light railway ballast	10
Light railway track assembled	8
Light railway rail	10
Light railway miscellaneous	5
Miscellaneous army tonnage:	
Empty shell cases	4
Salvage	5
Ordnance	9
Sand	10
Personnel	4
Rations	5
Road metal	10
Water	8

Six combat divisions were supplied by light-railway units operating 270 miles, with 2,086 officers and men and the following equipment:

47 steam locomotives.
25 gasoline locomotives.
752 20-foot cars.

Between the nights of August 4 and 9, 1918, inclusive, 23,125 men were moved by light railway an average distance of 10 miles, 35 men to the car, with full equipment. Fifty-nine trains were used, hauling 694 loads, or 11.75 cars per train. Assuming that the movement could have been made with trucks, 18 men to a truck, it would have required 1,280 truck loads to accomplish the same results. The maximum movement of troops in any one night was 6,175.

Between March 29, 1918, with a beginning of 30 miles, and February 1, 1919, with a total of 585 miles, American light railways in France handled a total of 860,652 tons, as follows:

	Tons.
Ammunition	166,202
Coal (except L. R.)	6,379
Engineer material	86,555
Forage	21,700
L. R. ballast	160,360
L. R. coal	17,305
Miscellaneous L. R. material	76,456
Miscellaneous army tonnage	81,146
Personnel	52,770
Rations	77,901
Road metal	98,857
Water	15,021

The maximum daily tonnage was:

	Tons.
Ammunition	640
Coal (except L. R.)	210
Engineer material	1,065
Forage	372
L. R. ballast	2,360
L. R. coal	114
L. R. material (miscellaneous)	708
Army material (miscellaneous)	298
Personnel	160
Rations	903
Road metal	1,080
Water	194
Total	8,104

Digitized by Google

Equipment: 104 steam locomotives, 51 gasoline locomotives, 1,695 20-foot cars.

Personnel: 55 officers and 2,585 men.

Mileage: 442.

The equipment used by the American light railways consisted of 2-6-2 type steam locomotives with a weight on drive wheels of 23,500 pounds, and a tractive effort of 62,025 pounds; and gasoline locomotives of 0-4-0 type weighing 14,000 and 8,000 pounds rated at 50 and 35 horsepower, respectively. The cars consisted of gondola, flat and tank types, with 4-wheel trucks 15 feet on centers.

The steam locomotives were found to be faulty in that the center of gravity was too high, thereby causing a great number of unnecessary derailments. It is recommended that exhaustive tests be made with the different types of locomotives used by all the belligerents, and a locomotive designed for general use, with a low center of gravity, similar to that used by the Germans.

All cars were faulty in the coupler construction, and a great amount of trouble was caused by cars becoming uncoupled or by the draw bars being bent when cars were being pushed around sharp curves. The main fault with the gondola car was that the sides dropped down instead of swinging out as in the British type. The sides of the American car were held up by a "T" stanchion, which, after very little use, was burred on the end and soon became a source of great annoyance.

There were a number of box cars shipped to France, but they were not found to be practicable. When loaded they were very easily derailed, and as ambulance cars were not a success.

The gasoline engines were too lightly constructed and required constant overhauling. A more rugged and simple type of engine is suggested, something similar to a heavy duty 2-cylinder engine.

The mechanical repairs were taken care of by a central shop at Abainville, where a very elaborate plant was installed and it was the plan to have all heavy repairs made at this central shop. At each rail head there was a similar machine shop and roundhouse. Experiments were made with shop trains at the rail heads which proved very satisfactory, and it is recommended that in any future campaign the system of using shop trains exclusively be adopted; *i. e.,* a shop train of 7 or 8 standard-gauge cars at each rail head fully equipped to carry on any class of repair work, supplemented by a light railway shop train of three cars for each operating company. These light railway trains can be used in the forward areas as near the front as safety would allow, with a reserve of standard shop trains at some central point. In this way all equipment would be mobile and easily advanced or brought back as the exigencies of the campaign dictated. It was found that even temporay shops at rail heads, which became more or less of a permanent character, in some cases had to be abandoned or destroyed in a retirement, such as happened to the 12th Engineers in the March 21, 1918, drive on the Somme.

The central shop as established at Abainville was of a very permanent character, and when the largest advance was made the haul back to the shop was almost prohibitive on account of the great distance, whereas if shop trains had been in use they would simply have been advanced with the armies and been available for immediate use when this advance halted.

The original plan for raising light railway units consisted of a regimental organization of separate operating, mechanical, maintenance and construction companies, but it was found that the regimental organization was cumbersome, and the units became widely scattered. It is recommended that the future organization be based on a balanced operating and mechanical company with the unit of organization a battalion, which would normally operate and maintain a railroad operating division of approximately 75 miles of light railway main line, one company covering approximately 25 miles. This would allow the battalion commander, who would hold a position analogous to a division superintendent, to co-ordinate all operating, mechanical and maintenance forces under his jurisdiction. It would make a more cohesive unit for administration.

A new source of skilled workmen.—Twelve thousand engineer soldiers are a part of the cutting edge of the new army. As matters now stand, it is a ragged edge. When the organizations of the World War were demobilized the old scheme of keeping up the army by voluntary enlistment went into effect again. Five thousand men have volunteered for service with the Engineers. So there are seven gaps and five teeth where there should be twelve teeth in that cutting edge.

The nation's need of men in industry prevents a campaign for skilled workmen to learn the tricks of the war-job of the Engineers. It is wrong to take this skill away from the business of production. But there must be some fit material for filling those seven gaps in the line.

You know men who need training and cannot afford to stop work. You know men who lack the punch of knowing how—and you know businesses that need the kind of men these men would be with half a chance. The Engineers can take these men and give them training that will fit them to be good workmen, can give them experience that will help them become foremen, can educate them along many lines, and can keep them clothed, fed, and in that healthy, husky state of body and mind that gets in the job with "Let's go, boys," for a password.

There is enough sport, comfort, and pay for beginners to make a "hitch" worth while. Any man who served for the first time during the emergency—when there was no time for direct self-betterment—can sign up for one year. If he wants a full course he can take three. Tell about this chance to the young men you know who want to get somewhere. Tell the manager of your business how he can get back a better man by lending his "comers" to the Engineers, A card to the Chief of Engineers will bring a man with the facts.

Bomb and bullet proof magazine has double roof.—Two-story, reinforced concrete explosive magazines designed to be bullet, fire and bomb proof against ordinary attack from either land or air, were built in Panama during the war. The second story is in reality formed by a double roof, the upper 7 inches thick and 7½ feet above the lower, which also serves as a floor and is 2 feet thick. In time of peace the upper story is intended for the storage of inflammable but non-explosive materials; in time of war it is to be filled with earth. All walls are 2 feet thick, and the footings, walls and roof of the lower floor are heavily reinforced with 70-pound steel rails. Ventilation is secured by zigzag ducts. The outer end of each duct is closed by a steel-plate door, and the inner end by closely spaced bars.—*Eng. News Rec.*

Is the Use of Narrow-Gauge Railways Profitable in War?

By

William Kelly

Lieutenant Colonel, Corps of Engineers
Formerly Division Engineer, 42nd Division, and
Corps Engineer, 4th Corps, A. E. F.

DURING the World War the Germans started the use of narrow-gauge (60 cm.) railways for distribution on their Western front shortly after that front became stabilized. They were probably led to the adoption of this kind of equipment by the fact that they had large manufacturers who supplied the bulk of the world with this class of equipment for industrial purposes before the war. The increasing shortage of animals and of essential supplies for motor transportation forced them to a greater and greater development of their narrow-gauge systems till toward the end of the war practically all of their distribution at the front was accomplished by this means.

The allies followed the lead of the Germans in this as in a number of other developments of the war. The British went in for narrow-gauge railways on a very large scale. The French were much more moderate in this respect and confined the use of their narrow-gauge systems almost entirely to the distribution of artillery ammunition.

When we entered the war our allied advisors insisted that we must make ample provision for narrow-gauge equipment. In the absence of personal experience we could not but follow their advice, and we proceeded to invest in two or three million dollars worth of such equipment and to organize for its use. A number of articles have been written on the excellent work of this organization both on the British front and on our own, but the writer has never seen any expression of opinion, as a result of this experience, as to whether it is advisable to include the use of such equipment in our plans for future wars; his experience with such equipment is not as broad as that of many other officers, but has been sufficient to convince him that in future all our mechanically operated light railway equipment should be designed for standard gauge, and it is with the hope that some good may result from discussing this subject that this article is being perpetrated.

One has only to see a 12-ton, 60-centimeter locomotive to recognize that it is an abortion. It is about as badly handicapped for getting over the ground as a Chinese woman with bandaged feet. It has the power to haul heavy loads and to develop good speed, but it is so top-heavy that it can not develop its power or speed except on a perfect track. If the same engine were provided with longer axles to fit standard gauge, it could do its work over nearly any kind of track.

It should be clearly understood that the writer is not attacking the use of light railway equipment, but is maintaining that such equipment should be made for standard gauge.

The advantages generally claimed for the narrow-gauge system are:

1. The track materials are lighter than for standard gauge, and therefore a greater length of track can be transported with a given amount of transportation;

2. Sharper curves and steeper grades can be used than with standard gauge;

3. The track can be made up in sections ready to lay, which greatly increases rate of laying.

The writer is willing to admit the value of these claims for a railroad on which to operate cars pushed by hand or hauled by animal, but maintains that the minute mechanical traction is introduced, these claimed advantages disappear.

The weight of the track material, the sharpness of curves, and the steepness of grades all depend primarily upon the weight and design of the equipment to be operated and only to a limited extent on the gauge of the road. There is no reason why equipment of practically any desired weight can not be designed to operate on standard gauge as well as on 60 centimeter.

It is true the standard track requires longer ties, which increase the weight of track material, but this is more than offset by the greater care required in preparing the subgrade and the greater amount of ballast needed to keep the track in line so that the narrow-gauge locomotives can operate over it without constant derailment.

The writer has discussed this question with a number of railroad engineers and has found them uniformly of the opinion that the mechanical and practical difficulties and the amount of labor required are greater for the construction of a 60-centimeter track, suitable to carry a given weight of mechanically operated equipment, than they would be for a standard-gauge track for the same equipment.

So much for the technical engineering side of the question. Let us now consider the tactical or military side.

The narrow-gauge road can be developed very satisfactorily for position warfare, but its usefulness is at once lost if there be an advance or retreat. The British lost all their light-gauge equipment on two or three different occasions when driven back by the Germans because it was impossible to withdraw the equipment farther to the rear than the narrow-gauge track extended.

In the final stages of the war the Germans suffered similar losses on a very large scale, and there is no doubt that their operations were greatly handicapped by these losses, because they had become so heavily dependent on their narrow gauge for the final distribution of all supplies and ammunition.

Had these systems been standard gauge, not only could the equipment have been withdrawn for subsequent use, but it could have been used to great advantage in assisting the movement of withdrawal.

The use of the narrow gauge entails the construction of large and expensive transfer yards and the rehandling of

Digitized by Google

all supplies and materials coming in to these yards at the expense of a great amount of labor.

It will probably always be necessary to rehandle the regular divisional supplies of food, forage, and clothing at a divisional rail head, but there are tremendous quantities of ammunition and engineer material, especially road material, that can be sent direct to forward dumps, or to points where it is to be used without rehandling if standard gauge is used instead of narrow gauge. Anyone who has had experience in the supply of an army in action will appreciate the desirability of such a saving in manpower on rehandling.

If standard gauge is used, it will be possible to design the system for its ready extension in case of an advance. The main lines going to the front can be designed to carry standard equipment and to be extended into the enemy's territory as the advance progresses, whereas the narrow-gauge system is incapable of extension beyond a limited extent.

At best, trains can not keep a schedule much faster than 3 miles per hour over narrow gauge, and this means that the standard gauge must be extended and new transfer yards built nearer to the front, with every advance of 10 to 15 miles.

In the Toul sector the American narrow-gauge system reached its highest development. While the lines remained fixed, this system was very satisfactory, but even with the moderate advance accomplished in the St. Mihiel operation it was rendered entirely useless for nearly two weeks and then began to operate under great handicap on account of the length of haul. It had been planned to extend this system very promptly after the advance by joining it with the German system at a number of points, but it was found that the advance German lines of railway were all of very light construction and unballasted, which meant that they must be carefully rebuilt to carry the American equipment. The troops engaged on these extensions did wonders to get the lines opened as soon as they did, and the only criticism that can be leveled at the service was that the traffic manager was over zealous and accepted large quantities of freight for shipment before the lines were opened, with the result that the shippers were disappointed in deliveries, and the construction gangs were handicapped in getting ballast up for their work by the congestion on the lines in rear.

It is certain that if this system had been standard gauge instead of 60 centimeter, the rail heads could have been promptly advanced much nearer to the front with a great saving in truck haul and that the temporary lines in extension could have been operated with light equipment without waiting to completely ballast them. The German 60-centimeter system could have been operated with captured German equipment to help out till our own system was developed, but the main need after all was means to get material hauled and delivered on the German side of the old trench systems; from there distribution could have been easily handled by the regular transportation of the organizations.

To conclude, the narrow-gauge railroad system is capable of being satisfactorily developed for position warfare, but breaks down completely as soon as the positions are changed. No war was ever won or ever will be won by position warfare, and such warfare can never be more than a temporary expedient which will end as soon as either side is strong enough to take the offensive.

Light railroads of standard gauge can be built and operated more economically and expeditiously for position warfare than the narrow-gauge system and have the great added advantage of ready adaptation to an advance or a retreat. It seems obvious, therefore, that the narrow-gauge systems should have no place in our future plans, but should be replaced by a light railway equipment on standard gauge.

Discussion

E. Jadwin
Colonel, Corps of Engineers
Formerly Brigadier General, Director of Light Railways, and Director of Construction and Forestry, A. E. F.

Colonel Kelly's article suggests a new and definite idea for the improvement of a useful service whose usefulness has heretofore had some undesirable limitations.

Taking up the more debatable points in the order in which he has presented them, the following remarks are submitted:

The equipment of the 60-centimeter railways, particularly the large locomotives, was certainly top-heavy. Its stability will manifestly be considerably increased if the gauge can be brought to standard without including compensating disadvantages.

There need not be any great increase in the weight or bulk of track materials, excepting ties. The use of longer ties will increase the amount of work required for preparing the road bed where the surface of the ground is not already clear and smooth. In case any large embankments are necessary, the amount of earth fill will be greatly increased. There may be greater difficulty in making a location along roads and other places of restricted width. These are not believed to be a sufficient objection to the proposed change.

It is doubted whether the use of transfer terminals can be entirely eliminated. More study and experiments, possibly trial in actual warfare, may be needed to settle this point. If all the ammunition and engineer material arriving at the rail heads can come in cars light enough to run on the light railways, the function of transfer stations can be reduced, if not altogether eliminated with a corresponding saving in man power and rehandling.

With respect to curves, it is understood that the light railways used curves with as short a radius as 100 feet approximately, or about 56-degree curves. I operated for several years a standard-gauge track entering a machine shop area with approximately a 30-degree curve, over which heavy standard-gauge cars were handled by a short switch engine. I also installed one curve about 33 degrees, around which standard-gauge dump cars were dragged by Porter and Belgian locomotives. This latter was only an expedient for a few months until a flatter curve could be provided. There is understood to be in the yards at Omaha a curve about as sharp as this, over which standard-gauge cars are handled by a switch engine with a short wheel base. Four-foot-gauge street cars in San Antonio round some corners with radii less than 50 feet. This gives a greater degree of curvature than was used on the light railways in France. It would seem, therefore, that curves as sharp as needed can be negotiated by specially designed locomotives and by cars whose trucks pivot freely.

Grades, as Colonel Kelly points out, depend primarily on the weight and design of equipment, and, as steep grades can be used with a standard gauge as with a narrow, provided no greater loads are hauled and the same weight locomotives are employed.

The 60-centimeter track can probably be made up in handier sections, ready for laying, than standard gauge. On the whole the technical advantages of the two gauges seem to fairly well offset each other for prolonged service

Digitized by Google

in a given area in trench warfare. If the standard gauge replaces the narrow gauge as the standard in such warfare, it may still be that the use of a limited amount of the narrow gauge will be advisable in special cases.

The loss of equipment and material due to inability to evacuate it on the standard-gauge track was a severe blow at different times both to the British and the Germans. The point that had these systems been standard gauge, not only could the equipment have been withdrawn for subsequent use, but could have been used to advantage in assisting the movement of withdrawal, and the further point that the standard gauge can be moved forward on its own wheels in an advance sufficient to reach the enemy's standard gauge are tactical advantages of importance. The narrow gauge can be connected across the enemy's narrow-gauge area and utilize his installation, if he will be considerate and strong enough to retreat only so far. The standard gauge can follow him as far as he may retreat, haul its own materiel and thereby make possible prompt start on the new installation.

Coming to Colonel Kelly's conclusion, while I doubt whether the light railways of standard gauge can be built more economically and expeditiously than those of narow gauge, I do not think the difference in cost and labor will be sufficient to determine a decision. Partly because they can probably be operated more economically, safely and expeditiously, but above all, because they have the added tactical advantage of greater adaptation to an advance or a retreat, standard-gauge railways are advantageous.

In conclusion, it is believed that many of the points he has raised can be determined with reasonable definiteness by peace-time experiments and that the advantage to the service of such experiments would be fully justified. An added reason for investigating the proposition closely, is that while it is new and offers advantages which seem obvious, now that Colonel Kelly has mentioned them, neither the allies nor Germans, so far as known, tried it at any time in their four years of trench warfare. And that is significant.

Wm. Barclay Parsons
Colonel, Engineer Reserve Corps; formerly Colonel 11th Engineers, A. E. F.

Colonel Kelly has made a very valuable contribution in his article on light railways. He is quite right that standard-gauge lines can be built almost as cheaply as narrow-gauge lines, and that standard-gauge equipment can be designed to pass curves with very short radii. The most striking instance of short radii curves on standard-gauge track is on the elevated railways in New York, where curves are found on the main line with a radius of only 90 feet. In my own practice, I have always opposed the construction of narrow-gauge lines as not being justified by economy.

In military work there are, however, other considerations than economy. In open warfare there is but one kind of railway to consider and that is one of the same gauge as the main lines of the country in which the operations are being conducted, whether that gauge be 3 feet, 3 feet 6 inches, 4 feet 8½ inches or 5 feet. Under such conditions there will probably be no time to construct new lines. The army commander will be obliged to take what he finds in existence and adapt it as best he can to meet his requirements. The question of gauge will, therefore, come up only in the case of warfare that is more or less stabilized, in which there will be involved the problem of distributing supplies beyond the fighting front. The factors that would influence if not control a decision in this case will be other than economy in first construction. Railway lines within, say, 3 miles of the actual front, will always be in poor physical condition, arising from either original light construction or frequent reconstruction of breaks caused by shell fire. To run heavy standard-gauge cars over such lines would result in more wrecks than locomotives with a high center of gravity would cause. It is useless to argue that orders should be issued forbidding heavy loads on forward railways. The people who have the directing of shipments are not engineers, and if the gauge will be such as to permit the running of heavy loads, heavy loads will at times be run. The writer had some experience in France with lightly built standard-gauge railways in the forward area in following up army advance, especially in the St. Mihiel and Argonne offensives, an experience in which, unfortunately, wrecks were not lacking. He knows, therefore, of the pressure from those in higher authority to run heavy loads over tracks unfit to carry them. A break in gauge is the only sure preventive.

The second reason in favor of light railways is that loads in the extreme front area are handled in small lots, and there is rarely any demand for a whole carload of, say, 30 tons. In practice, therefore, it is convenient, if not actually necessary that materiel arriving in standard-gauge cars should be unloaded at an advance rail head, and thence distributed in small lots to a number of points. It is also found that at times cars at the front must be pushed by hand, in which case a car with its load weighing 33,000 pounds is more easily handled than one weighing 99,000 pounds.

In short, the question of light railways is one that will be answered by practical and local conditions rather than engineering considerations of construction. The writer would deem it unwise to abandon the idea of light railways with a narrow gauge, although he is not wedded to the gauge of 60 centimeters (1 foot 11½ inches), as used in France. The gauge of 2 feet 6 inches might be better.

In open warfare such light railways would have no application, but in stabilized warfare the writer believes that they will be found highly useful. When they are used the rule should be laid down that the transfer rail head should be as near the front as local conditions permit, which in France was about 5 miles. Whenever a change in front occurs the rail head should be carried forward with the advance. This would keep the minimum amount of light railway in use and only between the advance rail head and the fighting front.

The impression is gathered from Colonel Kelly's paper that the light railways of 60-centimeter gauge were one of the outcomes of the war. Is this justified? That gauge had been adopted by the General Staff of both France and Germany prior to the war, and was the same as that used by Japan, following German tuition, in the Russo-Japanese war of 1905.

H. Deakyne
Colonel, Engineers; formerly Brigadier General Chief Engineer, 2nd Army, A. E. F.

I agree with Colonel Kelly that the use of the 60-centimeter railway in France should not commit us to the policy of considering it a necessary part of our equipment for warfare under all conditions. We fell heir to the narrow-gauge railway as one of the many features of the war that had already become settled facts before we entered.

The 60-centimeter track is undoubtedly a very narrow affair on which to handle locomotives or cars of any considerable weight. The meter gauge always appeared to be a much more satisfactory system for the purpose.

Digitized by Google

Some of the defects of the narrow-gauge railways pointed out by Colonel Kelly are not without remedy. For example, the loss of equipment in case of a retreat can be avoided by the provision of main stems running directly to the rear at proper intervals. The Division of Light Railways and Roads had plans in the summer of 1918 for the construction of such stems for this purpose, and one such was constructed from Abainville to Sorcy. Another way of saving light railway equipment is to run it back to a standard-gauge rail head and then load it on standard-gauge rolling stock, provided the standard-gauge lines are free to handle it.

The advantages claimed for the narrow-gauge railway are those stated by Colonel Kelly, and one other, which is the use of light bridges. In the line from Abainville to Sorcy, it was necessary to cross a canal at Void. The crossing was made with a very simple bridge, which would have been totally inadequate for standard-gauge equipment capable of carrying standard-gauge loads.

The basic economic advantage of a narrow-gauge railway is that it can be laid almost on the natural surface of the ground. This means, however, that steep grades and sharp curves must be used to prevent undue lengthening of the line. There is no reason why a standard-gauge railway can not be laid in practically the same manner, but it is an error to assume that a line so constructed can be adapted to use as a main line by simply improving the ballast. The grades and curves would have to be entirely different for a main line, and this would mean a complete relocation.

The use of the narrow-gauge does entail the construction of expensive transfer yards and the rehandling of supplies, but the use of a light standard gauge would not evade similar yards and similar rehandling. If the light system is to be used strictly as a light railway, the heavy rolling stock bringing the heavy loads from the base can not be allowed upon it. The supposed advantage of a standard-gauge light railway system that would permit ammunition and road material to be sent on toward the front without rehandling, implies that the grades, curves and bridges of the light railway line are suitable for heavy equipment. If this is the case, it is no longer a light railway line, but a regular standard gauge.

A standard-gauge light railway line was used in the latter part of 1918 and the early part of 1919 between Commercy and Woinville. It was made by relaying the rails of a meter-gauge line, using longer ties. Considerable difficulty was found in securing light locomotives for use on this line, and the line was a source of uneasiness, because the bridges were not designed for heavy rolling stock. There was always the danger that the transportation department would send over the line a heavy locomotive or a car loaded beyond proper limit, causing a disaster at one of the bridges. This is an inherent defect in the plan for using a standard-gauge light railway. The change in gauge has, at least, the merit of making certain that no heavy rolling stock is going to find its way by mistake to the light railway system.

In open warfare, the supplies will follow the troops primarily in trucks, and the standard gauge will be brought forward as rapidly as possible to the limit of safety for a rail head. If the warfare becomes stabilized, as it was in France, there is a field for a narrow-gauge line. However, I should consider a gauge of 36 or 40 inches as more satisfactory than the 60 centimeter used in France.

Jno. P. Hogan
Lieutenant Colonel, Engineer Reserve Corps; formerly Lieutenant Colonel, 11th Engineers, and General Staff, A. E. F.

The first general use of 60-centimeter lines in military operations was during the Russo-Japanese war, and the motive power was largely man or horse. It was so successful that both the French and Germans adopted them as standard practice. Whether mechanical traction was contemplated is not known by the writer, but it is certain that the 60-centimeter line first made its appearance in the Great War with men and horses as motive power. The Germans were the first to employ light mechanical traction, and it is noteworthy that they always kept their equipment light, while the allies gradually introduced heavier equipment. This necessitated the use of intermediate wooden ties on the "Decauville" and of more or less ballast.

The Germans, by force of necessity, came to rely more and more on the 60-centimeter lines as their horse and automobile transport declined. At the time of the armistice they had been driven out of their narrow-gauge belt, with the loss of most of their track and equipment, and it is believed that their collapse was imminent from this cause alone unless they had been able to retreat and re-form behind the Rhine.

Their situation emphasizes the need of a well-balanced army and equipment to permit of meeting all the varying phases of warfare. This immediately brings up the question, whether the phase of warfare seen on the western front is apt to be repeated; *i. e.*, a situation where the forces engaged are too large for the theater of operations. The answer is yes for that theater of operations, but in general not necessarily so, for any other, though locally analogous situations may arise.

It is believed that the United States Army should be prepared primarily for operations on this continent and, secondarily, for operations abroad, which will probably be in conjunction with an ally or allies *now unknown*. If operating in conjunction with an ally or allies, the American army *being the last in the field* must conform as far as possible to their equipment, in order to permit intimate cooperation. (The Italics are *ours*.—Ed.)

For operations in this country or for open warfare anywhere, the principle set forth by Colonel Kelly of using light equipment on hastily laid standard-gauge track, is believed to be so correct that it does not need discussion. It is not believed that this would obviate the necessity of rehandling, since in this country, more than any other, the standard railroad car is increasing in size and could not be taken off standard main-line track. It would permit, however, the rehandling and classification depots to be located farther in the rear. Rigid discipline in keeping standard equipment off of hastily built tracks would have to be enforced. Its real advantage is in flexibility in a war movement.

Before adoption of Colonel Kelly's proposal there is one question that must be considered; *i. e.*, What is the present equipment available in the United States? The modern army can not have on hand sufficient mechanical equipment for its purposes and must rely on an industrial mobilization. The writer is aware that there is in existence in this country a considerable amount of 24-inch and 30-inch gauge equipment. How much light-weight standard-gauge equipment is there, capable of running on such tracks as Colonel Kelly proposes?

While the principles advanced are, therefore, thought to be sound, it is believed that a census should be taken of the equipment available, and that the final decision should be based on the industrial situation and tendencies.

F. G. Jonah
Formerly Colonel, Engineers (Light Rys.) A. E. F.

The writer desires to say at the outset that he does not regard the proposals of Colonel Kelly as offering any im-

Digitized by Google

provement on the existing type of light railway track, material and equipment.

The light railway was developed by the French. The Decauville plant was manufacturing track and equipment for commercial purposes as early as 1882. It was shortly thereafter adopted by the French Army, and the German Army adopted it in 1892. Its extensive use by the Germans in the late war was due to the fact that they were short of rubber and gasoline, two essentials for motor transport, but having the steel plants and coal mines of France and Belgium in their possession, were enabled to make the utmost use of steam transportation, both standard and narrow gauge.

It does not seem that light railway track and equipment built to standard gauge would serve any useful purpose, unless the track was strong enough to carry the usual standard-gauge equipment operating in the rear, in which case it would at once cease to be a light railway track. The advantage of standard gauge, assuming that it could be built up to the trenches and battery positions, would be the saving of labor in transferring supplies at the rail head, but this saving of transfer labor would be much more than offset by the increased labor required to construct a standard-gauge track, no matter how crude the construction might be. There will be twice as much work involved in the grading of a standard-gauge track as a 60-centimeter line, and twice as much ballast required for its maintenance, and when it is recalled that 25 per cent of the labor employed in the construction of our light railways in France were engaged in making and applying ballast, this becomes a matter of great importance.

A light railway can be fitted to contours of the ground, can go through gorges, narrow passes, streets, or alleys, where it would be impossible to carry a standard gauge. When it is remembered that the equipment of a light railway is 5½ feet wide, and a standard gauge 9½, it will not be hard to recall places where the one could be used quickly and the other not at all. Apart from the question of grading or ballast, if the track is standard gauge, it is absolutely certain that it can never be assembled or laid with anything like the speed that can be made with the 60-centimeter gauge.

Colonel Kelly's conclusions as to the desirability of standard-gauge railway extenstions in forward areas are correct, and everyone will agree that we failed to carry our standard-gauge construction forward as rapidly as it might have been done, after the St. Mihiel drive and also during the Meuse-Argonne battle. Take the case of the conversion of the metre gauge to standard gauge running north from Commercy, this work dragged along, and was completed only as far as Woinville; had it been extended a few miles farther to Vigneulles, it would have connected with a standard gauge leading from there to Chambley, thus making connection with the German standard-gauge system west of Metz.

It is a mistake to say that the light railways ceased to function after position warfare ceased. They were in constant use, as it was only a short time before connections were made between our advanced lines and the most westwardly extension of the German light railway lines, which were well built and ballasted; at least in the St. Mihiel sector—the writer saw many of them and has talked with the officers of the 12th Engineers (Railway), who operated these lines after the St. Mihiel drive, and until March, 1919. These officers state that, after "No Man's Land" was passed, the German lines were all in good condition, and a plentiful supply of good ballast was distributed along the tracks for repairs. This regiment hauled supplies from the Sorcy railroad to Conflans over light railways. To be sure, this was too long a haul for that kind of equipment, but there was not sufficient motor transport available, and as the army failed to extend the standard gauge from Woinville to Vigneulles, there was nothing else to do but haul on the narrow gauge. On this long haul a schedule of 5 miles an hour was maintained instead of 3, and on many of the short hauls a speed of 8 miles an hour was regularly maintained.

Colonel Kelly refers to delays in connecting up our lines to the German track. The 12th Engineers have written a history of their operations, from which I quote:

> Order from G. H. Q. of November 11 forbade anyone going north of the positions of the front line of November 11 until the 3d Army units had started forward. These restrictions ceased at 5:30 a. m. of the 16th . . . and by November 20 American light railway trains were operating into Conflans. Beyond "No Man's Land" the track was found to be, on the whole, in fair condition. There had been some damage in the back areas caused by bombs and few instances of deliberate demolition were encountered. The enemy had, however, accumulated adequate ballast and track material, and had distributed these at points along the line.

As to what can be done with a light railway after position warfare ceases, I quote from this history:

> The connections and new track being in condition, the operating forces were faced with the problem of handling large amounts of all kinds of army stores as far north as Conflans and Saint Jean. Rations constituted a large part of these supplies, and it is true that the 12th Engineers fed the Third Army until it passed into Belgium. This tonnage for the Conflans area originated chiefly in the old railroads—Sorcy, Belleville, Bernécourt, Manonville, Leonval, and Trondes. A glance at the map is sufficient to make clear to anyone familiar with the limitations of the "Soixante" just what a problem this was for the operating forces. This Trans-Siberian haul, as it was known around headquarters, amounted to approximately 70 kilometers, or 44 miles—a large contract it is true, but the goods were delivered and delivered promptly. . . .

After the highways were repaired and the motor transport restored, this regiment was turned over to salvage operation—bringing back ammunition and engineering material from the forward areas. This tonnage became very heavy, and on January 3, 1919, the greatest volume hauled in any one day was 5,112 tons, which could not have been taken off the battlefields as economically or as quickly by any other means.

The writer is not unmindful of the fact that many of these valuable uses to which the light railways were put was after hostilities ceased, but believes a much greater use could have been made of them prior thereto, and is firmly convinced that a light railway can be built in less time than a highway on which motor trucks could operate, and certainly in much less time than any kind of a standard-gauge railway could be built.

E. M. Markham

Lieutenant Colonel, Corps of Engineers; formerly Colonel, Chief Engineer, 3rd Army, A. E. F.

The writer disagrees with Colonel Kelly's conclusion "that the narrow-gauge systems should have no place in our future plans;" but, on the other hand, accepts as sound the desideratum of broad-gauge extension with such rapidity and to such forward points as is consistent with conditions *de facto*. He views as hazardous, in this and many other matters pertaining to American operation in France, deductions arrived at upon the exclusive, or nearly exclusive, foundation of American performance in the particular event. He hopes that deliberate planning for the future may reckon with a better measure of preparedness, with a better and more business-like understanding of the issues, and with a clearer staff conception of its functions, all of

Digitized by Google

which have important relation to the value of narrow-gauge railways.

The writer's observation of narrow gauge mainly concerned a period with the British, and duty with the Division of Light Railways at American General Headquarters.

In the former case, the British (Canadian) system behind Arras was noted to be operating in manner and location such that it could not possibly have been replaced by broad gauge. Road bed and rolling stock were substantially consistent with the necessities of the case; operations were scheduled, well balanced and controlled; speed capacity and radius of activity were well understood and respected. The system was performing its functions with great efficiency, relieving truck transportation to an invaluable extent.

In the American sector, narrow gauge appeared to the writer to have been both constructed and operated under what may well be described as "slap-dash" American methods, stimulated largely by urgency for premature operation, the inevitable result of which, at times, could be none other than confusion and derailment. The situation was additionally complicated by the frequent mania for speed, first, by the impulse and lack of judgment of the operator, and, second, by the staff demand for delivery. Again, the compulsory taking of business by staff direction over essentially absurd lengths of haul in the Toul sector, and generally throughout the American area after the armistice (to which Colonel Kelly refers), could give no other impression than that narrow gauge was not "up to the job." A street car ordered to transcontinental business is a not too impertinent simile. The fact was, however, that broad gauge did not exist, or, where existing, would not take the business, and that new construction was impossible. The efficient operating radius of narrow gauge is probably 25 to 30 kilometers. The futility of directing greatly extended performance, for whatever reason, detracts nothing from the usefulness and value of the facility within its proper sphere.

Narrow gauge is strictly a local agency—a mere community collector and distributor, so to speak, to and from broad gauge. It should not be considered, much less utilized, in replacement of the latter to any degree whatsoever. The functions of the two, short of emergency, must be regarded as wholly distinctive. Narrow gauge should not be regarded as abortive because of derailment or confusion occasioned by particular defect or insufficiency, any more than motor-truck transportation should be similarly classified because of individual mismanagement, distribution, failure of maintenance, or what not.

The fundamental of narrow-gauge employment upon proper occasion, is believed to be sound, and until a different view is deliberately adopted, incidental deficiencies of rolling-stock design, troubles resultant from premature operation over inadequate road bed, and similar matters should not be overweighted.

No sufficient reason is known to accept the proposition that the 60-centimeter locomotive "is an abortion." It would be unusual if its stability could not be improved upon; but, granting that desideratum, it should be remembered that the type made many thousand miles without trouble or derailment, and that where such occurred something was in all likelihood involved other than fundamental unsuitability because of gauge.

The loss of British and German equipment is viewed simply as one of the fortunes of war, the agencies responsible for the installations presumably having sufficient justification for their original conceptions. Broad gauge could probably not have been adopted in any of the localities served by light railway, and the abandonment of the latter was unquestionably occasioned by a debacle which neither side could have conceived to be possible, short of the event itself.

The writer is unable to follow the idea, whether for position warfare or for advance, that broad gauge, however lightly constructed and loaded, can replace narrow gauge; and he is especially confused by the suggestion of a hybrid, and unavoidably flimsy, broad gauge, taking standard equipment and standard cargo in avoidance of rehandling. The extent of necessary side hill cutting, sharpness of curves, steepness of grades, weight and volume of trestles, bridges, ties and ballast, all reflected in time and man-power requirements of original construction and maintenance, are believed to be more important elements of the equation than implied by Colonel Kelly, and to be prohibitive of the employment of broad gauge toward the extreme front, or in any manner or situation other than of deliberate layout, thorough-going construction, and minimum hazard of traffic interruption.

In the writer's judgment, narrow-gauge equipment should be redesigned to the end of lowering to the limit the center of gravity of the power unit, and of similarly treating all rolling stock. He is unprepared to say what is such limit. Redesign was, in fact, under way at the time of the armistice. If combined with redesign, there is balanced discretion from the top, and especially upon the part of the staff, regarding physical conditions, the limitations of frequently untried operators, the folly of impossible expectations as to speed and capacity, and if further, also from the top, demands be intelligently restrained to a radius of operation consistent with efficiency, narrow-gauge railroads will perform a most valuable service whenever there is a stabilized condition of such likely duration as to supply the fundamental occasion for their use at all. Even for a reasonable speed of advance, figures compiled at Chaumont suggest the great value of narrow gauge, impossible of substitution within acceptable limits of time, materials and labor, by any similar advance of broad gauge.

The writer shies at conclusions of the kind expressed in Colonel Kelly's article as determinative of requirements for "our future wars." He can not imagine more than incidental light railway provision for advance into Mexico, just as he can not conceive of a repetition of the European event without its use upon a generous scale. He would avoid, as well, a too comprehensive application of the conclusion that "no war was ever won, or ever will be won, by position warfare"; certainly "future plans" should not be inflexibly formulated upon any theory that casts out the possibility of temporary, and wholly unavoidable, position warfare. He believes that the amount and character of narrow-gauge reserve stock, personnel and instruction, should be determined upon without the use of superlatives.

The writer is confident of the truth of the following propositions: That narrow gauge should be reckoned with for any campaign of a character involving great forces and uncertainty of predetermined rate of advance with reference to existing distribution properties; that narrow-gauge facilities should be in hand in reasonable volume and at proper location, ready for installation in forward areas during any static period of duration; that, totally without regard to the existence of narrow gauge, broad gauge should be pushed forward as fast as practicable, and as far as consistent with not too destructive operation—narrow gauge overlapped by such construction to be at once thrown out, and its salvage suitably disposed in storage. Upon advance of greater or less depth, and presuming upon a further static period, light railways should be extended from their existing situation, or should be installed *de novo,* retaining to the rear only tentacle connections with central shops and

Digitized by Google

depots for purposes of repair and replacement. In complete disregard of this advance of narrow gauge, broad gauge should again be extended to the limit of reasonably safe construction and operation as fast as material and men can be supplied, eliminating anew whatever light railway becomes possible of displacement.

In the writer's judgment, the use of narrow gauge, or the contrary, its field extension or displacement, can not be predetermined as broadly as Colonel Kelly suggests, nor in fact command intelligent discussion except as the elements of individual events, having to do with objectives, forces, terrain and similar matters, are scrutinized and the necessities of the case appropriately determined. Pending such opportunity of justifiable conclusion, reasonable provision for narrow-gauge instruction and reserve should be made, with a persistent eye to the better stability of its rolling stock.

Marshall R. Pugh
Formerly Major, 21st Engineers (Light Ry.), A. E. F.

Colonel Kelly in a few words has raised a question of the greatest moment: Shall the light railways of the future be standard or narrow gauge?

In 1916 or early 1917 Maj. Guy Boyer, of the Canadian Army, in a report to Gen. Sir Henry Jacob said, "The section of rail now employed for track is much too light, and I would suggest that nothing under a 36-pound section be used. With this heavier section, I propose that the gauge of all trackage be reconstructed to the standard gauge of 4 feet 8½ inches, which, I submit, would, in the event of advancement allow the existing mechanical powered lines to advance accordingly without delay . . . another advantage of standardizing the gauge of the train lines, is that the trucks, once filled at the base, will proceed direct to their objective without having to be unloaded as at present, owing to the difference in gauge of the tracks." His suggestion was not looked on with favor, and the narrow-gauge continued to be employed.

The British and Germans both lost large amounts of equipment during enemy drives that could have been withdrawn in time had the gauge been standard. It is a fact that the narrow-gauge railroad system is capable of being satisfactorily developed for position warfare, and that it has broken down in a warfare of movement, which, as Colonel Kelly points out, is the only way in which a war ever was or ever will be won.

Admitting all this, the writer can nevertheless not fully concur in Colonel Kelly's conclusion that light railroads of standard gauge can be built and operated more economically and expeditiously for position warfare than the narrow gauge and have the great added advantage of ready adaptation to an advance or a retreat.

In France the extension of standard-gauge railways was not able to keep up in any way with the advance of the 60-centimeter track. No railroad engineer would undertake to keep track construction of any gauge up with an army on even a fairly rapid advance, and with standard gauge the difficulty would be increased at least threefold. In the first place the writer has always taken exception to those who argued for the use of wooden ties throughout. They are undoubtedly desirable from the fact that surface and line can be more readily kept, but in forward areas the superior speed with which sectional track can be laid, especially at night, the lessened demand for skilled labor, and the avoidance of noise due to spiking, make the bolted sections preferable. When opportunity occurs they can be replaced by ordinary rail on wood ties, as was done in places in the light railway in the Toul sector. A revision of design of the standard American track as used in the A. E. F. appears desirable. The sections were 5 m. (16 feet 5 inches) long, and had eight ties, with a total bearing area of 13.76 square feet per section. The German sections were not all alike, but in general had ten ties to the section. One type of these German sections had ties 4 feet long by 7 inches wide as compared with our ties 3 feet 7 inches long and 5½ inches wide, which gave a bearing area of 23.2 square feet or 176 percent of that of the American section. Furthermore, recent investigations* indicate that "with jarring" the increased width of the German tie would enable it to support a load of approximately 160 per cent of that of the American tie. Therefore a section of German track would support a load 100 per cent greater than the American track, a most important advantage on poor soil. Such track with 20-pound rail would weigh about 550 pounds per section.

Remembering that ballast was the great bugbear and cause of delay in light railway construction in France, and that from a tenth to a quarter of all the traffic on our light railways was ballast, it is interesting to note that whereas a standard-gauge road, thinly ballasted, would take about 1,800 cubic yards per mile, a 24-inch gauge track would take 1,026 cubic yards per mile with wood ties or 520 cubic yards per mile with steel ties. A 30-inch gauge would take 624 cubic yards ballast per mile. The ties alone for a standard-gauge track would weigh at least 165 tons per mile, while the entire sectional track of a 30-inch gauge, rail and ties included, would weigh but 88 tons per mile.

Since heavy equipment could not well be employed on a "light" standard-gauge road bed, and since it would scarcely be feasible to run light equipment far to the rear, a transfer yard and rehandling would still be necessary, not only for divisional food, forage and clothing, but ammunition and engineer material as well.

Standard-gauge locomotives have been built of as light a weight as 7 tons. A number of such locomotives were successfully operated in the New York subways hauling track material.

The writer is informed by Lt. Harvey W. Bell that the stability of the rolling stock is not a matter of gauge but of design; that if correct design is used, the stability is practically the same for 24-inch, 30-inch or 36-inch gauge. His wide experience in design, manufacture and operation of light railway rolling stock entitle his opinions to great weight.

A 2-foot gauge (60 centimeters) was doubtless desirable in France to conform to that of all the combatants. Elsewhere a 30-inch gauge would be far preferable and would eliminate many troubles experienced on the *soixante*. It would involve no additional cost or additional weight of either rolling stock or track, and much greater stability would be afforded.

One marked advantage of the narrow gauge in the neighborhood of the enemy is its immunity from injury by shell fire, and the 30-inch gauge would be practically equal to the 24-inch in this respect. So narrow a target is seldom hit, whereas experience has shown that the standard gauge is quite vulnerable and far more difficult to repair quickly.

The description of an American steam locomotive is highly original and absolutely correct. The writer agrees fully with it, but would suggest a different remedy.

---

*Second Progress Report, Special Committee to Report on Stresses in Railroad Track: Proceedings Am. Soc. C. E., February, 1920—page 133.

Digitized by Google

Colonel Kelly admits that so long as the cars are pushed by hand or hauled by animals the narrow gauge has three points of advantage—permits use of lighter track material; permits use of sharper curves and steeper grades; permits use of sectional track. He maintains, however, that the minute mechanical traction is introduced these advantages disappear. The writer is not prepared to coincide fully with this opinion, but the locomotives and cars must be properly designed, with low centers of gravity. The French had a car that was excellently designed for keeping the rails, and their double-end steam locomotive was a marvel. It is at least questionable, however, whether it would not be better to employ gasoline exclusively. In the recent war locomotives had at times to remain for days away from water, coal and pit tracks. Some of the mechanical experts of the 21st Engineers are of opinion that a double-truck gasoline locomotive with all the weight on the drivers, a motor of about 75 horsepower and a four-speed transmission would be a most desirable type of tractor. Our steam locomotives were all that Colonel Kelly says, and then some. One captain in the 21st Engineers re-railed 65 locomotives in one month. I never saw a French steam or gasoline locomotive off the track. The Germans had a dense network of light railways opposite the American front, and when these were captured "it was found that the lines of the German system contained many sharp curves and heavy grades, which called for reduction before American equipment could be successfully operated." (From "Historical Report of the Chief Engineer," A. E. F.) It is American equipment that is thus by inference indicted. Instead of 24-foot cars of 22,000 pounds capacity, a four-wheel car of half that capacity and a third the weight should be tried out. It would keep the track better and could be readily re-railed.

Our light railways were miniature standard-gauge roads, whereas one should look to the logging road or contractor's construction railway for suggestions. To completely fulfill the functions of light railways they should be capable of quick extension; of the rapid construction of a dense network of tracks at certain points, and ability to run sidings and spurs to all kinds of inaccessible battery positions, machine-gun nests and trenches. There is a wide variation between a warfare of position, such as for four years existed in France, and an expedition chasing guerrilla bands in the mountains of northern Mexico. A careful study should therefore be made to determine where the light railway is advisable and where not. Experiments should be carried out to test the merits of different types of track and rolling stock; these to include rush emergency construction under adverse conditions to determine practically with what speed a line can be extended; how it will hold up under traffic, and how well adapted the rolling stock is to its purpose. Bring the track up to good condition as opportunity permits, but bear in mind that under battle conditions and in rush construction poor track is inevitable; therefore have rolling stock that can run on the poorest track.

E. D. Peek

Major, Corps of Engineers; formerly Colonel, Engineers, in Charge of Railroad Construction and Maintenance in the 1st Army, A. E. F.

It must be admitted that, granting the success of our light railway operations, they were fraught with many handicaps which we brought upon ourselves inadvertently. The American light railway equipment, both locomotives and cars, is much heavier and has a higher center of gravity than either the French or the British materiel. This type of construction, with the same width of gauge, demands a better and more stable road bed, and as a matter of fact, our experience in the war amply demonstrated that our light railway equipment demanded a better road bed than would be required for a light standard-gauge railroad.

The heavy equipment and high center of gravity, with an American personnel demanding higher speed and heavier loads than the French, resulted in increased derailments and increased demand for track maintenance.

The German lines, which fell into our hands in the vicinity of "No Man's Land," were all of the character upon which the Germans operated only short, light, push cars or tram cars and which could not be used by the American materiel, both on account of the weight of the rail and the degree of curvature.

It is believed that light railways or narrow-gauge railways were not thoroughly developed. When the World War began, a 60-centimeter light railway system was universally used in most of the industries in both Germany and France. In France it was also used in the fortified towns for the distribution of the heavy and bulky Engineer and Ordnance material. In this latter construction, during peace there was opportunity for obtaining good road beds as ample time was available. War brought on the necessity for a narrow gauge in the field, and we found that the French made great developments, especially in the vicinity of fortified towns, as Verdun, Toul and Epinal. In the vicinity of these towns the fortification systems for heavy artillery were extended into the field, and a standard commercial light railway project was utilized.

The narrow gauge, to be a successful light railway, should be developed in and under field conditions. It requires light equipment which means the minimum of preparation for the laying of the road bed and for prompt operation. It requires the utilization of light cars and engines properly built.

These conditions can be brought about only by experiments under actual field conditions, and it is thought that these tests will develop improvements along the following lines:

(*a*) Lower center of gravity of engines.

(*b*) Engines with double movable trucks in order to take sharper curves.

(*c*) Engines equipped with chain or gear drive in order to insure uniform power, permitting movements over rougher track and preventing derailments.

(*d*) Lighter rails.

(*e*) Lighter cars with lower center of gravity.

Even if all of these experiments are made—and there is a marked advance in the probable use of the light railway along these lines—it is still believed that the use of the equipment for defense will not be as easily and profitably accomplished as was the case with our light-weight standard-gauge equipment.

The experience in our Northern States upon logging roads, in which the ties are laid upon the ground without ballast and with little or no grading, gives rapid and efficient results. The equipment for the light railways now designed precludes even the remotest possibility of a similar use.

In large depots, storehouses, yards, fortifications and stabilized warfare, the narrow-gauge undoubtedly has its place. However, the character of war we are to wage on our borders must never be other than an offensive campaign in which the light standard railroad equipment has its pronounced advantage and should undoubtedly be used.

Paul McGeehan
Major, Engineer Reserve Corps; formerly
Major, 12th Engineers (Ry.)

Colonel Kelly's article leads one far into the realm of speculation as to the character of future wars. It may be true that position warfare will have no place in future military operations, but it seems to the writer that our military authorities should so plan for the future, as to prepare us to meet an antagonist of at least equal strength to our own. With such an enemy any extensive land campaign must pass through a stage of deadlock where position warfare will be a necessity. If we are always fortunate enough to have wars where our victories are easy and our advances rapid, of course we will have no use for light railways. For they will only come into play when desperate resistance makes enormous concentration of men and artillery necessary on narrow fronts.

Granting the possibility of our becoming again involved in such a conflict, the question of what kind of light railways are to be used is very much in order.

In such a war the main standard-gauge railways will be advanced as far to the front as possible. The terminals of these main lines must be far enough to the rear, however, to avoid destruction, and to avoid too much annoyance from the enemy's heavy artillery. The zone of greater danger in front of these terminals must be served by the wagon roads and light railways. These will radiate out in fan-shaped systems toward the front from the rail heads. So if you make a small advance and capture the enemy's light railway system, you will find that his tracks are not designed well for your use, and that the fans all point in the wrong direction. And you are also liable to find that your new construction connecting your tracks with his can not be used for some time on account of soft embankments and lack of ballast.

This brings up a big question which an army commander must consider, whether an advance of less than the depth of the enemy's light railway system is really worth while at all. Such an advance is sure to disarrange ones own supply and transportation systems about as much as it does that of the enemy.

The 2d Army on the Toul front had this experience. The dumps were all established, and where the advance, after the St. Mihiel push, was only a few miles these were not moved forward, thus there resulted an excessively long haul for the light railways between the old rail heads and the new fighting front, requiring the operation of much new soft track, and the maintenance of long stretches of track at the rear. which it would have been much better to have abandoned. A young officer of the 11th Engineers from New York, aptly summed up the situation when he said that the 2d Army dumps were just "two battles behind."

In retreat it is obvious that the fan-shaped plan of the light railways will soon be wiped out if the retreat is at all extensive. It is also apparent that on account of the expense, organization of these tracks in depth is not practicable. If a retreat is among the possibilities, occasional lines running straight to the rear should be provided in order to save the rolling stock, and not leave a defeated army in what the British described as a "ghastly situation," when they found that practically all of their light railway equipment had been captured. The British had provided these stems to the rear, but they were so imperfectly supplied with watering stations and were in such a poor state of maintenance that the withdrawal had to be made at a snail's pace, and no time was availble when the ends of the tracks were reached, to load the locomotives on the standard-gauge trains.

So the writer is in entire accord with Colonel Kelly in his statement that light railways are not of much aid to an army either in advance or retreat, and is of the opinion that this fact should be accepted as an axiom in military engineering.

A discussion of the article therefore settles down to a question of gauge of the tracks. Again the writer agrees that the *soixante* gauge is too narrow. This 60-centimeter or 2-foot gauge may have been suitable in the early stages of the war, but the large American cars and the Baldwin locomotive have undoubtedly made it obsolete. The writer has previously advocated a wider gauge. Anyone who has ever ridden on the top of a water tank ahead of a locomotive and has watched this little narrow track move out from under him, first on one side and then on the other, with the swaying of the train, is liable to come to the conclusion that he is riding on a monorail rather than a railroad. It used to seem almost miraculous that cars loaded with baled hay 10 or 12 feet high ever stayed on the track. Many derailments and the constant slow speed of trains can be laid directly at the door of too narrow a gauge.

While the writer agrees that 2 feet is too narrow, he is not inclined to the belief that it should be increased to as much as 4′ 8½″, the standard gauge. In the first place, the narrow-gauge railways are cheap in money and in what is much more important under war conditions, require less human effort in their construction. The rails are not over a third as heavy as those of the standard gauge, and one man can handle a rail or a tie with ease.

Light railways should reach the front at intervals of a mile or so, and thus must follow up most of the small valleys which extend in that direction. This means that they must be adapted at small cost to the meanderings of small creeks. Narrow-gauge railways can be successfully operated on very sharp curves, of less than 100 feet radius, and by the use of this curvature all heavy cutting in earth and rock can be eliminated. One must remember that practically all of the grading at the front must be done by hand with pick and shovel, and that the labor available is usually both scarce and inexpert. And besides the writer has never noticed that the morale of troops was ever improved by requiring them to perform such labor.

It is granted that electric railways use even sharper curvature than that mentioned here for light railways, but the standard-gauge equipment of this country, on which we must depend in war, will not pass around such sharp curves. So the advantage mentioned by Colonel Kelly of turning these light railways into trunk lines later in case of an advance, disappears. Besides only the larger valleys can be utilized for the trunk lines, for long trains can be hauled only on tracks with light grades and easy curves. Usually the larger valleys will already have been occupied by the railways of peace time.

So generally the only railways suitable for advances will be the main lines in use before the war. These with their solidified road bed and their bed of ballast, can be utilized in a minimum length of time, even when their bridges have been destroyed.

If the narrow gauge is to be abandoned and the standard substituted, it would be found that it would be no easier to advance such a system than it is to advance the narrow-gauge tracks; because neither is designed for through business, and their usefulness as light railways would be decreased if they were so designed.

Then the standard-gauge tracks would be more conspicu-

Digitized by Google

ous and would be sure to attract artillery fire. The enemy doesn't bother the 2-foot gauge tracks because they can be repaired with such ease after they are hit. And they are harder to hit because they are more crooked.

Another objection to the standard-gauge track would be that of having all ones eggs in one basket, and one shell would put it out of business. Whereas if the cost be divided amongst several narrow-gauge tracks at a distance from each other, the enemy would be put to more trouble and expense in annoying us.

The greater ease of concealment of narrow-gauge railways is another advantage. Narrow-gauge tracks can be built in a forest and so wound around among the larger trees that the skyline is not broken, and the tracks remain hidden from airplane observation.

The writer is of the opinion that the American light railway equipment of the latter stages of the war was ideal. The 10-ton gondola cars are as large as necessary and so are the locomotives. In his opinion the gauge ought to be increased to 30 inches. This gauge with the same rolling stock, built to negotiate sharp curves will enable the light railways to double their speed and greatly reduce delays from derailments. This widening of the gauge (6 inches) would not lose any of the advantages possessed by the 2-foot gauge. And coupled with the use of wooden ties it would materially reduce the amount of ballast and track labor required to keep the trains moving. Usually ballast is scarce on the battlefield, and inferior in quality. Anything tending to reduce the amount of ballast required furnishes a distinct advantage to light railway operations.

The writer was greatly impressed with the experience of the British in the first battle of Cambrai in November, 1917. In this push they concentrated all of the troops and artillery on the front to be attacked, that could be supplied by the wagon roads and light railways. In other words, if the excellent French wagon roads would have allowed them to haul up more food and ammunition, they would have employed more troops on this sector for their attack. Light railways located at a distance from the wagon roads materially augmented the British lorries in delivering supplies to the front.

In a great campaign in a country like America where good wagon roads are so scarce, concentration of men and materiel for offensive purposes, comparable to those in France, would be impossible without light railways. Perhaps the railways would be more highly developed than those of France because of the scarcity of good roads, which would throw a greater burden upon them. And such a campaign might develop a new rule of warfare, for victory may actually go to the belligerent having the most light railways, rather than to the one having the most artillery.

Harry L. Hodges
Formerly Colonel, General Staff (Cavalry) A. E. F.
Member Military Board of Allied Supply

The writer hopes that Colonel Kelly's article will serve the useful purpose of provoking a discussion of the efficiency of narrow-gauge railways. (It did.—Ed.)

His conclusion is, "that it seems obvious, therefore, that the narrow-gauge systems have no place in our future plans, but should be replaced by a light railway equipment on standard gauge."

Considering this statement from its purely engineering side, the writer does not deem himself qualified to express an opinion.

The American tendency in the use of light railways was to demand of them greater loads and greater speed than they were designed to accommodate. Should there be no change of gauge, there will be undoubtedly an endeavor, following this practice, to utilize the standard-gauge heavy equipment on the light standard-gauge lines, which use would probably cause as great a number of difficulties as occurred in the use of the narrow-gauge lines.

Perhaps the loss of narrow-gauge equipment, to which reference is made in the article under review, was due rather to the fact that army systems of light railway were not connected at that time, and so the equipment could not be shifted to the flank when occasion demanded it.

Should it be necessary to transfer shipments from a heavy standard-gauge line to a light railway equipment on the light standard-gauge line, there will be a necessity for transfer points, which Colonel Kelly cites as one of the weaknesses of a change in gauge, and as an advantage in light standard gauge.

Economy of construction, administration and maintenance are undoubtedly the reasons for the existence in peace times of the narrow-gauge systems, in the United States, France and Germany and of the "Vicinal" system in Belgium. These same reasons demanded their use in war. But there is an additional reason for the use of a peace-time gauge in war—the fact that it is capable of immediate quantity production.

The choice of gauge is largely the result of the conditions under which narrow-gauge lines are to be used, mechanically the wider the gauge the better so long as fabricated sections can be used.

The gauge employed by the British was chosen by them largely due to the fact that the German military narrow-gauge lines were all 60-centimeter gauge, and when captured could be immediately utilized.

It is accepted that there is a necessity for the utilization of light railway lines during stabilized warfare.

In any operations in which conditions exact intensive use of the highways, or where the capacity of the highways, due to their construction and condition, is reduced, steps were taken during the great war and will be taken under similar conditions in future wars to relieve them of all possible traffic, and to relieve motor and horse transport from the necessity of transporting such articles as can be otherwise transported, leaving them for a more mobile use. Light railways and standard-gauge railways perform in common these duties, but they have two essentially different functions; the standard-gauge railway is in great part an organ of procurement and storage; the light railway divides with the motor, horse and man transport the duty of distribution of supplies. It is a tactical rather than a strategic agency. It was decided daily in the French Direction de L'Arriere what proportion of the duty of distribution should be handled by light railways and what by motor and horse transport.

A doubt is expressed as to whether light railways can be utilized in a war of movement. In a war all of movement and in which the daily advance of the armies exceeds the possible rate of construction of light railways, there is room for serious doubt as to the possibility of their continuous use, but in a war in which there are periods of stabilization light railways can be and were used by both the French and British for a period during the break from a war of stabilization to a war of movement. Even in a war all of movement they can be used where an army holds a position for any length of time while other forces accomplish a strategic envelopment, thus relieving motor transport for more mobile use.

In fact their use in the break from a war of stabilization

Digitized by Google

to a war of movement was contemplated by the Supreme High Command, who caused this subject to be studied by the Military Board of Allied Supply, which as a result of this study organized, for this purpose, an inter-allied reserve of light railway equipment. At the meeting of the Board, held on August 11, the French member, Marshal Foch's Chief of Supply and Transport, presented a note dealing with the problem of transportation on the front and the use which narrow-gauge railways could be put to in order to meet the increasing difficulties. He laid stress upon the fact that in the probable event of the enemy's retreat the Allied Armies would have to follow him up through devastated regions. Past experience gained during the war showed that this devastation comprised systematic destruction of all lines of communication, including the taking away of all material, thus rendering the re-establishment of railway lines a lengthy matter. It also greatly limited the number of immediately usable roads. Light railways could be used to form a link between standard-gauge rail heads and the troops on the front, thereby reducing the strain put upon the motor transport services and releasing a portion of same for more urgent or efficient use at other points. They could be constructed also with less difficulty and delay.

It is of interest to note the policy of light railways in each of the Allied Armies:

In the British the policy of light railways generally was based on the stabilized front. It is not found desirable to attempt to push broad-gauge rail heads nearer the front than 7 miles, and the average distance behind the front lines of these rail heads may be put at about 10 miles. Light railways are definitely regarded as essentially providing means of transport from the line beyond which broad gauge can not normally and regularly pass, and this interpretation of the scope of light railways has been strictly adhered to. The early policy laid down was that, in the event of a small advance, the light railways system would be deepened by approximately the depth of the advance. If the advance were strictly limited, broad-gauge rail heads might not be advanced, but in the event of successive advances the broad-gauge railheads would be moved forward to a position relative to the front similar to that occupied before the advance. It was considered in view of the difficulty of constructing suitable broad-gauge rail heads, that the light railway system should be allowed to grow considerably in depth before the broad-gauge rail head was advanced. A separate policy was, however, laid down for a considerable advance, and it was definitely decided that broad-gauge railways were to be the means of supplying the armies in such a case, light railways as *feeders to the armies* dropping out with an advance of great depth.

In the French, established at first as a remedy for insufficient ground communications, they developed into a regular system for the relief of the horse and motor transport for the hauling of ammunition, particularly where intensive fire was necessary. They were utilized, however, for field artillery, engineer and road supplies.

During the advance it was found that between the new positions of the enemy and those that he had abandoned there was a devastated zone in which the roads and normal-gauge railways could not be put into immediate use.

If the roads could be quickly enough repaired, the same was not the case with the normal-gauge railways for which one could not count on a daily advance in excess of 800 meters.

On the other hand, the relatively small power of motor transport made it necessary to use the latter for the transportation of personnel and food. It became necessary, therefore, to carry on, at the same time as the repair of roads and the normal-gauge railways, the construction of 60-centimeter lines.

In the Belgian the object of the 60-centimeter railway was chiefly to reduce wagon traffic on the roads as much as possible. Its need was felt more and more as the roads in the rear of the Belgian front were often in bad condition, very narrow and crowded (their width being hardly sufficient for the passage of an automobile) and muddy in rainy seasons.

The 60 centimeter was the only means of assuring the supply of ammunition to guns of large caliber; of transporting large quantities of stone material for repairing roads and for concrete works.

Finally in case of an advance the 60-centimeter was used in crossing shell-torn terrain and aiding in the reconstruction of the standard-gauge railways by the transport of men and material.

In the Italian the following policy was adopted in the construction of narrow-gauge railways:

To construct with 75-centimeter gauge railways where they might be used after the war, and to build 60-centimeter gauge railways when exclusively for war purposes and therefore temporary.

For the use of these railways the following policies were adopted:

1. To open up new lines of communication in places where railways did not exist, as they were easy to operate and could be built quickly.
2. To carry materials and ammunition to those places where the normal railways could not reach, saving in this way, mechanical and horse transportation.
3. To assist the railways in the zone of operations in supplying the troops operating in that zone.

F. W. Green

Formerly Lieutenant Colonel, Transportation Corps, A. E. F.

The writer considers Colonel Kelly's article to be a very interesting and timely contribution to any consideration of the practicability of narrow-gauge or light railways in war. In the summer and fall of 1917 he was engaged, while an officer in the 12th Engineers, in the operation of 60-centimeter light railways, serving the 3d British Army in the Cambrai sector. At that time the front was thoroughly stabilized, and, in general, conditions were most favorable for light railway operation.

The design of the light railway steam locomotives was not satisfactory. Water tanks of the saddle type were carried upon the locomotive boiler, which, considered with the narrow gauge, produced a high center of gravity, and consequent overturning moment. The driving wheels were only about 24 inches in diameter, and the angularity of the main rods consequently excessive. The ratio of grate area to heating surface was too small, and there was too much overhang at each end of the locomotives, rendering them particularly susceptible to derailment on poorly surfaced track. The design of the cars in use by the 3d British Army was, on the whole, satisfactory. The writer believes, however, that by carrying the water and coal in a tender attached to the locomotive, by altering the design of the boiler and frames, and by the use of an underframe system of spring suspension, that even with the 60-centimeter gauge, the light railway lines could be made a very serviceable and practicable utility.

The gas and gas-electric tractors, used immediately behind the front lines, where the use of steam locomotives was impracticable, were also susceptible of material improvements in design. In order that these units may properly function, it is necessary that either the gauge be widened and the resisting moment to overturning correspondingly increased, or that the center of gravity be lower. It is believed that a careful revision of the design of these units could develop material improvements. The light railway ought to be considered merely as an adjunct to the standard-gauge railway. It is usually considered impracticable, from a tactical standpoint, to undertake the operation of standard-gauge railways closer than from 5 to 8 miles from the location of the enemy's artillery. Light railways may be operated in comparative safety up to within 2 miles, or sometimes even less, except in the case where a line of the light railway is directly enfiladed by the enemy's guns.

Considered as an auxiliary service, the light railway, under ordinary conditions, ought never to be called upon to furnish transportation for more than one division, or, in extremely favorable cases, more than an army corps. The writer recommends that in all cases units larger than a corps should be served by standard-gauge railways, using the light railways at the standard-gauge rail head for distributing materials and supplies from the railroad to the divisions. With proper plans and a proper organization

Digitized by Google

of the personnel, it ought to be entirely practicable to follow up an advance in open warfare with light railways, provided the advance does not progress at a rate faster than 6 or 8 miles per day. At the same time, dispositions should be so made as to insure that the standard-gauge railroad construction will progress at the same rate. The writer advocates the construction of duplicate light railway lines from the rail head to the front, using one line entirely for supplies, under normal conditions, and the duplicate line for transporting railway material for the next day's advance. As the broad-gauge construction progresses, the light railway track can be taken up and moved forward on this duplicate construction track, and ballast and other repair material for the operating line can be brought up to the place where needed, unloaded and applied without interference with the trains performing transportation service for the troops. Moreover, in case of tactical reverses, the duplicate track could be used in moving back material, personnel, and at the same time provide a means for withdrawing equipment and salvaged railway track. In case a need should arise for large reinforcements, the double track could be used for forward movement, or as a double-track line, as circumstances might require.

It has been the writer's observation that the failure of the light railways to properly function, aside from the difficulties in design, above pointed out, has been due to imperfect organization of the light railway service and imperfect staff co-ordination of the light railway service with other services. It is believed that the attempt to move supplies for an army, for a distance of 50 or more kilometers, over a light railway, is a serious error, and that the failure of the light railway service grew out of the expectation that the light railway could successfully function for such long distances.

The writer seriously doubts the wisdom of definitely abandoning the light narrow-gauge railway in favor of a light standard-gauge railway. The expense of construction and maintenance would be enormously greater, and the difficulties of distribution at the front vastly increased. It must be remembered that the primary reason for the use of the light railway was the large economies resulting therefrom, as compared with the distributing from standard-gauge rail head of material and supplies by motor truck. Where large concentrations of troops occurred, as in the late war, the wear and tear upon highways by motor trucks, in some instances, was so great as to require as many trucks to haul road material as for the hauling of other supplies. In its place it is believed that the light railway is an important auxiliary service, but there is a limit to its capacity, as above pointed out. In the case of a relatively small expeditionary force, for example, the Pershing Expedition into Mexico in 1916, it is believed that the light railway would prove a more economical means of transportation than the use of either horse or motor drawn vehicles for such long distances.

H. W. Durham

Major, Engineer Reserve Corps; formerly Major 41st Engineers, A. E. F.

At a recent meeting of the American Society of Civil Engineers, there developed considerable discussion on the question raised by Col. Kelly—the value of 60-centimeter gauge railways as developed in the war in France—and there was much agreement expressed with his points of criticism.

It is doubtful, however, whether the reasons given for the adoption of this type of equipment are correct. It is true that German manufacturers made large quantities of light industrial railway equipment before the war, but so did British and French manufacturers. In particular the Decauville 60-centimeter portable track and rolling stock was much used in France and her colonies for a generation before the war. When the Isthmian Canal Commission took over the French Panama Canal plant in 1904, there were great quantities of this stock on the Isthmus, and the writer, who was there during the first three years of construction, made much use of the old French equipment of this type. Several 60-centimeter railways were constructed for the supplying of materials to reservoir sites, distant from standard-gauge track, while locomotives and other rolling stock were put into service after twenty years' idleness in the jungle—a service very satisfactorily performed. To the pioneers at Panama these little railways were no strangers when met in France. For the first year of canal construction this track also formed the most available reinforcing material for concrete construction; in particular Ancon reservoir and the Caledonia highway bridge over the track near the Panama railroad station.

Others have already drawn attention to the fact that there were two main reasons for German dependence on these light railways. First, the shortage of rubber for motor tires, and, second, their inferior highway lines of communication. The latter were neither as extensive, as well located nor as well built as those behind our lines. Our army fought in a country supplied with the most comprehensive highway system in the world, and may not always be so well provided, as those who have been on the Mexican border well know. It is the writer's belief then, that good highways when available are infinitely superior and capable of much more elastic use than light railways; but if the question is one of the latter's use as compared with standard gauge, it seems as if our army experience with them in France was too brief and limited by which to determine the question, and that it would be better to do this with reference to the experience along the British front. Our army probably built and used more new light railway lines in its forestry operations than with the armies. During the early part of 1918 the writer was in charge of lumbering operations near St. Dizier and built over 10 miles of this light track for logging railways to reach the standard-gauge line at the mill. Several French Decauville locomotives were used, and it was found necessary to ballast all track to reduce the number of derailments which caused frequent delays. A French line on an adjoining project took as much track work as a standard-gauge line. More satisfactory results were obtained by extending the standard-gauge lines and using teams for motive power on the 60-centimeter track.

From his experience, both at Panama and in France, the writer agrees with Colonel Kelly in preferring standard-gauge track wherever possible, but does not think he has made a case for the absolute elimination of gauges other than standard. More consideration should be given to British and German experience before ruling out the portable lines from war use. The author also does not make it clear what would be the "light" standard-gauge equipment to which he refers. It could hardly possess the quality of portability. If we are to fight all over the world, we can not adopt any inflexible standard equipment good for all regions, for if we try to, we shall but repeat our experience with the ponton material so abundantly provided at Washington for crossing the Rhine.

T. D. Sterling
Major, Engineers; formerly 21st Engineers (Light Railways), A.E.F.

Primarily light railways belong to a war of position and are comparatively of little use in a war of movement, as the normal-gauge lines can generally be utilized if proper preparations are made. The primary function of the 60-centimeter railway is to deliver ammunition, troops, rations, supplies and army and engineer material from standard-gauge rail-heads to points near the front. In other words, the field of construction and operation of the 60-centimeter railway is within the enemy's field of fire. It was considered impracticable, during the world war, to use standard-gauge lines in any sector within the field of fire.

Assuming that it is decided to build standard-gauge lines within the field of fire and to use on these lines light railway equipment altered to suit the gauge, there are many good reasons why it would be impracticable to build such lines, with the expectation of using on them light railway equipment altered to fit the standard gauge:

1. Assuming that the standard-gauge track would afterward be in use by standard-gauge equipment, it will be found that the located line of a 60-centimeter railway, with its sharp curves and steeper grades, can not be used successfully by standard-gauge equipment.

2. The amount of clearing, grubbing and grading for a standard-gauge line will require from one-third to one-half more man-days of labor than a 60-centimeter line.

3. *Track laying.*—Ties for the standard-gauge track will be the usual standard-gauge railroad ties, 8 feet in length and require for expeditious handling four men per tie. Ties for a 60-centimeter railway are 5 to 6 feet in length and never require more than two men per tie. If rails suitable for 60-centimeter railway are proposed for use on the standard-gauge ties, it will be found that standard-gauge equipment on which the track material will probably be loaded can not be brought forward on the light rails without serious damage to the track. If heavier rails are used, suitable for standard-gauge equipment, there will be a large increase in the force of men required. If track material is not brought forward on the standard-gauge equipment, on which it is most likely to be shipped, then it will be necessary to reload it onto the altered light railway equipment at the rail head. It is this rehandling of material at rail heads which it is proposed to avoid by the use of standard-gauge track directly to the front.

4. Assuming that the proposed lines are built to standard gauge, with a rail which will sustain standard-gauge equipment, it will be found, in case of a retreat, that the lost track material will represent many times the cost of a 60-centimeter railway.

5. *Rail-heads.*—It will always be necessary to have a certain amount of yard tracks and storage room at divisional rail-heads. (There will be a certain amount of truck haul at all times.) There is very little additional expense necessary to provide 60-centimeter trackage for such material as will be handled by the narrow-gauge lines.

Objections to the construction of standard-gauge lines close to the front may be briefly summed up as follows:

(*a*) Impossibility of locating a standard-gauge line in all places where a 60-centimeter line could be located.

(*b*) Greater amount of labor required for construction.

(*c*) Greater cost of material used.

(*d*) Greater difficulty of concealment from enemy view. (Standard-gauge lines show up very plainly in aerial photographs, whereas 60-centimeter lines may be easily concealed.)

(*e*) Because of greater cost of material and labor for construction there would be a consequent greater loss in case of retreat. There is bound to be loss in a retreat, but it is hardly good military policy to plan equipment on the supposition that a retrograde movement will predominate.

(*f*) No noticeable advantage in reduction of transfer yards, as such yards will always be required at some places.

In reply to the statement that light railways were rendered entirely useless for nearly two weeks after the beginning of the St. Mihiel drive, this can not be strictly true, as 60-centimeter lines were continually in operation from the day of the drive. It is admitted that there was much congestion and delay to traffic. This was due to insufficient labor and material being provided for the work to be done. There was also much trouble with the motive power.

The narrow-gauge railway admittedly can not replace the standard gauge, but equally so a standard gauge can not replace, to advantage, a narrow gauge. While the 60-centimeter railway has its limitations, it is the only practicable means of transportation in any sector which is lacking in good roads, and is the best means of aiding transportation by trucks and teams. Many of the objections to the use of the 60-centimeter railway are based on the performance of those lines in France, where the motive power and equipment were found to be incorrect in design, of poor construction and unsuited to the requirements of the campaign. The highway, the standard-gauge railway and the narrow-gauge railway each appears to have its own field which can not be filled satisfactorily by either of the others.

Aerial Mapping with the Tri-Lens Camera

By

M. P. Taylor
Captain, Engineers

One of the most important phases of work yet developed by the Bagley 3-Lens Camera is the mapping of large and, heretofore, unmapped sections of territory. There is much of this territory in the United States, of which no maps of any usable degree of accuracy are available, and the Bagley camera offers a solution for supplying, in minimum time, maps which are fairly accurate.

Up to the present time, a great question for debate seems to be whether the required amount of accuracy for present-day maps can be secured by aerial photographic methods. Aside from this question, there is no doubt but that a fairly accurate map is much better than none at all, for such a map allows a working basis and can be corrected as occasion permits.

In connection with the military mapping operations in the Southern Department, work is under way for mapping, by aerial methods, a large area in Southern Arizona. This territory extends from Nogales to Yuma, and from the Mexican Border northward to the Southern Pacific Railroad, comprising in all some 16,000 square miles of territory. The field work, or photographic operations, in this section is near completion.

For the area under consideration, there are no available maps that show the territory with even a fair degree of accuracy. Before starting the field work, the best possible maps were acquired. After starting operations it was found that these maps were so inaccurate and incomplete, for the most part, that they would not even serve as a base on which to plat the result of the photographic work. The country in this vicinity is a combination of desert and

Digitized by Google

mountains, with few towns, railroads or other artificial markings on the topography. The available maps show the mountain ranges, but inaccurately, omitting many of the smaller mountains altogether. There is scarcely any drainage shown, and the roads and trails are shown incorrectly.

The work was laid out so as to be handled from three stations successfully, beginning at Yuma, the most western point; then from Ajo, in about the middle of the section; and finishing up at Tucson, on the east. The area to be covered from Yuma was about 4,000 square miles, and from each of the other places about 6,000. It was planned to fly the photographic courses in due east and west directions as nearly as possible, with a north and south course every 20 miles, for use as a control. This plan was adhered to throughout the work. It must be understood that there is a certain amount of variation from any outlined plan for this work, due to the physical impossibilities of flying courses exactly as laid out. This is especially true when there are no good maps to fly by, but at any time cross winds may interfere so as to make it almost impossible to fly a correct course.

All photography on this work is conducted from an altitude of 11,000 feet above the base of operations. The distance above sea level then may be secured by adding 11,000 to the altitude of the various stations; 200 for Yuma, 1,700 for Ajo, and 2,200 for Tucson. The elevation for carrying on operations was chosen arbitrarily, the necessary facts to consider being amount of detail to be shown and relative costs of carrying on work from different altitudes. The amount of film used, and therefore the amount of flying time necessary, varies inversely as the square of the altitude above the ground. At 11,000 feet the photographs give an approximate scale of 1: 20,000, and each exposure covers an area of some 1½ by 6½ miles.

Due to the rough nature of the country, the distance from the ground to the camera is a variable quantity, and the scale of the photographs changes accordingly. This is a condition incident to work in country of this nature. It cannot be eliminated in the field work, but can be corrected in the office preparation of maps from the photographs, provided sufficient ground control has been secured.

An overlap of about 50 per cent is used between consecutive photographs, and about 25 per cent between consecutive strips. This allows a sufficient amount for the variation in courses as flown, and also permits of using the central part of all photographs, which is of course the most accurate.

The field work was started April 5, 1920, and will be completed about July 5, 1920. To date about 13,000 feet of film have been used on this work, and the amount will be 16,000 before the work is complete. It can be readily seen that an unusual amount of work must be expended before this amount of film can be transformed into maps. All film developing is done in the field but no endeavor is made to handle the printing there. The exposures made with oblique lenses must be put through the transforming camera, and this is perhaps the longest part of the process.

It is estimated that it will take a year for the photographs of this territory to be worked up into map form, the force consisting of three laboratory men and six draftsmen. That would make fifteen months from the beginning of field work to the completion of the map. Considering the speed of ordinary mapping methods, this is remarkable.

Were ordinary mapping methods applied to the territory under discussion, progress would be much slower than in most places. The country is sparsely settled, water is scarce and, what there is, often of poor quality. The desert roads are very poor and impassable in many places. Survey parties can operate only under great difficulty, and with a small degree of efficiency. It is likely that the cost of mapping this region by ground methods would be twice the usual cost of such work.

The completed photographic map will show all horizontal detail, mountains, drainage, roads, trails and settlements. It is impossible to state now what the limits of accuracy will be as the ground control is unfinished, but a reasonable amount of accuracy is expected. At any rate the map will give correctly the general topography of the region, and be an effective basis for future operations.

Much has been said of the cost of aerial photographic mapping as compared to ordinary methods. This would seem to be rather unimportant, at least as far as the field costs go. It would undoubtedly be out of the question for any commercial organization to make maps economically by aerial methods. But the government has the equipment and the personnel, and moreover photographic mapping should be a part of all airplane pilots' training, as they will be fitted for it in war time. There is no apparent reason why this work should not occupy a prominent position in the aviation calendar.

Infantry Howitzer.—The Infantry accompanying guns, which were tested at Aberdeen Proving Ground, were manufactured by the Ordnance Department, the two types being copies of Italian designs examined by the Caliber Board in Europe. The first design completed was a 70-millimeter gun, firing a 6-pound projectile; the second design was a 75-millimeter gun, firing an 8.5-pound projectile. The object of manufacturing these two types was to provide models at an early date, in order to crystallize ideas and opinions on what characteristics this type of weapon should embody. The tests have clearly shown that these two models are not satisfactory to fulfill the specifications which have been proposed; *i. e.*, that this weapon shall be suitable as a substitute for both the 37-millimeter gun and the 3-inch trench mortar.

The Ordnance Department is now preparing designs of a weapon that will fire a 6-pound shell for direct fire, and a 10-pound shell for indirect plunging fire. The tests of the two Italian types have been suspended pending a metallurgical investigation which was found necessary.

Railway Artillery.—The outstanding features in the development of railway artillery in the United States during the last two years lies in the construction and test of the 14-inch gun railway mount, model "E." This gun and mount were designed in the Ordnance Office; the gun was built at Watervliet Arsenal, N. Y., and the mount at Watertown Arsenal, Mass. Gun and carriage tests at the Army Proving Grounds, and service tests at one of the seacoast fortifications have proven this mount to be one of the most serviceable pieces of railway artillery that we have.

The mount may be fired as a sliding mount from any well-ballasted track, but without any specially prepared foundations; it is provided with several degrees of traverse, so that a curved track is not necessary, as in the case of the usual type of sliding mount where no traverse is provided. The carriage is equipped with a base plate suitable for setting on bare ground or on a concrete plug, from either of which the gun can be fired in any azimuth. In target practice, at both long and short ranges, where moving targets giving the extreme rate of change in direction were employed, the practical use of this mount was well established, the general operation, rate of fire and percentage of hits being most gratifying.

The Methods of Construction in War

By

E. Graves

Major, Corps of Engineers; formerly Colonel, Engineers, Division of Construction and Forestry, A. E. F.

[*Note.* Engineering construction of all classes is one of the chief features of modern war. During the late conflict the engineers of the American Army covered the theatre of war from the base ports to the battle line with structures of every conceivable variety. Hundreds of thousands of men, including many of the ablest engineers in America, were engaged in this great work, so vital to the success of our arms.

Of the many men who directed this mighty undertaking none was better equipped by ability and training, none enjoyed a wider experience or achieved more conspicuous success than the distinguished author of this article, which we are glad to present to the engineering profession.

Colonel Graves lays down in clear and convincing language the basic economic principles which govern military construction. He then shows in detail the application of these principles to the various classes of work.

This treatise will be of value not alone as a guide to the military engineer of the future. Many of the principles and methods discussed by the author are quite applicable to many civil works, when prompt results adequate to the needs of the case and no more than adequate, are desired; and when the returns must justify the outlay.

The engineer of the future must be more than a mere builder of structures, a mere technician. He must understand the basic principles on which the success of construction enterprises whether in war or commerce are based, otherwise he cannot justly assume the title "engineer." Herein are some beacon lights to guide him in his future course.—ED.]

Fundamental economic principles

Bare necessities alone. Construction, both in the theatre of operations and out of it, is one of the functions of warfare that is susceptible of great mismanagement and incorrect judgment, if the fundamental economic principles of war are not continually heeded and applied. When warfare is started in any locality, the struggle of opposing forces means that there will be great scarcity of materials, supplies and transportation. It is inevitable that there should be a scarcity of all supplies, and that food, ammunition and men will have priority in transportation. It is therefore certain that construction will be done under most difficult conditions. That only bare necessities should be provided is axiomatic. A reserve engineer officer in the Great War said that when he went back to civil life, he might not be able to make a living because every time any one sought to employ him to construct anything he might follow his war-time training and persuade his client that he didn't need what he asked. So bear in mind, the principle of *bare necessities only* is of primary importance. Of course the decision as to what constitutes bare necessities rests with the military authorities.

Safety and durability of minor importance. While in civil construction great weight is properly given to safety, permanence, cost, etc., in military construction these features are of much less importance. Factors of safety need not be so great, although they are somewhat dependent upon the nature and purpose of the structure and other circumstances. For instance, if a military force is entirely dependent on *one* wharf for its supplies, it is necessary for that structure to have as great a factor of safety as in civil practice, but if, on the other hand, many buildings are being constructed for storehouses and personnel, it matters little if one or two of these houses fall down.* The saving of materials by building all the houses with a factor of safety of less than two, more than overbalances the loss of one or two structures. Also, the length of time a structure for military purposes will be required is always short and generally uncertain, so that it does not pay to build except for the present.

Planning, procedure and order of importance. In planning construction, where large expansion may develop, it is proper that structures should be so laid out that expansion is feasible. However, it is essential that the building program should be so carried out that each usable unit is completed in succession, in such a way that it can be used immediately. Thus the construction will lend itself continuously and progressively to the military necessity, and a change in the military situation which stops all the construction will not leave such a large proportion unused and useless as in civil practice where ultimate completion of the whole is generally the aim. It sometimes happens that work carried on in this way is more costly of labor and material, than if parts requiring similar construction methods are built at the same time. However, the satisfying of the immediate military requirements is usually the first consideration, and should rule. For instance it is wrong to start a number of storehouses when one house is needed, and all labor and material could be devoted to providing this necessity immediately. Similarly, it is wrong to lay ten railroad tracks in a yard before aligning and ballasting any, when perhaps only three tracks are needed immediately, and the available labor could be devoted to laying, aligning and ballasting these first. When electric power is required it is generally better to use a small gasoline unit to fulfill immediate needs and to add units as the demand increases, rather than start a large power house which may never operate at all. The loss of efficiency due to using small units is insignificant compared to the importance of fulfilling the requirements of the military situation. Intelligent supervision and planning will keep construction ahead of military necessities, while blind and senseless adherence to plans will not provide necessities in time.

Administration, organization, and control. In the administration of construction work over an extended territory two things are quite essential; 1st, there should be an engineer in each locality in charge of all engineering work, including buildings, railroads, electricity, water supply, and every other kind of construction, and, 2d, responsibility and authority should be decentralized as much as possible. The only way in which limited materials and labor can be most usefully applied is for one head to decide which feature of construction is most in demand, and to apply all available means to the job most necessary. This is in accordance with the principle stated above that a usable unit must be

*An amusing story illustrating this idea is related of Colonel Graves. While he was engaged in the construction of a large storage depot in France, one of his subordinates, greatly disturbed, entered his office and reported, "Colonel, two of your storehouses have fallen down." Far from reflecting the perturbation of his aid, Colonel Graves smiled and replied: "Good. I have been waiting for this. I now know how far I can reduce my factor of safety."

Digitized by Google

rushed to completion, before parts of other units are started. Thus is avoided the spectacle heretofore too often presented, of several construction agencies, each obsessed with the supreme importance of its own task, vying with each other for the exclusive control of all available facilities. The head which supervises all engineering work in a theatre of operations must have similar heads in various localities. The work should not divide into specialties until it is small enough to be supervised in detail by one man. This is true of control, but does not mean that higher supervising heads should not have advisers in specialties. However, these advisers should not be permitted to interfere with the supervision of local heads over the various specialties.

Higher supervisers should delegate as much authority and responsibility to subordinates as is possible, because in war communication is slow, and local necessities are best known by the local man.

Plans should be considered only as guides to keep the local man informed of general policies, and should be changed at will to meet local conditions, and to conform to available materials and labor.

Simplicity. The maxim of Napoleon that simplicity should characterize all the operations of war, is as applicable to construction as to any other feature. All designs should be of the simplest nature, requiring only the most common construction materials, and supplies. For instance, water supply equipment should be of a few standard sizes of pipe and fittings with simple pumps. Electrical installations should be made with simple machines that do not require extraordinary personnel to install and repair, etc., etc.

Construction for personnel

The construction necessities are cover, water and latrines.

Cover in general. Men require protection from the weather according to climate, season of the year, etc. The nature of this protection is dependent upon the probable time of occupancy. Soldiers on the march rest and sleep in the shelter tents which they carry on their backs. If they are to stop in one locality for several weeks, it is desirable that large tents be provided. If occupancy seems fairly certain for an extended period, barracks may be advisable, and economical from the standpoint of transportation, materials, and health. In the World War the use of barracks rather than large tents in many cases was a mistake. Stationary and trench warfare created a false impression as to the advisability of barracks, which was not fully realized. It was useless for the first American Army to attempt a large barrack program in the front line area, because movements were too rapid for barrack erection. Transportation facilities were acute and were growing more so every day. Large tentage could have moved with a small percentage of the freight cars which were required for barracks. It is believed that large tentage should be kept on hand for about 40 per cent of any military force so as to avoid unnecessary barrack construction, and that barracks should be used only when occupancy for long periods is assured, since the wear of tents makes the use of lumber advisable only when long occupation is contemplated.

Layout and location. In locating a camp of any kind, either of tents or barracks, care should be exercised to take advantage of all local facilities to avoid unnecessary construction. If tents are likely to be changed to barracks, space allowances should be sufficient to permit of the change. Any existing roads should be taken advantage of in order to avoid road construction which is most expensive in labor, materials, and transportation. Kitchens should be placed adjacent to the road and latrines on the opposite side. Fire risk should be reduced by proper spacing. Layouts shown in Field Service Regulations should be followed in principle, local conditions as to roads and railroads, visibility, drainage, water, direction of prevailing winds, etc., being duly considered.

Space allowances. Military necessity often takes precedence over sanitary requirement in the matter of space allowances. Medical authorities say that a man should have about 600 cubic feet of space. Sometimes they prescribe even more. Generally they say, certainly not less than 400 cubic feet. In discussing barrack space, this is usually spoken of in square feet, the barrack being assumed to have an average height of 10 feet, which may or may not be so. The decision in this matter is made by the tactical military authorities, since the medical authority can not carry the responsibility incident to the necessary reduction in his recommendation for air space. In the World War, the foreign armies allowed about 40 square feet of barrack space per man, but the American Army operated and increased its personnel so fast that by necessity its allowances were about half of this. Men were placed in double tiered 4 and 8-men bunks, and received an allowance of not over 20 square feet per man. The following quotation from orders of G. H. Q., A. E. F., shows what military necessity brought about in the World War:

3. The following allowances of floor space will govern officers charged with constructing shelter for our troops:

(*a*) Enlisted men. Bunks 2′ 8″ by 6′ 6″, double tier, in sets of four, 2′ 8″ apart, giving one linear foot of Adrian barrack (20 sq. ft.) per man. For company (250 men) kitchen and store room, 12 linear feet of Adrian barrack (240 sq. ft.), and one additional linear foot (20 sq. ft.) for each three men of the organization as dining room.

(*b*) Nurses. One room 10′ x 14′ for each two nurses. Kitchen allowance same as for enlisted men.

Dining room allowance, 2 linear feet of barrack (40 sq ft.) for each three nurses.

Where nurses are now accommodated in Adrian or other similar type barracks, their quarters will be altered to conform to the above.

(*c*) Officers. One room 10′ x 14′ for each colonel; one similar room for each lieutenant colonel or major. For officers below the grade of major, rooms will be provided for use in common on a basis of not less than 70 sq. ft. of floor space for each officer. When officers are quartered in an Adrian or similar barrack 14 sq. ft. of space allowed for each officer will be taken for a common assembly room, which will be separated from the balance of the building by a full height partition. For kitchen and store room for officers 10 linear feet of barrack (200 sq. ft.) will be allowed, and for dining room 2 linear feet of barrack for each three officers (13 1-3 sq. ft. per officer).

(*d*) Hospitals. One bed for each 3 linear (*) (60 sq ft.) of Adrian barrack. Kitchen allowance, 18 linear feet (360 sq. ft.) of Adrian barrack for 300 men, and 24 linear feet (480 sq. ft.) for 500 men. Dining room allowance, 2 linear feet (40 sq. ft.) of Adrian barrack for each 3 men of hospital capacity.

4. Lower bunk frames should clear the floor by 18″ and there should be room enough between the upper and lower bunks to allow a person to sit upright in the lower bunk. Company barracks, kitchen and dining rooms will not be floored.

5. The stove allowance is amended to give one stove for each 33 linear feet (660 sq. ft.) of Adrian barrack, or one stove to each room.

Types of barracks. In determining upon the type of house to use, it is well to consider local practice. In France designs were used which could be made from the short lengths of lumber used in that country. Demountable buildings were used to a large extent, because they could be made up in shops with machinery and economy in labor and in lumber. In the Punitive Expedition into Mexico huts were made of "Dobe" brick which could be made on the site and sun dried. Where the barrack has to be transported any distance, it is certain that wood or wood and corrugated iron are best, because more cover can be obtained for the

*Instructions to provide equipment for 1,200 patients in a 1,000 bed unit modify this to about 40 sq. ft. per patient.

Digitized by Google

same amount of transportation than with any other materials.

In general, except where special conditions obtain, barracks for personnel about 20′ x 100′ are best on account of simplicity of construction. Where space is limited, a two-story barrack may be advisable, but this is exceptional. A larger barrack may be more economical in the materiel used per man, but complications in roof trusses, and the inadvisability of putting too many men in one building make the smaller building best in general. The use of corrugated iron brings quicker results, and takes less transportation to bring the material to the site, but the house is not so comfortable as wood, it being colder in winter and warmer in summer. On the other hand, the fire risk is less for iron than for wood. At Bordeaux some two-story barracks were constructed because ground space was not available for single-story buildings and at Brest some large corrugated iron barracks were erected because needs were so urgent that time overruled every other consideration.

Dining rooms and kitchens. As stated in the order quoted, a building 20′ x 100′ was made to serve one company of 250 men for dining room and kitchen in Europe in the World War. This was supposed to be equipped with rough lumber tables and benches but was not always so fixed. This kind of dining room was provided in divisional areas, and in certain large depots with more or less permanent personnel. In replacement camps, rest camps, and debarkation camps where large numbers of men were fed rapidly from one kitchen, other special types of dining rooms were developed. These did not provide seats, but stands on which the men can place their mess kits, and shelter from the weather should always be provided.

Screening. In France there were few flies, comparatively speaking, and it was prescribed that screening would not be used except for operating rooms and kitchens in hospitals. After the Armistice this was modified by screening being prescribed for kitchens and dining rooms at some of the ports, or where the warm climate made flies more prevalent. At the debarkation camp at St. Nazaire screens were not used, because, according to the Commanding Officer, flies could be controlled by cleanliness. Such large numbers of men were fed continuously that it was impossible to keep either the kitchens or dining places closed to flies, and screening was useless. At this place there were almost no flies. In warmer climates in America screening will always be demanded although with rough construction it is very difficult to keep a house fly-proof.

Windows. In the World War, glass could not be obtained. In addition, its transportation is always difficult. Various types of window substitute have been developed, consisting either of some kind of transparent cloth or tough paper, or of wire netting coated with a transparent film of gelatin substance, which may be inflammable or not and soluble in water or not, preferably *not*, of course. Window substitute in rolls provides a large amount of window material requiring little transportation space.

Water allowances. The amount of water men use, depends chiefly upon what they can get. While European cities use from 20 to 30 gallons per inhabitant, per diem, American cities use from 60 to 250 gallons per inhabitant. Men in camp will get along for cooking and drinking purposes alone (not including washing) on about one gallon per man per day. One camp in France, of about 20,000 men, had wash water two or three feet below the ground surface, and hauled for several months drinking and cooking water, getting along very nicely by hauling one gallon or less per man, per day. The large debarkation camps in France had water supplies providing a maximum of 10 gallons per man. So 10 gallons or less per man or animal, per day, will take care of a camp quite nicely although, of course, it will not provide for street sprinkling and such uses. Where water is piped to separate companies, one faucet per company can be made to serve and no provision for washing faces and hands is *necessary*, although it is sometimes made.

Bath houses. In the divisional areas in France, one bath house per battalion area was provided. It had a "bain douche" of 8 showers, and was a house 12′ x 23′ with a partition giving a room 8′ x 12′ for the shower, and a room 12′ x 15′ for dressing. When practicable a four-inch concrete floor was put in the shower room and a wooden floor in the dressing room. The "bain douche," a French affair, is a most economical device in material and in water used. The above mentioned allowance is quite small and requires good administration and supervision in the use of a bath house by a company, and bathing by squad. Somewhat better facilities were provided in some large camps, but the above represents *bare necessity*.

Drainage. In camps, drainage should be by open ditches, and piping should not be used.

Latrines. Latrines should be of the simplest type. About one seat to 20 men is desirable, although one seat to 40 men can be made to serve. No floor or concrete is necessary around a latrine. A roof with enough siding for a screen is desirable although by no means an absolute necessity. The French squat latrine is economical but does not conform to American standards of comfort like the American seat latrine. Whether a latrine has sides, roof, and seats depends upon availability of material. No sides or roof at all, or simply pieces of canvas or brush are frequently made to serve. In war, flush water, septic tanks, and other sewage disposal devices should be avoided as there are never materials or labor available for such purposes.

Electric lights. Where electric power and materials for lighting are available, it is a convenience to have electric lights in a camp, and they may be installed. However, such installations are made only when the facilities for their construction are easily available. When camps are lighted there need not be over four 25 watt lights per barrack (20′ x 100′) and one 25 watt light per officer. Ordinarily in war only divisional headquarters and other higher headquarters have electric lights. A divisional headquarters require about 3 kilowatts for lights.

Laundries. The use of laundries in the A. E. F., except for troops going in and out of the front line and for hospital patients, was forbidden, for reasons of economy.

Hospitalization

Percentage of hospitalization for a military force. In the beginning, hospital provision to accommodate 7 or 8 per cent of the personnel in France was authorized by G. H. Q., A. E. F. This was to be obtained by renting existing buildings and by new construction. Later this percentage was increased until it became 15 per cent. Just before the Armistice the sick and wounded increased rapidly and became 12 or 13 per cent. The combination of flu and desperate fighting accounts for such a high percentage of hospital patients. It is believed that it must be a most desperate war in which hospital provision of over 10 per cent is necessary. When fighting is not severe and not continuous, 5 to 7 per cent ought to be an ample allowance. A divisional training area in France was allowed a camp hos-

Digitized by Google

pital of 300 beds, *i. e.*, 300 beds to 28,000 men or a little over 1 per cent.

Base hospitals were constructed in 1,000 bed units. As mentioned above, the space allowance per patient as prescribed was 60 square feet, but later instructions to provide for 1,200 beds in the so-called 1,000 bed units made the actual allowance from 46 to 54 square feet per patient.

There was provided for the actual use of a patient from 55 to 76 sq. ft. of space. This figure corresponds to the figure of 28 sq. ft. which was provided for the ordinary soldier. The overhead space in the base hospital units varied from 13 to 17 sq. ft. per patient and the total space per patient including space of attending personnel, was from 88 to 117 sq. ft. For the camp hospital these figures were 46 to 77 sq. ft. for actual use of each patient, and 65 to 108 sq. ft. total allowance per patient.

Water supply and sewerage. In France water supplies for base hospitals were designed on the basis of 25 gallons per patient, per diem, but not always was so much water available. Latrines with cans were used, the contents from the cans being generally burned. Drainage pipes for wash water and urine were laid. This is believed to have been a mistake. Piping for drain water and not for sewage is not worth the labor and material involved, and there was not enough water to permit of sewage being carried into the drains. An enormous amount of labor and material would have been conserved if no such drainage had been attempted. Stationary wash basins could have been dispensed with, and tin basins on a bench substituted. Sinks can be improvised from any materials available.

Electricity. The electric lights placed in each ward should not exceed six. The power provided has to be suitable in voltage and sufficient to meet the requirements of the apparatus in the operating rooms.

Remount depots and veterinary hospitals

A large program of remount depots and veterinary hospitals was carried out in France, although the scarcity of animals hardly warranted so much construction. For horse shelters and other buildings round poles can be used for posts when squared timber is scarce. Also hay racks and horse troughs can be placed on the ground and made of corrugated iron, where lumber is scarce. Disinfecting or sulphur chambers are constructed with any material available. They are nothing more than fume-tight houses in which animals are backed into stalls, and the doors closed, with the heads of the animals projecting outside. Horse dips made of concrete were constructed at veterinary hospitals.

Air service construction

The Air Service may require special construction at assembly plants, training centers, depots and landing fields in addition to provisions for personnel.

Assembly plants. If aeroplanes are delivered unassembled as they were in France, an assembly plant will be necessary. In France this plant was located where parts arriving at all ports could be collected. It was laid out on a very large scale and constructed progressively by unit, so that it could function to meet immediate needs. The units used were assembly shed with motor testing adjunct, salvage shed, shop, store sheds, hangars, and landing field.

One assembly shed was composed of three houses, 50 feet wide by 500 feet long placed side by side and five houses placed perpendicular to these from 50 to 110 feet wide and about 350 feet long. In the three sheds first mentioned the planes were unpacked and partially assembled. They were then moved into the perpendicular sheds where the wings were put on. The width of these sheds varies to suit different sized planes, and it was expected that planes might finally be received having a width of 100 feet. It was claimed that floors were necessary in these sheds, but the planes were assembled without floors, although certain parts of the sheds were finally floored with concrete to facilitate work. Between the sheds forming the unit, the valleys in the roof were covered and water was carried off by simple wooden troughs. The sheds were generally steel frames covered with corrugated iron, although some were made of wood.

The salvage shed was identical with the assembly shed.

The shop was a building about the same size as the assembly shed. On account of machinery being used, concrete floors were greatly desired, and were partially laid, although they were done without for awhile. Power was furnished by a 50-horsepower gasoline unit at first. More power was to be added.

Store sheds about 50′ x 500′ were used to store parts in. They were simple sheds without floors, containing certain racks to fit special parts.

A landing field adjacent to the plant was used on which to test planes before they were sent to the front. Hangars were placed on the side of this field.

Training centers. The training centers in France contained provisions for personnel (which were supposed to be the same as for all Army personnel), landing fields, with hangars, and shops for minor repairs.

Depots. Air depots in France were located away from general depots, because the air supplies did not follow the same lines of travel as other supplies. The depots had store sheds without floors the same as general depots.

Landing fields. Landing fields were constructed at assembly plants, at training centers, and behind the front. Some of these were located where weeds had to be cut down and grubbed; others were more properly located on open ground, where smoothing only was necessary.

These fields have to be made smooth, and planted in grass. Preparing a field is a long job, and should be carefully considered and found necessary before being started. Plows, scrapers, graders, rollers and tractors are used. A large 75-horsepower tractor, with a grader having a 12-foot blade will do such work, or it can be done with smaller apparatus. Small Grey tractors were used to a great extent in France.

Hangars. Hangars can be made of steel, wood, or canvas. Canvas, of course, is most expedient, but where long use is assured, or where extremely wide spans are required wood or steel is used. The Bessenau hangar, used in France, consisted of a light wooden truss covered with canvas. It had widths as great as 23 meters. This type of hangar is the most economical in material and in transportation, and it can be easily moved. Spans under 70 feet can be made with wooden trusses. Greater spans than this make steel almost essential and even smaller spans may make steel more expedient.

Motor transport construction

Motor transport facilities include assembly plants, shops and parks. Each port in France had an assembly plant. There was one large shop in the Intermediate Section, and parks with shops were scattered throughout the Advance Section behind the front. All these layouts contained similar structures varying in size. The construction work was building sheds, roads, and storage parks.

Digitized by Google

Sheds. The sheds were made of both wood and steel. Sometimes they had concrete floors. Sheds were permitted only for work and for storage of spare parts.

Roads. Heavy traffic around motor facilities requires much road work. It has to be done with dirt, gravel, or rock, whichever is most available. Drainage is exceedingly important, because with good drainage almost any material will do well. Road work for any purpose is drainage and rock, and in war whatever is available must be used, with drainage always in mind.

Parks. Storage ground for motor vehicles in France was sometimes graded and drained, but it was rarely surfaced with rock or gravel. Generally grading for drainage will keep the ground firm enough to permit storage of motor vehicles; and only those portions of a park which are subjected to traffic have to be surfaced with rock. However, at places in France mud became so bad that tractors had to be used to move motor vehicles.

Supply

The British found the requirements for their Army in France varied from 28 to 30 lbs. per man per day. The experience of our Army indicated a larger figure than this (about 36 lbs.), but we were storing up a large 90-day reserve all the time and were constructing storage therefor. In addition, we never had a regular basis of supply for a fixed number of men. It is considered that 30 lbs. per man per day is an ample allowance for planning for an ordinary expedition and that 40 lbs. per man is sufficient for any contingency. The figure, of course, depends upon the reserve planned for.

The plan of storage for our expeditionary force in the World War was first to have a reserve supply of 90 days for 2,000,000 men. Later this was changed to 45 days supply for 4,000,000 men. One-half of this was to be stored in the Base Sections near the ports; one-third in the Intermediate Section; and one-sixth in the Advance Section. In order to handle and care for such a large supply, extensive port, railroad and storage plans were necessary.

Port construction

Dock requirements. Experience of the British and American Armies showed that there could be unloaded 1.25 tons per day per lineal foot of dock. On the basis of 40 lbs. per man, 1,600 feet of dock length would supply 100,000 men, and 16,000 feet would supply 1,000,000 men.

Freight handling apparatus. In France there was great difference of opinion as to the advisability of installing cargo handling apparatus, and the kind of such apparatus most expedient. Large Gantry cranes straddling three tracks were advocated by some; smaller cranes straddling only one track were advocated by others; and others advocated only ships tackle. At first only ships tackle was available. On the large dock at Bordeaux, large Gantry cranes were later partially installed. Other derrick devices lighter than Gantry cranes were tried with differences of opinion as to results. It is fairly certain that military necessities will have to be first met with no dock handling devices at all, and if civil practices come in later, when tonnage is sufficient to supply them in addition to necessities, they can be designed according to existing conditions. In France, the railroads never succeeded in removing all the supplies from the docks, so the unloading of the ships was not the critical requirement.

At Antwerp, Belgium, a wharf used by the A. E. F. after the war had unloading equipment that is considered reasonable if devices other than ships tackle are possible. This wharf had a space 55 feet wide between the classification shed and the front of the wharf, with three railroad tracks on it. The outer track was spanned by a crane, so materials such as rail, iron and steel could be loaded direct from ship to flat cars. A cargo requiring classification could be deposited on a one-horse truck, which would carry it into the large classification shed on the rear of the dock, and deposit it, where it was desired. Railroad tracks were located also on the far side of the classification shed, so cars could be loaded therefrom. The principle of this dock by which, in addition to railroad cars, liberal use can be made of horses, trucks or men to move stuff away from the ship's side, is good.

The questions of ballast for ships, coaling, unloading exceptionally heavy pieces, etc., are problems which require special solutions, depending upon existing local conditions.

Dock construction. Any rapid wharf construction, and rapidity of construction will certainly always be necessary in military operations, must be wood construction and probably it will be pile construction. A pile wharf is the quickest and most economical in materials. The Montoir Pier is considered the best type of work of this kind done in France from a military standpoint.

Railroad facilities

General requirements. In any theatre of operations, the main lines of communication will utilize existing railroads and these will ordinarily be found adequate, insofar as main line tracks are concerned, but, as in France, extra facilities may be found necessary. Ordinarily, construction necessary will be included in one of the following classes:

Passing tracks.
Tracks on docks and from docks to yards.
Receiving, classification, and departure yards, near docks at engine terminals, at depots, or at any place where trains are made up.
Engine terminals.
Water tanks.
Railroad shops.
Regulating stations.
Railhead sidings.

Weight of rail. In France practically all the railroad laid was in the form of yards and sidings. Although several lines ten or fifteen miles long were constructed to connect wharves with storage yards, or aviation centers with main lines, this was the exception rather than the rule. Since in yards and on sidings trains move slowly, it is not necessary to have as heavy rail as on main lines. In France 80-lb. rail, and 14 ties to the rail were used. It would have brought about a great saving in tonnage if about a 60-lb. rail had been used, and rail of this weight would have served the purpose. Perhaps 16 or 18 ties to the rail would have been advisable for the lighter rail, but nevertheless the resulting saving in tonnage and transportation would have been enormous.

Tracks on docks and from docks to yards. There are usually at least three tracks used on a dock in front of the classification shed, to take the cargo direct from ship. With three tracks, cars can stand on one to receive loads and be moving on and off, on the other two. If rails are laid at floor level, supplies can more easily be moved by animal, by truck or by hand truck, off the dock into the classification shed. Back of the classification shed there should be two or more tracks to receive cargo from this shed. Two or more tracks should be laid from the dock to receiving, classification and departure yards.

Railroad yards. At places where trains are made up and at depots, receiving, classification and departure yards with

Digitized by Google

tracks from 1,500 to 2,000 feet long are necessary. Tracks in France were spaced first with 14 ft. centers, then with 16 ft. centers to permit locomotive cranes on hand to be used. While plans should be made providing for ultimate expansion into elaborate yards, the construction should be carried on progressively to fit immediate and urgent needs. In France plans were never completed entirely. Supplies moved eastward only, and all types of cars were used for any and all purposes, indiscriminately, so the need for classification westward did not exist, since only empties traveled in that direction.

The layout used at Gievres, France, served the Intermediate Depot; served as an engine terminal; and during the German attacks near Chateau Thierry, served as an advance depot and regulating station for the Paris Group of American Forces. In other words, these yards were made to serve every requirement under most difficult conditions. One track (about 1,700 feet long) along one side of the storehouses was found sufficient. The yard was designated with the idea that each storehouse was similar to a freight storehouse in New York, Chicago or San Francisco. In such a storehouse freight comes in for Jones, Smith, etc., at the same time that it is going out for Thompson, Jackson, etc., so the facilities for handling into the house from cars and out of the house into cars at the same time are necessary. At Gievres it was different. Everything that came in was for Uncle Sam and everything that went out was for Uncle Sam, and practically everything that came in on the railroad went out on the railroad. One house generally carried only one article, and if that article was to be shipped to Uncle Sam, the same article, if in cars, would simply be reconsigned in the same cars without unloading. The entire yard of about 125 storehouses was just as if it were one house with many tracks through it. Unloading and loading from the same tracks was never necessary because each particular item was always stored on more than one track. Items coming in would be unloaded on entirely different tracks from the one on which loading was necessary. In the area where wagons were unloaded, assembled and then reloaded for the front, three adjacent tracks and a locomotive crane were used. Of course such a layout as this is constructed in order as the facilities are needed, and where topography makes construction difficult, that part of the yard is simply omitted and extensions are made where construction is easy and rapid. Ballasting was not done here at all, and is never done until it is demonstrated to be necessary.

Engine terminals. On a main line engine terminals are placed about 75 or 100 miles apart. These terminals consist of receiving yard, turntable or Y, ash pit, inspection pit, water tank, coaling facility, engine house, boiler house, oil house, standing tracks and departure yard. A classification yard is necessary only if trains are broken and made up anew at the terminal. The yards are constructed only as needed. Ash pits and inspection pits may be constructed of concrete or of old ties. Coaling was from a pit, by locomotive crane.

Engine house construction in France followed civil practice. It should have consisted of simple sheds, containing each about two tracks. Thus there would have been light from the sides, and complicated sawtooth construction requiring glass would have been avoided.

Water tanks. Water tanks have to be placed on main lines about every ten or fifteen miles, at engine terminals and at places where switching is necessary. Tanks can be improvised from any lumber available. A plank 3″ thick is desirable. When a tank must be improvised, 25,000 gallons is a convenient size. Posts for such a tank can be 8″ x 8″ resting on wooden blocks instead of concrete. Any available iron rods can be used for bands. If turnbuckles are not available a substitute can be improvised by taking a piece of pipe, mashing it together in the middle longitudinally, passing the rods through the two tubes thus formed, and securing them with nuts on opposite ends. If regular crane and large pipe is not available, 4″ or 6″ pipe and fittings can be used.

Regulating stations. A regulating station is nothing more than yards to receive, classify and make up trains for serving troops with a daily automatic supply. Cars containing complete rations are made up into trains, so that cars for one unit, generally a division, can be easily shifted out of a train. Supplies for a division for one day, other than ammunition, generally require cars carrying from 50 to 80 tons. The regulating officer receives requisitions from troops, and supervises the making up of trains. A regulating station may or may not be at the same place as the advance depot.

Rail head sidings. Where a division receives its supplies, sidings and storehouse space are necessary to only a limited extent. As the supply is automatic and daily, usually store space for one or two days' supply, with corresponding sidings is sufficient.

Ammunition depots

Depots for ammunition other than small arms ammunition, are constructed separately from General Depots.

Layout. In France, advance ammunition depots were so laid out that each storehouse (about 50 x 500) was located apart from other storehouses. Intermediate and base depots were first laid out with the storehouses in groups of eight houses, each 50′ x 1000′. Later, the depots in the rear were designed on the same principle as the advance depots. Although yards of eleven or more tracks were planned in France, five tracks filled every need which developed. A water tank near the yard was found necessary.

The sheds for ammunition are the same as the sheds for general stores. Designs of sheds, with earth protection on the sides and overhead, were made in France but there was never material and labor for such construction. Such a storehouse would simply make an explosion more disastrous, as the earthen walls and roof would act as tamping for the explosive. Safety is obtained by separating the ammunition, so as to localize any explosion. Intermediate and base depots are located beyond the range of hostile aeroplanes, so protection for them is not logical. Separation of storehouses gives a certain amount of concealment from aeroplanes. As a matter of fact, a great deal of the ammunition in the World War was stored outside, and this can be done in any war, if materials and labor are too scarce to permit of the construction of store-sheds. If sheds are constructed, it is not necessary to build the ground up to car level, since in war man power for operations is always more plentiful than building facilities. It is important to get something that can be used quickly and to give little consideration to the number of men necessary for operation.

Electric lighting. At the advance depot in France, electric lights were installed in the sheds, and power units were placed on push cars so that they could be placed on tracks adjacent to shed and connection made to lighting wires. It is rare that loading is going on from more than one or two sheds at the same time at night. At intermediate and base depots night work will rarely be necessary, so electric lights are not essential.

Personnel. The operating personnel for an ammunition depot in France was about one thousand men, and camps for

Digitized by Google

them were located on existing roads nearby. It is better to locate men in separate small camps, if possible, so that there are workmen near all parts of the depot.

General storage depots

Plans and development. All supplies other than ammunition, aeroplanes and motor vehicles will ordinarily be stored in general storage depots, whose location will depend upon conditions. The storage depot at Gievres, France, in the intermediate section was most used, and was successful. It was constructed progressively according to immediate and urgent needs, and was never completed according to plan. This is, or should be, typical of storage depots for military purposes.

The storehouse area is laid out in sections, each section having a ladder track on each side connected by house tracks about 1,700 feet long, there being one of these to each three warehouses. These tracks are about 150 feet apart, which gives space enough for open storage on the opposite side of the track from the houses, as well as space for fire breaks. A section can be started with a ladder track on one side, the ladder on the other side added later. Running tracks are added when found necessary.

In constructing a storage depot, in the beginning the space should be laid out in separate areas for each department of the army, in the necessary proportion, and the construction should proceed so that each department can begin storing supplies, and expand without mixing up its supplies with those of other departments. At Montierchaume all the railroad sections were started at the same time, so each department could have its own expansion area.

In addition different types of storehouses should be distributed on separate tracks so that any one commodity can be stored on separate tracks, this so that if desirable the same commodity may be loaded from one track while it is being received on another.

In constructing the yards no existing roads should be closed by warehouses or tracks, as roads are almost impossible to construct with the means at hand, and available roads should be used.

Each department will desire one or more storehouses from which shipments can be made by truck. These warehouses should be selected adjacent to existing roads so that each department has one warehouse on a road. At Montierchaume wagon yards, and open engineer storage were distributed throughout the depot to make fire breaks between the storehouses.

Fire protection. In the layout of the depots, the warehouses are intentionally spaced far enough apart so that fire can not spread from one to another, and groups of warehouses are separated by open storage spaces. In addition, much of the contents of the warehouses is not inflammable, and generally the warehouses are built of corrugated iron, and are not extremely inflammable. No artificial fire protection is necessary. The cost of such a system in material far exceeds any probable loss from fire. Fire should be prevented from spreading by keeping the areas between the warehouses clear of rubbish and inflammable material. To lower the fire risk, all offices and facilities which use fire should, when practicable, be located outside of the sections which contain warehouses. At Montierchaume, wagon yards, and open engineer storage were distributed throughout the depot to make fire breaks between storehouses. Sidings or spurs far removed from other stores are laid for the storage of hay, and dynamite, for localizing fire risk.

Coal pile. A reserve coal pile in addition to the coaling facility for locomotives may be necessary. Such a pile is formed by unloading by hand from two or more tracks. As the coal increases, the tracks are raised until the pile gets about 10 feet high at the higher end, then a new pile is started. Cars, standing on tracks laid on level ground alongside such a coal pile, can be loaded with coal when it is desired for use. Coal piles such as described may catch on fire inside. For this reason, their height should be limited to about ten feet, and they should have spaces between them. If fire develops, it has to be stopped by digging around the fire, and localizing it.

Types of warehouses. The storehouse most used in France was 50 feet wide and 400 or 500 feet long. It was made with wooden frame and corrugated iron roof and sides. Designs used in France had very small factors of safety, and would have to be strengthened if used where large wind or snow loads are expected. In France frequently no sides were put on these houses, and they were used as open sheds. Sides were placed only on houses which carried perishable supplies, such as flour or sugar. In place of windows, siding was simply carried up to within about a foot or eighteen inches of the roof, and a continuous opening was left at the top which was protected by the eaves. Doors were generally not used, canvas being placed over openings where it was necessary to close them. Of course this did not contemplate protection from theft except by guards. The frames of buildings were made with round posts and rough lumber. Mostly no floors at all were placed. Dunnage was used to keep supplies off the damp ground. Supplies very sensitive to water, such as flour and sugar, were placed on a floor or dunnage consisting of wood poles with rough edged plank laid on them. Economy in labor of operations is of minor importance in war, so floors at car level do not warrant the labor, materials and time necessary to construct them.

In addition to the flimsy structures described, there were used in France some all metal warehouses of the same sizes as the wooden framed ones. One type of steel building came from America, and another type from England. The two types illustrated the difference in proper construction methods in peace and in war. The American building was perfectly safe and was good for many years. The English building had a very small factor of safety and was good for only one or two years. The American building consisted of many different and non-interchangeable parts, while the English building had more simple parts. One hundred such American buildings were received in France and they were of different designs. It proved exceedingly difficult to get the parts of any one building together. In addition some parts were so heavy that handling was very difficult. These buildings should all have been of the same design, their parts should have been as nearly interchangeable as possible, and there should have been as few parts as possible. The parts should have been light, and the entire building could have been much lighter, and less durable, thereby saving labor, material, time and money.

In war, materials are necessarily scarce, and just as no labor saving construction is warranted, likewise, absolute safety from fire, theft, and weather is not as important as in peace time, since everything is more or less temporary, and chances must be taken. Forty per cent of the rations and a large proportion of other stores can be stored outside for periods of two or three months without any appreciable loss. It is foolish for the supply departments in war to play a perfectly safe game and pay heavily for it, when at the front large losses are a mere incident.

Cold storage. Where soldiers are to have fresh meat,

Digitized by Google

cold storage plants may be necessary. These are used only to freeze or store meat between shipments, and not to store a reserve supply. Reserve rations are kept in the form of canned meats. In France some plants of this kind were built. The one at Gievres with rated capacity of 5,000 tons, stored at times 6,500 tons of meat, it being piled in quarters with 2″ x 4″ strips between. The floor space used was 896′ x 110′, with about 11′ head room. This makes the area occupied from 15 to 20 sq. ft. per ton stored. These plants were first designed in the same way that they are designed in civil practice. Later they were modified, and when built, the ice freezing feature, spare boilers and water for condensing purposes were omitted. While such a structure, on account of its technical nature must be most carefully constructed, a designer having in mind the military requirements of simplicity, economy of materials and time, and the lack of durability, can modify for the better the structures designed from civil experience.

Bakeries. If the depot is required to make automatic shipments of rations to the front, bakeries may be necessary. It is necessary to carefully consider their location with reference to water since the water requirements of a bakery are very large. In war where simplicity is the rule, a corrugated iron house for each bakery company is better than any complicated mechanical bakery. The house can be constructed to fit the bakery organization. Sometimes it is difficult to obtain fire brick for use with the field bakeries, but as they are supposed to operate in the field, the lack of such brick should not be serious.

Freight house for small shipments. The depot will probably have to make a large number of less than carload shipments from the various departments, and it will probably be necessary to use about 15,000 sq. ft. for a shipping warehouse for L. C. L. This warehouse should be located near a connection to the mainline outgoing railroad.

Camps for operating personnel should be located on existing roads, and should be distributed around the depot, so that personnel belonging to each department is within walking distance of its work. Such distribution lends itself also to sanitation and reduced fire risk. The total operating personnel at Gievres, which carried 30 days supply for one million men, was about 22,000.

Electric lights. The working of labor at night is an uneconomical procedure, and is avoided as much as possible. Experience has shown that in the intermediate and base depots very little night work is necessary, so it is unnecessary to install electric lights in the warehouses. On the rare occasions when night work is necessary, acetylene flares can be used.

Mapping Northern Russia for the Archangel Expedition

An interesting article under the above title by Robert C. Johnson, appears in *The Wisconsin Engineer* for April, 1920. The article points out the absolute need for maps in a military expedition, no matter how great the difficulties of obtaining them. Some of the difficulties are well expressed by the author, who was a member of the American engineer battalion which took part in the Archangel expedition (1st Bn., 310th Engrs.).

A few days before we sailed from England for Archangel the colonel checked up the British pioneer equipment which had been issued in place of our own, and discovered a shortage of topographical supplies. Upon requisitioning additional material from the War Office, in London, he was informed *that Russia was too vast a country to be mapped during operations*, so no further equipment would be necessary. In spite of this careless disposition of the matter, we purchased a few antiquated supplies, which had been passed over by the British Army, and hopefully ordered a great many more from France.

When we arrived in Archangel, which is a city of 40,000 inhabitants with many fine buildings, we found the British trying to revise a Russian survey made in 1880. Because they were not prepared to do this work, they assigned it to us. As the only map we had was on a scale of 1: 1,000,000 and covered the area from the North Pole to Petrograd, no one knew the exact location of the front or of the separate units.

A search through the government offices in Archangel revealed a map of 800 sheets, printed in Russian, and of such a large scale as to be of little use for reproduction or distribution. There was only one copy of this map. Our problem then was to make an operations map showing the location of roads, villages and rivers—this to be done in the dead of winter and through a densely wooded area of 120,000 square miles.

We immediately organized a mapping section consisting of twenty Russian civilians and five Russian soldiers (none of whom could read, write or speak a word of English), three British officers, six British N. C. O's, and twenty American engineers—all under the command of an American engineer officer.

As no mapping section was specifically authorized for our campaign, everyone in G. H. Q. felt, when one was created, that it belonged to his particular department. At least that was the feeling when there was any work to be unloaded on the section, even to the painting of door signs; but when the section needed men or equipment, it was only a poor orphan.

The cheerful alacrity with which this tiny party attacked the task of mapping the huge area is characteristic of the American engineer under all conditions.

Strategy was resorted to to keep down drafting and painting demands irrelevant to the mapping.

Existing Russian maps were pantographed and translated for use as the base, and field parties made plane table check of the roads to give a map of sufficient accuracy for the plotting of artillery ranges. The writer describes in full the office methods used.

Thirty men were in the office, twenty-two of whom were Russians. The latter were very slow and careless, although their work was neat. A careful check had to be made of all their lettering as none of them understood English. They struck periodically for higher wages or shorter hours; but were usually bluffed into returning when fired. They did not realize that we couldn't get along without them.

The gravest question was one of sufficient supplies with which to carry on the work. Our stock was estimated to last only six weeks, and there was a general shortage of pens, pencils, erasers, thumb tacks and other things which are so plentiful in our own country. Our only methods of reproduction were by blue printing and hectographing. The latter method is always unsatisfactory and can be used efficiently only up to twenty-five copies. Our supply of blue-print paper was not sufficient to make one complete copy of the entire map. Nevertheless, work was pushed ahead, and cablegrams were sent to rush supplies.

Difficulties were encountered in making the various Russian maps join.

This was due to two causes: First, the forty years (since it was made); and, second, working in from the edges of the map (the method adopted) made all errors cumulative toward the center (where they became very noticeable and embarrassing.—Ed.). A chart was made of the magnetic variations during the forty years and corrections were applied to the respective surveys. The residual error was then distributed uniformly over the entire area so that only a small variation

Digitized by Google

occurred at any one point. (One of the original forms of "Camouflage." —Ed.)

Paper tracings of the territory along the front were blue printed. Our print paper was slow, and as the sun shines there only four hours a day during the winter this blue printing was an arduous job. Daylight prints required a full hour of exposure. Finally, an old arc-light machine was discovered at the shipyards; but, as the current was on only eight hours a day, the printing ran way behind the drawing. However, by the 1st of January, the field parties were furnished with enough material to keep them busy.

Each field party was commanded by a Royal Engineer officer, and consisted of Russian forestry men and British or American N. C. O's.

The detailed methods and difficulties of carrying out the field work are described in full by the author.

Not a single day was lost because of cold weather, although the Russians had to stay out when the temperature stuck around 30 degrees below zero. One field party of three American N. C. O.'s and six Russians made 1,200 miles of road traverses in the six weeks from January 1 to February 12. No attempt was made to run out a base line or make solar observations, so that the work was unquestionably in error, but was sufficiently accurate for our purposes.

All through December and January the supply officer met every boat arriving in Archangel so as to be sure no one else obtained our supplies, should any arrive. Every department acted as a free lance whenever ships came in, because they all needed everything aboard. One of the last ships to arrive was met by the usual battalion of supply officers, only to find that the thoughtful War Office had sent up telephone poles. Archangel is a lumber city with forty saw mills. (This strikes a familiar chord in all our breasts.—Ed.)

Finally a shipment of lithographic supplies was received and unpacked; but the gasoline engine was minus everything but the flywheel and muffler, the press had no bolts with which to assemble it, and the circular glass of the arc-light machine was broken. These would have been trivial matters anywhere except in Archangel, where the nearest replacements are two thousand miles away. After much work the press was set up and an electric motor attached. All of the lithographers and pressmen swore they had never seen such a machine, as their oldest acquaintance dates back only to 1880. Modern presses are adjusted to print about 1,200 sheets an hour, so the motor had been geared for this speed. The first time the switch was closed the 2-ton plate carrier developed so much energy that it forgot to come back at the end of its run and kept going until a wall interfered. This caused a two weeks' delay while the blacksmiths made repairs and adjusting pulleys were erected for the motor.

When the mapping section was first organized two lithographers were placed in a Russian lithographic shop to become familiar with the local machinery. This was done so they would be ready to go ahead in case our own equipment failed to come. On the arrival of the press from England an inventory showed that no chemicals were included, so lists were made up and the materials purchased locally. This was a difficult task, as the Russians were very jealous of their supplies and concealed them in barns, attics and warehouses. Finally enough were gathered so that the plates could be made.

Contact printing from tracings onto sensitized zinc plates was first used in plate preparation, and although first appearing to be the most desirable method it was abandoned in favor of the method by drawing directly on the zinc by use of carbon paper. Maps were prepared in three colors—lettering, rivers, lakes and villages in black, roads and trails in red, and co-ordinate lines in yellow. The paper was very poor.

The scale of the main map was 1 inch=10 versts or .66 mile (very close to 1/40,000) and some 500 sheets (28 inches by 18 inches) were required to cover the area held by the allies. About 100 sheets covering the front and lines of communication were prepared by lithography before the departure of the American troops, lack of time preventing the preparation of all of the sheets.

In June, when the 1st Battalion, 310th Engineers, left Archangel, the British Expedition had been furnished by us with a complete series of Army maps. As the London War Office was not yet convinced that Russia *could* be mapped, no English Sections or equipment were sent to replace us. Therefore, on our way home we left our originals at the War Office in London for reproduction on heavy paper and transmittal back to Archangel.

Note.—The desire of most officers to have colored maps for facility in reading is a considerable handicap in reproducing maps in the field. The reproduction problem is greatly simplified if officers can be induced to use maps in black. Each color used requires the preparation of a separate plate and then considerable time is taken up in setting the different color plates on the press to obtain proper register. Much time is also lost in "washing up" the press between colors. Aside from these items the time of press running to produce any given map is directly proportional to the number of colors used. So in the problem of the topographical section of the Archangel force, instead of producing but 100 map sheets in the time available, at least

A familiar figure in unfamiliar surroundings. American soldier sketching in the frozen northland of Russia

300 maps sheets and in all probability the entire 500 map sheets could have been completed if those in charge could have been induced to accept maps in black only.

Life of cast-iron pipe in Philadelphia.—The first cast-iron water pipe in Philadelphia was laid in 1817. It was flange pipe, imported from England. It was in continuous service until 1914, a period of 97 years, when it was replaced by larger pipes, in anticipation of street repavement. It was in good condition when taken up and had evidently by no means reached the limit of its useful life, except through obsolescence. Soon after a transition from flange to bell and spigot pipe occurred, and in 1915 a line of this old pipe laid in 1827 was removed during subway construction. It was in excellent condition after 88 years service, but was not relaid, as a main of larger capacity was desirable.

Several hundred feet of 30 inch pipe laid in 1850 was taken up in 1918 to facilitate parkway construction, and was found to be in such satisfactory condition that after being cleaned it was relaid.—*Eng. and Cont.*

Water power act regulations being drafted.—Regulations to be used in carrying the Water Power Act into effect are being drafted by Oscar C. Merrill, the executive secretary of the Federal Power Commission; Gen. Enoch H. Crowder, representing the War Department, and Herman Stabler, representing the Interior Department. Applications for permits under the new act now approximate 1,000,000 horse power. Lt. Col. William Kelly, of the Engineer Corps, has been appointed by the President to serve with the Power Commission as Engineer Officer. Much of Colonel Kelly's experience in the Engineer Corps has been in California, where he has been brought in contact with water-power problems. He was in France with the 117th Engineers, and as Corps Engineer, 4th Corps.

Death of General Marshall*

ON July 2d of this year there passed away a really notable and outstanding figure in the history of engineering, both civil and military. This was General William Louis Marshall, U. S. Army, Retired, formerly Chief of Engineers, and, at the time of his death, Consulting Engineer to the Secretary of the Interior in connection with the projects of the Reclamation Service. General Marshall was a strong man, a unique personality, an able, courageous and original engineer, and an American citizen of the very highest type.

His long career, characterized as it was by many well-known achievements as a constructing engineer, is familiar to those who have studied the development of the art in this country, for he led where others followed. Born in Kentucky on June 11, 1846, a member of the celebrated Virginia Marshall family, of which the most famous member was the Chief Justice, John Marshall, as a boy of 16 he left school and enlisted in the Union Army in the 10th Kentucky Cavalry, serving as a private and corporal from August 16, 1862, to September 17, 1863, when he was taken with typhoid, from which it took months to recover. In June, 1864, he entered the Military Academy, from which he was graduated, number seven in his class, on June 15, 1868, and assigned to the Corps of Engineers. Among his classmates were the late Gen. J. G. D. Knight, who was No. 2; Gen. R. L. Hoxie, who was No. 3; Prof. E. W. Bass, who was No. 4, and Richard Henry Savage, who was No. 6.

Following his graduation, Gen. Marshall served with the Engineer Battalion at Willets Point until July 5, 1872, with an interval of one year during which he was Assistant Professor of Philosophy at West Point. Thereafter he served as Assistant Engineer on Western explorations under Lieutenant Wheeler between July 5, 1872, and August 8, 1876. During this period, on horseback and on foot, he covered a very large part of the country west of the Rocky Mountains, riding and walking many thousands of miles. Perhaps one of his most notable achievements was the discovery of Marshall Pass, the lowest pass through the main ridge of the Rocky Mountains, now occupied by the main line of the Denver and Rio Grande Railroad.

After this he served on river improvements in Tennessee, Georgia, Alabama and on the Mississippi River until April 21, 1884, and he was then assigned to duty on the improvement of rivers and harbors in Wisconsin and Illinois, being stationed in succession at Milwaukee and Chicago until 1899. It was at this time that some of his most notable work was done, for amongst other important improvements he began and virtually completed the Illinois and Mississippi Canal, the so-called Hennepin Canal connecting the Illinois River at Big Bend just below La Salle with the Mississippi River near Rock Island. This canal, whose construction was ordered by Congress without any favorable recommendation on the part of the Corps of Engineers, was intended to form part of a through route between the Great Lakes and the Upper Mississippi River, but, unfortunately, Congress did not then provide, and has not since arranged, for the construction of the portion between Chicago and La Salle. While, therefore, the Hennepin Canal has not been a commercial success, it is remarkable as an example of skillful and original engineering. Begun in the early nineties before the art of concrete construction had become well known among engineers, all of its masonry is concrete. This courageous departure from the then existing practice was due entirely to General Marshall's sound judgment and bold initiative, and he then developed the details of methods which were subsequently adopted by the entire engineering profession and have continued in force practically unchanged to the present day. For this service to society, productive as it has been of great saving of time and money, the highest commendation and gratitude are due him.

The Hennepin Canal affords instances of practically every type of structure used by the canal engineer. It has more than 30 locks, there are 7 or 8 aqueducts, numerous bridges, a number of emergency gates or weirs and several dams, at one of which water power is developed. All of these structures are admirable examples of the art of engineering and remain to this day models of what should be done under similar circumstances. Some of them were patented by him —notably, an automatic lock gate and an automatic emergency weir, and these are ingenious, simple and dependable. All of his patents were freely placed at the disposal of the United States.

During his stay at Chicago, General Marshall acted also as Consulting Engineer for the Lincoln Park Board, and while in this service developed and patented a type of lake-shore revetment that is still in highly successful use and will probably continue to be used as long as the need for this kind of structure exists.

He was relieved from Chicago in 1899 and sent to New York, where he engaged in the local work of river and harbor improvement and, in addition, was assigned to the construction of fortifications in and near New York Harbor. Here, too, his bold and original genius found scope and expression. The Ambrose Channel, a most successful piece of work, was completed under him; his fortification work became the standard in details and methods for other similar work throughout the United States, and he planned and completed the enlargement of Governors Island. In 1908 he was promoted to be Chief of Engineers, and in 1910 by operation of law he retired from active service as an officer of the Army, after an honorable and distinguished career of 40 years.

He was a man of strong and decided views but of simple, unaffected manner, and the soul of good nature and geniality. Generous, sturdy and upright in all his relations, he was incapable of anything small or petty, and unwilling to suspect impropriety in others. So fine was his character as to attract the affection, confidence and admiration of all with whom he came in contact, in high places as well as in low.

Thus it was that on his retirement as Chief of Engineers, General Marshall was signally honored by President Taft, who, unwilling to permit the services of so brilliant an engineer and so splendid a man to be lost to the government, created for him the position of Consulting Engineer to the Secretary of the Interior. In this capacity General Marshall continued to serve until his lamented illness and death.

In him his country, his family, his friends and his profession have suffered the loss of a most upright, brilliant and accomplished and lovable personality.

"He was a man, take him for all in all
I shall not look upon his like again."

Death of General Gorgas

WILLIAM CRAWFORD GORGAS, the noted sanitarian, the implacable foe of "Yellow Jack" and of all other diseases that afflict humanity, was not an engineer by profession; but his life work was so closely allied with engineering achievement, and in so large measure responsible for one of its noblest monuments, the Panama Canal, that in his death the engineering profession experiences a sense of personal loss.

General Gorgas died at London on July 4, 1920, following a stroke of apoplexy, He was born in Mobile, Alabama, October 3, 1854, the son of Gen. Josiah Gorgas, a graduate of West Point, and an officer of the Confederate Army. William C. Gorgas entered the U. S. Army in 1880 and rose to the rank of Major General and Surgeon General of the Army, which position he occupied during the World War.

His life history is a record of continuous achievement, which was recognized by every worth-while honor that might be conferred upon a scientist and a benefactor of his race.

His greatest service, which entitles him to foremost rank amongst the truly great saviors of mankind, was his long and successful fight against yellow fever. His methods of combating the dread disease were based on the epoch-making discovery of Major Walter Reed, U. S. A., that the mosquito is the means of transmission. Following the Spanish-American War General Gorgas rid the city of Havana of yellow fever, and subsequently he rendered possible the construction of the Panama Canal by holding "Yellow Jack" in check on the Isthmus.

Portrait by Harris & Ewing

But Gorgas was not satisfied with the defeat of this enemy of mankind. He knew that its total destruction was possible, by localizing and successively eradicating it from every center of infection. To this noble work he had pledged his life, and had he been spared for a few years he would have seen its consummation.

Under the direction of the Rockefeller Foundation the humanitarian work will be carried on by others, to whom the example of General Gorgas' unswerving devotion to a dangerous duty will ever serve as a guide and an inspiration—a pillar of cloud in the day of success and prosperity, and a pillar of fire in the night of trial and adversity.

Death came to this noted American at the pinnacle of his fame. His victory over disease was won, acknowledged and honored throughout the civilized world during his own life time—a happy and fitting tribute to a great man whose gentleness of heart and modesty of character formed so striking and pleasing a contrast to the wonder of his achievements. And he died, as he had lived, "in harness" in the service of mankind—en route to South Africa to ameliorate sanitary conditions there.

Christie Mount for 155-millimeter Gun.—The Christie self-propelled mount for the 155-millimeter gun, Model 1918 (Filloux), was designed for the Ordnance Department by Walter Christie, of the Front Drive Motor Co., Hoboken, N. J. The design embodies new features in this class of artillery, the principal one being that the vehicle is designed to travel on rubber-tired wheels on good roads and is convertible into a track-laying vehicle when desired. When traveling on wheels, the caterpillar track is carried on the vehicle, and is so arranged as to be easily dismounted from the shelves and wrapped on the same rubber-tired wheels, when it becomes a caterpillar vehicle. There are eight rubber-tired wheels, the two at the breech end of the mount arranged to steer the vehicle, and the two at the rear end geared to the transmission, so that they are the drivers under both conditions, while the four intermediate wheels are spring mounted in such a manner as to carry weight or not, as desired. The whole unit weighs 44,000 pounds and is capable of traveling over 15 miles an hour on the rubber tires. It can travel practically as fast on the caterpillar tracks, except that the steering slows down the progress to a certain extent. It can be run in either direction with ease, but normally it travels breech first. Firing tests have proved that this mount will be a very satisfactory vehicle, and the Ordnance Department is ordering three more in order to submit them to a service test.

Future Coast Defense Artillery

Digest of an article, by Lt. Col. Sanderford Jarman, Coast Artillery Corps, in the U. S. Artillery Journal
Discussion by Col. C. O. Sherrill, Engineers, and Col. E. P. King, Field Artillery

[*Note.* The Great War did not upset the "eternal principles" of the art, but it has brought about notable modifications of the methods of applying those principles. Radical changes have been and are still to be made as a result of our late experiences. Important amongst these are the changes in permanent land fortification, with which this country is less concerned than is Europe; and changes in the methods of sea-coast defense, which is a matter of much concern to us. Radical and revolutionary ideas are being advanced, and this is well, for only thus can we make the rapid progress necessary to keep pace with the march of events. But we must not go to extremes. We must avoid the mistakes of those who declared, after the deadlock had set in on the Western Front, that mobile warfare would never again be seen, and who subsequently, when the deadlock was broken, as confidently asserted that there was now an end to trench warfare. The golden mean is nature's solution of most questions, and somewhere between the views of the ultra-radical and those of the ultra-conservative, the true answer is usually found. The following somewhat divergent views of exceptionally well informed officers of all the arms concerned with artillery defenses, both fixed and mobile, will be of special interest to all our readers as throwing light on the vital, fundamental problems of our coast defense.—*Ed.*]

COLONEL JARMAN classifies artillery materiel in accordance with its mission, as fixed or harbor, heavy tractor or self-propelled, pre-major caliber railway, and major caliber railway. All types of the fixed or harbor artillery now in existence are given a sub-classification, as follows:

Secondary Armament:
Minor caliber 3-inch
Intermediate caliber 6-inch
Primary Armament:
12, 14 and 16-inch guns and 12-inch mortars.

Considering the target against which harbor defense guns will be used, only two general divisions are made, which are armored and unarmored ships. The probable forms of attack are: in force to capture a port, long range bombardment, long range attack to cover a run-by.

Secondary armament.

As the 3-inch gun, primarily intended for attack on unarmored ships, is outranged by similar armament now carried by the latter, there is no place for this type, except for anti-aircraft defense and for augmenting the secondary armament.

The 6-inch gun mounted on a barbette type of mount is limited in range due to type of mount to combat unarmored warcraft. The development of this weapon should secure greater range. This country is well supplied with excellent 155 millimeter G. P. F.* mobile guns adequate for secondary armament in coast defenses.

Major caliber fixed armament.

While this armament now consists of 8, 10, 12, 14 and 16-inch guns and 12-inch mortars, a considerable number of the 8, 10 and 12 inch guns and 12-inch mortars were withdrawn to supply the demand of the American Expeditionary Forces for high-powered long-range artillery. All of this armament is the outcome of studies and designs laid down prior to the Spanish-American War.

The radical changes and development of naval construction caused attempts to bring the fixed armament up to date to meet such naval developments, but a point has been reached where further modifications and alterations are impossible, its main deficiency being its fixed position and inability to meet attacks from the rear or the flanks. The 12-inch mortar is limited to a range of less than 16,000 yards. The 12-inch guns in some instances have recently been mounted on a new type of barbette mount permitting an elevation of 35 degrees and consequent increase of range. But as modern ships are constantly adding more armor, they make a most unfavorable target for the long range guns. The attempt to combat with a 12-inch gun an enemy ship armed with 14, 15 or 16-inch guns and possibly 18-inch guns is believed unwarranted.

The short 14-inch and 16-inch guns now emplaced with low muzzle velocity and short range are inferior to modern naval guns. The development of naval guns to obtain an elevation of 40 degrees leads to the conclusion that it will be practicable to mount them to fire at any angle, which, together with aerial observation, will materially aid the accuracy of fire from ships. The mission of this general class of coast defense armament as it now exists is *only to prevent an enemy from using the port as a base of operations.*

The War Department, in view of these defects, in 1916 adopted the 16-inch rifle and 16-inch mortar as the new types of major caliber armament, in addition to which the 12-inch guns are now being remounted to permit a range of 27,000 yards and 360° traverse. This barbette type of mount permits the laying of the piece for range at maximum elevation in nine seconds.

The 16-inch 25-caliber howitzer and 16-inch 50-caliber gun are to be mounted "En barbette" giving firing positions from 0 to 65 degrees, with ranges of 22,000 and 40,000 yards, respectively.

Judging by past developments the trend of future developments will be toward longer range, higher powered weapons. Rumors even now mention recent installation of an 18-inch gun in a foreign navy.

The range of guns during the Nelsonian era was limited, gradually increasing to a decisive range of 17,000 yards in the battle of Jutland. The 16-inch gun is expected to obtain its maximum range at 53 degrees which will give it preponderance over foreign naval guns which do not permit an elevation of over 40 degrees. The general tendency analogous with the policies of the navies of the world is for the seacoast defenses to reduce the number of types to a minimum.

The proper mission of the major caliber armament is to protect our large seaboard centers of population, naval bases and public utilities. The 16-inch howitzer is outranged by guns of foreign navies and an immeasurably greater gain in power at long ranges would be had by retaining only the 16-inch gun, as the gun can perform the functions of the howitzer but also may be used as a direct fire gun within the range of the howitzer. Since the future calls for a cannon of 18-inch caliber, it is safe to say that the 16-inch howitzer is obsolescent.

*G. P. F.—*Grande Puissance Filloux*, the high-powered 155 millimeter gun designed by Filloux.

Digitized by Google

Heavy tractor or self-propelled artillery.

There are now in existence several high powered tractor drawn guns. This class of armament is capable of attacking unarmored vessels and due to its mobility is superior to fixed secondary harbor defense. Its use would be to cover fields of fire in place of the armament recently declared obsolete or removed for use in the A. E. F.; to cover fields of fire where additional secondary armament is deemed necessary; and to support troops defending landing places.

The 240 millimeter howitzer will serve as reinforcing gun for troops defending landing places, holding transports too far out to debark troops. It will also serve as local protection for attacks from the landside.

The two types now under development, the 155 mm. G. P. F. gun and the 240 mm. howitzer, will fulfill all of the above requirements. This was made possible by the great development of gas engines and caterpillars. As an auxiliary, the 4.7-inch anti-aircraft gun with its ability to fire at 0 degrees and with an arc of 360 degrees will serve most efficiently.

Pre-major caliber railway artillery.

This covers certain cannon removed from harbor defenses and mounted on railway mounts for use in the A. E. F. The limit of range of these weapons is 22,000 yards for the 8-inch gun and 16,000 yards for the 12-inch mortar, effectively covering and making ineffective the secondary armament of a fleet at a range of 16,000 yards.

The projected development of this class is as follows:

8-inch 50 caliber gun, 240 pound projectile, 35,000 yard range.

12-inch 20 caliber howitzer, 700 pound projectile, 25,000 yard range, both with a traverse of 360 degrees.

They should be held in strategic location and used for unprotected landing places only.

Major caliber railway artillery.

There are a number of types of 10, 12 and 14-inch railway guns and a 16-inch howitzer now in the hands of the Army. Of these, only two are effective for seacoast defense, viz., the 14-inch gun and 16-inch howitzer, Type E, of which only one each has been made.

The Westervelt Board recommended the following two types:

14-inch 50 caliber gun, range 40,000 yards, 1,400 lb. projectile. 16-inch 25 caliber howitzer, range 30,000 yards, 1,600 lb. projectile, both with a 360 degree arc of fire.

This recommendation no doubt was based on the understanding that these two were the largest types possible to be mounted on barbette railway mounts, and also probably considered economic reasons.

The final type of mount should be a unit type with the gun on its mount at all times, incorporating all refinements found possible on fixed barbette mounts, giving it the advantages of rate of fire and accuracy of the latter in addition to mobility.

A full review must be made of seacoast defenses before considering the ideal weapon. The doctrine of all navies of the world is that shore guns cannot be effectively attacked by naval vessels and there is not going to be any attack unless it is felt there is a fair chance of success. Our major caliber railway mount will give an additional weapon producing doubt as to strength of the coast defense. Concrete to protect guns from ships' fire will not keep the enemy away but gun fire will perform this mission.

While it is hardly conceivable that we will be attacked on the Atlantic and the Pacific Coast at the same time, if the major caliber armament has mobility it can be moved from coast to coast. The proper use of this type will be as the primary armament in the protection of ports, naval bases, and public works from attack by armored ships.

There seem to be no insurmountable difficulties in placing a 16-inch 50-caliber gun on a railway mount even if of necessity transported in two units and assembled with the aid of a crane. This will permit its being used and supplant the present fixed armament of like caliber.

The present policy of coast defense makes the Department Commander responsible for his department except when an independent commander has been assigned. The Coast Guard Commander is independent of the Coast Defense Commander but must co-operate with him. There are also commanders of division and field armies holding strategic centers. There is lacking a complete and outlined plan of organization, dependence being placed on the expectation that there would be time for organizing an adequate defense. The development of railway, heavy tractor and self-propelled artillery will cause a revamping of the policy governing the defense of the seacoast.

The following seems a feasible system of defense. Considering the seaboard of the United States, the Canadian and Mexican Border as defense line divided into three army sectors, the first army should cover from North Dakota, exclusive, to Chespeake Bay, inclusive; second army from Chesapeake Bay to Pacific Ocean; third army from lower California to North Dakota, inclusive, each army to include a proper proportion of inland states. Each army sector is to be divided into Corps areas. The Corps staff should be charged with the duties of coast defense plans, which would primarily be based on the great mobility of railway artillery of today and the future.

With a plan based on concentration of responsibility for the defense of any sector in the Corps, there is no violation of the fundamental precept of the present policy of actually meeting the invaders at the water's edge; but it makes the principle more workable by concentrating all agencies under one control, and due to the extreme mobility and ranges possible with the tractor and pre-major caliber railway artillery, the total number of field army troops can be materially reduced.

Discussion

C. O. Sherrill
Colonel, Engineers

Colonel Jarman has presented a number of important conclusions as to the present status of seacoast defense and its desirable development, and states that a logical system of defense of the frontiers of the United States should consider the problem as a whole, placing upon territorial commanders under the War Department full responsibility for all defensive measures within their sectors. This principle has the official sanction of the War Department and is thoroughly sound. It cannot be gainsaid that the present defensive system, which contemplates entirely independent commanders for each of the separate agencies used in the defense, is entirely wrong.

As Col. Jarman well says, the adoption of this policy has been influenced undoubtedly by the fact that from a practical standpoint all means actually in existence for carrying out the defense of our seacoast consisted of fixed harbor defenses, but he is incorrect in assuming that the continuation of fixed harbor defenses necessarily prevents a logical

Digitized by Google

assembling of the various elements necessary for an effective defense of the entire coast line; for, it is believed that the fixed armament should be considered as part of the general line of defense, exactly as redoubts are in mobile warfare, and that all artillery, both seacoast and mobile, should be under the territorial army commander.

With the conclusions arrived at in the paper under discussion, the undersigned is in general accord, but must take exception to certain views, especially with reference to railway artillery.

The principle which requires 360 degree traverse for all guns is generally sound, but each particular case should be decided on its own merits, as there are many locations where it is not only useless and needlessly expensive to provide fire over certain sectors, but positively dangerous in that an enemy having captured the gun could turn it on the city or other area defended by it.

It has not by any means been as yet demonstrated that mobile guns of any type are as effective against rapidly moving targets, even for direct fire at short ranges, as the highly accurate seacoast guns on fixed and carefully adjusted bases. This, however, is a question that can easily be determined, and if field guns prove able to do the work effectively, they should by all means replace fixed guns.

The following pages are devoted to a discussion of the entire subject of railway guns in seacoast defense and mobile warfare. These remarks are not made with the idea of condemning railway guns, if they can be shown to be a useful means of defense, but simply to point out the fact that up to the present time this utility has been assumed rather than demonstrated, and to suggest a line of action which will allow a correct conclusion to be arrived at on this subject, so important to the entire army. In the past, correct tactics of coast defense have been subordinated to fixed guns, and there appears to be danger that in the future the desire to use railway guns will be the controlling feature of coast defense plans.

As a result of the experience gained by the operation of railway guns in France, Coast Artillery officers are now generally beginning to feel that much simpler installations and improvised auxiliaries are sufficient unto results. If results can be thus secured against naval targets with railway guns, the same principle can be advantageously applied in the construction of fixed emplacements, for the installation of the gun itself on a fixed mount is an extremely small item as compared with the provision of bomb-proofed utilities and elaborate fire control installations heretofore required. The Chief of Engineer's office is now investigating this question of a simplified type of installation based upon the principles of dispersion and concealment.

As yet, but little consideration has been given to the powers and limitations of railway artillery in seacoast defense and mobile warfare. In arriving at conclusions as to the general applicability of this type of armament to both seacoast and mobile warfare, this important matter should be given full and careful consideration before opinion in the army becomes crystallized and an extensive and expensive program of construction of railway artillery carriages and the organization of railway artillery troops is undertaken.

As visualized by the paper under discussion, railway artillery is to form the important connecting link between the highly mobile artillery of minor calibers accompanying a field army and guns of the heaviest type on fixed emplacements installed for service against naval targets and as a protection to our more important harbors and naval stations.

Railway artillery, therefore, is assumed to fill two distinct roles:

(1) Defense against the rapidly moving targets presented by naval vessels in coast defense.

(2) Long range fire against fixed targets as an adjunct to the field army.

The value of railway artillery for these two uses should of course determine the extent to which it is to be used in our army.

Railway artillery in seacoast Defense

Relative merits of fixed and railway mounts.

Guns in fixed emplacements have the great advantage of being located just where they are needed, after careful study and investigation, and have a soothing psychological effect upon the local inhabitants, by the very fact of their presence alone. For each important harbor and naval base which, according to our theories of defense, requires complete protection from hostile navies, there is a certain minimum armament which must be permanently maintained and always available for its defense. For this minimum armament, therefore, only the most economical and effective type should be employed. If guns on railway mounts fulfill this condition, this type should be used.

For reinforcing armament which may be necessary in addition to the above mentioned minimum, railroad guns should be used if, after thorough study, they are found to be more desirable than guns on fixed emplacements.

Guns on railway mounts, it is claimed, have the advantage that they can be moved from place to place as needed, and they can likewise, theoretically at least, be temporarily withdrawn if the enemy's fire becomes too heavy, and can later be put back in position. Whatever type the portable mount takes, it can never be made mobile as the guns on an enemy's ship. Consequently, if an enemy makes a feint in strength at one place, say on the New England coast, and presses this feint with such vigor as to cause shipment to the New England coast of the available portable guns, he can suddenly shift his attack to the mouth of the Chesapeake with such rapidity that the portable guns can not be withdrawn from position and moved by land from the New England coast to the new region in time to meet the new attack. Therefore, if our sole, or even our main reliance, be placed upon portable guns, the number to be provided would probably have to be nearly or quite as great as the guns otherwise required to be mounted in fixed emplacements.

At the present time, the railroad mounts for heavy guns are of two classes, one of which fires from the car itself, the other from a prepared site. It is generally agreed at this time that only the latter is worthy of consideration for the major calibers in seacoast defense. With this type of mount, the cars are moved to a site prepared in advance, the mount is removed from its tracks and lowered upon a base prepared in advance. When once the gun has thus been placed in firing position, it has many of the disadvantages of a fixed mount and few of its advantages. Moreover, the process of placing it on its tracks and moving it away is necessarily too slow to prevent its being destroyed by a concentrated hostile fire once it is "spotted."

Fixed emplacements have the great advantage of providing solid horizontal immovable platforms, carefully adjusted and levelled so that the gun can easily and accurately be aimed both in azimuth and elevation. Where the gun is removed from its tracks and placed upon a base, such bases must either be prepared in advance of concrete and steel, at considerable cost, or else there will be more or less

Digitized by Google

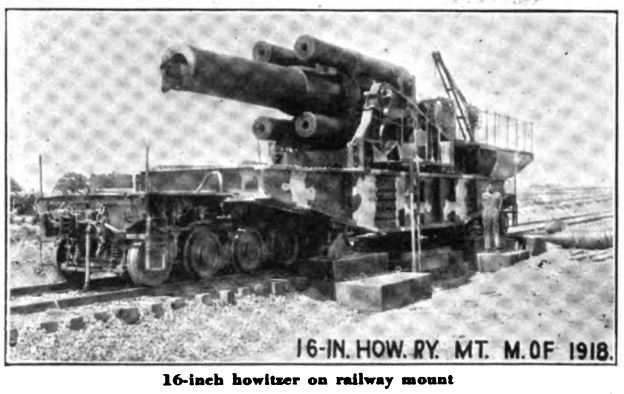
settling of the foundations during the process of firing, with resulting errors in level and consequently in the accuracy of fire.

As at present designed, fixed emplacements have the additional advantage of providing protected magazines fitted with carefully designed appliances for ammunition service, permitting the maximum rate of fire of the gun. To such an extent has this ammunition service been perfected that 12-inch guns have been fired at 19 second intervals. The recent 14-inch and 16-inch emplacements have been designed to permit a possible rate of fire of only 25 to 30 seconds between rounds and a rate of fire in action of one shot every 40 seconds, making it impossible to maneuver the ship out of the danger area of the next shot. As compared to this high rate of fire of fixed mounts, the results of the only tests yet held of the 14-inch railway mount rifle, viz., those at Fort Story, are cited, in which the average rate of fire was one shot every 3 minutes, the best record yet made by these guns. The speed of a modern battleship is at last 2,000 yards for the 3-minute interval between these shots. It can be readily seen that in this period it would be quite feasible to change the direction of the ship by zigzags so as to render spotting useless for determining the next position of the vessel.

7-inch siege howitzer on railway mount

This is a true railway mount. No special track or special installation of any kind required, other than the jacks shown. Can be fired from any locality (except a bridge). All-round traverse.

This deliberate rate of fire is sufficient in firing against a fixed land target, but where the target is moving at a rate of from 20 to 35 miles per hour, the question of rapidity of fire is of the greatest importance; consequently a gun on a fixed emplacement which can fire from 3 to 6 times as rapidly as a gun on a railway mount is for the time being at the very least more than 3 to 6 times as effective.



Relative Costs

Fixed emplacements, as now designed, have the disadvantage of costing more per gun than portable carriages on railways, moreover, the present type of fixed installations have extensive auxiliaries for increasing accuracy, rate of fire and protection to material and personnel. These cost several times more than the mere mounting of the gun. But it should be noted that, in addition to the railway cars carrying the guns, there must be supplied other cars of special design carrying ammunition and special appliances for handling the ammunition between the cars and the gun. The cost for the various bases prepared in advance must also be charged against the railway mounts as well as the cost of the necessary modifications of track, grades and alignment and extensions of track, firing spurs, sidings for auxiliary cars, etc. Also it is to be remarked that it is possible to simplify the designs and reduce the costs of our fixed emplacements without greatly reducing their efficiency. Cheaper emplacements and less elaborate provisions for range finding and other accessories are possible.

The railways along the seacoast are not suitably located for the effective use of railway guns except in a limited number of places, and even in these few places they are often of a light type not adapted to carrying the major caliber railway mounts. All of these light tracks would require strengthening to carry railway guns and the construction of extensions to provide adequate firing positions before they could be used. The methods proposed for handling these railways guns involve improvised facilities for ammunition service, fire control, command, and fire direction. It therefore would be highly instructive to compare the results under these conditions with those obtainable with the very efficient auxiliaries provided by fixed emplacements; also to make a comparison of cost and efficiency between the railway guns with improvised auxiliaries and fixed guns with similarly improvised auxiliaries.

Intermediate armament

For those localities where railways exist in proper position for effective use of railway guns against naval targets, many of the disadvantages of the major caliber railway guns do not apply to intermediate calibers which can be fired directly from the track; but, intermediate armament on wheel and tractor mounts are at least as effective as those on railway mounts in coast defense, so it would appear to to be inadvisable to consider railway guns for such use, as even the smaller caliber guns on such mounts will cost more and be of less general adaptability than those on wheel and fire; the other is that they must be placed in positions from which they can reach the classes of naval vessels against which their fire is efficacious. The armament considered

16-inch howitzer on railway mount

A semi-permanent installation. Requires a specially prepared track. The blocking shown is carried on railway cars and placed by a portable crane. It can be moved to another locality in a few hours. Limited traverse.

tractor mounts for both coast line defense and land warfare purposes.

For the provision of intermediate armament for the coast defenses, consideration should be given to the large number of 6, 8 and 10-inch guns on fixed mounts recently declared obsolete, and obsolete naval guns, for installation on gun blocks at vital locations, rather than the withdrawal of efficient mobile guns from the mobile army or the construction of additional intermediate caliber guns.

16-inch vs. 14-inch guns against battleships.

Two fundamental considerations must be satisfied by armament to be successfully used in seacoast defense. One is that the weapons must be capable of accurate and rapid necessary by all authorities for use in seacoast defense is

Digitized by Google

divided into primary (major caliber) and secondary (intermediate and minor). The primary armament should consist of weapons capable of penetrating the most modern type of battleship, either through its deck or through its side. This can be accomplished effectively by the 16-inch guns and 16-inch howitzers now approved as the standard for major caliber fixed emplacements. The largest gun contemplated at the present time on railway mounts is the 14-inch with a penetrating power sufficient up to 7.5 miles, to pierce the 15-inch side armor of the latest designed type of battleship, and from 16.9 miles to 22.8 miles, capable of piercing the deck of this battleship. As compared with the 16-inch gun on fixed emplacement, this is relatively inefficient, inasmuch as the latter will pierce the side or deck armor effectively at all ranges up to 45,000 yards; the side armor as far as 12.8 miles and the deck from 6.2 miles to 25.5 miles range. It will be noted that the 14-inch gun leaves a zone 9.4 miles wide within which neither deck nor side armor can be penetrated, where the enemy could lie in

Foundation for 12-inch rifle on railway mount

This foundation can be installed at any locality after some preparation. The material is transported on railway carriages, and requires about 6 hours to put in place. The traverse is limited, hence the direction of the track must be such as to permit the gun to cover its assigned field of fire. This may require that spur tracks or turnouts be built, and in fact this would usually be necessary that traffic on the main line, including ammunition supply, be not interrupted.

relative safety and bring his concentrated fire on the coast defenses.

It is known that the latest types of battleship are being armed with 15-inch guns and at least one late British vessel with 18-inch guns is understood to be under design. In view of this high powered armament, the expenditure of large sums of money in providing railway mounts for the relatively more or less obsolescent 12 and 14-inch rifles in lieu of 16-inch guns seems of doubtful advisability.

Assuming, however, for the sake of argument, that the 14-inch guns are sufficiently powerful to justify their extensive use in seacoast defense it will be necessary to determine their hitting efficiency on railway mounts before accepting them for future construction. Up to the present time, so far as known, only 13 record shots have been fired by this type of armament against moving targets in the test firings at Fort Story in the fall of 1919. This limited number of shots appears to be insufficient to furnish the basis of sound deductions as to the accuracy of railway artillery. The efficiency of the following armament against rapidly moving naval targets has apparently been assumed by the author of the paper under discussion to have been demonstrated:

12-inch mortars, 14-inch rifles, 8-inch rifles.

With the present information available, the undersigned cannot subscribe to this view, and he is of the opinion that exhaustive tests should be made before such a conclusion is accepted.

Scope of investigations necessary

Assuming that tests will demonstrate the ability of railway guns to hit naval targets, there are many other questions to be determined before adopting them in place of fixed emplacements. Some of the subjects to be considered are the rate of fire and the possibility of predicting successive changes of position of the target with sufficient accuracy between shots to allow hits to be made; the efficiency of the improvised ammunition service used with these guns; the effectiveness of improvised range finding systems; the relative costs of coast defense by use of railway mounts as compared with fixed guns; the determination of the localities at which railways are available from which railway guns can bring effective fire upon dangerous naval targets; the relative merits of intermediate armament on wheel and tractor mount as compared with railway mount; the value of railway artillery with the mobile army, etc.

System of coast defense involving only a permanent nucleus of personnel.

The operation of railway guns requires a trained gun crew, able to function at various localities with which the members of the crew are more or less unfamiliar, using improvised auxiliaries for ammunition service, range finding and command. This operation is virtually equivalent to having guns of calibers suited to probable targets installed on simple gun blocks at salient points for the protection of our harbors with no permanent auxiliaries whatever, so that, from time to time, for drill, and in case of emergency, gun crews could be moved up to operate these guns. This presents the thought that the cheapest and most effective harbor defense may be secured *by installing guns on fixed blocks, but instead of permanently maintaining gun crews in the vicinity of each gun, as has been the custom in the past, to keep necessary gun crews mobilized at central points for use at positions threatened by an enemy.*

This might advantageously be carried a step further by maintaining only a nucleus of permanent personnel at these central stations, sufficient to train local reserves or militia living near the gun positions in the proper handling of the armament in their localities. In view of the fact that these guns are fixed in position and the militia gun crews would not be subject to withdrawal to remote and foreign fields of operation, there is no part of the system of national defense that can be so well handled entirely by local militia or reserves as the operation of our seacoast guns.

The principal item of expense incurred heretofore in connection with seacoast defense has been the maintenance of personnel to man the guns and auxiliaries; the cost of the gun itself and its emplacement is trifling in comparison with the continuing cost of the upkeep of the personnel for its operation. In fact, as elaborate as the fixed emplacements have heretofore been, *their cost is only about one-sixth of the cost of maintaining the battery personnel.* In the period since the World War, there has developed a decided change of view on the part of the Coast Artillery as to the necessity of elaborate emplacements provided with every facility for protection, convenience and comfort of personnel, and for rapidity and accuracy of fire. It was formerly considered essential to have full bombproof protection for all utilities, but now the tendency is toward the elimination of all protection, and reliance upon dispersion, concealment, and duplication of vital elements to insure

Digitized by Google

that the armament will work under all reasonably probable conditions of engagement. If a system of defense could be evolved with only guns on gun blocks, without the expensive auxiliaries heretofore provided, and without permanent maintenance of full personnel at each gun, its cost would undoubtedly be found to be far less than an equally effective defense by the present system or railway artillery.

Railway guns in mobile warfare.

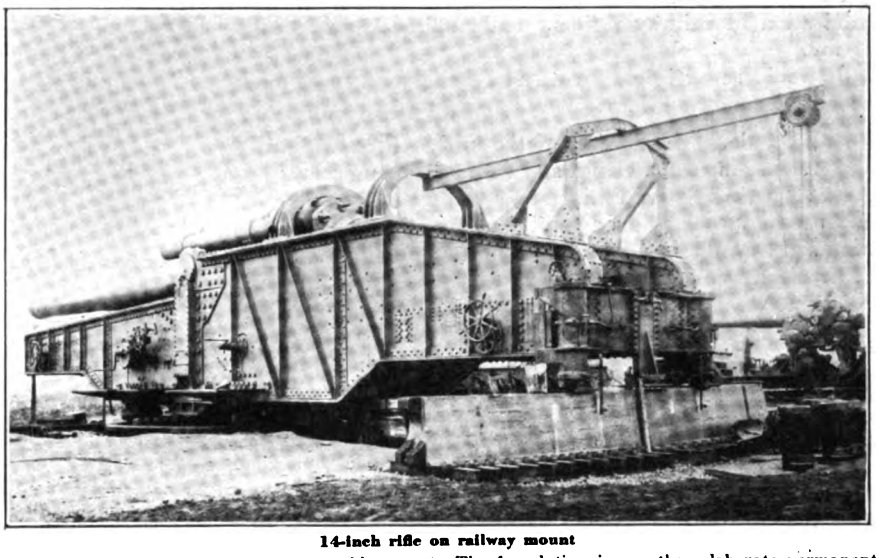
The next subject for consideration is the utility of railway artillery in mobile warefare. This use has many ardent advocates in the Coast Artillery, but, among those best qualified to speak on the use of railway guns, none is perhaps better equipped than Brigadier General Johnson Hagood, who, under date of January 27, 1920, in a report to The Adjutant General of the Army, makes the statement:

"For the benefit of those who do not care to be burdened with the details, I will state my conclusions first. They are as follows:

"Ninety-nine per cent of the value of railway artillery in the United States is in its use against water targets. * * *

"Stabilized warfare: The stablized character of warfare on the Western Front in Europe lent itself peculiarly to the use of railway artillery. These big guns, located from 5 to 10 miles back of the lines, were used with powerful effect to bombard cities, to destroy railway terminals, depots of supply, railway bridges and concrete fortifications of the enemy. The maximum range obtained by the Allies was less than 30 miles; but the Germans obtained a range of almost 70 miles.

"Practically all of the firing of the railway artillery was done by map. The penetration into enemy lines was so deep that it was always impossible to get terrestrial observation and generally impossible to get aerial observation. A similar use of railway artillery against land targets in a war in the United States *would require maps of the whole country very much more accurate than any now in existence, and a stabilized condition of warfare which it is impossible for any of us to imagine. Moreover, it would require that we should take as our targets our own cities, railway terminals, depots of supply, railway bridges and other public works.*



"It is hardly consistent with the principles of American military policy or the genius of the American people that we should plan war on any such basis."

It will be noted from these quotations that General Hagood asserts that 99 per cent of the value of railway artillery will be against water targets. This is equivalent to stating that unless railway artillery can be justified by its utility in coast defense against naval targets, it will be inadvisable to consider its use with the mobile army under the conditions existing in our country.

It is a principle of mobile warfare that the smallest caliber gun that will accomplish a certain result is the one that should be used for the purpose. This principle is so fundamental that it is believed unnecessary to do more than to call attention to a few principal reasons, such as, the greater rapidity of fire, greater mobility, greater rapidity of going into and out of action and in changing position, decrease of the transportation required to supply ammunition and the lower cost of construction and operation of the smaller guns. If this principle be accepted, then it follows that with a mobile army no guns should be furnished larger than essential for its purposes. On this subject, the Board of Artillery officers, appointed by Special Orders 289, War Department, 1918, recommended as follows:

It will be seen that the normal artillery missions of a field army can be accomplished by the assignment of six calibers, *i. e.*, two light weapons, two medium weapons, and two heavy weapons, a gun and a howitzer in each class, and a satisfactory anti-aircraft gun.

In accordance with the principle enunciated by the Artillery Board, these weapons would, therefore, be approximately 3-inch guns, 4-inch howitzers; 4.7-inch guns, 6-inch howitzers; 6-inch guns, 9.5-inch howitzers; all on wheel or tractor mounts. The ranges effectively and sufficiently covered by these weapons would include all those up to 25,000 yards. The railway guns with the mobile army of calibers larger than the 6-inch rifle and 9.5-inch howitzer would be unnecessary except for firing at ranges in excess of 25,000 yards. For the reasons enunciated by General Hagood it will be apparent that there is no probable use to be made of our field armies which would justify the construction of railway guns for use only at ranges greater than 25,000 yards. Fire of railway guns, as General Hagood says, must be almost entirely by map and must be directed at targets of such extent and nature as one not likely to be met in our operations. The attack of targets far in the rear of the lines should be bombing planes rather than by super-caliber railway guns.

14-inch rifle on railway mount

This is a movable rather than a portable mount. The foundation is a rather elaborate permanent installation involving the use of concrete. The gun carriage can be moved from one such foundation to another in a short time. The installation as here shown allows only limited traverse, but this may be increased to any desired amount by extending the foundation. Note chain block and trolley for handling shells. This is the highest development to date of railway artillery.

Camouflage

General Hagood states that big guns in the open, properly camouflaged, cannot readily be discovered, nor are such targets liable to serious damage by naval fire. This has been fully demonstrated by the results of naval bombardment of the defenses on the coast of Belgium and at the Dardanelles. Although the emplacements on the Belgian coast were only slightly camouflaged, they were located in

Digitized by Google

the rear of the line of small sand dues and there were very few hits recorded out of a great number of shots fired, and of these few, only in isolated cases was any serious damage done to the guns or emplacements. Similar results were noted at the Dardanelles. My conclusion from a consideration of the experiences of the World War agrees with the view of General Hagood as to ease of camouflage. Moreover, it has been found that big guns unconnected by railway tracks are far more readily camouflaged than those located on railroads, which advertise the presence of the guns, with the cars, engines, and other adjuncts necessary for their operation. In other words, a major caliber gun, emplaced on a simple concrete gun block a few hundred yards from the shore, without bombproof magazines, and with ammunition and other auxiliaries distributed in small units, all suitably camouflaged, could be concealed, so as to be an almost impossible target for a hostile navy, more easily than railway mounts with their tell-tale tracks.

Conclusion

In view of all the considerations it is believed that the general utility of railway guns in seacoast defense and with the mobile army has not yet been sufficiently established to justify extensive construction of this armament or the organization of railway artillery units in the United States Army.

It would be advisable for a full investigation to be made along the following lines:

(*a*) On the entire subject of the utility of railway artillery for use in coast defense and with the mobile army;

(*b*) On the relative utility and cost of a system of coast defense by means of fixed emplacements alone and by railway artillery alone;

(*c*) By fixed emplacements supplemented by railway and other mobile artillery, taking into consideration the present elaborate types of emplacements and auxiliaries; also on the basis of a simplified type of emplacement with improvised auxiliaries;

(*d*) On the relative utility of the present system of permanently maintaining full personnel for all coast defense armament as compared with one involving the maintenance in peace of a nucleus to care for the armament and for training militia and reserves in the operation of the coast defenses in their locality.

E. P. King, Jr.
Colonel, Field Artillery

The first thought that occurs to the Field Artilleryman on reading Colonel Jarman's article is that he has not properly differentiated between the duties of the mobile army and those of the Coast Artillery, or rather, that he appears to have given the Coast Artillery two inconsistent missions to perform: The first, the protection of especially selected strong points and the second, co-operation with the mobile army at other threatened points along the coast. Doubtless Colonel Jarman's own ideas on this subject are clear and well defined, but the term "Coast Defense" has been so long applied to the defense of particular points of our coast line that most readers assign this meaning to that term and do not consider it as applying to the defense of the coast line as a whole. It would, perhaps, be well then to examine into the missions of the various parts of our military forces in defending the seacoast.

From the standpoint of defense, the coast line may be considered as being divided into two parts; first, certain strong points whose strategical and economical value require that they be held at all hazards, and second, other points which embrace all the coast line between the strong points and which are to be defended only in case an enemy attempts to make a landing. Ordinarily the points selected as strong points have been the seacoast cities and the harbors. These have been fortified and garrisoned by Coast Artillery troops. As long as these strong points are heavily fortified, armed and actively guarded by appropriate garrisons, it is highly improbable that an enemy will attack them. This is the intention in so fortifying, arming and guarding them. It must be realized, however, that if for any reason, such as to reinforce the mobile army, the troops charged with the duty of guarding the strong points are to any great extent withdrawn therefrom, these important places will be at the mercy of the enemy, and his attack, even though planned for elsewhere, will undoubtedly be diverted to these points which present every advantage for effecting a landing when not sufficiently guarded. It is not safe to assume that garrisons can be withdrawn from our strong points without the knowledge of the enemy, and consequently in case of a hostile effort against our coast line the garrisons of the strong points must necessarily be maintained at full strength.

The duty of protecting that part of the coast line which lies between the strong points inevitably falls upon the field army, and that organization alone should be charged with this duty. The field army for this purpose should be complete within itself so that it may function at maximum efficiency without requiring that the strong points of the coast line be left unguarded at the time of all times when they should be completely protected. An enemy in ships is more mobile than troops on shore, and his point of attack may be changed more quickly than the disposition of the defensive forces operating to prevent a landing.

According to all of our previous organization and ideas, the artillery which accompanies a field army is Field Artillery; that is to say, is a part of the Field Artillery arm of the service. The artillery which is charged with the defense of the strong points of the coast line is Coast Artillery. Hitherto, except in emergencies, the Coast Artillery has been charged with no other duty. The primary essential of Field Artillery is mobility; in other words, it must be able to accompany the army in the field. Apart from the field army, the Field Artillery has no function.

Colonel Jarman discusses at some length the use of mobile artillery materiel in the defense of the strong points of the coast line. It is not desired to attack such a use of mobile artillery materiel. It is immaterial whether the strong points are protected by guns on wheels or by guns on fixed mounts. The one essential is that the guns shall always be at the strong points so that the enemy may not take advantage of their absence and of the superior mobility of his ships in order to attack the strong points successfully. Whether the mobile artillery materiel fulfills the technical requirements of the defense of the strong points is a question for which there is no place in this discussion. The essential point is that if mobile artillery materiel is to be so employed, no advantage can safely be taken of its mobility until the situation has developed to such an extent that it has been definitely determined to be impossible for the enemy to attack the strong point. According to Colonel Jarman's statements, some of the mobile artillery materiel which he discusses is not suited to the defense of strong points, but nevertheless, he suggests its use by Coast Artillery in support of field army troops when repulsing landings.

The railway artillery which Colonel Jarman discusses at considerable length is subject to different considerations and rules from those affecting other classes of artillery. It is

Digitized by Google

mobile only in a very limited sense of the word. It is movable rather than mobile. A position must be secured for it by the field army; railways must be built, or existing lines of railway strengthened or repaired and the necessary sidings and other auxiliaries provided before this artillery can be brought into position to support the field army. As the army moves and occupies new positions, these must be prepared for the railway artillery in the same manner. Really, the formalities are very great. Strictly speaking then, the railway artillery cannot accompany an army in the field but can only follow it under certain conditions. This means that the railway artillery is not true field artillery and would tend to confirm the statement by General Hagood that 99 per cent of the usefulness of railway artillery is in the coast defenses. The use of this class of artillery in the defenses of strong points is open to the objection previously mentioned in connection with the employment of mobile artillery; that is, it may be a satisfactory weapon in a strong point as long as no advantage is taken of its

Base ring of emplacement for 14-inch rifle

This is the base of the emplacement shown in the preceding illustration. It involves the use of concrete and hence requires a considerable time to install.

mobility, but as soon as it is moved out of its position, the strong point becomes relatively weak. If guns on fixed mounts are technically inferior to railway guns, then without question the latter are better adapted to the defense of strong points than are the former, but not otherwise.

It would seem then, that the field army should be as stated before, completely organized within itself, and provided with all needed artillery materiel and personnel organized into mobile units capable of rendering to other troops of the field army the support which they may properly expect from their artillery, without reinforcement from any forces outside of the field army. Or, to put it more briefly, all the artillery which accompanies the field army should be field artillery, organized, trained, employed, and commanded as such.

Emergencies have arisen in our past history in which garrisons for the strong points of our coast line were not required. Similar emergencies may arise in the future. If they do it would be criminal to leave the garrisons of our strong points unemployed when they were needed elsewhere, no matter in what capacity. No sane person can object to their reasonable employment elsewhere when they are not needed in the strong points of the coast line. But their employment elsewhere should be based upon absolute and definite knowledge that the strong points are secure against attack. If we assume the field army to be employed in preventing a landing upon our coast, we must necessarily also assume superior naval strength on the part of our enemy, in fact so superior, that he must have overcome our navy, else he could not attempt to effect a landing in any great force. Under these conditions it would certainly be impossible to withdraw from the strong points of the coast line the garrisons assigned to their defense, and if we have not supplied the field army with the necessary artillery, separate and distinct from the garrisons of the strong points, the field army will be needlessly weakened by this neglect. *The arms of the service should be organized in accordance with their normal missions.* The Coast Artillery should be organized to defend the points on the coast line selected and organized as strong points, and the Field Artillery should be organized to support the field army with all the artillery fire that it can properly demand or expect. This makes the distinction between these two arms a very plain and simple matter and strictly in accord with the definitions of Field Artillery and Coast Artillery enacted by Congress when these two arms of the service were established. Duties and tactical employment determine the arm, and not the materiel with which units are equipped.

Chemical Merger Expected.—Negotiations looking to the merger of several of the large by-product and chemical companies are said to be progressing satisfactorily. The plan involves the merger of the General Chemical Co., Barrett Co., Semet-Solvay Co. and National Aniline Co. It is possible that an announcement bearing upon the proposed merger may be made before the close of the month. Prices at which the shares of certain of the subsidiary companies will go into the merger have been agreed upon.

It is understood that the aggregate earnings of the companies to be embodied in the merger—Barrett, National Aniline, General Chemical and Semet-Solvay—are now runninge at rate of $30,000,000 annually of which National Aniline contributes about $12,000,000.

Range Tables for Machine Guns.—The Small Arms Ballistic Station was established at Miami, Fla., for the purpose of revision of range tables for the firing manuals was made as a result of these tests and of tests carried on in France. It was found that, for the Model 1906 ammunition, the data given in the handbooks was not reliable at the longer ranges, due principally to lack of adequate range facilities before the World War.

Muzzle-brake for Guns.—Tests were conducted at Government proving ground last fall of several types of muzzle-brakes or gas deflectors. These devices were in each case a series of discs or vanes of varying shapes attached to the muzzle of the gun. Against these vanes a portion of the powder gases impinged on leaving the muzzle, the effect of which was the reducing of both the length of recoil and the carriage stresses. These tests were made on the 2.95 and 3 inch guns. The greatest amount of energy of recoil absorbed by these brakes was obtained in the case of the 3-inch gun, which was about 80 per cent. The results of these tests on the whole are promising, and tests are being continued with muzzle brakes attached to guns of larger caliber.

Erosion of Machine-gun Barrels.—A great number of tests on erosion of machine-gun barrels have been made. Barrels of different kinds of steel and different types of riffling have been made and tested. In addition to this, a large number of routine tests have been conducted to determine the accuracy life of the standard machine-gun barrels with ammunition of different types. These tests are not yet completed.

VOL. XII SEPTEMBER-OCTOBER, 1920 No. 65

A Pilgrim's Progress

OUR predecessor and forebear, Professional Memoirs, was, during its entire career, a semi-official publication, which was printed at the Engineer School plant at Washington Barracks, D. C., at a very moderate cost to the journal. It led a quiet existence, shielded by circumstance from the vicissitudes of life.

Recent legislation has forbidden the publication of journals of this class in government plants. It is necessary that they be published commercially, paying all their own expenses.

Professional Memoirs faced a crisis. Its accumulated resources and current income did not permit its publication on a purely commercial basis. There were two alternatives open. One was to reduce the size and scope of the journal to something more modest and more in keeping with its financial resources. The other was the reverse of this, to enlarge and expand, to make our journal more interesting and more useful, and to appeal to a larger class of readers. It was decided that we had an important mission to fulfill, and the second alternative, to wit, expansion, was adopted. In this decision the Society of American Military Engineers and its journal The Military Engineer, had their origin.

Decision must be followed by action, and very prompt action was necessary in this case. In the apathy succeeding the war the subscription list of Professional Memoirs was approaching the vanishing point. Interest in the periodical was at its lowest ebb. There was only one thing to do, to issue a larger and better journal. If it aroused the interest and met the approval of the profession, success was assured. And no outcome, other than this, was ever considered.

To fulfill our mission of promoting the National Defense, an organization of some kind, a society, was essential. And to maintain a national society, whose membership is scattered from coast to coast, some organ of communication, a live and up-to-date journal, was likewise essential. Hence our magazine must be continued, it must be made more interesting and appealing than heretofore.

The first number of The Military Engineer was printed at a commercial plant in Washington. Conditions in the printing world were bad. They were especially unfavorable to a new periodical. The difficulties of getting work done were very great and prices were high. Moreover, the new magazine, different in form from the old, was to be designed, its details worked up as it was being printed. These difficulties caused the first number to appear fully two months late. Nevertheless our first number was favorably received, and our Society showed signs of growth that encouraged us to persevere in the face of difficulties.

It was decided to establish our own plant, but funds were not at the time available for the project. So it was carried out in part only. A "composing" plant was purchased and installed, and the second number was set up in our own establishment, but printed commercially. The difficulties of getting presswork done were as great as ever. We were unable to make up our lost time, and it was quite evident that satisfactory results could be obtained only by having a complete plant of our own. The process of acquiring the plant, installing it and putting it in operation, was slow and painful. Our old quarters were too small, and we were compelled to move elsewhere. Just at this difficult juncture our efficient business manager, Major Richards, was taken seriously ill and has not yet returned to duty.

Digitized by Google

During the month of June the installation of our plant was finished. In April we had found ourselves several thousand dollars in debt, with our cash exhausted. But our Society was growing rapidly, and at present with our membership approaching 3,000, with a healthy growth in our advertising columns, and with a thoroughly equipped plant, we are independent of conditions in the printing business, except for the difficulty of obtaining supplies, and we are solvent financially.

This number of THE MILITARY ENGINEER is, from cover to cover, the product of our own plant. Many of our members have told us that, typographically, we need not fear comparison with any other professional journal. This result has been made possible by the loyal work of our business and circulation managers and our printer, and by the hearty support and encouragement of THE SOCIETY OF AMERICAN MILITARY ENGINEERS.

The crest of our difficulties appears to have been surmounted, and the outlook for the future is promising. By the first of the coming year our Society will be strong enough to support even so ambitious a journal as THE MILITARY ENGINEER. And the mission of our Society, the promotion of engineering preparedness for the defense of our country, we *can* and *will* accomplish.

Society of American Military Engineers initiates organization of Local Posts

BEGINNING in June there opened an important era in the history of our Society. In our May-June issue we announced our intention of organizing local posts in some of the larger communities. In June and July preliminary meetings looking to the organization of these posts were held in most of the large cities, and a number of smaller one.

The meetings were in most cases well attended, and in all cases very enthusiastic. Many eminent engineers, members of our Society, are backing the movement, local engineering societies and clubs and commercial organizations have lent their support.

In practically every case a number of charter members of the new post were enrolled, in the majority of cases an organization was effected and officers, or temporary officers, were elected, in a few cases preliminary details were discussed and future meetings schduled.

The influence of the local posts has already been strongly felt in a considerable increase in the membership of the parent society as a direct result of the local posts.

An excellent start has been made, and the outlook for the future is bright.

It is regarded as most important that the growth and activities of the local posts be given publicity, and THE MILITARY ENGINEER will devote whatever space is necessary to this purpose. The activities of each post will furnish valuable suggestions and stimulus to other posts. Our Society is co-operative, and only by working together can we accomplish our mission. It is urged, therefore, that all posts send to the Secretary of the Society, from time to time, reports of an informal nature concerning their activities, portraits of their officers, news items, membership, personal notes, plans for the future, etc.

Every member of the National Society should promptly join the post in his locality, if there be one.

Reports from the local posts are not as complete as we would desire, but the following summary will indicate how much progress has been made in a very short time.

CHICAGO, ILLINOIS.

Address: Mr. J. T. Montgomery, Secretary, 31 North State Street.

First Meeting: June 15, called by Col. W. V. Judson. Elected temporary officers: John deN. Macomb, President; G. B. McClary, Secretary-Treasurer. Recommended substitution of name "Section" for "Local Post."

Second Meeting: June 28, elected officers. Col. C. Vandeventer, President; Mr. J. T. Montgomery, Secretary-Treasurer.

CLEVELAND, OHIO.

Address: Capt. James H. Reding, Secretary, 13900 Savannah Avenue.

First Meeting: June 16, called by Col. R. R. Raymond. Elected temporary officers: Col. J. R. McQuigg, Temporary Chairman; Capt. J. H. Reding, Temporary Secretary.

DULUTH, MINNESOTA.
(Lake Superior Post.)

Address: Mr. William S. Morris, Secretary, Commercial Club.

First Meeting: June 12, called by Col. F. A. Pope. Temporary Officers elected. Col. F. A. Pope, President; Mr. Frank McComber, Vice President; Mr. William S. Morris, Secretary; Mr. A. G. Hatch, Treasurer; Mr. J. R. Rubey, Assistant Secretary.

JACKSONVILLE, FLORIDA.

Address: Mr. J. M. Braxton, U. S. Engineer Office, Masonic Temple.

First Meeting: June 15, called by Col. W. J. Barden. Temporary officers elected. Mr. J. M. Braxton, President.

Second Meeting: July 10 (no details).

LOS ANGELES, CALIFORNIA.

Address: Mr. Burt Harmon, Secretary, 745 West Ocean Avenue.

First Meeting: June 15, called by Col. F. B. Downing. Temporary officers elected: Mr. Charles T. Leeds, President; Mr. Carl B. Wirsching, 1st Vice President; Mr. John A. Griffin, 2d Vice President; Mr. Burt Harmon, Secretary; Mr. G. C. Fitzgerald, Treasurer.

MILWAUKEE, WISCONSIN.

Address: Maj. F. C. Best, Secretary, care of U. S. Engineer Officer.

First Meeting: June 25, called by Col. E. H. Schulz. Temporary officers elected. Col. Edward H. Schulz, Presi-

Digitized by Google

dent; Mr. T. C. Hatton, Vice President; Maj. F. C. Best, Secretary.

Meetings July 2 and 9 (no details).

MONTGOMERY, ALABAMA.

Address: Mr. Dwight C. Trevarthen, Secretary, P. O. Box 763.

First Meeting: June 15, called by Maj. W. A. Johnson. Officers elected: Maj. W. A. McCalla, Vice-President; Mr. Dwight Trevarthen, Secretary-Treasurer.

NEW ORLEANS, LOUISIANA.

Address: Lt. Col. H. P. Ralston, Secretary, 2302 Prytania Street.

First Meeting: June 15, called by Maj. E. J. Dent. Temporary officers elected: Maj. E. J. Dent, President; Maj. A. M. Shaw, Vice President; Lt. Col. H. P. Ralston, Secretary; Capt. J. H. Carruth, 1st Director; Lt. Col. Pendleton Morris, 2d Director.

Second Meeting: June 22, application for charter.

NEW YORK CITY.

Address: Maj. Percy E. Barbour, Secretary, 29 West 39th Street.

First Meeting: June 15, called by Col. Edward Burr. Temporary officers elected: Col. F. A. Molitor, Chairman; Col. G. D. Snyder, Vice-Chairman; Maj. Percy E. Barbour, Secretary.

Second Meeting: June 29 (no details).

PHILADELPHIA, PENNSYLVANIA.

Address: Lt. Col. W. B. Ladue, 815 Witherspoon Building.

First Meeting: June 15, called by Col. W. B. Ladue. Maj. Marshall R. Pugh, presided (no details).

PITTSBURGH, PENNSYLVANIA.

Address: Mr. Wm. M. McKee, Secretary, 1708 Farmers Bank Building.

First Meeting: June 17, called by Col. H. B. Ferguson. Temporary officers elected: Mr. E. A. Gibbs, President; Mr. E. F. Archibald, Vice-President; Mr. William M. McKee, Secretary; Mr. F. W. Henrici, Treasurer; Mr. W. H. Horton, Jr., Assistant Treasurer.

PORTLAND, OREGON.

Address: Capt. P. Hetherton, Secretary, Chamber of Commerce.

First Meeting: June 15, called by Col. J. R. Slattery.

Second Meeting: June 28. Officers elected: Maj. Lyman Griswold, President; Maj. W. H. Emerick, Vice-President; Capt. P. Hetherton, Secretary; Capt. J. W. Morris, Treasurer; Capt. R. E. Kremers, Assistant Treasurer.

SAN FRANCISCO, CALIFORNIA.

Address: Capt. D. W. Dodge, Secretary, 733 Rialto Building.

First Meeting: June 29, called by Col. Thos. H. Rees. Elected temporary officers: Col. T. H. Rees, President; Lt. Col. Chas. B. Wing, Vice-President; Capt. D. W. Dodge, Secretary; Capt. J. D. Cleary, Treasurer; Col. J. W. Williams, Assistant Treasurer.

ST. LOUIS, MISSOURI.

Address: Lt. Col. John L. Buchanan, 7th and Clark Ave.

First Meeting: June 15, called by Maj. DeWitt C. Jones. Elected officers: Maj. DeWitt C. Jones, President; Lt. Col. F. G. Jonah, Vice-President; Lt. Col. J. L. Buchanan, Secretary; Maj. J. W. Skelly, Treasurer; Maj. W. W. Burden, Assistant Treasurer.

Second meeting: June 23, signed application for charter.

SEATTLE, WASHINGTON.

Address: Secretary, Seattle Post, Society of American Military Engineers, U. S. Engineer Office, Seattle.

First Meeting: June 15, called by Col. J. A. Woodruff. Committee appointed to organize: Col. J. A. Woodruff, Mr. J. M. Clapp, Capt. Bertram D. Dean, Capt. K. C. Bean, Maj. A. O. Piper.

WILMINGTON, DELAWARE.

Address: Mr. Pearson Winslow, Secretary, Engineering Department, DuPont Building.

First Meeting: June 15, called by Col. E. N. Johnston. Officers elected: Maj. W. F. Beyer, President; Mr. W. M. McIntosh, Vice President; Mr. Pearson Winslow, Secretary-Treasurer.

Morale in war and peace

IT was Napoleon who said "In war the moral is to the physical as three to one." His estimate was very conservative, especially perhaps as applied to his own people, the French.

Unquestionably, the best demonstration of moral power which history records, was given by Joan of Arc. Joan was a poor country maiden, totally ignorant in all things concerning state-craft and the art of war. She exercised no leadership, if by this we mean that the leader must know what he is doing and direct the operations of those under them. Yet she defeated the previously victorious army of a great nation and placed a King on the throne of France.

These results Joan achieved solely by the romantic stimulus she gave to the highly sensitive morale of the French people. Napoleon himself, while knowing the art of war better than any other man, owed his success quite as much to his power to influence the morale of his soldiers. This is well illustrated by the following anecdote:

In their assaults on the Borodino Redoubt (in the Russian campaign) the French had been several times repulsed with heavy losses. Without reinforcements, with their morale low as a result of defeat, it seemed useless to send the French army again to the assault. The last day happened to be the anniversary of the great French victory at Austerlitz. As noon approached, the French battalions were assembled for the final assault. The morning had been cloudy, but at noon the sun broke forth and gloriously illuminated the field of battle. The great commander, quick to take advantage of any favorable circumstances, pointed to the brilliant orb and exclaimed: "Soldiers, it is the sun of Austerlitz that shines upon you." With shouts of enthusiasm the excitable Frenchmen charged, and in the twinkling of an eye captured the stronghold which had resisted all their previous efforts.

We are prone to think of "morale" as a military term. But it is fully as applicable to the affairs of peace as to those of war. The most successful leaders both in war and peace are those who know best how

Digitized by Google

to stimulate the enthusiasm of their followers. Warm enthusiasm wins the battles of peace, after cold reason has pronounced them lost.

We all realize, in a more or less academic way, the power of enthusiasm. Yet how frequently we neglect to take practical advantage of our knowledge, and of the thousand and one opportunities constantly afforded us to stimulate the enthusiasm of our "soldiers." A little stroll around the work or through the plant, just to let "the boss" be seen, a little show of interest, a cheery greeting, a word of approval and encouragement, a kindly inquiry, a reminder of good performances in the past—all these will work wonders in achieving results.

It has been said that such opportunities are no. presented in the great armies of the present day, the great "soulless" corporations in modern industry, where personal contact between the leader and his followers is impossible. This is not true. Through organization the leader directs and controls the acts of subordinates he never sees or knows. It is quite as easy to affect their morale, to stimulate or depress their enthusiasm, by the same means. The personality of an enthusiastic leader is a living force which pervades the entire organization, however large it ma be. Subordinates will take a pride in serving such a leader, and his personality becomes a power in their lives, even though he be unseen.

The Army Ordnance Association

EARLY in August the first issue of *Army Ordnance,* Journal of the Army Ordnance Association, made its appearance. We are convinced that no technical magazine ever made a more splendid showing from the beginning. The new journal is most handsome and attractive. Beautifully printed and illustrated, its contents from cover to cover are of absorbing interest. Amongst the leading articles are "Decentralized Production," by Gen. Guy E. Tripp, chairman of the Board of Directors of the Westinghouse Electric and Mfg. Co.; "The Ordnance Engineer," an appreciation of his services by Gen. William Crozier, late Chief of Ordnance, U. S. Army; "Motorized Artillery," by Col. L. B. Moody; "Government Nitrate Plants," by Col. J. H. Burns; "Manufacture of Tanks at Rock Island Arsenal," by Col. H. B. Jordan; "The Machine Gun of the Future," by Maj. J. S. Hatcher, etc.

The Army Ordnance Association, already a strong and flourishing society, is pledged to the promotion of industrial preparedness as one of the strongest guarantees of peace. All American citizens available to the government in connection with the design, production, inspection, purchase, etc., of ordnance material, are eligible to membership in the new society.

The offices of the new society are in the Munsey Building, Washington, D. C. Charter membership is now open, the annual dues are $5. Maj. J. L. Walsh is Secretary of the society and Editor of *Army Ordnance,* and Mr. Harry P. Taber is Consulting Editor.

The R.O.T.C. Camp

THOSE who favor universal training or universal education (it smells just as sweet or otherwise by either name), have consistently maintained that education, being the greatest national as well as personal need, should be a function of the supreme governing power of the land. Especially is this true in a *democracy,* whose success is dependent on the intelligence of its citizens, whereas in an autocracy success, or at least perpetuity of autocratic control, is too often dependent on their ignorance. According to this theory education and democracy go hand in hand, each is or should be at once both the cause and effect of the other.

The Army is devoting much of its energies at present to a practical demonstration of the power of the Federal Government to educate our citizenry. This mission of the Army is one of the great "new ideas" that are the aftermath of the war. Yet after all this idea is not so very new.

An important feature of this demonstration is the series of summer camps for the instruction of the Reserve Officers' Training Corps. In this issue we present an interesting article describing the Engineer Camp at Camp Humphreys, Va., its purpose and the methods by which it has sought to achieve this purpose. All those who believe that right training or education is a fundamental human need will find much to interest them in Captain Styer's entertaining story of what has been done at Camp Humphreys.

What is our mission?

A lively correspondent whose morale is manifestly still good, contributes the following:

In action whenever a commander becomes confused, when he seems to be getting lost, when all things seem to be going wrong, it is his duty to stop and think—What is my mission?

To-day in the Army when many things are going wrong, when hundreds of officers are leaving, when an amazingly small number of men are re-enlisting, when it costs hundreds if not thousands of dollars to get a recruit, when those officers who are not cowed by threats from above announce that morale is at a low ebb, is it not well for the Regular Army to ask itself, What is our Mission?

Is it the purpose of the Regular Army to increase the educational tone of the country; is it the mission of the Army to offer amazing educational opportunities to the youth of the land when it is being daily demonstrated that such offers cannot be carried out under the "voluntary" system without an expenditure out of proportion to the results attained; is it the mission of the Army to stand silently by and see some of its best material, both commissioned and enlisted, leaving the service; or is it the mission of the Army to insist that it remain a sound reliable military organization, capable of giving the last ounce of its strength to the country and to the best advantage, while so maintaining the true military character of the nation, so keeping abreast with military progress, so formulating military plans, as to guarantee a virile, healthy military body, capable of effective expansion in time of war?

Without question the mission of the Regular Army is to be fit, to be

Digitized by Google

prepared, to be ready for any emergency. To do this it must first of all things maintain a strong, efficient personnel. It may be small but it must be good. Next, we must not be blind to the experiences of the great war but keen and alive to apply them to our problems of the present and future. We must look with suspicion and constructive criticism into all our habits which embarrassed us during the recent emergency. We must recognize that any method of training, administration or routine, which undermines soldierly efficiency and hampers progress in war should be eliminated. We must realize that in time of emergency when every member of the regular service should be capable of assuming tremendously increased responsibilities, his military character and training must be sound if he is to endoctrinate all the new men placed under him with proper military methods, practice, habits and ideals.

In the matter of discipline it is time we realized that in a democracy such as ours the only criterion for superior rank is superior worth and leadership; that no officer has any business holding a commission unless he is a better soldier than the men he commands, but that an officer does not have to pet and pamper new recruits in order to show his democratic spirit. We are thankful to realize that Americans are still sufficiently virile to admire a strong man who is efficient and capable, and to want to follow him. On the other hand, the day of the snarling martinet is past, as is the day of a privileged officer class. We must admit the fact that the army has no room for an officer who, while requiring the highest degree of smartness and courtesy from his men, remains seated, smoking in front of his tent, while his men come to "attention" and salute him.

We of the regular service must not quit the service nor must we desert our idea's. We see our true mission. As our vision has cleared and expanded during the war so must our courage and determination strengthen to stand four square and see it through.

The Engineer Emergency Officer in World War

By

C. O. Sherrill

Major, Corps of Engineers

[*Note.*—It gives us a peculiar pleasure to here record this tribute to the services of the "emergency" engineer officer, by a regular officer of high standing and wide experience. Colonel Sherrill voices the opinion of all his brother officers during the war. They have been weighed and not found wanting by those best qualified to judge the value of their services—the engineer officers of the Regular Establishment.—ED.]

AT the beginning of operations by the United States against the European Central powers, there were 256 officers in the Corps of Engineers of the United States Army.

The Corps of Engineers in time of war is charged with activities of such variety and magnitude that long before the war the necessity for a Reserve Corps of Engineers was recognized, and when war was declared there were approximately 364 civilian engineers commissioned in the Engineer Reserve Corps. Very few of these had any military training or had knowledge of the functions of the Engineers in war, but having been so commissioned, were supposed to have cognizance of the requirements—officers by Act of Congress.

In May, 1917, the first officers' training camps were started and, about a month later, special engineer officers' training camps were organized, to which all Engineer officers then in other training camps were transferred. Later, additional engineer officers' training courses were inaugurated, which covered a course of about 12 weeks; also, a great number of civilian engineers with special qualifications were commissioned and put on active service, till the total number of officers in the Engineers on November 26, 1918, reached 11,133; of which 449 were Regular Army Engineer Officers and the balance were commissioned only for the emergency, with the exception of 30 who, on account of being on inactive duty, retained their commissions as reserve officers. Including officers who had previously been on active duty at one time or another during the World War, there were altogether about 13,000 officers in the Engineers.

The training of Engineer reserve officers at training camps gave them a knowledge of military organization and routine, the latter a much abused term but essential to any organization which is to function smoothly and systematically. The Engineer reserve officers who served with combat engineer organizations found such training of the greatest value, but the civilian engineer on purely engineering work found that the training so acquired, by giving a broad view, was also a great help to him.

The emergency engineer officers were among the best of the engineering profession in the United States, ranging from young men just graduated or about to graduate from technical schools, to railroad presidents. Every conceivable specialty of technical endeavor was represented, and almost every one was needed and placed in his proper sphere as nearly as a qualification system devised by experienced specialists, and knowledge of the man by direct personal contact could place him. His surroundings were new and his contact with men somewhat different from that in time of peace and particularly so in France. It took time for many to get accustomed to it; most of them did it quickly, very few never; but the latter probably would not have fitted anywhere.

Engineering work in war is a service for the achievement of the common end—the conquering of the enemy. To arrive at this result, a co-ordination of all military services is a prime requisite and a co-ordination of the branches in each service a necessity. Engineers in civil life have held similar relations to industrial and commercial activities and their entrance into the military life probably was not so complete a transition as in other branches of the service After all, the military engineer service is not materially different from any other highly organized force, as railroad or large contracting organizations. The man who was a success in the latter was bound to be a very valuable member in the former, and such proved the case.

The limitations of law at first did not permit the appointment of officers above the grade of Major in the Engineer Reserve Corps, and too much praise cannot be given to the patriotism and self-abnegation of the men above draft age, holding positions of great responsibility, who volunteered for this service. Men of international reputation as engineers and some of the highest paid engineering executives entered the service, and while of course at first nearly all reserve officers were placed under Regular Army officers, as soon as adjustments could be made these able men were placed in positions commensurate with their ability and experience.

While rank in the Army in general established precedence, this, particularly in the engineering service in the S. O. S., was often set aside when the situation required it, until correction could be made by appropriate promotion, which later was authorized.

Most professions or trades have a language peculiar to such occupation, and one of the first difficulties, but of really minor importance and very soon overcome, was the lack of ability of the civilian engineer to understand the military vocabulary, not necessarily slang, but as different from the ordinary language as is the railroad man's professional vernacular. When this handicap was overcome, the common ground between the reserve officer and the army

Digitized by Google

as a whole was found, and things commenced to move; he could now "speak the language" of the service.

Engineer reserve officers occupied every position in the Corps of Engineers from second lieutenant to brigadier general; they took charge of many organizations at the front and rendered excellent services of a purely military character; their specialized technical knowledge was taken advantage of in every way and seldom if ever did they fail to respond to any demand on them, whether it was a purely military or other specialized technical requirement; they gave the best that was in them.

The regular army officer could not and did not attempt to specialize to the extent required in this war, but his general knowledge of military affairs and engineering, and his trained executive powers were taken advantage of to the full. The combination of the broad outlook of the regular with the highly expert and specialized knowledge and aggressiveness of the emergency officer was a combination hard to beat, and Germany could not beat it.

While, of course, the regular army engineer had endeavored, through direction of public works and association with the civil engineering profession, to keep abreast of all modern improvements and new lines of thought in his profession, the close contact with the men from civil life during the war has given him opportunities to observe and learn, often even how not to do things. Similar experience was gained by the emergency officers, and should another emergency arise within their life-time the mutual experience gained will be of invaluable aid to the defense of this country.

The emergency engineer officer was an American and as such never willing to be a mere machine. Unfortunately, this was often his conception of military duty as laid down in regulations. When he found out that military organization may be likened to a machine, but that the human factor is never overlooked in the American Army, he became the valuable human part in the organization, to create which was the object of every one connected therewith, and who served with the one aim in view to defeat the enemy, not alone with brute force, but by the exercise of every faculty of the human brain.

The work done by the emergency officers of Engineers covered every conceivable engineering activity, and to enumerate these would show as many and probably more items than the Trade Index of the New York City directory. The Engineer reserve officers loyally followed the motto of the Corps of Engineers: "Essayons," "Let us try," and they succeeded. Lest the Corps of Engineers shall be thought to minimize the eminent services, it is desired here to render final acknowledgment to this self-sacrificing body of men, without whom the war could not have been won.

Still sliding at Panama

That the end of the slides at Panama is not yet and that the engineers charged with keeping open the "big ditch" still have their troubles, is indicated by the following extracts from a report by J. W. Pratt, Superintendent of Dredging on the Canal:

During October, 1919, a slide occurred at Cucharacha, which had remained quiet for three years, causing over 200,000 cubic yards of earth and rock to come into the canal. This was removed and everything was quiet until the 22d of last February, when another movement at the same place commenced, and since that time we have had four distinct movements besides a gradual creeping part of the time. Over 500,000 cubic yards have been brought into the canal by these latter movements. In one night the canal was closed to shipping, and it took four days to open a way for ships to pass. We fought every day for two months to keep sufficient channel open for ships to pass. One can walk to the center of the canal now. The trouble with removing the material is that it is largely composed of rock, some very large that have to be blasted. These rock are pushed out from the hills, and into the canal, some moving clear across to the opposite bank. Some of them are 150 feet long, 50 feet wide and 40 feet thick. They have to be drilled and blasted before being removed. We have three 15-yard dipper dredges, and these are the only kind that can successfully handle this material. The material is put in scows and towed about 15 miles to the dumping ground. So, of course, the work is very costly, and proceeds night and day, Sundays and holidays.

As to the magnitude of these slides, the area that moved covers 35 acres. The movement was primarily caused by the collapse of a rock ridge that had served as a retaining wall when the big slide occurred there four years ago. The collapse was due to the gradual deterioration of the rock in this wall. Material immediately behind this wall, a huge hill, pushed out, carrying everything before it, the high ground behind the hill settled 100 feet by pushing forward, and the movement extended to a distance of one-half mile from the canal. The hill there is 500 feet high, mostly rock. A huge piece, 1,000 feet by 400 feet, settled and broke up, pushing forward and causing everything before it to move. The movement is very deep—perhaps 200 feet. This movement is affecting a hill 600 feet high that is to one side of it and nearer the canal. The rock in these hills is slowly crumbling and falling into pieces as if struck by a series of blows. There must be very great vibration to cause it. There is considerably over 3,000,000 cubic yards of material in motion. To add to our troubles, a part of the movement is behind a huge rock hill that is on the bank of the canal. And the canal will be closed for a long time if this hill is pushed over. We are using large hydraulic graders in an effort to relieve the pressure from behind this hill and divert the material around it. It sometimes moves up to this hill at the rate of 2 feet an hour, and moves up the steep slope to within a few feet of the top. It would overflow it like water were it not for our efforts. It is strange to see huge rocks moved up the almost perpendicular slope. The earth is as dry as powder, dusty, and yet it flows like water with that pressure behind it.

The British battleship *Renown*, with the Prince of Wales on board, had to wait four hours while we blasted the top off a large bowlder in order to give sufficient depth. That was a very trying day. The Prince was much interested in our operations. He could see from the ship what we were doing. The work was highly praised by the Governor, who was naturally anxious to get the boat through on schedule time.

Autofrettage for Guns.—The Ordnance Department is investigating the so-called "autofrettage" method of constructing guns, with a view to comparing its merits with the built-up and wire-wrapped methods. The latter two forms of construction have hitherto been used in all modern guns. The principle involved has been the support of the tube of the gun by the shrinkage of hoops around it in the built-up construction, and the wrapping of wire under tension around the tube in the wire construction. The pressure of the hoops or wire reinforced the inner tube, enabling it to support a greater internal pressure than a single tube could withstand.

In the autofrettage method of gun construction, the gun may be constructed in one piece. Before the bore is finally completed, hydraulic pressure is applied, sufficient to cause an actual expansion of the gun. The elastic reaction which takes place after the hydraulic pressure is removed places the inner part of the walls of the gun under compression and the outer part under tension, which is the same general effect as is obtained in the built-up or wire construction. If this method of construction is otherwise satisfactory, it will probably be cheaper than either the built-up or wire method. Furthermore, the time required for manufacturing the gun will be reduced to a considerable extent, and it may be possible to obtain a gun of equal power and lighter weight.

Cost of American forces in France.—The average daily cost of maintaining the American forces in Germany varied from $1,271,000 in February, 1919, to $76,000 in May, 1920. This is paid by Germany.—*Statistics Br. G. S.*

Chemical Warfare in Attack

By

Amos A. Fries

Brigadier General, Chief of Chemical Warfare Service, U. S. Army
formerly, Chief of Chemical Warfare Service, A. E. F.

[*Note.*—Gen. Amos A. Fries, the author of this article, at the outbreak of the war was a Lieutenant-Colonel of the Corps of Engineers. He was appointed Chief of the Chemical Warfare Service of the A. E. F. and subsequently promoted to the rank of Brigadier General. He served throughout the war in this capacity. On the reorganization of the Army following the war General Fries was appointed Chief of the Chemical Warfare Service, for which position he was the logical candidate. He is thus unquestionably the best qualified man in America to write with authority on the tactical use of poison gas in war. In his article General Fries sets forth in a singularly lucid and convincing manner the sound doctrine of chemical warfare as developed in the A. E. F. under his direction. He tells what has been accomplished and dissipates many popular misconceptions concerning the use of gas. But the most interesting and useful part of the article is his portrayal, based on fact and sound reasoning, of the possible future developments of this now important arm of warfare. These predictions by our leading authority cannot fail to be of absorbing interest to all our readers.—ED.]

What chemical warfare includes.

CHEMICAL warfare material includes all gas, smoke and incendiary materials and all defensive appliances, chief of which is the mask, used by the Army. Some of the items or materials in both offense and defense are used by the entire army, while a few are used only by Chemical Warfare Service troops.

Meaning of term "Gas."

The term "gas" is now taken to include all materials that are carried to the enemy by the air, after their liberation from cylinders, bombs or shells. It is necessary that this broad use of the term "gas" be thoroughly understood, because some of these materials are solids, while all others are liquids, until liberated from the containers at the time of the attack. These containers may be special cylinders for cloud gas attacks, special bombs for Livens projectors and mortars, or artillery shell, and even aviation bombs. Some of the liquids which have a very low boiling point volatilize quickly upon exposure to air, and hence require only enough explosive to open the shell and allow the liquid to escape, while practically all solids have to be pulverized by a large amount of high explosive.

Chemical warfare highly technical.

Chemical warfare, besides being the newest, is also the most technical and most highly specialized service of war. There is no class of people in civil life, and no officers or men in the War Department who can take up chemical warfare successfully until they have received thorough training. This applies to the use of materials in both attack and defense. Ten years from now perhaps this will not be true. It is certainly hoped that it will not be. By that time the entire army should be pretty thoroughly trained in the general principles and many of the special features of chemical warfare. If not, chemical warfare can not be used in the field with the fullest efficiency and success. Furthermore, it is believed that within ten years the knowledge of the gases used in chemical warfare will be so common through the development and use of these same materials in civil life, that it will not be so difficult as at present to find civilians who are acquainted with Chemical Warfare Service materials.

Effectiveness of Gas.

Chemical warfare materials were used during the war by Chemical Warfare Service troops, by the artillery and by the infantry. For the future the air service will be added. Chemical warfare, even under the inelastic methods of the Germans, proved one of the most powerful means of offense with which the American troops had to contend. To prove its effectiveness it need only be said that more than 27 out of every 100 men killed and wounded on the field of battle were from gas alone. Unquestionably many of those who died on the battle field from other causes suffered also from gas. No other single element of war, accounted for so many casualties among the American troops. Indeed, it is believed that a greater number of casualties was not inflicted by any other arm of the service, unless possibly the infantry, and even in that case it would be necessary to account for all injured by bullets, the bayonet, machine guns and hand grenades. This is true, in spite of the fact that the German was so nearly out of gas when the Americans began their offensive at St. Mihiel and the Argonne, that practically no gas casualties occurred during the St. Mihiel offensive, and only a very few until after a week of the Argonne fighting. Furthermore, the Germans knew that an extensive use of mustard gas against the American lines on the day the attack was made, and also on the line that marked the end of the first advance a few days later, would have produced tremendous casualties. Judging from the results achieved at other times by an extensive use of mustard gas, it is believed that had the German possessed this gas and used it as he had used it a few other times, American casualties in the Argonne would have been doubled. In fact, the advance might even have been entirely stopped, thus prolonging the war into the year 1919.

Humanity of Gas.

A few words here as to the humanity of gas are not out of place, notwithstanding the army and the general public have now so completely indorsed chemical warfare that it is not believed the argument of inhumanity has any weight whatever. There were three great reasons why chemical warfare was first widely advertised throughout the world as inhumane and horrible. These reasons may be summed up as follows:

The original gas used at Ypres in 1915 was chlorine, one of a group of gases known as suffocants, which cause death generally by suffocating the patient through spasms of the epiglottis and throat. That is the most agonizing effect produced by any gas.

The English had no masks, no gas-proof dugouts, nor any of the other paraphernalia that was later employed to protect against poisonous gas. Consequently, the death rate

Digitized by Google

in the first gas attack at Ypres was very high, probably 35 per cent. As a matter of fact, every man who was close to the front line got a fatal dose and died. The only ones who escaped were those on the edges of the cloud of gas or so far to the rear that the concentration had become decreased below the deadly point.

It was good war propaganda to impress upon everybody the fact that the German was capable of using any means that he could develop in order to win a victory. He had no respect for previous agreements or ideas concerning warfare. This propaganda kept up the morale and fighting spirit of the Allies, and was thoroughly justifiable upon that score even when it led to wild exaggeration.

The chlorine used in the first attack by the German is the least poisonous of the gases now used. Those later introduced such as phosgene, mustard gas and diphenylchlorarsine are from five to ten times as effective.

The measure of humanity for any form of warfare is the percentage of deaths to the total number injured by the particular method of warfare under consideration.

American Gas Casualties

The official list of casualties in battle as compiled by the Surgeon General's office covering all cases reported up to September 1, 1919, is 274,217. Of these, 74,799 or 27.3 per cent were gas casualties; also, of the above casualties 48,059 resulted in death, of these 1,400 only were due to gas. From these figures it is readily deduced that while 23.4 per cent of all casualties from bullets and high explosives resulted in death, only 1.87 per cent of those wounded by gas resulted in death. That is, a man wounded on the battle field with gas had twelve times as many chances of recovery as the man who was wounded with bullets and high explosives.

Telephoning and directing artillery fire through gas mask and megaphone. In the Argonne, Oct. 18. The soldier must perform all his proper functions—gas or no gas

Fundamentals of chemical warfare.

Before taking up in detail the methods of projecting gas upon the enemy, it is very desirable to understand the fundamentals of chemical warfare, insofar as they pertain to poisonous gases.

Following the first use of pure chlorine all the principal nations engaged in the war began investigations of gases in the hope of finding others more poisonous, more easily produced, and more readily projected upon the enemy. These investigations led to the use of a large number of gases which seriously complicated manufacture, supply, and the actual use of the gases in the field. Gradually a more rational conception of chemical warfare led both the Allies and the enemy to restrict the numbers of gases to a comparative few, and still later to divide all gases into three groups. Thus the German divided his into three groups known as (1) Green Cross, the highly poisonous non-persistent gases, (2) Blue Cross, or diphenylchlorarsine, popularly known as sneezing gas, and (3) Yellow Cross, highly persistent gases, such as mustard gas. In the American Chemical Warfare Service we have finally divided all gases into two primary groups. These groups are known as "non-persistent" and "persistent." The "non-persistent" gases are those quickly volatilizing upon exposure to the air, and hence those that are carried away by air currents, or which in a dead calm will be in a few hours completely dissipated into the surrounding air. If sufficient high explosive be used to pulverize solids they may be used in the same way, and to a large extent certain highly persistent liquid gases may have their persistency greatly reduced by using a large amount of high explosive that divides the liquid into a fine spray. The "persistent" group includes those gases that are very slowly volatilized upon exposure to the atmosphere. The principal ones of these now used or proposed are mustard gas (dichlorethylsulphide), and brombenzylcyanide, a tear gas. For purposes of economy, and hence efficiency, certain gases, both persistent and non-persistent, are placed in a third group known as the "irritant group." These gases are effective in extremely low concentrations against the lungs and other air passages, or the eyes. Diphenylchlorarsine, and some other solids when divided into minute particles by high explosive or heat, irritate the nose, throat and lungs to such an extent in a concentration of one part in ten millions of air as to be unbearable in a few minutes. The tear gases are equally powerful in their effects on the eyes. The irritating gases are used to force the wearing of the mask, which reduces the physical vigor and efficiency of the troops. This reduction in efficiency, even with the best masks, is probably 25 per cent for short periods, and much more if prolonged wearing of the mask is forced.

One pound of the irritant gases is equal to 500 to 1,000 pounds of other gases when forcing the wearing of the mask alone is desired. The great economy resulting from their use is thus apparent. Due to the rapid evaporation of the non-persistent gases they are used generally only in dense clouds, whether those clouds be produced from cylinders, called "cloud gas," or from bombs. These gases are used only for producing immediate casualties, as the necessary amount of gas to force the enemy to constantly wear his mask by the use of non-persistent gases alone could not possibly be taken to the front.

Mustard gas, which is highly persistent and also attacks the lungs, eyes and skin of the body may, and will be used to force the wearing of the mask. It has one disadvantage when it is desired to force immediately the wearing of the mask, and that is its delay action and the fact that it acts so slowly, and is usually encountered in such slight concentrations that several hours' exposure are necessary to produce a severe casuality. For these reasons the enemy may often take chances in the heat of battle with mustard gas, and while himself becoming a casualty inflict quite heavy casualties upon opposing troops by continuing to operate his guns or rifles as the case may be. A powerful tear gas on the other hand forces the immediate wearing of the mask.

Chemical warfare materials used by C. W. S. Troops.

Chemical Warfare Service troops in making gas attacks use cylinders for the cloud or wave attack, and the Livens

Digitized by Google

projector and four-inch Stokes mortar for attacks with heavy concentrations of gas projected by bombs with ranges up to a mile. This distance will in the future probably be increased to one and one-half or one and three-quarters miles. The original cylinders used in wave attacks were heavy, cumbersome and very laborious to install, and hence notwithstanding the wave attack was known to be the deadliest form of gas attack used in the war, it fell into disrepute after the use of gas in artillery shells and in special bombs became general.

Cloud gas.

The Americans at once concluded that since cloud gas attacks were so effective, efforts should be made to make these attacks of frequent occurrence by decreasing the weight of the cylinders, and by increasing the portability and improving the methods of discharging the cylinders.

Cloud gas attacks will usually be made at night, when due to fatigue and sleepiness men are careless, lose their way, neglect their masks, and are thus caught. Experience in the war proved that a wave attack always produced casualties even, as was several times the case when the enemy or the Allied troops knew some hours beforehand that the attack was coming. The English estimated these casualties to be 10 or 11 per cent of the troops exposed.

Livens projectors.

The next most effective weapon for using gas by gas troops was and will be the Livens projector. This projector is nothing more than the simplest form of mortar consisting of a straight drawn steel tube and a steel base plate. As used during the World War by the Allies it did not even have a firing pin or other mechanism in the base, the electric wires for firing passing out through the muzzle and alongside the drum or projectile which was small enough to permit that method of firing. These were set by the hundreds very close behind or even in front of the front line trenches. They were all fired at the same instant, or as nearly at the same instant as watches could be synchronized, and firing batteries operated. These mortars were emplaced deep enough in the ground to bring their muzzles practically level with the surface. As the ones most generally used were 2 feet 9 inches long, the work entailed was very great. Thus it usually took several days to prepare the attack, and consequently allowed an opportunity for the enemy to detect the work by aeroplane photographs or by raids, and destroy the emplacements by artillery fire. It should be added, however, that notwithstanding this apparent great difficulty, very few attacks were broken up in that way. Nevertheless, in line with the general policy of the American troops to get away from anything that savored of trench warfare, and to make the fighting as nearly continuous as possible with every means available, the American Chemical Warfare Service set at work at once to develop an easy method of making projector attacks.

Emplacing projectors.

It was early found that if the excavation was made just deep enough so that the base plate could be set at the proper angle, the drums or projectiles were fired as accurately as when the projectors or mortars were set so that the muzzles were level with the surface. The time required to emplace a given number of mortars in this way was only about one-fifth of that required for digging them completely in. However, one problem in connection with this method of firing remained unsolved to the end of the war, and hence it was not used.

The firing batteries used by the Chemical Warfare Service were ordinarily used for blasting purposes in the United States, and would fire only twenty to thirty fuzes each. As it was highly desirable, if not absolutely necessary at all times to set a great number of these mortars close together, they had to be fired exactly simultaneously, when set above the ground, or else the shock of discharge from nearby projectors threw those not discharged at the same instant entirely out of line. A machine that will fire 100 to 500 at one time will be developed, and will make this method practicable in the field.

Coupled of course with these proposed improvements in methods, studies were made and are being made to produce lighter mortars, better powder charges, and better gas checks in order to develop the full force of the powder. Many improvements along this line can be made, all of which will result in greater mobility, more frequent attacks, and greater efficiency.

4-inch Stokes mortar.

The Stokes mortar is not different from that used by the Infantry, except that it is 4 inch, while the Infantry Stokes is 3 inch. The 4 inch was chosen by the British for gas, as it was the largest calibre that could be fired rapidly and yet be moderately mobile. Its range of only about 1,100 yards handicapped it considerably. The poor design of the bomb was partly responsible for this. The powder charges also were neither well chosen nor well designed. It is believed that great improvements can be made in the shape of the bomb and in the powder charge, which will result in much longer range and higher efficiency, while in no way increasing the weight of the bomb or decreasing the rate of fire. These last two weapons were used during the World War, and will be extensively used in the future for firing high explosive, phosphorus, thermite and similar materials that non-technical troops may handle.

C. W. S. Troops handle all short-range mortars.

Since, however, gas has proven without the shadow of a doubt, that it will produce more casualties for an equal amount of material transported to the front than any other substance yet devised, all troops using short range guns or mortars should be trained to fire gas whenever weather conditions are right. When weather conditions are not right they should fire the other substances mentioned. The Livens projector with its 60-pound bomb, of which 30 pounds will be gas or high explosive, is a wonderful gun up to the limit of its range. The bomb not being pointed does not sink into the ground, and hence upon exploding exerts the full force of high explosive upon the surroundings, whether bombs, pill boxes, barbed wire or trenches, to say nothing of personnel.

High explosive in projectors.

When these are burst by the hundreds on a small area everything movable is blotted out. Thus concrete machine gun emplacements, lookout stations, bomb-proofs, wire emplacements are destroyed, trenches filled up, and the personnel annihilated. This was amply demonstrated on the few occasions when it was actually used at the front. The American infantry wherever they saw it tried out were wild to have more of it used. The German was apparently equally anxious to have the use stopped. It is, however, one of the things that must be reckoned with in the future. It means practically that No Man's Land in the future will be just as wide as the extreme range of these crude mortars, and here a word of caution. While efforts have been made to increase the range of these mortars, whether of the Livens or Stokes variety, no increase will be attempted that re-

Digitized by Google

duces the speed of firing or the efficiency of the projectile. In other words results depend upon large quantities of material delivered at the same instant on the point attacked, and if this can not be obtained the method is useless. For this reason these mortars will never be a competitor of the artillery. The artillery will have all that it can do to cover the field within its range, beyond that reached by the mortars.

Phosphorus in 4-inch Stokes.

Phosphorus will be used largely by gas troops, but only in whatever Stokes mortar may be finally adopted as best. The Livens projector carries too great a quantity, and being essentially a single shot gun, is not adapted to keeping

Close burst of a gas shell. The 6th Marines in the Sommedieue Sector near Verdun, April 30, 1918

up a smoke screen by slow and continued firing, or of being transported so as to keep up with the infantry. Phosphorus has also very great value for attacking personnel. Anyone who has been burned with phosphorus or has witnessed the ease with which it burns when exposed to air, wet or dry, has a most wholesome fear of it. The result of it in the war showed that the enemy machine gunners or other troops would not stand up under a bombardment of phosphorus fired from the 4-inch Stokes mortar, where each bomb contains about seven pounds.

Thermite.

Thermite is used in the same way, and while the idea of molten metal falling upon men and burning through clothing and even helmets is attractive in theory, it proved absolutely worthless on the field of battle. It was found impossible to land large enough quantities of molten metal on a given spot to cause any considerable burn. In other words, the rapid spreading out and cooling of the metal almost entirely ruined its effectiveness, except its effect on the morale. This latter, however, was considerable, as one might judge from seeing the thermite shells burst in air. For this reason thermite may find a limited use in the future.

Height of gas cloud.

A few words concerning the behavior of gas on the field of battle are in order. The height to which gas rises in a gas cloud is not known exactly, but is believed to be not much more than fifty feet, and then only at a considerable distance from the point of discharge. Moving pictures taken of gas clouds show this to be true. It is also indicated by the fact that pigeons, which are very susceptible to poisonous gas, practically always return to their cages safely when liberated in a gas cloud. This was a good deal of a mystery until it was realized that the pigeon escaped through his rising so quickly above the gas as to not get enough to affect him seriously. This of course would be expected when it is known that practically all gases successfully used were three or more times as heavy as air. Such gases rise only by slow diffusion, or when carried upwards by rising currents. The absence of these upward currents at night is one of the reasons why gas attacks are more effective at night than during the day.

Horizontal spread of gas.

Another important thing to know in regard to the behavior of the wave of gas is the horizontal spread of a cloud. If gas be emitted from a cylinder the spread in both directions from that point is from twenty to thirty degrees, or pretty closely an average of twenty-five degrees. This varies of course with the wind. The higher the wind the less the angle, though the variation is not as great as might be expected. This horizontal spread of the gas cloud was measured experimentally, and the results checked by airplane pictures taken of heavy wave attacks over the enemy line. In the latter case the path of the gas was very closely indicated by the dead vegetation, grass and bushes. This vegetation was killed and bleached so that it readily showed up in airplane photographs. The visibility of a gas cloud arises from the fact that when a large amount of liquid is suddenly evaporated, the air is cooled and moisture condensed, thereby creating a fog. With gases such as mustard and others of slight volatility, a visible cloud is not formed. For purposes of identification of points struck by shell, smoke substances are occasionally added, or a few smoke shell fired with the gas shell. As future battle fields will be dotted everywhere with smoke clouds, a point that will be touched upon more fully later, the addition of smoke

The Livens projector. The type shown is an 18 cm. German gun captured during the Second Battle of the Marne

to gas shell or the firing of smoke with gas shell will probably be the rule and not the exception.

Requirements for a successful gas.

If we succeed in finding a poisonous gas that has no odor it will be highly desirable to fire it so that it will not be visible. In that case no smoke will be used. Carbon monoxide is such a gas, but there are several very powerful reasons why it has not been used in war. First, its temperature of liquefaction at atmospheric pressure is 139° below

Digitized by Google

0 Centigrade. This means too high a pressure in the bomb or shell at ordinary temperatures. In the second place the weight of carbon monoxide is slightly less than that of air, which keeps it from rolling into depressions, dugouts and trenches, as in the case of ordinary gases, and also permits of its rather quick rise and dissipation into the surrounding atmosphere. A third reason is its comparatively low toxic value, it being in that respect only about one-fifth as poisonous as phosgene. However, as it can be breathed without any discomfort, or indeed without any knowledge that it is being breathed, and as it has some delay action, its lack of poisonous qualities would not seriously militate against its use were it not for the other two reasons given.

These considerations in regard to carbon monoxide indicate the general requirements for a successful poison gas. If non-persistent it must be quickly volatilized, or must be capable of being driven off by heat or by other means which can be readily and safely produced in the field. It must be highly poisonous, producing deaths in high concentrations, and more or less serious injuries when taken into the system in quantities as small as one-tenth of that necessary to produce death. If it has a slight delay action with no intervening discomfort, it is still better than one that produces immediate discomfort and more or less immediate action. It must be readily compressed into a liquid and remain so at ordinary temperatures, with the pressure not much above twenty-five or thirty pounds per square inch.

As a persistent gas it must be effective in extremely low concentrations, in addition to having the other qualities mentioned above.

These general characteristics concerning gases apply whether used by the Chemical Warfare Service troops, the Artillery, the Air Service, or the Infantry. In speaking of these substances being used by the Infantry it is understood that ample Chemical Warfare Service officers will be present to insure that the gases may not be turned loose when weather conditions are such that the gas might drift back and become a menace to our own troops. This is absolutely essential since no troops who have as varied duties to perform as the infantry can be sufficiently trained in the technical side of chemical warfare to know when to put it off with safety.

Use of gas by artillery.

The artillery of the future will probably fire more gas than any other branch of the Army. There are two reasons for this, first, the large number of guns now accompanying every army, and second, the long range of many of these guns. As before indicated, the gases are adaptable to various uses, and hence to guns differing both in caliber and range. The gas will be fired by practically all guns—from the 75 millimeter to the very largest in use. It is even possible that if the guns smaller than the 75 millimeter become generally useful certain gases will be fired by them.

Efficiency of artillery gas shell.

It is well to remember in the beginning that all artillery shell so far designed and used, contain only about ten per cent by weight of gas. It is hoped that gas shell may be so designed later that a somewhat greater proportion of the total weight of the shell will be gas. This is very desirable for reasons of efficiency. The bombs used by C. W. S. troops contain nearly fifty per cent by weight of gas, and hence are nearly five times as efficient as artillery shell within the limit of range of these bombs. This fact alone is enough to warrant the use of gas troops to their full maximum capacity in order that the artillery may not be required to fire gas at the ranges covered by these troops.

Guns firing persistent and non-persistent gases.

Considering the firing of non-persistent and persistent gases, it may be said generally that persistent gases will be fired only by the medium calibers which are available in large numbers. In fact, the firing of non-persistent gases will be confined mainly to the 6-inch or 155-millimeter gun.

As our Army was organized in France, and as it is organized at present, the number of 155-millimeter guns will be greater than all others put together, except the 75-millimeters. In order that a non-persistent gas may be effective a high concentration must be built up very quickly. This necessitates the use of the largest caliber shell that are available in large numbers. Of course, a certain percentage of the gas shell of other calibers may consist of non-persistent gases in order to help out the 155-millimeter gun. This is in accordance with the present program for loading gas shell.

Few ideally persistent or non-persistent gases.

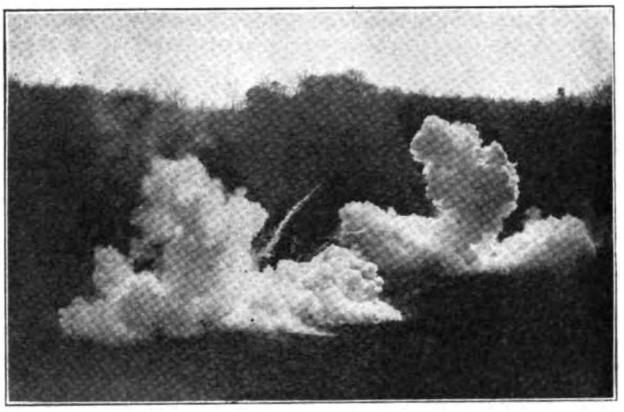
Naturally there will be very few gases that are ideally non-persistent or ideally persistent. The groups will merge into one another. Those on the border line will be arbitrarily assigned to one group or the other. It might be said definitely, however, that a gas which will linger more than six or eight hours under any conditions, except great cold, will not be considered non-persistent. For reasons of efficiency and economy persistent gases will not be chosen unless they will persist under ordinary conditions for two or three days or more. Accordingly, a gas which would persist for a day would have to be extraordinarily useful to lead to its adoption.

Firing non-persistent gases.

Of the non-persistent gases phosgene, a chemical compound of carbon monoxide and chlorine, is the one most used at present. Furthermore, so far as can now be foreseen, it will continue to be the non-persistent gas most used. It volatizes very quickly upon the bursting of the shell. Accordingly, in order that the shell fired at the beginning of a gas "shoot," as they are generally referred to in the field, shall still be effective when the last shell are fired, it is necessary that the whole number be fired within two to five minutes. The temperature and velocity of the wind both affect this. If it be in a dead calm, the time may be considerably extended; if in a considerable wind, it must be shortened. Another important consideration requiring the rapid firing of non-persistent gases is the fact that nearly all masks thoroughly protect against phosgene and similar gases. It is accordingly necessary to take the enemy unawares and gas him before he can adjust his mask; otherwise, practically no harm will result. From the considerations previously mentioned, these "gas shoots" are usually made at night when, as before stated, carelessness, sleepiness and the resulting confusion of battle conditions always insure more casualties than in the daytime.

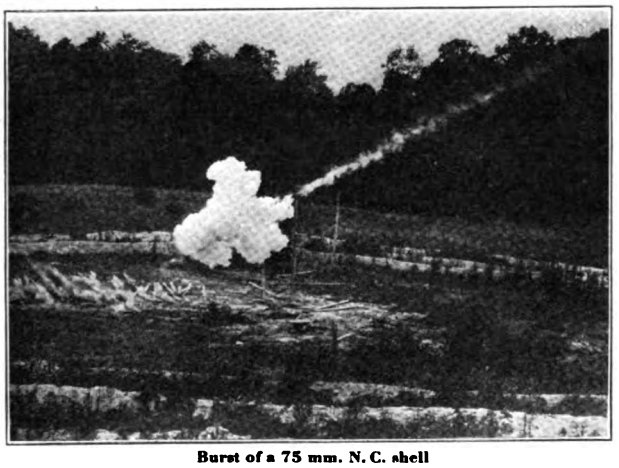
Firing persistent gases.

The persistent gases will be fired by all caliber guns, but to a less extent by the 155-millimeter than the other calibers. Persistent gases must be sufficiently effective in low concentrations to act more or less alone. If it be desirable to fill an atmosphere over a given area with mustard gas, the firing may extend for two or three, or even five or six, hours and all shell still act together. The same is true of brombenzylcyanide, the tear gas. This, then, permits the minimum number of guns to be used in firing these persistent gases. Inasmuch as they persist and force the wear-



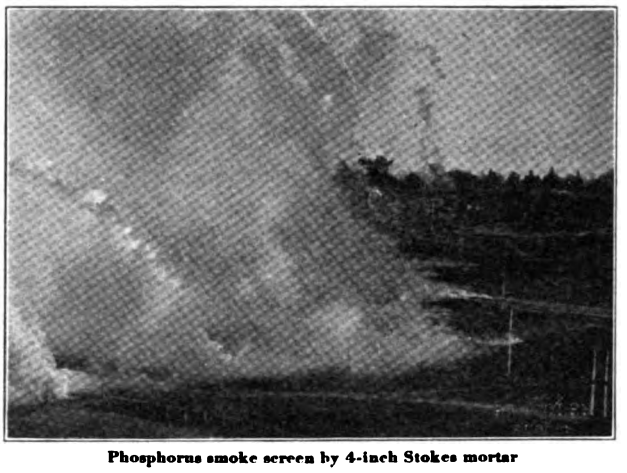
Digitized by Google

ing of the mask, they are available for use in long-range, large caliber guns for interdiction firing on cross-roads, in villages, and on woods that afford hiding places, as well as other similar concentration points.

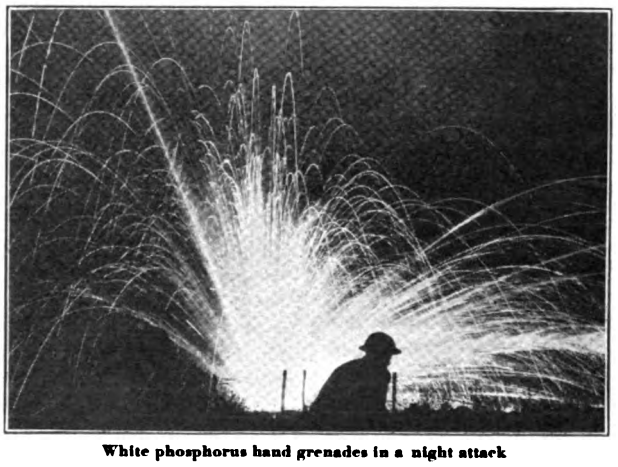


Firing irritant gases

The irritant gases will be fired by the various caliber guns in the same manner as the persistent and non-persistent gases. We will have non-persistent and persistent irritant gases. They are, however, considered as a group because they are used for harassing purposes, due to their efficiency in forcing the wearing of the mask.



Before the signing of the armistice, the General Staff, A. E. F., had authorized, beginning January 1, 1919, the filling of 25 per cent of all shell with Chemical Warfare Service materials. The interpretation there given to shell was that it included both shrapnel and high explosive.



Burst of 4-inch Stokes mortar bomb filled with N. C. (20% gas and 80% smoke)

Burst of a 75 mm. N. C. shell

Phosphorus smoke screen by 4-inch Stokes mortar

White phosphorus hand grenades in a night attack

Of the field guns in use, the 75-millimeter will be best, up to the limit of its range, for persistent gas such as mustard gas, and the tear gas, brombenzyleyanide. A considerable number, however, were filled with non-persistent gases and will probably continue to be so, since, due to the very large number of 75 millimeter guns available, they can be used to add greatly at times to the amount of non-persistent gas that can be fired upon a given point.

Use of gas by the Air Service.

No gas was used by aeroplanes in the World War. Many rumors were spread during the latter part of the war to the effect that the Germans had dropped gas here or there from aeroplanes. Every such report reaching the Chemical Warfare Service Headquarters was run down and in every case was found to be incorrect. However, there was absolutely no reason for not so using gas, except that the German was afraid. In the early days of the use of gas he did not have enough gas, nor had he developed the use of aeroplanes to the point where it would have seemed advisable. When, however, he had the aeroplanes the war had not only begun to go against him, but he had become particularly fearful of gas and of aeroplane bombing.

It does not seem to be generally known, but it is a fact, that after three or four months' propaganda the enemy made a direct appeal to the Allies to stop the use of gas sometime during the month of March, 1918. This propaganda took the form of an appeal by a Professor of Chemistry who had access to Switzerland, to prevent the annihilation of the Allied forces by a German gas that was to make its appearance in 1918. This German professor claimed that, while wishing the Germans to win the war, he had too much human sympathy to desire to see the slaughter that would be caused by the use of the new gas. The Allies believed that this was simply an expression of fear and that the German had no such gas. The Germans were accordingly informed that the Allies would not then give up the use of gas. Later events proved these conclusions to be absolutely correct. The German evidently felt

Digitized by Google

that the manufacturing possibilities of the Allies' gas would put them in a more predominant position with gas than with anything else. In that he was entirely correct.

The use of gas by aeroplanes will not differ from its use in artillery or by Chemical Warfare Service troops. Non-persistent gases may be dropped on the field of battle, upon concentration points, in rest areas, or other troop encampments to produce immediate casualties. Persistent gases will be dropped particularly around cross-roads, railroad yards, concentration points and encampments that can not be reached by the artillery.

The aviation gas bomb will be highly efficient inasmuch as it has to be only strong enough to withstand the low pressure of the gas and ordinary handling, whereas artillery shell must be strong enough to withstand the shock of discharge in the gun.

The use of C. W. S. materials by the Infantry.

The use of Chemical Warfare Service materials by the infantry will be limited to fool-proof and readily portable containers of gas.

It will be at once argued that the infantry is already overloaded. That is true, but in the future, as in the past, the infantryman will increase or decrease his load of a given material just as its efficiency warrants. If he finds that gas will get casualties and help him win victories more readily than an equal weight of any other material, he will carry gas. A study of the articles of equipment abandoned by 10,000 stragglers in the British Army picked up during the great German drive towards Amiens in March, 1918, illustrates this very clearly. As I recall, more than 6,000 stragglers had discarded their rifles. The helmets were thrown away to a somewhat less extent, but the gas mask had been thrown away by only 800 out of the 10,000. Now the gas mask is not a particularly easy thing to carry, nor was the English type comfortable to wear, but the English soldier had learned that in a gas attack he had no chance whatever of escape if his gas mask failed him. Accordingly, he hung on to the gas mask after he had discarded nearly everything else in his possession. The same thing will be true of any other gas equipment if it proves its worth.

Smoke and incendiary materials.

The use of smoke or incendiary materials is not dependent upon weather conditions to anything near the extent that gas is. Second, the smokes not being poisonous, are not a danger to our own troops, although they may hamper movements and add to the difficulty of taking a position if used improperly. Of the two classes of materials, smoke and incendiary, smoke materials may be said to be at least a thousand times as important as the incendiary materials. A material that will burst into flame when a shell is opened or that will scatter balls of burning fire appeals to the popular imagination, and yet actual results achieved by such materials on the field of battle have been almost nil. About the only results worth while achieved by incendiary materials have been in occasionally firing ammunition dumps and more frequently, setting fire to warehouses and other storage places. This will undoubtedly continue in the future.

Flame thrower.

Of the incendiary materials the least valuable is the flame thrower. It is mentioned to forestall the question. Even the German, who invented it and who, during the two years of trench warfare had full opportunity for developing its use, finally came to using it largely as a means of executing people that he did not want to shoot himself. Men falling in that class were equipped with flame throwers and sent over the top. The German knew, as did the Allies, that each man with a flame thrower became a target for every rifle and machine gun nearby. The flame thrower is very quickly exhausted when the one equipped with it has no means of offensive action, and in addition, is saddled with a heavy load hampering all movements, whether to escape or to advance.

Inflammable materials.

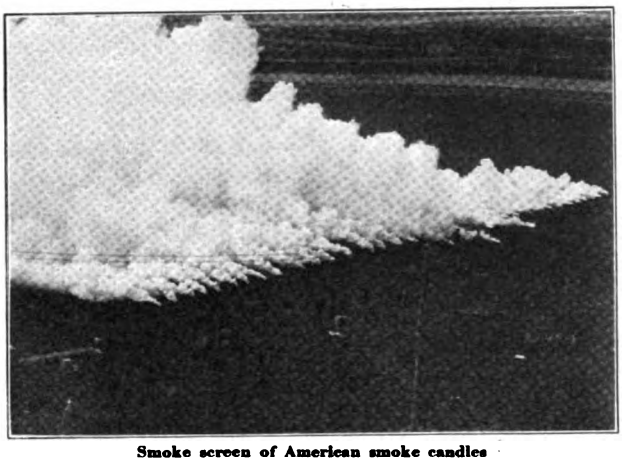
There will probably be some use for materials such as metallic sodium that will burst into flame and burn when exposed to the air, though white phosphorus is probably equal, and in most cases vastly superior, to anything else so far suggested. Phosphorus, while it burns with an unquenchable flame when exposed to the air, whether wet or dry, has comparatively little value as an incendiary material. It is, however, of great value for screening purposes, and for use against the enemy's troops. The German did not use phosphorus simply because he did not have it, just as he did not use helium in his observation balloons.

The value of phosphorus was just beginning to be realized when the Americans entered the war, while its full value was not appreciated even by the American troops when the war closed.

The work of the First Gas Regiment with phosphorus against machine gun nests proved how valuable it is. It proved also its tremendous value as a screen.

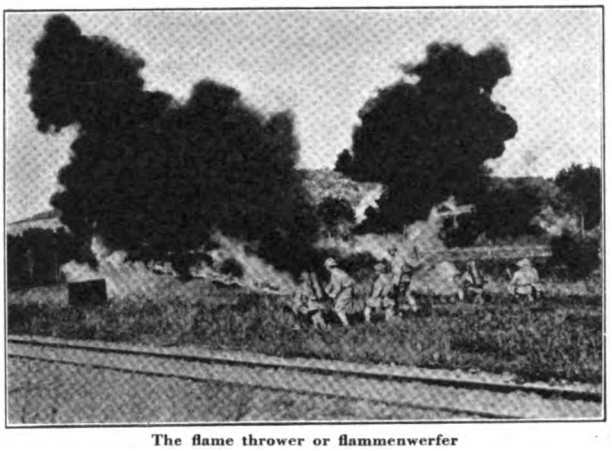
The Chemical Warfare Service was prepared to fill a great number of artillery shell with phosphorus, but due to the failure of our shell program, phosphorus was not used by American artillery to any appreciable extent.

Smoke used by everyone.



Smoke will be used by every fighting arm of the service in practically every battle, both by day and by night. Anyone who has tried to shoot at a target that was just beginning to be obscured by a fog, will recognize the difficulty of hitting anything by firing through an impenetrable smoke screen. It is simply shooting in the dark. Future battles will witness smoke formed by smoke candles that are kept at the trenches or carried by the troops, by smoke from bursting artillery shell and rifle grenades, from aeroplane bombs and possibly even from what is known as the smoke knapsack. This last is a very efficient apparatus, with two cylinders containing different substances which are brought together near the nozzle. It produces a very dense white smoke and very economically, but will probably not be much used. This is because, notwithstanding its efficiency, the knapsack can not be projected to a distance, that is, the smoke screen is generated on the person carrying the knapsack. On the other hand the great value of phosphorus is that it can be fired to considerable distances in rifle grenades or artillery shell, and dropped from aviation bombs. The smoke screen is thus established in front of the object it is desired to cut off, whether it be a battery of artillery, an advancing wave of infantry, or a lookout station. Thus smoke, for screening purposes alone, will be used to a tremendous extent. It will also be used in conjunction with gas.

Due to the smoky appearance of an ordinary gas cloud, no one on the field of battle in the future will ever be certain that any given smoke cloud is not also a poisonous cloud until he has actually tested it. And there lies an opportunity for the most intense study and for the greatest use of the proverbial American ingenuity that war has ever furnished.



With the variations that can be played with smoke con-

Digitized by Google

taining gas, or not containing gas, with smoke hurled long distances by the artillery or dropped from aeroplanes, the possibilities indeed are unlimited. Every officer will need to study the possibilities of smoke, both in its use against him and in his use of it against the enemy. He can probably save more casualties among his own troops by skilful use of the smoke than by any other one thing at his command. On the other hand, the unskilful use of the smoke on the part of one side in a battle may lead to very great casualties in proportion to those of the enemy.

Smoke screen of American smoke candles

The flame thrower or flammenwerfer

Protection by smoke

Smoke in the future will be the greatest protective device available to the soldier. It shuts out not only the view in daylight, but the searching of ground at night by searchlights, by star bombs or other means for illuminating the battlefield. It has already been used extensively by the Navy and undoubtedly will be used far more extensively in the future.

Too much secrecy

It is realized that some of these facts have not been given much publicity. In saying this we are not unmindful that all probable enemies of the next score of years know these things very likely as well as we do. We believe that too great attempts at secrecy only hamper our own movements and do not deceive the enemy, and hence the Chemical Warfare Service is adopting the policy of letting the Army know what it can do, what it proposes to do in the future, and the lines of development along which it is working. We are giving great attention to the subject of smoke and will continue, believing that smoke materials will in the future be of equal importance with either of the two great tactical groups of gases.

Simplicity.

Simplicity should be the keynote in all military paraphernalia and operations. Gas is effective almost in direct proportion to the quantities used. By keeping the bombs, the gas, the shells, or other containers of gas, of as simple construction as possible and with as simple rules for use as are efficient, we will get the quantities that mean success. And this brings up the subject of marking of shells.

Shell markings

Modern artillery shell have distinctive colors for high explosive, for shrapnel, for incendiary materials, and for gases. A grayish color has been adopted as the general color of the paint on all gas shells, bombs and cylinders. In addition, a system of colored bands has been adopted. These bands are white to indicate poisonous non-persistent substances, and red, persistent. Yellow is used to indicate smoke. With any given combination of red and white and yellow bands, the artilleryman at the front can tell, at a glance, whether the gas is non-persistent or whether it is persistent, and also whether or not it contains smoke. There will be secondary markings on each shell which, to the trained Chemical Warfare Service officer, will indicate the particular gas or gases in the shell. These markings, however, will be inconspicuous and no attempt will be made to give the information to the soldier or even to the average officer firing gas.

These secondary markings are for the purpose of enabling the Chemical Warfare Service officers in charge to use certain gases for particular uses in those comparatively rare cases when sufficient gas is on hand and sufficient time available to enable such a choice to be made.

Conclusion.

Simplicity of machinery and materials used at the front is worth the study of every man having to do with military operations, whether in research, design, manufacturing or the actual handling of troops. No soldier under the stress and noise of modern battle can be expected to keep in mind more than two or three basic principles, and any attempt to get him to do otherwise will simply lead to confusion and inefficiency.

Platinum Reserve.—In response to a request from the Assistant Secretary of War for an expression of the attitude of the Ordnance Department in the matter of maintaining a platinum reserve, he has been advised that after a thorough study of the conditions in this country covering the reserve from which platinum can be obtained in times of emergency and the needs of the War Department, a reservation of 25,000 ounces of platinum has been authorized. This reserve is to be stored in the New York Assay Office, subject to call by the proper officers of the War Department. Approximately 20,000 ounces of this reserve at the time of the signing of the armistice was in the form of "contact mass," but in order to properly safeguard this material the mass has been or is being treated for the recovery of the metallic platinum for transfer, as stated above, to the New York Assay Office. This has been effected at a very moderate cost.

Methods of Placing Concrete Under Water

In early subaqueous concrete work, the concrete was deposited directly under the water by means of a box with a movable bottom, or placed in bags. Of late years three other methods have been used: The tensile or spout system, the ram system and the gravity flow system—the last two were employed on work on the Lachine Canal, New Montreal, Canada. The tremie system has been used on the Detroit tunnel and other work in America.

Ram System.—The ram system is the name given to first method used in the relining work on the canal, but it was used only on thin walls, or where the narrow space between the back wall and the face mold or form might cause the concrete to jam and thus prevent its flow. In wider spaces the gravity flow system was adopted.

The slope walls of the canal had to be rebuilt or faced, without interfering with navigation. A system of large wooden molds, 100 feet by 22 feet, and secured at from 1½ to 2 feet from the slope walls was adopted. The mixing plant, which was operated on scows, was provided with a movable oblique arm, at the end of which was built an iron box, with movable top and bottom. This arm, called the ram, carried the concrete down, and at the required depth the box was opened by a steel cable and the concrete deposited. At times the ram was not operated, but kept near the top and used as a chute, the concrete being deposited in such a manner that it took a natural slope and pushed itself forward.

Gravity Flow System.—Figure 1 is an illustration of the gravity flow method. The concrete is confined both back and front by molds, or by a mold and a previously built wall or embankment, and at the starting end by a bulkhead.

Work is started in one corner, the position of the mixer being indicated by the letter A in the diagram. The various deposits of concrete take a decided shape as indicated by the numerals 1, 2, 3, 4. After the point 4 is reached the concrete is dumped on the top and pushed forward with little effort, by men with light wooden scrapers or a tool in the form of a rake. It then flows down to take the position indicated by 5A, which represents the last material placed by the mixer at A, before it is moved forward to its second position at B—and so on.

This method has been used to build a wall, 9 feet wide at the bottom, 4 feet at the top and 18 feet deep, the structure being in water 17 feet deep, flowing at 6 or 7 miles per hour. There is nothing difficult about it, everything depending upon the quality of the concrete, and careful supervision.

The chief advantage of this method lies in the fact that the concrete flows forward in one direction with its narrowest face for the wash surface; this face is the oblique cross-section shown by the plane of the angle of repose.

Methods Employed on Lachine Dam.—Figure 2 is a sketch of the method of carrying out the underwater reconstruction of the Lachine Dam, in which the "gravity flow method" was employed. The original dam was built of cribwork and filled with heavy stone, but the repeated action of the ice flows and natural water made it quite unstable. With a head of about 1 foot there was a flow of water through the dam, portions of which were undermined. The main difficulty was to secure the big 100-foot molds in place, and to stop this flow; it was also necessary to control the current formed by the inward flow of the water toward the mouth of the canal.

Figure 2 shows a big mold in place, held by inner and outer steel cables, with posts as struts; this method was also used during the construction of some of the 5 miles of walls previously built.

Before the molds were placed a dredge cleaned out the site, and the foundation was further dredged out, partially by machine and finally by the divers. Upstream and downstream bulkheads were used as illustrated in Figure 1. In several places there was difficulty in stopping the flow of water through the timbers of the dam. Sheets of 11 ounce canvas, 24 feet wide, sewed up in lengths of about 60 feet, were placed against the face of the old dam and secured at the top and bottom; in this manner the water was made quite still, and when the concrete was being placed no cement was washed through. No difficulty was experienced in holding the molds, and no slides occurred. As a rule these dangers lie in bringing the concrete too high on the first day's work. It is well to fill only part way and permit this to set, at least over night, before continuing.

When once a sufficient length is finished, such a section, A in Figure 1, and set hard, the concreting can proceed continuously and will flow forward without any trouble.

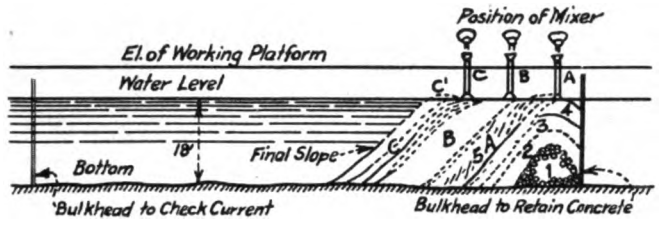
Precautions in Subaqueous Concrete Work.—In laying concrete under water the points to be noted are:

The stiffness and rigidity of the forms and the bracing of same; cracks in the molds will cause wash lines.

If working in a current begin at the downstream end and block the upper end of a bulkhead to prevent any wash of the water.

Do not commence operations too soon in the year when the water is ice cold, or continue too late in the fall, for the same reason.

Don't remove the molds too early; although in favorable conditions and with good concrete, five days is often not too soon. Take longer time if vessels are apt to bump against the work shortly after completion.



All materials should be the best of their kind. A good quick setting cement should be selected, but only after it has stood satisfactory setting tests in the coldest temperature at which it is going to be used.

A mechanical batch mixer is necessary on all work of this kind, as a constant flow of concrete should be kept up. The concrete should first be emptied into a receiver placed below the mixer from which it can be allowed to flow, as required—the flow being regulated by an automatic gate. A drum mixer is preferable, and each batch of concrete should be turned for at least two minutes at the regular speed of the drum before it is deposited into the receiver. From 180 to 200 cubic yards in 10 hours may be considered a maximum day's work.

Digitized by Google

Unless the molds are secured very solidly and their stability is beyond doubt, the depth of any one layer of concrete should not be over 10 or 15 feet, although it is always best to come up to water level.

Continuous mixers with automatic measuring devices have no place on an underwater concrete job. Every batch must be up to the standard and be able to stand the inspection of

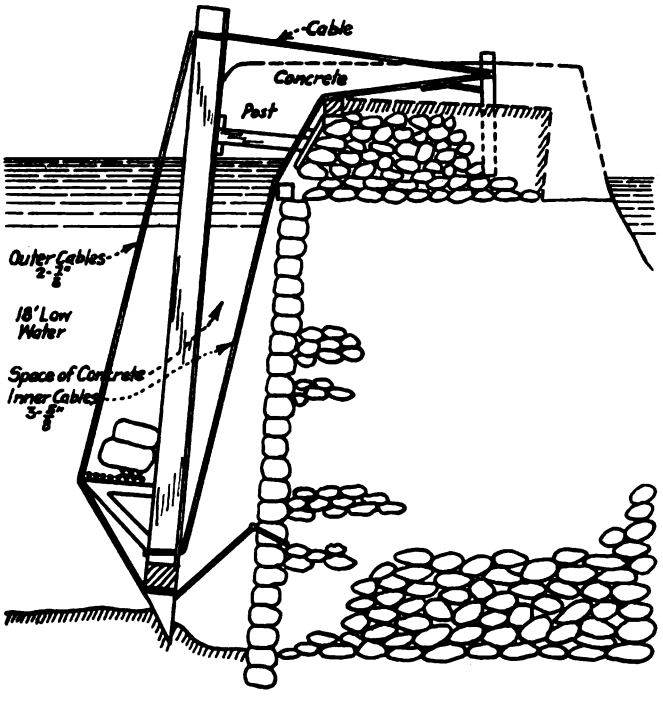


Fig. 1 (upper); Fig. 2 (lower).

an experienced man who can readily detect an off-mix by its color and consistency.

The proportions of cement, sand, and ballast should be within the limits of a 1 to 2 or 2½ of cement and sand, to 5 parts of stone.

The mix should be what is called putty, and care must be taken to insure sufficient water.

On most underwater work it is necessary to have a good diver with capable assistants and an efficient diving outfit.

Subaqueous or underwater concrete is as easy and as sure as any work done in the dry, but it requires, as in all engineering work, care, more care, and still more care. Without that, it will fail.—*Eng. and Cont.*

Another Champion of the Field Lithograph Equipment

It was with some concern that I read the array of heavyweight opinion against the continuance of the lithograph set in the Engineer Regimental equipment expressed in the article and its discussions published in the January-February issue under the title, "Engineer Duties in the Field." Colonel Boggs' defense of this equipment in the March-April number encourages me to step forward as one of its champions.

Throughout the service of the 318th Engineers, 6th Division, in France and in Germany, the topographical section was at all times a busy and useful unit. It contained expert draftsmen and lithographers. At no time did the G2 section at Division Headquarters have either. The work there produced always made that fact evident.

Particularly during the winter of 1918-19 did this equipment justify itself by permitting a task, otherwise difficult, to be performed with ease and with credit. The condition of the roads made it necessary to work the engineer regiment and some 2,000 other troops of the division on their repair. It became evident at the start that work was only one-half the game and that traffic regulation was its complement. To appeal to G1 to properly instruct his M. P.'s and to request G2 to prepare maps would hardly have made the Division Engineer popular.

A map prepared by the topographical section, showing the condition of all roads in the area, clearly indicating by heavy lines those fit for motor-truck traffic and by arrows the proper routing of that traffic, and bearing a legend containing traffic rules, was submitted to the Division Commander with recommendations that it be issued to all motor-truck drivers and chauffeurs and to all M. P.'s. A presentable map, produced in quantity, giving graphically orders that even an M. P. could understand, was gratifyingly acceptable to G1. Its issue was ordered. The results in improving road conditions were immediate. It actually oriented the M. P.'s and transferred truck drivers, never properly provided with maps from the "lost" to the "found" column. Its general usefulness as an area map caused frequent requests to come from various regimental headquarters for additional copies. Thus the Division Engineer actually controlled traffic (though no one knew it, and he kept it a secret, lest that satisfying equilibrium of staff perfection be disturbed).

Similar maps covering two different areas in Germany were issued later with the same real results.

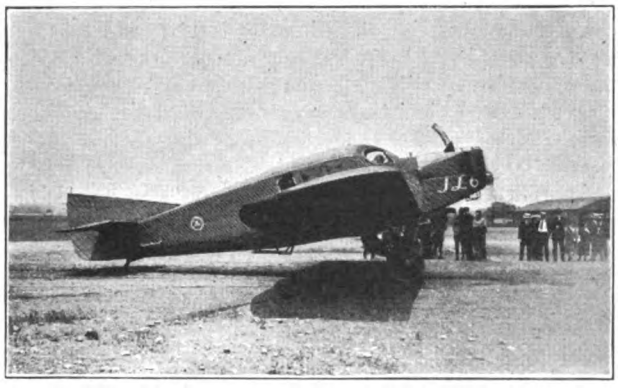
G1 was gratified.

G-3 early became discouraged with the hectograph prints produced by the G-2 section. The Engineer topographic section produced contour maneuver maps of creditable appearance in sufficient quantity to cause a rare and encouraging diffusion of intelligence.

G-3 beamed and became our friend.

Reports were often demanded for which proper forms were not available. The lithograph outfit provided our own needs and occasionally the needs of others, bringing that credit in their submission that other processes failed to secure.

For the divisional horseshow and football games, artistic posters in three and four colors were produced. These were placed in all the towns and on all motor trucks, advertising the event and indirectly the Engineer regiment.



Later the Corps Commander made a personal request that a similar poster be designed and printed by the 318th Engineers for the corps horseshow. In a corps of four divisions the lithographic equipment normally furnished the engineer regiment was the best means of printing that a corps commander had at his call.

Before the war this equipment in the field was considered essential. Since that time our means of transport have greatly improved. During the last war the G-2 section of a division did not have equal equipment or the personnel to properly use it. And yet when a motor truck instead of an escort wagon provides a generous corner for an equipment really not very large, and after having suffered two long years from an overdose of illegible mimeographs and blurred hectographs, its abandonment is considered.

Trabajemos! Let us not willingly reduce our field of usefulness.—C. P. Gross, Captain, Corps of Engineers.

All-metal aeroplane.—The J. Larsen all-metal monoplane is a new departure in aircraft construction. It is both fire and weather proof and carries four passengers in addition to crew of two. The wings and fuselage are of "duralumi-

num," an alloy. The wings are cantilevered from the fuselage, having no external struts or braces. Each wing contains a gas tank of 35 gallons capacity. This is a step forward in standardization. The machine will be developed in various sizes, both as an aeroplane and hydroplane.

On June 12 Army officers took part in a test of two of these machines, with the inventor, J. Larsen. The flight was from Bolling Field, Washington, to Prospect Park, Long Island, about 250 miles. During the flights the passengers changed seats at will, ate lunch and wrote letters.

Handbook for the automatic rifle.—The handbook for the automatic rifle was prepared at the Infantry School, Camp Benning, Georgia. This handbook covers only description, mechanism, nomenclature, operation and care of the Browning Automatic Rifle. The manuscript was referred to The Adjutant General of the Army for printing.

The Infantry School, Camp Benning, Georgia, is also at present at work on another manual entitled "Automatic Rifle Marksmanship." This will cover the technique and training methods of shooting with the automatic rifle and will be for the automatic rifle what the "Small Arms Firing Manual" was for the rifle. It is expected that this manuscript will be received by the General Staff for consideration in about three weeks.

It is contemplated that the tactical handling of the automatic rifle will be considered in conjunction with the next revision of the Infantry Drill Regulations, which revision, however, is not contemplated until the lessons of the World War have been thoroughly studied and digested.

From an article in the *Proceedings of the U. S. Naval Institute,* by Rear Admiral Fiske, we cull the following gems of thought.

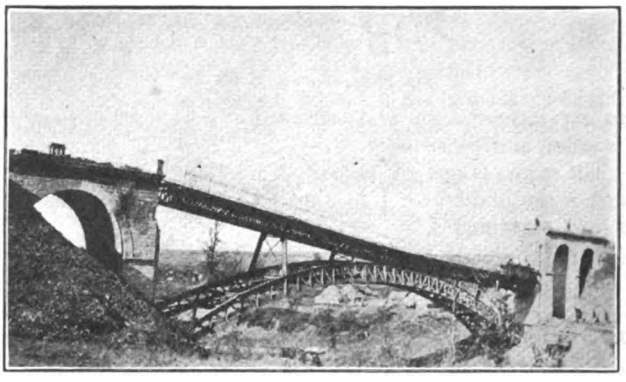
Not until the great war was the advisability of utilizing the inventor in war recognized. It had been feared, and with reason, that we might trust too much to invention, and too little to adequate preparation.

Inventions are not limited to mechanical appliances. Every great idea is an invention, every plan with which a resourceful man meets an emergency is an invention.

The most important inventions were the weapons with which primitive man conquered nature, for thus alone was man able to progress along the pathway of civilization.

Each of the victories of Alexander, Cæsar, Napoleon, was a display of inventive genius of the highest order.

Civilization was created and has progressed by invention. The most important single agency in maintaining civilization has been war. By war the wild beasts were conquered, by war the barbarians who sought to destroy civilization were held in check; and by war these forces of barbarism must continually be held in check now and henceforth.



The other agencies of civilization, religion, morality, industry, etc., have likewise progressed by invention.

Accordingly, invention and war are the most important constructive forces of civilization.

The average mind cannot have a thorough grasp of details and general principles at the same time. A different mentality is required for each. The man who showed the greatest capacity for both was Napoleon.

New small-arms projectiles.—In an endeavor to design a small-arms ammunition for machine-gun use which would give an effective range of 3,500 meters, a large number of different types have been tested at Miami and Daytona by the Small Arms Ballistic Station. One type, on which the greatest amount of firing has been done is a caliber .30 boat-tail bullet. Tests have been made with this type of bullet at velocities of 2,400, 2,500 and 2,600 feet per second. The bullet with 2,600 foot-muzzle velocity gives an extremely long range, possible in excess of 4,500 meters. It has been tested to 4,300. This bullet has a slightly flatter trajectory than the regular service bullet up to 1,000 yards, and the trajectory is much flatter than the service bullet at ranges beyond that. This can all be considered to be in the experimental state, as no decision has been reached to adopt any of the various types of ammunition being tested.

The steel arch bridge carrying the narrow-gauge railway over the ravine near Flirey, France, in the St. Mihiel Sector. It was designed by the French in 1914 by cutting

the arch rings and truss near the north abutment. The span of this bridge was 64 meters.

Canadian Power Co. to build hydro-electric plant.—The Bridge River Power Co., Ltd., of Vancouver, B. C., is to develop hydro-electric power at the Bridge River power site. A total of 400,000 continuous hp. will be available when the site is fully developed and power in blocks of from 5,000 kw. up will be available within two years' time. Power will be sold as low as $16 per hp. year, depending on whether the plant consuming the power is located at the power house or at a distance, also on the power and load factors.

Summer Camp of Instruction for the Engineer Reserve Officers' Training Corps

at Camp Humphreys, Virginia

By

W. D. Styer

Captain, Corps of Engineers

[*Note.*—We present with great pleasure Capt. Styer's entertaining article on the summer instruction camp of the R. O. T. C., because we believe that it is of great interest, not alone to engineering students in every college or university in our land, but also to the faculties of those institutions, and to the engineering profession at large. This first camp of 1920 promises to be an epoch making event. It promises to fill one of the great needs of the profession, to-wit: more *practical outdoor* instruction in engineering for the undergraduates of technical colleges. Its vast possibilities of usefulness as a means of promoting the national defense are well set forth by the author and will be appreciated by every patriotic engineer.

But from a purely civil point of view these camps will justify themselves, and should have the support and co-operation of the colleges and of the engineering profession. In the first place, viewed merely as a refreshing and generally beneficial summer outing, the camp was a great success. It was thoroughly enjoyed by all the participants, and it is believed that all of them will wish to come again, and that every young man who hears of it will wish to attend future camps. Men of wealth spend millions of dollars to send their sons to summer camps. Here is a camp, providing facilities far better than private capital can furnish, which all boys of the right kind may attend without cost. The camp will be popular, and that is the first condition precedent to its success. It combines in the most effective manner the delights of a summer outing in the country with the benefits of practical instruction in engineering.

The disciplinary training, wisely and tactfully applied, will be of incalculable benefit to these young men in all all their future careers, whether purely the careers of peace, or whether including service to their country in case of war.

The possibilities of usefulness of the R. O. T. C. camp are almost unlimited. It is hoped that the scheme may grow and expand until every engineering undergraduate in America may attend one or more of these summer outings, which will promote his physical health and vigor, bring him in contact with a lot of fine, clean young men from all parts of the country, give him useful practical instruction in his chosen profession, make him a better and more useful citizen in time of peace and a better defender of his country in case of war.—Ed.]

IN these days, when nations at war put forth their entire strength in the conflict, there is only one effective scheme of national preparedness, which is involved in the conception of "a nation in arms." This scheme contemplates a regular army of moderate size and a trained reserve of officers and men in civil life, available in case of emergency. To provide a trained reserve of men universal military training is necessary. This we have not, and so, in the next war as in all previous wars, we will take the field with green troops, who will suffer for the nation's neglect.

Universal training alone, however, would not supply the officers necessary to command our troops, for which additional measures are required. As the number of officers is small compared to the number of men (about 1 to 20), the problem of training officers, while more difficult, is of smaller proportions.

Our existing laws provide two means of obtaining at least a few of the officers that would be needed. One of these is the Officers' Reserve Corps, with which all readers of this journal are familiar. The other is the Reserve Officers' Training Corps. The latter is nothing more than an effort to systematize, control and turn to the national advantage the military training now given to students at many educational institutions. In such colleges as desire it the government establishes a military course, with army officers and noncommissioned officers detailed as instructors. Units are organized amongst the students corresponding to the various arms of the service. At a number of engineering colleges engineer units have been establishd.

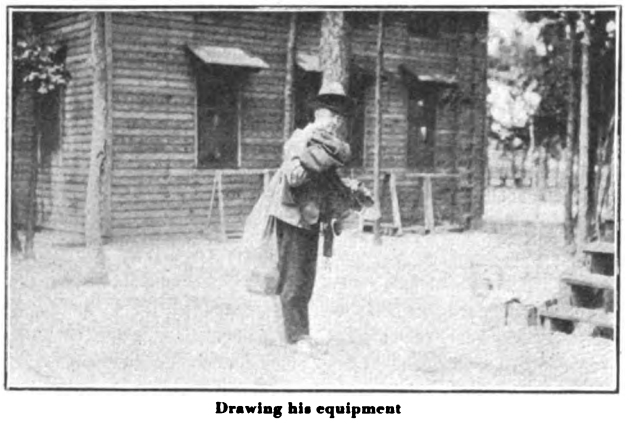
The chief disadvantage of this training, or the greatest difficulty under which it labors, is that, because of the limited time and facilities available, the instruction, with the exception of infantry drill, is too largely theoretical and too little practical. This is especially true of engineering instruction. The average engineering college has very inadequate facilities for practical instruction in engineering. This is a great disadvantage inasmuch as engineering, both civil and military, is a practical profession. The average engineering graduate, lacking proper practical instruction, can hardly be said to be an engineer. He does not become such until he has gained experience, and his early experiences are often so narrow and one-sided that it may be many years before he becomes a competent, practical, all-around engineer, in whatever field he enters.

The Reserve Officers' Training Corps, with the co-operation and support of the college authorities, can go far in remedying this deficiency. It has been frequently pointed out, and will be fully realized by everyone who took part in the late war, that the practical problems of civil and military engineering are not essentially different in their nature. Training or experience in either fits the engineer for both. The problems of the military engineer are the same as those of the civil engineer, except that they are encountered under more trying conditions, and therefore demand more initiative and resourcefulness.

The "applicatory system" of instruction, which means the actual solution of carefully prepared practical problems, has long been utilized in military training, but it is quite as applicable to any other practical calling.

In order to supplement the theoretical instruction at colleges with practical work, training camps for the R.O.T.C. are to be held each summer. Here the students from various institutions are assembled on a government reservation where the conditions, including available instructors, terrain, plant and equipment are far better than they can possibly be at any college. The practical instruction at the camp vitalizes the theoretical instruction at the college by giving the student a training which will be quite as valuable in his

Digitized by Google



future civil industrial career as it would be should he be called upon to lead the armed forces of the nation in the event of war.

The value of such practical instruction during summer vacation periods has been long recognized by engineering colleges, but their facilities and resources do not enable them to provide a course at all comparable to that which the resources of the Federal Government can provide. Such instruction has been too often limited to surveying and visits to industrial plants or engineering works, etc.

The engineer units of the Reserve Officers' Training Corps were assembled this year at Camp A. A. Humphreys, Virginia, for six weeks of summer camp instruction. This camp site is located at the Engineer School, U. S. Army, on Belvoir Peninsula, about 15 miles south of Washington, D. C., and presents a particularly suitable location for a camp of this kind, due to the excellent facilities it offers for training in practically every phase of civil and military engineering.

The students undergoing instruction numbered about 230 and represented the following educational institutions throughout the country:

Alabama Polytechnic Institute, University of Alabama, Colorado School of Mines, University of Illinois, Iowa State College, Massachusetts Institute of Technology, Missouri School of Mines, State University of Iowa, Oregon Agricultural College, University of Tennessee, California Institute of Technology, Virginia Military Institute, Virginia Polytechnic Institute, University of West Virginia and Yale University.

Drawing his equipment

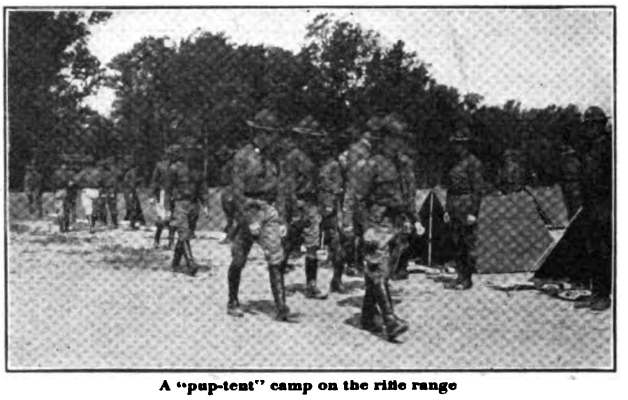
Upon reporting, students were assigned to companies according to the number of years of military training with which each was credited. "A" Company, the senior company, is composed of men who have had three years of military training; "B" Company, of those who have had two years, and "C" Company, those who have had but one year.

Attendance at this camp is entirely voluntary, and it was fully realized that if it was to accomplish its purpose it must be made interesting and pleasant to the students. It should be such that every boy who attends camp will wish to come again, and all of his friends to whom he tells his experiences will also wish to come. The government possesses ample machinery with which to accomplish this purpose, and no millionaire's summer camp for boys can offer anything approaching the facilities which are provided free of charge at Camp Humphreys. The camp is situated on the water, where every form of water sport may be enjoyed. There is a large theater where lectures, moving pictures and other entertainments are provided. Excellent reading rooms are available, with a "canteen" where refreshments are obtainable. There is an excellent dance hall, and Washington is able and willing to furnish all the young ladies required to make social functions a great success. There are stables with plenty of animals for those desiring to ride. Hospital facilities are provided with medical officers in attendance.

Every effort has been made to make the living conditions of the students at camp healthful, attractive and comfortable. Messing arrangements are handled by hired cooks and waiters, and each company has an excellent mess. A minimum amount of fatigue duty is required of the students in order that a maximum amount of time may be devoted to instruction and healthful recreation. Facilities are provided and time is set aside for athletics, recreation and amusements. Drills end promptly at 4 p. m. daily, except two days a week when parade is held. No night study is required. Week-end passes are granted from immediately after inspection on Saturday morning until 9 p. m. Sunday. Baseball teams have been organized and games have been played with visiting teams; boxing, wrestling, tennis, swimming, boating, fishing, horseback riding, massed games, etc., are encouraged and provided for. Recreation rooms, reading rooms, writing material, a lunch counter and canteen, etc., are at the disposal of the students. Dances are held every Friday evening, and moving picture entertainments are given nightly. The students organized a jazz orchestra and a vaudeville troop which have given entertainments. Students are encouraged during their week-ends to avail themselves of the opportunity to visit the points of interest in the Nation's Capital and vicinity, and means are provided to transport the men to and from camp.

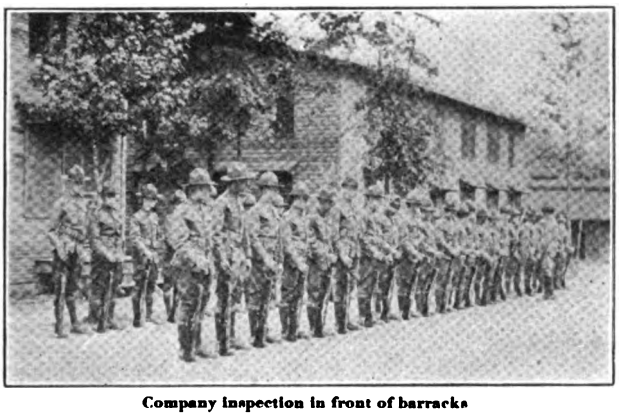
The students began reporting on June 17, and the period from June 17 to 20 was devoted entirely to assigning, organizing, providing uniforms and equipment, examining and inoculating the men, so as to have nothing interfere with the instruction proper, which began on Monday, June 21.

The first week of instruction was a practical review of the R. O. T. C. course and a test, which included the subjects of infantry drill physical training, bayonet fighting, manual of courts-martial, administration, preliminary target practice, rigging, knots and lashings, spar and trestle bridges, preliminary ponton bridge work, demolition, first aid, defense against gas, fortification, etc., and was practically the same for both the advanced and the basic groups. These subjects were arranged in the first week so that the students would progress by degrees to the work demanding more strenuous physical exertion which was to follow in the succeeding weeks. During this period the material for student officers and noncommissioned officers was selected, and the companies were organized into platoons. In this organization into platoons an attempt was made to average up each platoon, the purpose being that in each platoon and in each squad there would be several trained men to set an example for those who were more backward.

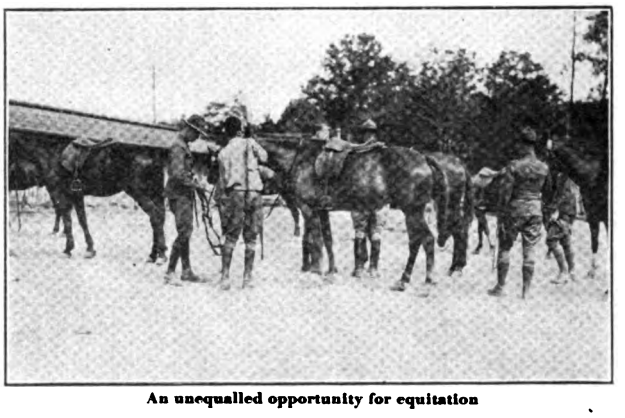


During the second and third weeks quite a radical change was made in the method of instruction, particularly as applied to the advanced group, "A" Company. These men had already had three years of military training and were mostly juniors and seniors in college. Their course of instruction was therefore enlarged and advanced, and consisted in the solution of practical problems which had been drawn up with the idea of instructing these men in the role of the military engineer and at the same time giving them practical instruction which will be of value to them in their preparation for careers in civil life.

Digitized by Google



In accordance with the above plan the students of "A" Company were divided into groups as nearly as possible according to the course in engineering which each was pursuing in college. A list of the practical problems (covering the fields of civil, mechanical and electrical engineering, etc.) to be given was also presented to the students, and they were allowed to express their preferences as to which problems they desired to take. One group was detailed by roster to act as noncommissioned officers with the two basic companies; the other groups were sent in rotation to solve the various problems.



Most of the time the men lived in comfortable barracks

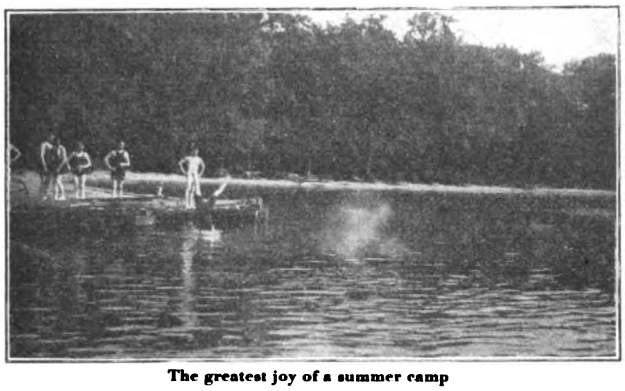
A "pup-tent" camp on the rifle range

Company inspection in front of barracks

An unequalled opportunity for equitation

Each problem is designed with a view to placing responsibility directly upon the student; to developing in him the ability to reason logically and come to a quick decision; to developing his initiative and resourcefulness, and acquainting him with some of the problems which confront both the military engineer and the engineer in civil life. The problems were all based upon assumed military situations and covered the following subjects: Location, design and construction of military bridges; location and construction of military railways (both light and standard gauge); sewerage and sewage disposal; camp water supply; hydrographic surveying; electrical and mechanical installations; military mining; military roads; military demolitions; field fortification; tactical problems, etc. Several problems were prepared under each heading. Some of these problems were based on those given at the Engineer School; others upon actual engineering problems which confronted engineers in the location and construction of the present camp. Each problem was handled by a selected instructor who had previous practical experience in the subject treated in the problem. The groups solving the problems ranged from about 8 to 25 men, thus permitting close supervision and individual instruction. The problems were solved on the ground after personal reconnaissance and inspection by the students, and as much practical work as time permitted was

Even the "kitchen police" enjoyed their work



Every form of sport may be indulged in

Digitized by Google

actually done in the field. The students have shown keen interest in this kind of work, and the results have been very satisfactory. Qualified students of "B" Company were given an opportunity to engage in this work during the last week of camp.

The fourth week was spent in shelter tent camp at the rifle range in small arms firing. The march from Camp

The greatest joy of a summer camp

Humphreys to the rifle range on July 12 was used for a maneuver problem. On arrival at the camp site on Pohick Bay the student battalion pitched camp immediately so that instruction practice with the rifle could begin at 1 p. m. the same day.

The site selected for the camp was a cleared field on a

"On with the dance"
A gay social event in the beautiful ballroom of the "Hostess House"

small peninsula projecting into Pohick Bay. Ponton boats were ferried from Belvoir to the camp by one of the companies. The boats were used for instruction in ponton bridging and for the construction of bathing piers. During the week at this camp the students lived under field-service conditions, performing all of the duties incident thereto except cooking meals.

Instruction during this period was devoted primarily to the rifle and pistol; but, taking advantage of the excellent opportunities afforded, instruction was also given in camp administration, sanitation and supply, care and handling of troops in the field, minor tactics including night maneuvers, ponton bridging and ferrying, swimming, etc. Rifle practice began on the afternoon of the first day and consisted of instruction firing at 200 and 500 yards, standing, sitting and prone.

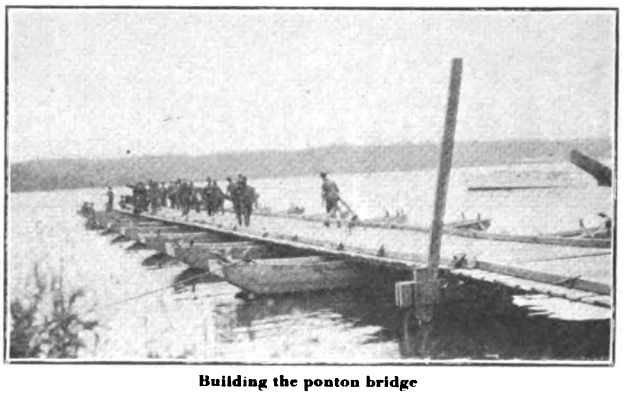
The record firing followed, and included:

200 yards, prone, slow fire "A" target.
200 yards, sitting, rapid fire "B" target.
500 yards, prone, slow fire "B" target.

During the course every effort was made to provide a maximum of individual instruction at the firing point. A coach and a scorer were provided for each man firing. The coaching at first was done by commissioned officers and master engineers, but as fast as good student shots were discovered or developed they were given additional instruction and utilized as coaches. The results obtained in the

The ponton bridge is the most interesting of the military engineer's works

rifle firing were very satisfactory considering the brief time allowed and the fact that a large number of the men had never fired a rifle before.



The final record was as follows:

Total number firing, 217.

Total qualified riflemen, 57 per cent, including 6 expert riflemen.

Sharpshooters, 51.

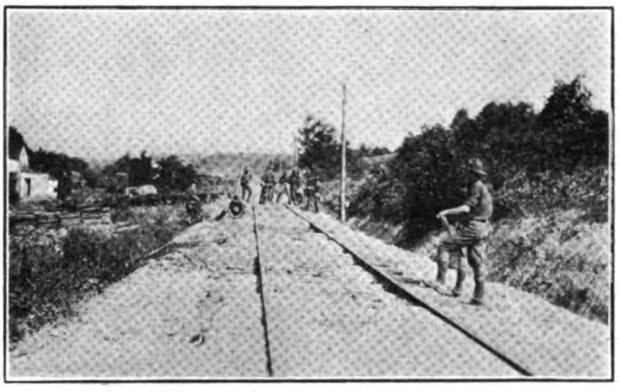
Marksmen, 67.

Building the ponton bridge

The fifth and final week of instruction was spent at Camp Humphreys and included two days of field exercises in which all companies took part. These exercises form part of the course in minor tactics and aim to give instruction in troop leading of units to include the company, through the various phases of combat. The last three days of this week were devoted to engineer troop problems designed to give practical instruction in the handling of engineer troops on various work in the field. This includes reconnaissance, planning of work, location, procurement and distribution of material, issue of tools and equipment, organization of labor and the actual construction of the work under service conditions.

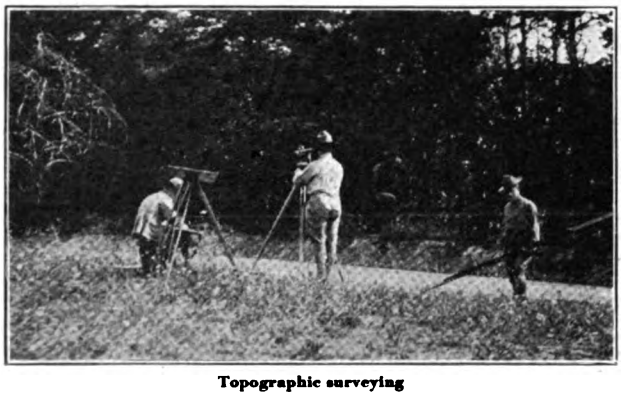
The course outlined was followed with no change, and the results accomplished have been quite gratifying. Provision was made for indoor drills in case of inclement weather, but fortunately there were few rainy days.

The drills had sufficient variety to keep the interest of the students at a high pitch throughout the course. The work of the instructors was very interesting, and the stu-



Digitized by Google

dents responded to the instruction in a very gratifying manner.



The course of instruction for the camp was planned and arranged with the following objects in view: To make the course interesting as well as instructive; to cover a maximum amount of practical work, leaving the bulk of the theoretical instruction to be covered at the institutions; to give instruction in phases of engineer work which, due to lack of proper facilities cannot be handled at the institutions; to instill in each student a high sense of discipline; to develop qualities of leadership, initiative and resourcefulness by placing the maximum amount of responsibility upon the individual; to teach the students to be instructors, and to give practical instruction in the problems of the military engineer, the solution of which will be of value to the student in his preparation for his future career in his chosen field of engineering.

A hasty trestle bridge, 150 feet long, built by one company in 4 hours

A railroad survey party

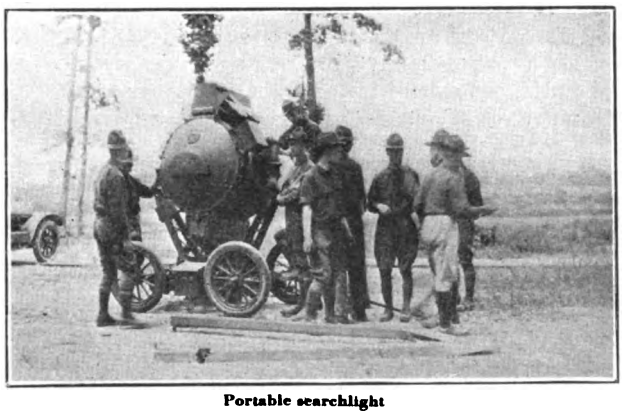
Topographic surveying

A task for both civil and mechanical engineers

Railroad survey, the transit party

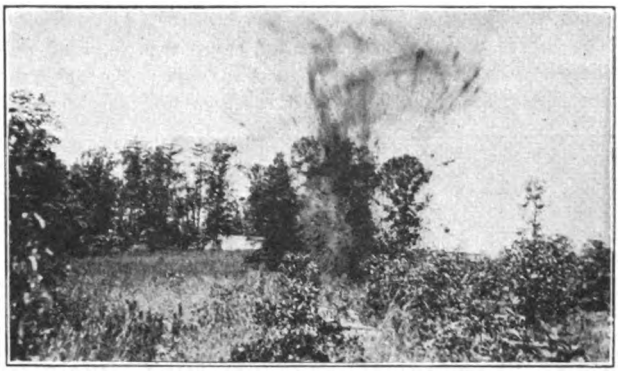
The army sketching board

It is impracticable within the limits of this article to give more than a general summary of the course of instruction. It consisted in general of (1) lectures; (2) drills; (3) practical problems in civil and military engineering, solved in the field. The drills included the following:



Infantry drill, physical exercises and games, bayonet training, first aid and gas defense, swimming, equitation, engineer reconnaissance, knots, lashing and rigging, ponton and trestle bridges, field fortification, demolitions, target practice, minor tactics and problems of engineer troops.

Practical problems covered the following subjects, in some of which students were permitted to take their choice:

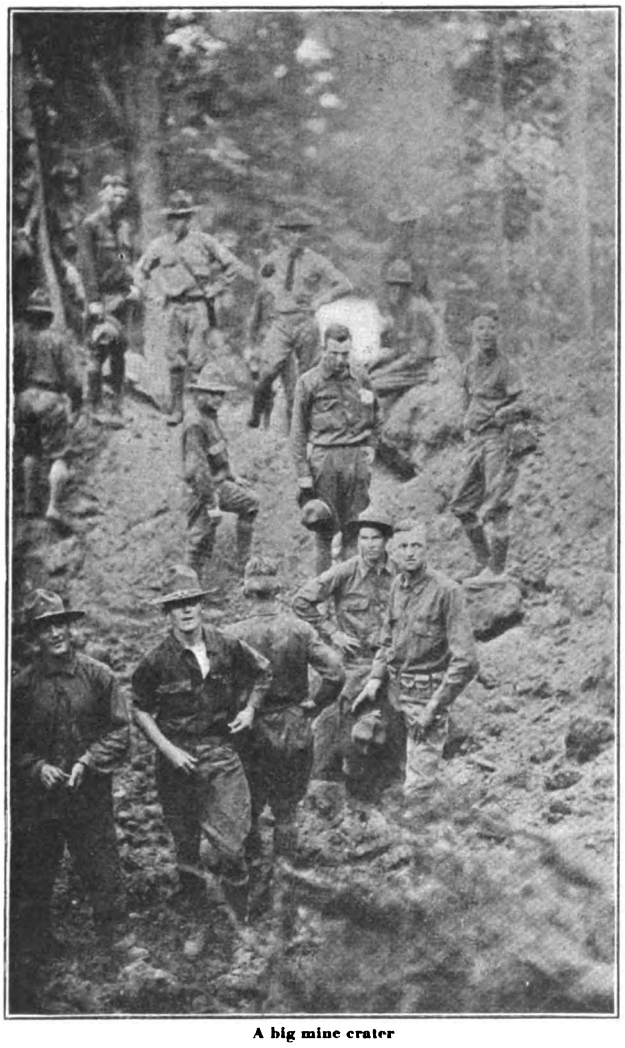


Military sketching, terrain exercises in tactics, survey of campsite, field fortification, engineer reconnaissance, military mining, demolition, bridges, road location, road construction, railroad location (standard and narrow gauge), hydrographic survey, camp water supply, sewage disposal, electrical and mechanical installations.

As indicating the manner in which the "applicatory sys-

Digitized by Google

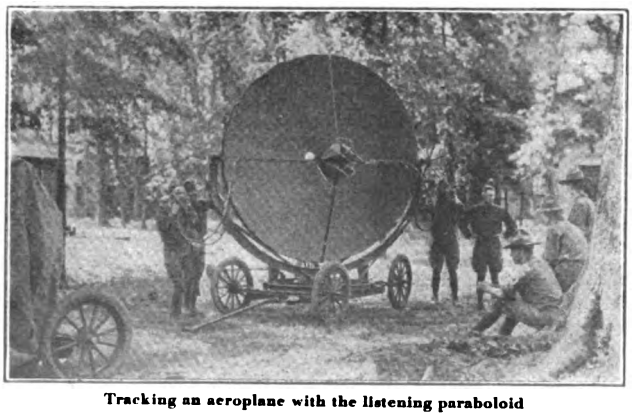
Portable searchlight



A land mine explosion

tem" of the military may be applied to the problems of the civil engineer, let us describe one of the problems in water supply. This problem was based upon a "situation" as follows:

"The United States has declared war on a foreign power. Mobilization has begun and the immediate construction of cantonments is necessary. It is intended to construct a 30,000-man cantonment on the Camp Humphreys reservation with the possibility of later expansion to accommodate 100,000 men."



With this general situation in view there had previously been collected and digested all necessary data concerning the available water sources in the vicinity of the reservation, such as extent of drainage areas, average annual rainfall, rainfall for dry years, collectible run-off, record minimum flow of streams, etc. There were also prepared figures showing the probable water consumption of a camp of the size required above, such as average per capita daily consumption, maximum requirements for fire protection, etc. This data was presented to the students solving the problem, who were then confronted with the special situation in which they were required to assume the role of an engineer officer and investigate and report as to whether sufficient water was available to supply the above requirements, to select the source to be developed, to outline the water supply system for the camp and to estimate the equipment and materials necessary for its installation.

A big mine crater

The students were then required to make a personal inspection and reconnaissance of the elements of the present water supply system, in the light of their own solutions of the problem. They were conducted to the Springfield dam and storage reservoir on Accotink Creek, to the diversion dam, filter beds, pumping plant, etc., and each phase of the system was explained and discussed.

Each student was furnished with a topographical map and permitted to use the manuals and text-books in making his solution. In

Tracking an aeroplane with the listening paraboloid

Watching an explosion from a safe place

Digitized by Google

the solution of this problem the responsibility was placed directly upon the shoulders of each individual student. He was required to make his own reconnaissance, estimate the situation, weigh the advantages and disadvantages of the various courses open to him and then come to a decision. And having reached his decision he was required to outline his plans and make his estimates for carrying it into effect. The instructors rendered all possible assistance in the way of furnishing information on various points, but in no way did they relieve the student of the responsibility of making his own decision and drawing up his own plans for carrying that decision into effect. The solutions of the students were then examined by the instructors and their mistakes pointed out to them.

Other problems in practical engineering were conducted in a similar manner. The students took an active interest in the work and welcomed every opportunity to visit and inspect works of engineering construction. It is certain that problems of this nature in which the student makes his own solution, and then examines in detail in actual physical existence, the solution made by some one else to meet the same requirements, will be of great benefit to him as a preparation for his industrial or professional career. Basing the problems on assumed military situations is of great value in the training of the student as a military engineer, as it indicates military requirements and furnishes the military atmosphere. It gives him an excellent idea of the kinds of problems which will probably confront him as a reserve engineer officer in case he is called into active service in an emergency. And it impresses upon him the fact that in war the military engineer, separated from the vast and varied resources of material, equipment, labor, etc., usually at the disposal of the civilian engineer, must accomplish his results with the always limited and sometimes very unsuitable material, equipment, labor, etc., which he may find at hand, and that, moreover, he must do his work in such time as allowed him by the military situation of the moment.

The camp was a great success, much appreciated and enjoyed by the students. It will be repeated each year, and a constantly increasing attendance is looked for. It was a splendid demonstration of the power of the Federal Government to administer training, and of the practicability of combining instruction in civil and military engineering without detriment to either.

Army Educational and Vocational Training at Camp Humphreys, Va.

The scholastic instruction and vocational training that is being given to enlisted men of the engineers at Camp Humphreys is typical of the new role of the Army as a great educational institution. Although working under many handicaps excellent results have been attained, the significance of which is far reaching as indicating the benefits which would occur to the nation from universal education under Federal control.

The vocational schools of Camp A. A. Humphreys, Va., were organized during October, 1919. The scope of the schools was to conform as far as possible to the list of authorized courses prescribed by the War Department, particular stress being placed on the organization of courses necessary to engineer troops. However, the purpose was not only to give the troops the necessary training, but also to enable the men to take up studies and trades which will be beneficial to them in later years in civil life.

In some ways the situation was favorable for quickly organizing certain courses, since the camp had previously been used as a training center for engineer troops. The machine shop was particularly well equipped for immediate work, as complete shop equipment was already in place and in operation. The carpentry shop was also running, although small, and was specially fitted for machine work. Another shop in good working condition was the blacksmith shop, and at the start it was capable of accommodating as many men as was thought possible to enroll. Due to the printing train of the 29th Engineers being housed temporarily in camp it was possible to start installation of equipment and organizing a complete printing school which would include all branches of the trade.

The preparation of the various courses consumed the early months of 1920, and it was not until about the middle of March that an outline of the various courses which were to be taught could be issued. This pamphlet was then issued to all troops in camp and sent out to the numerous recruiting parties. The increase of the enrollment was almost immediate, the total jumping from 51, which had been the enrollment since January, to 254 on May 1, when eleven courses started operations. The courses before May 1 had been extremely limited, there being only the elementary school, blacksmith, machine and automotive schools in operation. This condition which existed during January to April, inclusive, was due largely to the very small number of troops in camp and to the fact that many of them expected to leave the service during the succeeding months. Besides this handicap, the school staff was insufficient to carry on the work.

It was found that a number of men were illiterates, hence measures were taken during March to send them to school. This was the beginning of the educational classes, which finally included not only the illiterates but also students up to about the eighth grade in grammar school. This educational work developed into the most popular of all the courses, and it was necessary to hire five instructors to take care of the different grades. Mathematics was made the major subject, the rest of the time being devoted to reading, spelling, penmanship, grammar and composition. No time was placed on the students specifying how long they should remain in one particular grade, but instead they were constantly under consideration for advancement by their instructor, and as soon as the necessary degree of proficiency was shown the students were advanced. This condition was found to be necessary since many of the men needed review more than additional instruction.

In connection with this educational work a class in languages was formed, and French, Spanish and Italian were taught. An advanced English section finally grew out of the language section, and through this medium the foreigners were taught English.

A class which was almost as popular as the educational classes was the automotive school. During the constructive period in the organization of our courses we were handicapped by the lack of equipment for this course. Much

Digitized by Google

time had to be spent on the theoretical work, since machines and tools were not available. Finally a shipment of cars and trucks from Camp Holabird (during April and May) relieved the strained conditions that had been experienced during the winter. Upon the arrival of this shipment many more men volunteered for automobile work, and the enrollment equalled that of any other course. With the new cars it was possible to enter into the field of practical automobile work, and the last part of the course has been devoted almost entirely to repairing, assembling and driving.

The demand for more efficient typists led to the organization of a typist school in which the touch system, a course in spelling, business correspondence and composition were to be taught. This course began on April 26 and was filled to its capacity of 30 men within a week. Later the class was enlarged by the addition of ten more machines, and this more than accommodated the rest of the applicants.

It was not until the middle of May that the electricians' course could be started, due to no students enrolling, and also to the lack of equipment. The men who enrolled for this course were given very good practical work under the supervision of the electrician employed by the school. These students, many of whom had had previous experience, did some very good work in installing a small power plant, which will be used to supply the school area. Besides this, many other tasks, such as wiring and storage battery work, were given the students.

Although a sheet metal course was planned, it was impossible to start, as the equipment failed to arrive, although ordered last February. What equipment there was on hand would have been sufficient only for the roofer's trade. There were no applicants for instruction in this work.

As the camp lies in a fairly good agricultural district of Virginia it was decided to organize and operate, under the supervision of the vocational schools, a model farm on which all branches of the subject could be taught. At the same time agriculture and its associate courses were being taught, it was thought possible to help supply the camp with fresh vegetables from this source. A tract of land was selected north of Accotink which suited the needs of such a farm fairly well. At first a few students were taken out to the farm daily to help the civilians who were hired to put the place in shape. Later it was found impracticable to have the students attend only three hours daily, hence a detail was sent out to the farm under the charge of a noncommissioned officer. This detail remained during the entire day, having their quarters and mess on the place. This arrangement was found to be most satisfactory.

The carpentry course failed to attract a sufficient number of students to justify the employment of an instructor until about May 10. However, the equipment and shop had been ready to accommodate students for about a month previous to this date. A number of carpenters' tool chests had been procured, and, together with the equipment already installed in the shop, provided everything which was necessary.

The machinists' course was most satisfactory from the first. The necessary equipment was already on hand, as this shop had been used only a few months previous by the engineer school for a class of officers. The tasks which had been prescribed for the officers were followed by means of mimeographed sheets, and when a student showed a sufficient degree of proficiency he was put on special work. Many capable machinists are being developed by this school.

The printing course was planned with the idea of teaching rather thoroughly all of the different phases of the trade. Starting May 1, as scheduled, the students were placed on job press work at once. These students have done some very creditable work, and as this class is continuing throughout the summer even better results are expected. The equipment in the printing shop includes everything necessary for a thorough course in this trade.

Soon after the welding class began the acetylene generator blew up, and although an order was placed immediately for another generator it failed to arrive in time to start again by May 1. It was therefore decided to incorporate the acetylene welding course in the blacksmith course, making the welding the final subject.

The blacksmith course, which was one of the first to be established, was well equipped in all respects and was also favored with a complete set of job sheets which had been used by the student officers of the Engineer School. Very little preparation for this course was necessary. Although the number of students was not large, those who attended were diligent and anxious to learn. Some of the same men continued the work through the summer as training for the regiment.

As a summary of the accomplishments of the vocational schools it can be said that during their short life they have undoubtedly served their purpose in helping the men to see what the Army has to offer, and to encourage them to take up the work again this fall when the schools reopen on a firmly established basis. Finally, the schools should be credited with increasing the qualifications of many men in educational and vocational lines. Many men who could not write before have, in this short time, written letters home, and a number of others have learned to operate machines in shops, drive automobiles, use a typewriter and so on. It is believed that the men have acquired a desire for knowledge, and if this is so our efforts have been more than repaid.

Educational and vocational schools received a great boom in February when a permanent board of education was appointed. It was found advisable to form various committees in this general board which could handle in detail subjects of equipment, class instruction and teachers. These various committees consisted of two to three officers who made thorough inspections of the school work, equipment, etc., and reported to the general board when regular meetings were called, every week or so.

The Board of Education early decided that educational and vocational training should cease May 31 for the summer period. Many of the vocational classes continued as engineer trade schools during the months of June, July and August. The classes were necessarily smaller, and the instruction not solely voluntary. The vocational schools will reopen on or about the 1st of September.

By far the most aggravating circumstance under which the vocational schools have had to function has been the lack of equipment in certain of the important classes. Quantities of equipment of all kinds were ordered during the latter months of 1919 and early in 1920. In addition the War Plans Division, General Staff, has allotted thousands of dollars worth of vocational training equipment to this camp for future use. It is expected that sufficient equipment will be on hand so that instruction may proceed on a grand scale in the fall. Automobile equipment consisting of 10 trucks, 10 automobiles, 10 motorcycles, trailers, etc., has arrived and has been put in order, so that when class is reopened there will be a sufficient number of machines available for driving and all other instructional work in automechanic course.

According to the plans of the War Plans Division the school for educational and vocational officers and instructors was held during the summer months at Camp Grant.

Professional Notes

of Military and Engineering Interest

Major Graves Objects to the Limber and Caisson Type of Tool Wagon

I learn that the type of tool wagon for engineer troops is under considration, and I submit the following thereon:

These appear to be the types of wagon to be considered, viz., the escort wagon, the Brown tool wagon, and the limber and caisson wagon.

The features to be considered appear to be the following:

(*a*) Number of men necessary to operate or drive.
(*b*) Animals and harness.
(*c*) Facility for going over roads of all kinds.
(*d*) Susceptibility to being divided into two parts.
(*e*) Ease in getting to contents.
(*f*) Susceptibility to use for hauling by removing tools.
(*g*) Interchangeability of parts with other army transportation.

(*a*) The limber and caisson wagons I have require two men to drive and another to operate the brakes. An escort wagon requires one man to do everything.

(*b*) Limber and caisson wagons use four horses. Escort wagons use four mules. Limber and caisson harness makes horses' necks sore. Horses eat more than mules, and require more care. Horses fail on account of neglect in campaign quicker than mules. Only horses could be used with limber and caisson wagons because mules are not subject to that kind of driving.

(*c*) Probably limber and caisson wagons will travel on a rougher road than an escort wagon, but an escort wagon will go anywhere that is necessary.

(*d*) The limber and caisson wagons ran be divided into two carts and the escort wagon cannot. Has anyone ever seen a necessity for dividing the tool wagon into two carts? I have not, and do not believe the feature is worth considering.

(*e*) It is easier to get at the contents in a limber and caisson wagon than in an escort wagon. The Brown tool wagon, which is nothing but a tool box on an escort frame, is as satisfactory in this respect as a limber and caisson wagon.

(*f*) The escort wagon is better than anything for emptying of tools and for any kind of hauling.

(*g*) The escort wagon has parts same as the bulk of all army transportation, and broken wheels, tongues, bolts, etc., can be quickly replaced almost anywhere. The Brown wagon has the same advantages. The limber and caisson wagon is certain to be extremely difficult to get repaired. This, to my mind, is the most important of all of the features discussed.

5. It is recommended that a wagon be adopted that can be driven by one man; that can be pulled by mules using the most common variety of harness; that is good enough for practically all roads; that does not need to be divided into carts; that affords sufficient facilities to get at contents; that can be easily used for other hauling; and above all, that can use the most available replacements in wagon parts, harness and animals. This wagon is either the Brown wagon or the escort wagon. The escort wagon is the better in my opinion, possessing as it does the supreme advantage of simplicity, so strongly urged by military sages and so greatly appreciated by practical military men.—*Ernest Graves, Major, Corps of Engineers, Comdg. 2d Engineers.*

Changes in Personnel in the Corps of Engineers

Contributed by Mr. J. A. EGAN, Office of the Chief of Engineers.

Since our last issue the following changes of personnel have occurred in the Corps of Engineers, U. S. Army:

Lt. Col. JOHN R. SLATTERY and Majs. Henry C. Jewett, R. R. Ralston, J. J. Bain and Robert S. Thomas have been sent to the School of the Line, Fort Leavenworth, Kans., as student officers.

Maj. WILDURR WILLING has been assigned as Department Engineer, Northeastern Department, relieving Capt. John S. Bragdon.

The following-named officers of the Corps have been relieved from Camp A. A. Humphreys, Va., and assigned as Assistant Professors of Military Science and Tactics at the institutions specified, to report not later than August 20, 1920.

Capt. D. A. DAVISON, Yale University, Sheffield Scientific School, New Haven, Conn.

Capt. LAYSON E. ATKINS, University of Illinois, Urbana, Ill.

Capt. PATRICK H. TANSEY, Oregon Agricultural College, Corvallis, Oreg.

Capt. MICHAEL C. GRENATA, University of Kansas, Lawrence, Kans.

Capt. LUCIUS DUB. CLAY, Alabama Polytechnic Institute, Auburn, Ala.

1st Lt. HOWARD L. PECKHAM, University of Tennessee, Knoxville, Tenn.

1st Lt. ALBERT RIANI, University of Iowa, Iowa City, Iowa.

1st Lt. EDWIN P. LOCK, jr., Missouri School of Mines, Rolla, Mo.

1st Lt. HARRY A. MONTGOMERY, Rose Polytechnic Institute, Terra Haute, Ind.

Capts. PAUL T. BOOK and Elroy S. J. Irvine, and 1st Lt. Frank O. Bowman have been relieved from Camp A. A. Humphreys, Va., and assigned to the office, Chief of Engineers.

1st Lt. FREDERICK FRENCH has been assigned to the 1st Engineers, Camp Taylor, Ky.

The following-named officers have been relieved from Camp A. A. Humphreys and assigned to duty under the immediate orders of the Chief of Engineers:

Capt. ALBERT G. MATTHEWS, Capt. Lewis T. Ross, Capt. Alexander M. Neilson, Capt. Charles E. McKee, Capt. Robert H. Elliott, 1st Lt. David A. D. Ogden, 1st Lt. Richard Lee, 1st Lt. Joseph J. Twitty.

1st Lt. MARK M. BOATNER has been assigned to the 9th Engineers, Camp Travis, Tex.

Maj. WALTER L. WEBB, 1st Lt. Cecil A. Clarke and 2d Lts. Bernard Marvin and Frank E. Briber have been honorably discharged the service.

1st Lt. GEO. F. BROCKMAN has been relieved from Camp A. A. Humphreys and assigned to Co. D., 7th Engineers, Camp Benning, Ga.

Capt. JOHN E. HARRIS has been assigned to duty in the Office of the Chief of Engineers.

Capt. G. B. TROLAND has been assigned to duty at New London, Conn., as assistant to the District Engineer.

Maj. THOMAS H. EMERSON, C. of E., has been relieved from the General Staff College and assigned to the office of the Chief of Staff.

The following-named officers have been assigned to temporary duty as assistants to the District Engineers at the places specified:

Capt. JOHN P. DEAN, Newport, R. I.; Capt. Charles F. Baish, Pittsburgh, Pa.; Capt. James M. Young, New York City; Capt. Preston W. Smith, Boston, Mass.; Capt. Patrick H. Timothy, jr., Boston, Mass.; Capt. Leland H. Hewitt, New York City.

Capt. THOMAS F. KERN and 1st Lts. James L. Rhodes and Robert G. Lovett have been ordered to Manila, P. I.

Capt. WILLIAM C. SHERMAN, upon his own request, has been transferred to the Air Service, with rank from July 1, 1920. Capt. W. H. Henderson and 1st Lts. Marcus P. Taylor and Ernest W. Dichman have been detailed for duty with the Air Service in accordance with the provisions of the Reorganization Act of June 4, 1920.

Capt. CHARLES P. GROSS has been detailed as Inspector-Instructor, Engineers, New York National Guard, with station at Governors Island, N. Y.

Capt. CLARENCE S. JARVIS has been assigned as assistant to the Constructing Quartermaster, Presidio, San Francisco.

Lt. Cols. JOHN M. WARD and Harry F. Cameron, under the provisions of an Act of Congress approved June 5, 1920, have been discharged from their commissions as lieutenant colonels and recommissioned majors, Quartermaster Corps.

Lt. Cols. WILLIAM H. LANAGAN and Bowyer B. Browne have been discharged under the provisions of an Act of Congress approved June 5, 1920, from their commissions as lieutenant colonels and recommissioned majors, Engineers, for the emergency.

Capt. NOTLEY Y. DUHAMEL has been assigned to the 5th Engineers, Camp Humphreys, Va.

Maj. HARRISON V. PITTMAN, Engineers, has been assigned to duty as assistant in the 1st Cincinnati District, Ohio.

Lt. Col. G. R. LUKESH has been assigned to duty as District Engineer, Louisville, Ky., relieving Col. Geo. M. Hoffman of that duty.

Maj. EARL NORTH has been assigned to duty as District Engineer, Mobile, Ala., relieving Maj. Robert S. Thomas of that duty.

Maj. GILBERT VAN B. WILKES has been assigned to duty as District Engineer, Kansas City, Mo., relieving Maj. R. T. Ward.

Col. C. S. SMITH has been assigned to duty commanding the 7th Engineers, Camp Gordon, Ga.

Maj. RICHARD PARK has been relieved from the 5th Engineers and assigned as District Engineer, 2d District, Portland, Oreg., relieving Lt. Col. J. R. Slattery.

Lt. Col. JAMES A. WOODRUFF and Maj. Robert P. Howell have been relieved from duty at Seattle, Wash., and at Vicksburg, Miss., and ordered to Camp A. A. Humphreys, Va.

Maj. JAMES A. O'CONNOR has been relieved from duty at Camp A. A. Humphreys, Va., where he was in command of the R.O.T.C., and ordered to Vicksburg, Miss., for duty as District engineer, relieving Maj. R. P. Howell. In addition, Major O'Connor will take charge of the 3d Mississippi River District.

Col. AMOS A. FRIES has been promoted to Brigadier General and Chief of the Chemical Warfare Service. General Fries was Chief of the C. W. S. of the A. E. F. during the war.

Capt. WILLIAM E. R. COVELL has been re-

Digitized by Google

lieved from Camp Humphreys and ordered to Buffalo, N. Y., as District Engineer, relieving Col. C. S. Smith.

Col. EDWARD H. SCHULZ has been relieved from Milwaukee, Wis., and ordered to Seattle, Wash., as District Engineer, relieving Lt. Col. J. A. Woodruff.

Col. WILLIAM W. HARTS has been assigned as Department Engineer, Eastern Department, with station at Governors Island, N. Y.

Maj. ROGER G. POWELL has been relieved as assistant to the Engineer Commissioner, District of Columbia, and ordered to duty in the Office of the Chief of Engineers.

Maj. PAUL REISINGER has been relieved from the Carnegie Institute of Technology and assigned to the 2d Engineers, Camp Travis, Tex.

1st Lt. FRANK O. BOWMAN has been relieved from duty in Washington, D. C., and assigned to the 2d Engineers, Camp Travis, Tex.

Maj. HERBERT J. WILD, Engineers, has been assigned to the 6th Engineers, Camp Pike, Ark.

Maj. CHARLES R. PETTIS has been ordered to the General Staff College, Washington Barracks, D. C., as student officer.

Maj. ULYSSES S. GRANT, 3d., has been relieved from duty in Washington and ordered to San Francisco, Calif., as District Engineer, 3d District, relieving Lt. Col. William Kelly.

1st Lt. EUGENE L. VIDAL has been ordered to Antwerp, Belgium, for duty in connection with the Olympic Games.

Col. GEO. P. HOWELL has, in addition to his other duties, been assigned as District Engineer, Charleston, S. C., relieving Lt. Col. G. R. Lukesh.

Majs. W. T. HANNUM, Mark Brooke and R. C. Moore have been ordered from Camp A A. Humphreys, Va., to Fort Leavenworth, Kans., as student officers at the General Staff School.

Capt. XENOPHON H. PRICE has been ordered to Boston, Mass., as student at the Massachusetts Institute of Technology.

Lt. Col. WILLIAM KELLY has been relieved from duty at San Francisco, Cal., and ordered to Washington for assignment to duty with the Federal Power Commission.

Maj. WILLIAM G. CAPLES has been relieved from duty at Fort Sam Houston, Tex., and detailed for General Recruiting Service, Fort Logan, Colo.

Lt. Col. GLENN S. SMITH has been ordered to Havana, Cuba, on temporary duty in connection with the proposed topographical survey of the Republic of Cuba.

1st Lt. EDWIN G. SHRADER has been relieved from Camp A. A. Humphreys, Va., and assigned to the 4th Engineers, Camp Lewis, Wash.

Col. JOSEPH H. PRATT, Reserve Corps, has been ordered to active duty in the office of the Chief of Staff.

Capt. WILLIAM F. HEAVEY has been relieved from Campt A. A. Humphreys, Va., and ordered to West Point, N. Y.

Capt. ALFRED L. GANAHL, upon the expiration of his leave of absence, will proceed to the Canal Zone, Panama, for duty.

Capt. ALBERT O. TRUE has been relieved from Norfolk, Va., and ordered to Fort Monroe, Va.

Maj. EARL J. ATKISSON, at his own request and under the provisions of an Act of Congress approved June 4, 1920, has been transferred to the Chemical Warfare Service, with rank from July 1, 1920.

The following officers have been promoted to the ranks indicated above their names:

To be Brigadier Generals: Col. Harry Taylor (Assistant Chief of Engineers), Lt. Col. William D. Connor.

To be Colonels: Meriwether L. Walker, Robert R. Raymond, William B. Ladue, William J. Barden, Edward H. Schulz, Harry Burgess, George M. Hoffman, Sherwood A. Cheney, Frederick W. Alstaetter, Harley B. Ferguson, Frank C. Boggs, Clarke S. Smith, William P. Wooten, Lytle Brown, Earl I. Brown, Curtis W. Otwell.

To be Lieutenant Colonel: Maj. Paul S. Bond.

The following-named graduates of the U. S. Military Academy, West Point, N. Y., have been assigned to the Corps of Engineers and ordered to Camp A. A. Humphreys, Va., for duty as student officers, Engineer School, for the basic course, 1920-21:

2d Lts. FRANCIS H. OXX, Thomas H. Stanley, Donald Greeley White, Henry George Lambert, William Weston Bessell, jr., Charles George Holle, Charles Sheafe Joslyn, Arthur Martin Andrews, Edward Crosby Harwood, John Wylie Moreland, Wayne Stewart Moore, Henry Franklin Hannis, Arthur Lee McCullough, Arthur Vinton Linwood James.

The resignations of the following-named officers have been accepted:

1st Lt. MARCUS P. TAYLOR and Wilson G. Saville.

The following officers of the Coast Artillery Corps have transferred to the Corps of Engineers under the provisions of the Act of Congress of June 4, 1920:

Capt. ROBERT A. LAIRD, 1st Lt. Cecil R. Moore, 1st Lt. Glenn H. Stough, 1st Lt. Milton Heilfron.

The following-named emergency officers of Engineers have been honorably discharged the service of the United States:

Lt. Col. ARCHIBALD O. POWELL; Majs. Reuben H. Oglesby, Louis D. Waldron; Capts. Fred A. Dailey, John H. Devine, Waterman C. Guerin, Arthur I. Hunting, George J. Lyon, Thomas B. Motz, Frank N. Smith, Harold A. Tyson; 2d Lts. Merle F. Bennett, Omar E. Swank.

Records of the World War.—The War Department is now preparing for publication the Records of the World War. There have already been prepared and sent to the printer the following volumes:

Field Orders and Annexes, 1st Army—Records of the World War. Class A, Section II, Vol. 1.

Summaries of Intelligence, 1st Army—Records of the World War. Class A, Section II, Vol. 3.

Field Orders, 2d Army Corps—Records of the World War. Class A, Section VI, Vol. 1.

Others will follow as prepared. These records are being published on the following plan:

Class A—Records of Military Operations Overseas.

Class B—Records of the Service of Supplies Overseas.

Class C—Records of Military Activities in the United States.

Each class will be subdivided into sections, and each section into volumes corresponding to the scheme of organization and record files of the War Department and American Expeditionary Forces.

The War Department will print only a limited number of sets strictly for official use, and the Government Printing Office has been asked to provide the sales edition to take care of the outside demand. In view of the limited edition to be printed the War Department will arrange a sales edition, and any one interested in obtaining copies should place his name on file, so that he may receive notice as each volume appears.

Enlistments in the Corps of Engineers.—The enlisted strength of the Corps of Engineers on July 31st was 4,631, or about 38 per cent of its authorized strength of 12,000. The largest unit is the 1st Engineers, which has 1,225 of which 867 are with the American Forces in Germany with Companies A, B and D, and 358 at Camp Dix, N. J., with Companies C, E and F.

Increase in strength of the National Guard and Regular Army.—During the month of August there was an increase of 3,431 in the enlisted strength of the National Guard. The actual strength of the entire guard at the end of the month was 60,545 as compared with the authorized strength of 180,607 (enlisted). At this rate 3 years will be required to bring the guard to its authorized strength, but an increase in the rate of enlistments is confidently expected.

During August enlistments in the Army exceeded 16,000.

War Department report recommends construction of Federal system of highways.—The construction of a Federal system of national highways is recommended in a report of the War Department to the Highways Committee of Congress, made public April 30. The report summarizes conclusions reached as a result of the army convoy of 73 trucks which blazed a trail from Washington to the Pacific Coast last summer.

The recommendations of the Department are:

That the necessity for a comprehensive system of national highways, including transcontinental, or through routes east and west, north and south, is real and urgent, as a commercial asset to further colonize and develop the sparsely settled sections of the country and, finally, as a defensive military necessity.

That existing roads and bridges, especially in the sparsely settled sections of the middle and far western states, are absolutely incapable of meeting present-day requirements, and until modern types of roads and bridges are constructed, which will permit the rapid movement of heavy motor cargo vehicles during any season of the year and in all conditions of weather, economical transcontinental highway traffic will continue to be but a vain hope.

The road problems of the middle and far western states are national rather than local problems, as the states, while possessing vast areas and tremendous mileage of highways, have only a sparse population which cannot possibly undertake the needed highway improvement work, which, moreover, is usually of greater importance to the country as a whole than to the individual states.—*Eng. and Cont.*

War Department expenditures in World War—

Appropriated	$25,544,000,000
Expended	$16,080,000,000
Obligated	352,000,000
Total	$16,432,000,000
Expected recoveries	2,538,000,000
Net ultimate expenditures	$13,894,000,000
Ultimate saving of appropriations	$11,650,000,000

—*Statistics Branch, General Staff*

cers applying for commissions under the reorganization act of June 4, 1920. Of these 30 are former colonels and 247 former lieutenant-colonels.

—*Statistics Branch, General Staff.*

Governmental expenditures in ante bellum days.—In 1913 expenditures for purposes of government were as follows:

Municipalities, 42 per cent	$1,247,000,000
Counties, 13 per cent	285,000,000
States, 13 per cent	382,000,000
U. S. Army and Navy, 10 per cent	294,000,000
Other Federal expenditures, 22 per cent	659,000,000
	$2,967,000,000

These expenditures are itemized as follows:

Recreation, health, misc., 5 per cent	$156,000,000
Interest on public debt, 6 per cent	189,000,000
Highways, 7 per cent	202,000,000
Permanent improvements, 20 per cent	586,000,000
General governmental purposes, 9 per cent	273,000,000
Army and Navy, 10 per cent	294,000,000
Other protection, 5 per cent	152,000,000
Public-service enterprises, 11 per cent	382,000,000
Education (schools and libraries), 15 per cent	442,000,000
	$2,967,000,000

—*Statistics Branch, General Staff.*

Foreign officers at Army Service Schools.—About 57 foreign officers, from Central and South American countries, will take courses at various U. S. Army Service Schools, beginning in September, 1920.

Good roads our paramount need.—Roads of all kinds and highway engineering are of paramount interest to both the civil and the military engineer. In time of war more than half the effort of the engineers with the combatant forces is devoted to the construction, repair and maintenance of roads. There is no more important duty of the engineer in war.

In common with *nearly all* the problems of the military engineer roads are of equal importance to the civil engineer in time of peace.

Even though the railroads get back to their normal basis within the next few months or years, the volume of freight which will be transported by truck will probably not decrease perceptibly. Rather it may be tremendously increased. The motor truck is here to stay, only if highways can be built to withstand its loads.

All of which led to the conclusion that engineers must study this phase of construction and must devise a type of road which will give the motor truck the highways it requires, while at the same time meeting the taxpayers' demand for low initial and maintenance costs.

Truck men have resented attacks made some time ago by officials of a motorists' organization against the havoc to improved roads, wrought, it was charged, by heavy duty motor vehicles last winter. Truck operators and dealers have been unanimous in declaring that trucks have done only a small share of this damage and that most of it is due to improper construction, lack of drainage and similar causes.

They point to two cases where pavements have gone to pieces, though no trucks were permitted on them. Obviously the cause is not in the kind of traffic, they say.

The wear and tear on roads incident to military operations far exceeds that of peace times. Roads designed and constructed to withstand heavy motor traffic are an essential item of any scheme of national defense.

Another basis for "cost-plus" contracts.—A correspondent submits the following:

A cost-plus percentage contract which was fair to the contractor as well as the government, was made necessary by conditions some years ago in the Philippines, and the details following offer suggestions for such an agreement which may be made applicable in the future.

The contract was originally let as a unit-price contract on designs prepared by the city engineer's office (Manila). Owing to heavy typhoon damages done between the time of letting the contract and the time designated for beginning the actual work, it was found equitable to enter into a new agreement with the same contractor, as he had placed a rather extensive plant on the site of the work and was ready to proceed under the original plans which, due to the typhoon damages, would have been inadequate. Plans were quickly changed, and the contract agreement mentioned below was made as a "supplemental agreement."

Overhead expenses covering general office, general superintendent, contractors' general shop, etc., were taken from the contractor's cost data sheets for the three preceding years. These were about 12 per cent (which was not excessive in the Philippines).

The time limit for completion set by the engineer was 150 days, to which the contractor agreed. This estimate was based primarily on progress of sheet pile driving which up to that time had always been done by manual labor.

This time limit being accepted, a clause was inserted in the contract making it a basis of compensation. To the actual costs of labor and materials 12 per cent was added for overhead expense and 15 per cent allowed for contractor's profit, also a daily plant rental was allowed.

The overhead allowance, profit and plant rental was to continue in force for 150 days, after the expiration of which time only actual cost of labor and material was to be allowed. If contract was completed in less than 150 days the contractor was to receive the plant rental for the whole period of 150 days.

The foresight of taking a contractor into partnership, so to speak, in this work was justified by the fact that he did satisfactory and good work; that he devised at his own expense and finally put to work on this job an electric sheet pile driver specially adapted for this work. This machine cost the contractor the equivalent of about 10 days plant rental for the entire plant on this job, but it paid him and incidentally also paid the government. Due to some saving in sheet pil driving the work was completed in 88 days, and the contractor saved for himself 62 days plant rental, and a considerable amount to the government in inspection and reduced labor costs and time.

Aerial mail routes.—An aerial mail service has been conducted daily, except Sundays, between New York and Washington, for two years; and between New York and Chicago for one year. Within a year it is hoped to establish a direct line between New York and San Francisco. An average of 3.2 miles is flown per gallon of gasoline.

Strikes and lockouts in 1919.—During the year 1919 there were 3,372 strikes and lockouts in the United States, involving 4,156,000 persons. It is estimated that the number of days of labor lost by strikes averaged about 36 for each person involved. On this basis the number of "man-days" lost was approximately 150,000,000. the average daily compensation of these workers be assumed at $5, the loss of wages alone, from strikes in 1919, was $750,000,000. Manifestly the strike is an expensive method of settling (or not settling) labor disputes.

Economical limit on "fineness of grinding" for cement.—At a recent conference between representatives of the United States, of the American Society for Testing Materials, and of the cement industry, the desirability of reconciling the government specification for fineness with that of the American Society for Testing Materials, was discussed.

It was stated that the value of finer grinding—that is to say, its effect upon the strength of cement—was quite well understood within the limits under consideration, namely, 78 to 80 per cent passing a No. 200 screen. It has been found that 1 per cent increase of fineness corresponds roughly to 1 per cent greater strength, or, in other words, near these limits the increase of 1 per cent in fineness might be held to justify the use of 1 per cent less cement. This, however, is not practicable for ordinary work, in which other conditions are not so readily controllable as is the quantity of cement used, so that the consensus of opinion was that the additional strength due to a small increase in fineness ought properly to be regarded merely as additional insurance.

A representative of the manufacturers stated that mills are now equipped to grind cement of such fineness as to pass 78 to 80 per cent through a No. 200 screen, and that it has been found that increasing the fineness of grinding of a particular mill, whose equipment has been balanced with a view to output of another, lower degree of fineness, caused a reduction in output. An effort was made to find what this reduction was per 1 per cent of fineness ranging between 78 and 83 per cent, and an average of reports received shows that this reduction in output was about 5.07 per cent for each per cent of increased fineness. He stated also that the cost of production did not increase directly in the same proportion, but that only 60 or 70 per cent of the total cost of production was correspondingly increased, making the final increase in the cost of a barrel of cement from 11 to 15 cents at the present market price of about $1.75 per barrel for a 2 per cent increase of fineness—this being the difference between the two specifications above referred to.

It was further stated that owing to the lack of uniformity of the screens, it was the practice of the cement trade to grind from 3 to 5 per cent finer than the low limit of the specifications—this simply as a measure of protection.

Alkali damages part of Winnipeg concrete aqueduct.—Four miles of the 97-mile aqueduct completed last year for the water supply of Winnipeg are being underdrained to protect the concrete conduit from destruction by alkaline ground water. tudies of the deterioration of concrete indicated that while other methods of protecting concrete from alkali might be effective, the best protection was the removal of the alkali, getting at the root of the evil. The drainage project involves completely uncovering the 8-foot conduit, throughout the affected sections, and the placing of continuous 8-inch open joint tile underdrains on each side of the trench, 2 feet 8 inches below the lowest point of the conduit and 6 feet 10 inches from the center line, and then back filling the trench. Cross drains at 1-mile intervals connect the two side drains with each other and with a drainage well off the line of the conduit. Six-inch vitrified pipe risers connect each drain

Digitized by Google

with the surface of the ground, for inspection purposes.—*Eng. News-Rec.*

Reservoir and plant for new Southern water power.—The Bridgewater reservoir of the Western Carolina Co., at Bridgewater, N. C., on the Catawba River, is designed to provide storage capacity, not only for the Bridgewater power-house, but for a number of allied down-river plants as well, by conserving the flood waters of the upper Catawba and discharging them through power-house into the lower river during periods of drought. The drainage area tributary to the Bridgewater reservoir is 370 square miles, over which the average annual rainfall is between 55 and 60 inches. During the flood of July 16, 1916, which was 100 per cent greater than any other flood ever recorded, the discharge into the reservoir site corresponded to 150 cubic feet per second per square mile of drainage area, equivalent to 5.58 inches over the entire watershed. The spillway capacity provides for twice the discharge of the flood of July 16, 1916, before the reservoir level would reach the top of any of the impounding earth dams.

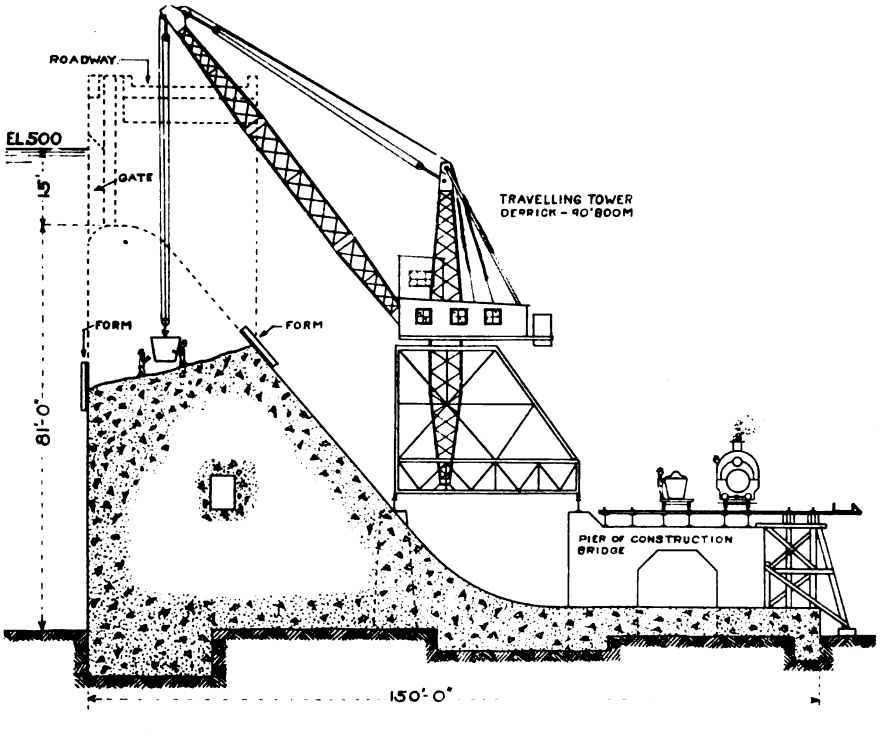
The reservoir consists of three arms, formed by the valleys of the Catawba and its two tributaries, Paddy Creek and Linville River, both on the north side, and involved the construction of three separate dams. The available storage capacity in the first is 5,315,599,000 cubic feet, and in the two latter is 7,266,244,000 cubic feet, giving a total available capacity of 12,581,843,000 cubic feet. Though providing only 42 per cent of the storage capacity, the Catawba discharges 75 per cent of the flow into the reservoir, and a 2,500-foot canal was constructed to connect the lower end of the Catawba reservoir with those of Paddy Creek and the Linville, which are themselves connected by natural arms. The cross-section of the canal is ample to pass flood waters at low velocities when water in the Catawba arm is at El. 1,167. When they are full, the water in all reservoirs will stand at El. 1,200, and the aggregate area of the reservoirs will be 6.509 acres.

As long as the water surface is above El. 1,167 all water is discharged through the turbines at Bridgewater. Below that elevation no water can pass through the turbines nor the diverting canal, but the Catawba reservoir may be emptied to El. 1,160 by sluice gates in the spillway. When the water surface in the Paddy Creek and Linville reservoir drops to 1,150, it is intended to suspend operation of the Linville power house. The stored water between Els. 1,150 and 1,105 may be discharged through the penstock, to make up the deficiencies of the flow in the Catawba below Bridgewater station. It is estimated that the total available storage can be exhausted 1.39 and 3.52 times in extreme dry and wet years, respectively. Not considering the Bridgewater station, the water released would be available for six down-river stations with an aggregate head at the stations of 353 feet. Using this head, a station efficiency of 80 per cent, and the available storage capacity of 12,581,843,000 cubic feet, the potential energy contained in the full reservoirs is 83,667,000 kilowatt-hours. The energy referred to the Bridgewater station of the storage available for that station is 18,490,000 kilowatt-hours.

The requirements of the new installation are for 17,000,000 kilowatt-hours for all stations in addition to their existing minimum output. Using the average head of 115 feet at Bridgewater and the 353-foot combined head of the lower stations, the Bridgewater station must produce monthly 4,177,000 kilowatt-hours in addition to its minimum primary output without storage regulation of 1,477,000 kilowatt-hours, giving a total of 5,624,000 kilowatt-hours as the maximum monthly output. The actual installation is 20,000 kilowatt-hours, giving a load factor of 39 per cent under extreme conditions.

The three dams in the Catawba, Paddy Creek and the Linville were decided upon rather than a single dam making one reservoir on account of property considerations. Earth dams were decided upon because of geological and topographical features, and the abundance of suitable material for earth fills, to meet the total requirements of 4,520,000 cubic yards. The spillway structures and the extensions tying in the earth work are of cyclopean masonry. No unusual features are involved in the design of the impounding structures or power installations.—*Eng. News-Rec.*

Alaska road commission.—The Alaska road commission, as recently reorganized, is now composed of Major Jas. G. Steese, Corps of Engineers, U. S. A., President,; Capt. John C. Gotwals, C. E., Engineer, and Capt. C. S. Ward, C. E., Secretary and Disbursing Officer. The headquarters of the commission are located at Juneau, Alaska, the capital of the Territory, and sub-offices are maintained at Valdez, Seward, Fairbanks, and Nome.



During the sixteen years of its existence, the commission has constructed and maintained a system of wagon roads, sled roads, and trails, which now aggregate nearly 5,000 miles, including a connected system of 4,600 miles reaching to all parts of the Territory. About 1,050 miles are classed as wagon roads. During the past summer, a regular service by automobile was maintained between Fairbanks and Chitina on the Copper River Railroad, a distance of 320 miles, the usual time being three days, with a record trip of 22 hours, actual running time. This road encounters about every possible construction difficulty from sub-tropical swamps to snow-covered mountains.

The Commission has at its disposal appropriations from the Federal Treasury for "Military and post roads, bridges, and trails" from the "Alaska Fund" supported from local federal taxes, and from the Territorial Legislature. In the forest areas it works in co-operation with the Department of Agriculture.

The Alaska Advisory Committee (Federal) reported on June 11, 1920 that "the construction of wagon roads and trails is one of the most important and urgent needs of Alaska. Without the construction of a large mileage of wagon roads and trails the resources of the Territory cannot be made available. Nothing will contribute more to development of tonnage for the Government Railroad than a system of tributary wagon roads. The Committee recommends that *Congress be asked to make an annual appropriation of not less than a million dollars for the construction and maintenance of wagon roads and trails in Alaska.*"

Progress on the Wilson dam.—The erection of seven traveling derricks for use on the spillway section of the Wilson dam, is now well advanced. Two of these derricks are in successful operation. They are briefly described as follows:

The derricks are of the traveling tower type, capable of revolving in all directions. The operator is about 40 feet above the tracks and from his platform controls all movements. The top of the mast is about 75 feet above the track and supports a boom 85 feet long. The capacity is 10 tons on a low boom, hoisted at 75 feet per minute, requiring a counterweight of about 17 tons. The swinging rate is 1 1-3 revolutions per minute and the travel rate 150 feet per minute. All operations are done by electricity and can be carried out simultaneously, the current being transmitted by three wires and a trolley. The motors are 3-phase, 60-cycle, 220-volt, alternating-current type, that for the hoisting being 75 horsepower; for the traveling, 52 horsepower, and for the swinging, 11 horsepower. Each of the four tower legs rests on a truck of two wheels. The maximum load on each front leg is 100,000 pounds, and on the back leg, 67,000 pounds. The bases of the legs are 38 ft. apart up and down stream and 36 feet across stream. They were constructed by the E. F. Terry Mfg. Co. See illustration.)

The Reserve Corps in the New Army

The following provisions of the Army Reorganization Act of June 4, 1920, will be of special interest to the Reserve Corps:

"For purposes of administration the continental area of the United States shall be divided into corps areas. Each corps area shall contain at least one division of the National Guard or Organized Reserves. Territorial distribution shall be made by a committee composed of members of the General Staff and an equal number of reserve officers, including reserve officers who hold or have held commissions in the National Guard.

"All policies affecting the organization, distribution and training of the National Guard and the Organized Reserve shall be prepared by committees of the General Staff to which shall be added an equal number of Reserve Officers, including Reserve Officers who hold or who have held commissions in the National Guard. While so serving such officers shall receive the pay and allowances of their grades.

"Persons hereafter commissioned as officers of the National Guard shall not be recognized unless they shall have been selected from the following classes: Reserve Officers, etc.

"So far as practicable, Reserve Officers shall be assigned to units in the locality of their places of residence. Any Reserve Officer may hold a commission in the National Guard without thereby vacating his Reserve Commission.

"After January 1, 1921, the Chief of the Militia Bureau shall be appointed by selection from lists of present and former National Guard officers who hold commissions in the Officers Reserve Corps. He shall have the rank, pay and allowances of a Major General of the Regular Army. The President may assign not exceeding 500 officers of the National Guard, who hold reserve commissions, to duty with the Regular Army, in addition to those attending service schools, and while so assigned they shall receive the same pay and allowances as Regular Army officers of like grade.

"Captains and Lieutenants belonging to organizations of the National Guard shall receive compensation at the rate of one-thirtieth of the monthly base bay of their grades as prescribed for the Regular Army, for each regular drill or other period of instruction authorized by the Secretary of War not exceeding five in any one calendar month at which they shall have been officially present during the entire required period. Captains commanding organizations shall receive $240 a year in addition to the drill pay herein prescribed. Officers above the grade of captain shall receive not more than $500 a year, and officers below the grade of major, not belonging to organizations, shall receive not more than four-thirtieths of the monthly base pay of their grades for satisfactory performance of their appropriate duties. Pay shall not accrue to any officer during a period when he shall be lawfully entitled to the same pay as an officer of corresponding grade in the Regular Army.

Commissions in the Regular Army still open to former emergency officers.—A *competitive* examination of eligible candidates who were for any good reason unable to take or complete the July examinations for appointment in the Regular Army, under Section Twenty-four, Act of June 4, 1920, will be held October 25, 1920, to fill two hundred vacancies in grades from Major to Second Lieutenant, inclusive.

Examinations will be similar to July examinations, and will contemplate appointment in the Infantry, Cavalry, Field Artillery, Coast Artillery Corps, Air Service, Corps of Engineers, Signal Corps, Ordnance Department, Chemical Warfare Service, Medical Corps and Dental Corps.

Applications for this examination will be accepted *only* from the following classes:

(*a*) Eligible persons who for any reason were not authorized to take the July examinations.

(*b*) Persons authorized to take the July examinations who for any good reason failed to appear before an examining board.

(*c*) Persons authorized to take the July examinations who appeared before an examining board but who for some good reason of their own volition or through illness or accident failed to complete the examination.

(*d*) Persons examined during the July examinations who were found disqualified on account of physical defects which have been removed by operation or do not exist at the time of the next examination. The physical qualifications of such persons to be finally determined at the time of the next examination without any further delay for recuperation or other examination at a later date.

All applications should be forwarded to The Adjutant General of the Army, Washington, D. C., on Form 739, A. G. O., and must reach the War Department *on or before October 9, 1920.*

When plans are developed for the examination of applicants for appointment in the Regular Army under the provisions of Section 24e, Act of Congress, approved June 4, 1920, announcement will be made through the public press, and those who are eligible may submit applications at that time.

Capt. J. H. DEVINE, formerly of the First Engineers, Camp Knox, Ky., has accepted a position with Edward R. Bacon Company as their District Representative at Sacramento, California.

Proposals

PROPOSALS FOR LEVEE WORK.—U. S. Engineer Office, 519 Canal Street, New Orleans, La.—Sealed proposals will be received here until 11 a. m., September 8, 1920, and then opened for constructing about 2,777,000 cubic yards of earthwork in the Atchafalaya, Lafourche, Barataria, Pontchartrain and Lake Borgne Levee Districts. Further information on application.

PROPOSALS FOR JETTY CONSTRUCTION.—U. S. Engineer Office, Customhouse, New Orleans, La.—Sealed proposals will be received here until 11 a. m., September 16, 1920, and then opened, for extending the jetties at the mouth of the Southwest Pass of the Mississippi River.

PROPOSALS FOR STEEL HULL FOR U. S. S. "CHISCA."—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Sealed proposals will be received here until 11 a. m., August 26, 1920, and then opened, for furnishing one steel hull for U. S. S. *Chisca.* Further information on application.

PROPOSALS FOR LEVEE WORK.—Office Third Mississippi River District, P. O. Box 404, Vicksburg, Miss.—Sealed proposals will be received here until 11 a. m., September 3, 1920, and then publicly opened for constructing about 260,000 cubic yards of levee work. Information on application.

U. S. ENGINEER OFFICE, NASHVILLE, TENN.—Sealed proposals for four steel barges will be received here until 11 a. m., September 13, 1920, and then opened. Further information on application.

U. S. ENGINEER OFFICE, JACKSONVILLE, Fla.—Sealed proposals will be received here until 12 m., September 15, 1920, and then opened, for jetty construction at entrance to St. Johns River, Fla. Information on application.

SALE OF GOVERNMENT PROPERTY.—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Under authority of the Secretary of War, dated July 21, 1920, contained in E. D. file 102092/3, there will be sold at Public Auction, at the Government Fleet, below the bridge, at Memphis, Tenn., at 10 o'clock a. m., September 2, 1920, one wooden hull, stern wheel steamboat belonging to the United States, 138 feet long by 28 feet 9 inches wide and 4 feet 10 inches deep. Terms: Cash at time of sale. Further information on application.

PROPOSALS FOR FIVE RETURN-FLUE BOILERS FOR U. S. S. "CHISCA."—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Sealed proposals will be received here until 11 a. m., August 26, 1920, and then opened, for furnishing and delivering five return-flue boilers for U. S. S. *Chisca.* Further information on application.

PROPOSALS FOR LEVEE WORK.—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Sealed proposals will be received here until 11 a. m., August 16, 1920, for constructing about 700,000 cubic yards of earthwork in the Upper and Lower St. Francis and White River Levee Districts. Further information on application.

PROPOSALS FOR STERN WHEEL STEEL TOWBOAT HULL.—Office Mississippi River Commission, 3d District, Vicksburg, Miss.—Sealed proposals will be received here until 11 a. m., August 23, 1920, and then publicly opened, for constructing one stern-wheel steel towboat hull. Information on application.

U. S. ENGINEER OFFICE, JACKSONVILLE, FLA.—Sealed proposals will be received here until 12 m., September 15, 1920, and then opened for constructing and delivering ponton catamarans for the dredge *Maj. J. C. Mallory.* Information on application.

PROPOSALS FOR HIRE OF TOWBOAT.—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Sealed proposals will be received here until 11 a. m., August 16, 1920, and then publicly opened, for the hire of a towboat of about the following dimensions: Length, 130 feet; beam, 28 feet; engine, 12 inches by 5 feet. Further information on application.

U. S. ENGINEER OFFICE, ST. LOUIS, MO. Sealed proposals for constructing and erecting a steel traveling yard-bridge for handling iron ore, coal, etc., from barges at St. Loius, Mo., will be received at this office until 11 a. m., August 21, 1920, and then opened. Information on application.

U. S. ENGINEER OFFICE, CUSTOM-HOUSE, ST. LOUIS, MO.—Construction of an all-steel traveling yard-bridge, length about 500 feet, clearance height above rail 70 feet, with electric trolley and clamshell bucket, capacity 500 tons per hour, is contemplated for unloading iron ore from river barges at St. Louis, Mo. The dock wall and foundations and track for the bridge will be furnished. Contractors with experience in the construction and erection of such machines are requested to communicate with this office.

U. S. ENGINEER OFFICE, LOUISVILLE, KY.—Sealed proposals for furnishing and delivering Structural Steel, Castings, etc., for Lock No. 44, Ohio River, will be received at this office until 12 o'clock noon (central time), September 9, 1920, and then opened. Information on application.

PROPOSALS FOR ROCK.—U. S. Engineer Office, 519 Canal Street, New Orleans, La.—Sealed proposals will be received here until 11 a. m., September 7, 1920, and then opened, for delivery of 20,000 tons of one-man rock. Further information on application.

PROPOSALS FOR DREDGING.—U. S. Engineer Office, Providence, R. I.—Sealed proposals will be received here until 2 p. m. (Eastern standard time), August 26, 1920, and then opened, for dredging in Providence River and Harbor, R. I. Further information on application.

PROPOSALS FOR REMOVING WRECK.—U. S. Engineer Office, Wilmington, Del.—Sealed proposals will be received here until 11 a. m. (standard time), September 7, 1920, and then opened, for removing sunken steamer *Sylvan Dell* from Salem River, N. J., the wreck to become the property of the contractor. Further information on application.

PROPOSALS FOR LEVEE WORK.—Office of the Secretary, Mississippi River Commission, 1311 International Life Building, St. Louis, Mo.—Sealed proposals will be received here until 11 a. m., September 30, 1920, for constructing about 55,000 cubic yards of earthwork in the Riverland Levee District, Mo. Further information on application.

Everlasting concrete was needed—

And Austin cube mixers were chosen exclusively to mix the concrete for these giant foundation pillars.

In addition they mixed the concrete for the 12 great locks, the deep channels, etc.; 5,000,000 cubic yards of it. One hundred machines did the job.

Never were mixers put to such a test of endurance and time; Austins passed it; made records, too—a triumph for the cube mixing principle.

The Fundamentals of Staff Control

By

G. R. Young
Captain, Corps of Engineers

[*Introductory note.*—It is with pleasure that we present to our readers the two articles which follow, with discussions, on the all-important subject of staff functions and organization in military operations. The subject is one of great importance and of interest, not alone to the "highbrows" (so called) of the staff, but to the plain soldier on the battlefront, or "doing his bit" back in the S. O. S., to whom the "staff" were mystical and little known individuals enthroned in those celestial (or infernal) regions called "headquarters," angels with flaming swords, or devils with tridents, to be referred to in awesome whispers, or loud curses, according to the reverence of the individual (or his lack of it), his mood at the time, or his most recent experiences.

The workings of the "staff," whether familiar or mysterious, are of vast interest to all military men, and in these articles are discussed in most illuminating and entertaining fashion.

The two authors, both of whom are engineer officers, saw, between them, the entire field of staff activity. Captain Young, of the Staff at G. H. Q., had a close view of and participated in the operations of the Great General Staff at Headquarters. He observed, so to speak, the workings of the central power plant. He was a keen observer and expert analyst of what he saw. Major Lee, many miles away, observed with equal acumen, the temper of the cutting edge of the tool. As G-3 and Chief of Staff of one of the most active of the combat divisions throughout its operations, he saw at close range, the workings of our staff system on the field of battle.

Each of the authors saw things beyond the other's ken. That these different points of view should have caused considerable divergence of opinion was to have been expected. But this divergence of opinion is both instructive and interesting. It makes good reading.

The various commentators, as keen and perspicacious as the authors themselves, fall in line with one or the other or develop new points of view, adding to the knowledge and gayety of nations. Amongst them are included men who gained national, even international reputations, in the functions of both staff and command.

The discussion of Captain Young's article closes with a lively comment by Major Lee, and Captain Young completes the discussion of Major Lee's views with an equally spirited comment. And the battle ends with a final review by Major Lee, which he submits to the editor with the remark: "Herewith my 'come-back' at your 'highbrow' friends."

In spite of differences of opinion, which are more apparent than real, truth struggles to the top in both articles and in the comments thereon. All of the writers are especially qualified by their abilities, training and experience, to speak with authority on the subject, and no reader who has any interest in military affairs or in our national defense, can afford to miss what they have to say.—ED.]

A LARGE part of the "army reorganization," of which one hears so much, will in the next few years center around the evolution of a satisfactory working relation between the General Staff and the bureaus of supply services. It appears to the writer that there are certain fundamentals in this relationship which we can not afford to lose sight of, and which should be written into our staff doctrine in plain words.

By "general staff" is here meant not only the staff organization at Washington, but also the general staff sections with territorial departments, field armies, corps and divisions, etc. Similarly the bureaus are represented in such organizations, on the technical and administrative staff. Contact between staff and bureaus thus exists throughout the army, and this will continue.

Before the war the problem scarcely existed, for our army, administratively, was built around the bureaus and The Adjutant General. The general staff was considered to be a body, august, remote, brooding on problems of strategy and Weltpolitik. It was presumed that when war broke out the staff would have its plans for a campaign with Germany "on file in the drawer marked 'G,' as the tale goes. Except for this, the staff seemed to the army at large to have little contact with reality. It was in fact principally an emasculated War Plans Division, or G-3, of a staff. It had never been permitted to be anything else; it labored under the burden of a curious national conception that a general staff was in some way bound up with militarism. The fact that the enunciators of this theory knew as little about the general staff as they did about militarism, did not prevent this concept from existing, and hindering a proper staff development.

It is true that Field Service Regulations outline a staff organization for units larger than a brigade, whose composition is almost that of the existing system. It includes (*a*) a Chief of Staff; (*b*) "Such assistants as are necessary" to handle the work of the "three general divisions of general staff work," *i. e.*, combat section, administrative section and intelligence section; and (*c*) a technical and administrative staff—representatives of the staff corps and departments.

But we had never until 1918 fought a great war under this organization; and there had never been worked out in practice the critical point in the above—the relation between the assistant chiefs of staff and the technical and administrative staff.

When a division wants a bridge built, what are the respective functions of G-1 and the division engineer? Such a concrete question is a type of the hundreds that arise, when the staff organization came into play on a large scale. And speaking for the army as a whole, there was not even any generally known doctrine on the matter, let alone the actual experience of the system needed to give a doctrine life.

With the working out of the problem during the war, with the various interpretations put on staff functions and the successes or failures in carrying it out, the writer has neither the space nor the experience to deal. But he believes that a clear statement, in Field Service Regulations and wherever else the subject is dealt with, of the following points, would aid materially in ensuring a smooth-working organization.

1. *What does the General Staff do?*

There are only two things that it can do—advise, or give orders. A general staff officer's functions are advisory with respect to his commander. To the subordinates of that command, within his province, his relation is that he gives orders.

There should be no mistake about this, for the point is often obscured. It is said, for example, that a staff officer does not exercise command. In his own name, of course, he does not. He issues orders in the name of his commanding general. The French express the same idea by saying that a general staff officer is "anonymous." The distinction is of importance when one considers, as I shall below, the *sphere* of general staff authority; but as regards the *nature* of the authority, is rather metaphysical than practical. If I, as a general staff officer, tie things up, I lose my job; but if I do not, if I run things as the gen-

Digitized by Google

eral wishes, then within my sphere I issue orders and exercise control. It matters little that to exercise it I must use the formula "by command of General Blank."

It is sometimes said that the general staff is "advisory." As stated above, this is true with regard to the commander. But this is only one side of the shield. It *would* be possible to have a purely advisory staff, a group of elder statesmen who sat to be consulted, and then relapsed while some one else did the work. But our staff does not work that way. G-1 of a division advises his general when consulted—just as the brigadier commanders do. But advice is not the sole nor even the principal function of either.

It is also sometimes said that the general staff "co-ordinates," or "supervises," or "outlines general policies." This again is dodging the issue. "Co-ordination" (surely the most overworked word in the army dictionary) implies, to begin with, a general getting together. But after the get-together is consummated, and everyone has said his say, some one must give orders. "Supervision" implies looking things over. But after they have been looked over, if anything is wrong, it must be righted by some one giving orders. "Outlining of general policies" implies a breadth of view essential to staff work; but you can neither outline a policy, nor put it into effect, without giving orders.

Advice—co-ordination—supervision—anonymity—general policies—all these words and phrases are valuable as expressing aspects and characteristics of staff work. But they should not be used to obscure the point that the general staff officer, besides thinking thoughts, has things to do, and that the way he does them is by giving orders.

2. *What is the nature of General Staff control?*

As stated above, a general staff officer gives orders as definitely as does anyone else in the army, except that his power to do so proceeds from position rather than from rank and is in the commander's name. The really distinguishing point about staff orders is what they are *about*.

Our pre-war army was used to two kinds of control—that of tactical or territorial commanders, and that of bureaus. Both consisted in the exercise of command over *men*, or over *organizations*, or over a certain *territory;* and as regards the men, or organizations, or territory in question, *all* matters arising which could not be settled by subordinates were referred to the single authority in question for decision.

There has now been introduced a third type, general staff control, which differs fundamentally from this. General staff authority is allocated and subdivided not over men, nor over organizations, nor over territory, nor (most particularly) over bureaus. It is allocated and subdivided by the *nature of the question.*

Suppose several questions arise in a brigade, or in a territorial department, or in a bureau organization such as the Corps of Engineers, for decision—let us say, a question of transportation, and a question of espionage, and a question of combat, and so on. There is no doubt in any officer's mind of who must settle those questions. They must be sent, if subordinates can not settle them, to the brigade or department commander or the Chief of Engineers as the case may be. *Whatever the nature* of the questions, they must, so long as they affect the territory or organizations in question, be routed to a certain man.

But suppose several such questions arise in units of a division and must go all the way up for a decision. "All the way" means to the division commander, but that in most cases means his general staff. To which staff section then shall they go? The answer is no longer inherent in the territory or men affected—in the *source* of the question—but in the *nature* of the question.

G-3 handles operation and combat questions; and if the infantry or engineers or signal troops are going to fight, they take their troubles to G-3. G-1 (divisional) handles supply and transport questions; and if the engineers or signal troops are going to establish a depot or run a convoy, and need a decision from higher authority, they go to G-1. The division engineer takes orders from G-1—make no mistake about that—but not *as* division engineer; he takes orders from G-1 *to the extent that* he has supply and transport *questions* that higher authority must solve. Similarly he takes orders from G-3 to the extent that he has combat questions.

This is the real meaning of the saying that a general staff officer "does not exercise command." For he controls not one man nor one foot of ground—wholly. But he controls perhaps millions of men, and a whole country, as regards *certain* of their activities. He is one element of the general's brain—magnified. And in general, chief of staff and G-sections should be considered as one unit giving decisions. Thus the elementary staff diagram is as shown in Fig. 1 (p. 507).

The lines indicate channels of reference of questions (up) and of decision (down). Point A may be taken as the adjutant, or whatever office receives and sorts papers. As indicated, questions are sorted at this point and pass up to the various staff sections according to the nature of the question, also, of course, according to the nature of the questioner who may take his difficulties direct to the staff officer concerned and thereby save time.

This expresses the meaning of "co-ordination." A question should not go up to the staff at all, as will be shown below, unless its answer affects some one other than the asker. So, when the division engineer goes to the general staff for a decision, it is because the answer will affect, say, the division quartermaster also. Say it is a question of which is to get the use of certain transportation. It must be decided—co-ordinated—by some one who thinks, not in terms of engineer or quartermaster questions, but in terms of transportation questions—namely, G-1. G-1 will not know one-tenth as much about engineer matters as the division engineer, and if he is wise, he will not pretend to. What he does know more about is what the general wants moved, and what there is to move it with. He co-ordinates. And co-ordination can be done only by this *functional* control.

This conception of functional control is simple enough—a regimental adjutant and regimental supply officer are common small-scale illustrations—but it is curious how often the point is missed in staff work. For example, I have heard it proposed that the bureaus or services of supply should be divided among the staff sections—the division quartermaster under G-1, for example, the division engineer under G-3. Or diagrammatically as in Figure 2.

In other words, G-3 would control, not only the operations activities of the division engineer, but also his supply activities. But that is not the business of G-3; he is the lobe of the general's brain that thinks operation thoughts, and nothing else. If the general wanted to subdivide his brain differently, and to think not combat and supply thoughts but engineer and quartermaster thoughts, he would not need any general staff; for the best thinker of engineer thoughts that he has is his division engineer. Another variation is the idea of putting all bureaus or supply services under one staff section. Do it, and you cease to have a staff section. You get instead a super-bureau, which still

Digitized by Google

has the typical bureau characteristic—it exercises organizational or territorial control, not functional control, and needs some one above it to be a real staff section and coordinate things.

The *character* of general staff control then is *functional.*

3. *What is the extent of general staff control?*

In other words, how far may the general staff control or interfere with the workings of the bureaus?

The elementary staff diagram (Fig. 1) shows that questions referred up to the staff are re-sorted en route. When they start up they are classified by source, when they arrive they are classified by character. With this difference, however, staff control is similar to the other kinds of control that we have been used to. The problem of determining its extent is simply that of deciding what questions must be referred up to the staff at all. The answer is the same as for any other kind of control.

X, a subordinate, should refer questions to Y, his superior, when, and only when, the answer affects some one else besides X and co-ordinates with or superiors to him.

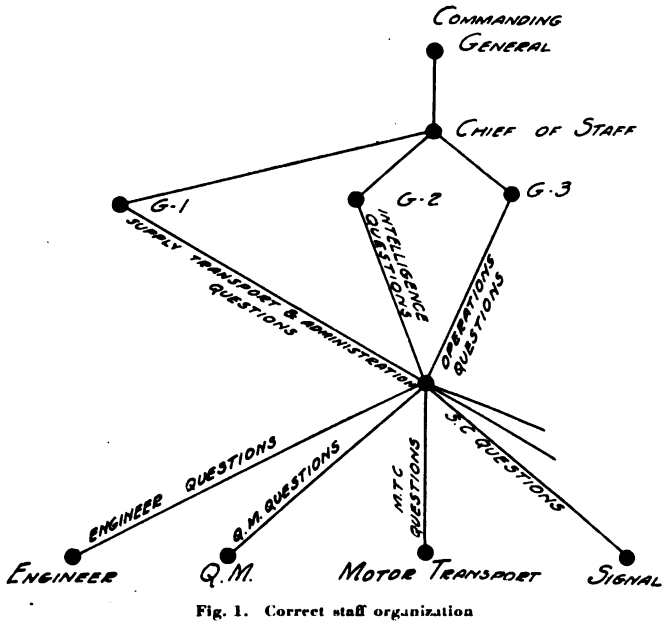

Fig. 1. Correct staff organization

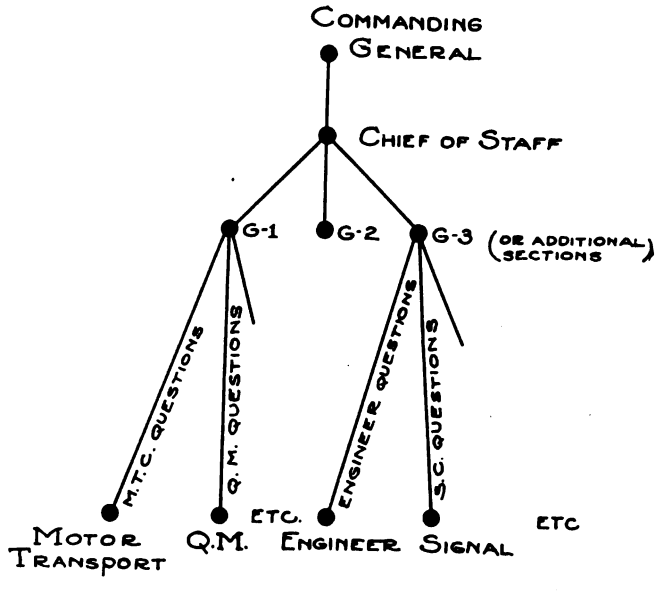

Fig. 2. Incorrect staff organization

Exceptions will be found to this, but as one goes higher and deals with larger and more decentralized units, the exceptions become progressively fewer. It is a good working rule.

Suppose a division engineer must build a bridge, preliminary to an attack. When and where shall it be built? What engineer troops, and what other troops shall be used? What engineer and what other transportation? Ponton or trestle—design—material—width of roadway—strength? What tools shall he provide, and how shall he organize his labor? These are samples of the questions put up to him. Which ones must be referred to the general staff for decision?

The time of construction, and in general the location, affect many people besides himself. If he needs troops or transport other than those under his control, that affects other people. And he must know what his bridge is to carry. These points must go to the general staff for decision, since they affect others than the division engineer. The other points mentioned do not, and he must be permitted to decide them himself.

Suppose the Chief of Engineers wants to buy, for engineer depots, some field searchlights and some canvas. A large war is on, and the production facilities of the country are strained to the limit. How far should the general staff concern itself with the purchase?

With the searchlights, not at all, except insofar as necessary to avoid complication of allocations of raw materials. Nobody issues field searchlights but the Engineers. With the canvas, yes, for many other bureaus issue it, and many arms of the service use it. Just what the staff would do here—whether it should make the purchase itself, limit the quantity which the Engineers purchase, etc.—I am not prepared to discuss. But it should do something; for if it permits the Engineers either to grab all the canvas or to be frozen out of the canvas market, if it permits uncontrolled price and priority competition in the market between bureaus, it is not on the job. Here, as in the first case, the general staff interferes when, and only when, some one besides the Engineers is concerned.

In discussions of the extent of staff control and interference, one finds—as elsewhere—much camouflage. It is said that the general staff should handle only "broad general" questions. This is well enough as far as it goes, but as a working rule it is a bit indefinite. It is said that the general staff should not interfere with "technical details." But this may not be correct. If our bridge-building division engineer wants to borrow the divisional supply train and build a rock fill half across a river, it is quite permissible for G-1 to ask if he can not arrange some other design needing less transportation to construct; and a highly technical discussion may develop. But if the engineer, *with his own forces,* can make that fill, and wants to, it is not a G-1 matter. The criterion is not the technicality of the question, but whether the answer affects anyone besides the division engineer.

G-1 may, of course, think that such a bridge will be washed out at the first flood and raise the question on that basis. But he takes his life in his hands if he does, for he is discussing with an expert a question which concerns only that expert. If the division engineer is on the job, he will demonstrate that his judgment is correct, and spend the next month telling his friends how he took a fall out of the general staff.

And, on the other hand, the method of cooking beans is a non-technical question; but no G-1 should interfere with the bean-cooking of the detachment working on the bridge, unless they showed signs of starvation, or at least chronic dyspepsia.

Digitized by Google

None of these formulæ cover the case. The writer believes that his own does. The general staff co-ordinates; and co-ordination is needed only when there is duplication, or competition, or combined action on the part of two or more bureaus. In other words, decisions are made by the staff when they affect more people than the man asking the decision.

Conclusions

The general staff system, which came in with the late war, did not arrive without much inevitable friction and complaint. Reduced to their fundamentals and stripped of complications of many kinds, these complaints are easily classified under one of two heads:

A—Complaints by general staff officers that bureau representatives object to receiving orders from them, or to being subjected to general staff control.

B—Complaints from bureau representatives that staff officers interfere unduly with them, trespass beyond their province and try to "run" the service.

[It is not, of course, meant that such complaints were universal or even customary; but when there *were* complaints, they were along these lines.]

As regards "A," the answer is inherent in the doctrine given under "1" above. The bureaus must cease to object. Of course the general staff gives them orders. What else is it for? It is the mouthpiece of the general.

For various reasons it often occurred in the late war, and may occur again, that general staff officers, especially in smaller units, were junior in rank and length of service. But there is no valid reason here for making trouble. A regimental adjutant is junior to a battalion commander, yet the latter receives orders over the former's signature.

As regards "B," the answer is believed to be the training of our general staff as stated in "2" and "3." The staff must remember that it *co-ordinates*, and that co-ordination implies two things—functional division of duties and non-interference except when questions concern two or more bureaus or services.

The writer believes that there is nothing new in the above; that it is the basis of our staff doctrine. But he also believes that there is a vast amount of uncertainty about it, and that the points are often slurred over or concealed in vague words. If the above doctrines are those approved as basic for our general staff practice, they should be enunciated in our regulations so clearly that no doubt exists about them in the minds of the Army.

For discussion see Page 561

Staff Organization and the "Theoretical Single Mind"

By

Jno. C. H. Lee

Major, Corps of Engineers; formerly Colonel, Chief of Staff, 89th Division, A. E. F.

In November, 1918, G. H. Q. of the A. E. F. issued a provisional Staff Manual. It was somewhat more complete, particularly in regard to higher staffs, than The Staff Manual published by the War Department in 1917. Neither publication, however, was at the time recognized to be complete, and both are known to have been loosely written. It is not the purpose of this article to present a staff manual, but it is hoped to offer a few principles of staff organization which the writer believes should be built into the foundation of a staff manual for the Army.

The Leavenworth "staff doctrine," which appears to have been the basis of both staff manuals, seems to be built on the following assumptions:

That the division or higher unit must be governed by "a theoretical single mind," the commander and his staff constituting the theoretical single mind which controls and influences the unit;

That the work of such a staff is logically divided into "general staff" and "technical and administrative" duties;

That a staff officer, as such, can give no orders in his own name;

And yet that a staff officer may properly control operations of the very troops themselves "in the name of the commander";

That a head of a service is expected "to function under" and "be co-ordinated by" one, two, or sometimes even three general staff "Gs";

That no limit is placed on the number of subordinates which a general staff "G" may be expected to "co-ordinate," "function over" or "control";

And that direct responsibility and command play no essential part in staff organization—a fair inference, since the idea is never expressed.

Moreover, the present doctrine coming from the Leavenworth schools in the form of lectures on staff organization, indicates that there has been no appreciable change in American staff policy as a result of our experience in the war.

It is not known why Leavenworth should indoctrinate the American Army with such an impracticable framework when the simple principles of organization can be applied to the staff as well as the line.

The writer has been told that the Leavenworth staff system was originally copied from the German, because it was thought that American armies would surely have political figureheads in command, much as the German armies must necessarily be led by titled figureheads, each case requiring trained technical experts to do the real brain work. If this were the hypothesis, our recent experience has eliminated the argument, for we had no political figureheads as higher commanders. Certain critics of the system say that it was formulated by a group of gifted young men desiring to create a system by which they, although juniors in rank, might gain control of the conduct of campaigns

Digitized by Google

which must be handled in name by their seniors in service. Such discussions are interesting but get us nowhere. Nearly every member of the American Army, however, has seen a few if not many of the bad effects of this system. Those of us who saw it intimately should, before we forget, endeavor to point out the reasons for poor results and suggest, if possible, improvements.

It is believed that the word "organization" is and has been the most misused word in the language of the American Army. In the line we have by regulation a spendid framework which should guarantee "organization" throughout all the units of tactical command from the brigade down. That for the great majority, these organizations were not, and are not, real organizations, is due mainly to the fact that the first principles of "organization" were not and are not put into effect.

The first principles of "organization" seem to the writer to be these:

1. There shall be a single head who commands the organization. He is responsible for it to his proper superior. This single head alone commands the organization as such, and all orders or instructions for the organization should come to or be known by him. This is his responsibility and his command. He is responsible for all results of his organization, all that it does or all that it fails to do. It is his. He must produce with it—or be replaced.

2. The organization commander must divide his task into several distinct parts, as few as possible consistent with his mission, and divide his personnel to carry out these tasks. He must place in command of each part a responsible principal assistant whom he charges with the duty of carrying on that part of the work. This is the first subdivision within the organization.

3. To each of his principal assistants the commander must make it clear—

a. That the commander is the assistant's boss.

b. Just what the assistant's own mission is.

c. Just what the assistant can count on as his own means in personnel and in materiel.

d. That the assistant will be considered the boss in his own subdivision, will be backed up so long as he produces results and lives within the law, but must be held responsible for everything that his subdivision does or fails to do.

4. Each principal assistant must similarly "organize" his own subdivision along the same lines and require his assistants to do likewise. In this way is created the chain of command.

5. In military organization no single man can be expected to supervise personally and effectively, the work of more than seven immediate subordinates. The corporal, the lowest ranking field commander, has seven men under his immediate orders. This is the maximum. If a man has more subordinates, he won't know what they are doing in action, or in other times of stress, when it is most important that he do know. As the administrative duties and brain work of the successive commanders increase, the number of immediate subordinates should decrease. Where a commander's organization is stationary, the force can consist of larger echelons than where it is mobile and must meet constantly changing conditions.

6. There must be no one in the organization who does not know who his immediate superior is, and no officer or N. C. O. who does not know what his own job is and what he has of his own to do the job with. It is well for each private to know his general's name and the cause of the war—but it is essential that he know his own corporal as his boss. No man must have more than one "boss." If a superior officer interposes an order, the subordinate must, of course, obey—but the man's loyalty to his own commander must prompt him immediately to inform his commander of the circumstances. Each man must feel that he "belongs" to his boss and is responsible to him for all his time.

7. In any real organization, civil, military, religious, or otherwise, there are two general classes of duties—line and staff. In the military profession the line has the primary mission in war of inflicting loss on the enemy—our allies used to say, "killing boches." The staff has as its mission the duty of assisting the line in every possible way.

There are other principles which should be followed in guaranteeing the continuance of sound organization, but it is believed that the above are the essential ones. True organization may not be the cure-all for military troubles, but it is believed that the faithful application of these principles will go further toward success in campaign than any other known phase of military art.

Take, for example, a statement I heard on the boat coming home, made by a general staff officer who had held a very important position in the A. E. F. He said, "It has been demonstrated that the company of 250 men is too large. No captain can command 250 men. Why, he can't even feed and clothe, let alone control 250 men in action." Of course not. Neither did Marshal Foch personally control the Allied Army in action. Had this officer said that "a squad of 250 men" is too large we would quite agree with him. He apparently forgot that the company commander's organization properly consists of four platoons and a company headquarters, each one of which is properly commanded by a platoon leader or a headquarters chief. The company commander, if his organization is properly developed, need deal ordinarily with only five men. He looks on the company, its needs, requirements, its mission, *as a company,* and he requires his assistants to take care of the details. This does not mean that the lieutenants commanding platoons must handle and discipline the privates. If they do, they are wearing themselves out unnecessarily, as most of the officers did, while utterly neglecting, as most of them did, the proper development of their non-commissioned officers. Few, if any, of our companies had sergeants who really commanded their sections. The sergeant is usually considered as an indeterminate factor, as a corporal who has graduated from hard work and who is available for any old job anybody wants to give him.

When a company is actually an organization, the corporal commands the privates. Each corporal has his squad of seven men, for all of whom he is responsible in billets, on the march and in action. He should, moreover, be responsible for the equipment, clothing, physical condition and discipline of each man in his squad. The corporal thus supervises seven men (and otherwise they will not be properly supervised), and, moreover, the corporal, if worthy, will develop rapidly in initiative and responsibility. The sergeant, next, is given the command of two or more squads for which he is held responsible and with which he must produce results in billets, on the march and in action. His principal duty is to know his corporals, to be sure that they are producing for him and that they have everything that is necessary. In a similar way the lieutenant commanding the platoon deals with his sergeants (section commanders) and with the N. C. O. who commands his platoon headquarters. It is poetic perhaps for the captain to look after the feet of his soldiers; but who expects him to care for 500 feet! He will do well to take good care of *two*. Let him be sure that the lieutenants see the sergeants' feet, and that they see to it each sergeant knows, personally, how his corporals' feet are, having each corporal assure his sergeant that the feet of each private in his squad are inspected and being cared for. Such a company will have marching feet, and what is far more important, will be an "organization."

Besides the great advantage of thus guaranteeing a real framework whereby results can be assured and responsibility at any time be fixed, there develops within the organization a splendid morale due to the fact that every non-commissioned officer has a job, every non-commissioned officer has responsibility, every non-commissioned officer is given an opportunity to make good. He can win commendation or he can be found lacking. Every man knows just where he stands. Where these principles are put into effect the great majority of the non-commissioned officers are able to step efficiently into the next higher grade. If

Digitized by Google

officers can give their attention to the larger phases of their tasks, the entire outfit is relieved of that curse of mental and physical strain causing the commander and one or two efficient men to break down from overwork which should have been performed by all.

In general, therefore, it is safe to say that true organization is based upon responsibility and command. These form the foundation and framework without which no military superstructure can be expected to stand through the storm of campaign.

Now let us apply these first principles to the organization of a combat division. The writer spent most of his war service on divisional staff work and is therefore familiar with this phase of the problem, although his observation elsewhere leads him to believe that the principles would work out much the same way in corps and general headquarters.

As to the division, the major general is the single head who commands it. He is responsible to his superior, the corps commander, for all that his division does or fails to do. All orders for the division must come to or be known by him. The corps engineer does not command the division engineer. The corps artillery commander does not command the divisions' guns. The corps commander himself should give no orders to a subordinate commander in the division without informing the division commander (and the subordinate must report it, too.) The corps chief of staff must not personally send orders to the division chief of staff. Orders must be addressed to the division commander. He properly wants assurance that such orders express the corps commander's wish either given in person, or by signed order, or by a recognized staff officer "by command of the corps commander." The division commander is the single head, but it is not a "theoretical single head" made up of some four or five enthusiastic "functionaries."

The division commander divides his task and his personnel into two general classes—line and staff. In the line are three brigades, each commanded by a brigadier, a logical subdivision for infantry relief and artillery support. These are the commander's line subdivisions, and upon them he must depend to carry out his will in battle. He must be sure of results. He must have direct responsibility without interference. In the chain of command he must let no one come between him and his brigadiers. They must feel the power of his personality, the strength of his will, his determination, and never forget their responsibility directly to him. A staff officer, even the Chief of Staff, can give orders to the brigadier only in the name of the major general. In fact the staff officer is merely a trusted bearer of dispatches, expressing the will of the commander, and is unable, of course, to assume any responsibility for the execution of the order, when the order, expressing the commanders' wish, is delivered and understood, the staff officer's responsibility ends.

Now, as to the other distinct part of the division commander's task,—the supplying of his troops with "everything," not only all the material things of arms, equipment, ammunition, clothing, food, transportation and roads, but also accurate information of the enemy, and sound profitable plans and orders explaining the commander's wish. All this is staffwork—assisting the line. It includes all the supply services, of course, the engineers, signal troops, trains, sanitary personnel—in fact, all "divisional" units other than the brigades—every element whose primary mission in battle is to *assist* the line in its duty of inflicting loss on the enemy.

The division commander has by regulation a "chief of staff." Sound organization requires that this man be put in responsible control of all staff functions. This means he must command the staff and all the staff troops. He will thus relieve the division commander of all staff details—be responsible for them, one and all. To the division commander and to the brigadiers, he is in fact the staff. They look to him for results and they should deal with him. The division commander thus holds his tactical assistants (brigadiers) responsible for the tactical details of the work while holding his staff assistant (chief of staff) responsible for all staff details. The distinction is important. The chief of staff has no authority over the brigadiers. But he has full authority over all the staff. He can not "control the troops," but he does give orders to the staff in his own name.

The division commander thus assures his four principal assistants that he is their boss—no one else. They owe all loyalty to him. Then to each he gives the proper mission which is briefly to command the brigade or staff, train it, keep it fit, and produce results with it. He makes it clear what each brigadier's command includes—and similarly for the chief of staff. The commander allots the material means available—billets, transportation, equipment. He assures each assistant that he won't undercut him and, so long as results are produced within the law and regulations, backing up will not be lacking. When any censure is to be handed out for failure, the brigadier or chief will catch it unless that officer can put his finger on the responsible person and correct the trouble. The commander is responsible that his assistants pull together as a team.

Each line brigade has its interior tactical organization. The brigadier general need only see that it is actual and effective. The chief of staff, however, has a harder task. If he follows the French system, which seems sound, he divides his task into three parts—supply of all material things, arms, ammunition, equipment, food, clothing, transportation, tools, wire, shelter, bridges, roads, lines of communication, traffic control, sanitary care, evacuation, replacement and all matters of administration—this is the "first bureau" (G-1), then all "intelligence" or enemy information placed in the hands of the line commander who can use it—all maps, photographs, captured documents, and the examination of prisoners, all that pertains to censorship—this is the "second bureau" (G-2); and finally the tactical office, the supply of sound tactical advice, plans and orders, of tactical information up and down, right and left, of training plans, the putting of the commanding general's wishes into orders certain of comprehension by the line and the staff—this is the 'third bureau" (G-3).

The first bureau has by far the widest range of activities. That is the one in which we as engineers are most interested. According to an old custom we are said to be on a "line status when serving with troops," but this must be considered an obsolete expression when dealing with the organization of a combat division. Although we proudly, and quite rightly, maintain that we are soldiers first and foremost, nevertheless our primary duty as sappers and pioneers is to assist the fighting man by doing engineering for him in battle. Before action and following it, and, indeed, for the large part during any active operation, the engineers of a combat division must perform innumerable services for the welfare and comfort of the line. Of course, this is not all. We not only provide and maintain roads and rail lines from the base or from the distributing point to the troops, but passable routes of advance into enemy territory, working alongside the fighting man. In combat the pioneer may do many things, but his main function is either to help

Digitized by Google

the line soldier get forward so as the better to reach and subdue the enemy, or in defense to stop the enemy by obstacles so that the line soldier can dispose of him at more leisure.

This duty of assisting the line in all phases of its activi ties, in a material and practical way, places the engineers in accordance with sound organization under the first bureau of the staff. There they must be trained, kept fit and employed for all divisional purposes. For tactical use in direct contact with the line soldier, engineer battalions, companies or platoons must be assigned temporarily under the orders of the tactical commanders. While so serving the tactical commander controls these engineers entirely and is responsible for them. When the emergency demanding their use has passed they should be returned to the division engineer under the first bureau for refitting, replacement and further service.

The G-1 officer must, of course, organize his bureau along sound lines, dividing his work into distinct parts and putting responsible assistants in charge of cash. With our present complement of staff and staff troops, the writer believes that the best subdivision is:

1. An assistant for administration, under whom will serve adjutant, judge advocate, inspector and the commanding officer of the headquarters troop and detachment, senior chaplain and welfare agents.
2. An assistant for supply, under whom will serve the quartermaster, the ordnance officer, an engineer officer for supply, a signal officer for supply, and such other representatives of supply departments as may be necessary.
3. The division engineer commanding the engineer regiment and engineer train.
4. The commanding officer of divisional trains, under whose orders will serve the division supply train, the military police, the division veterinarian and the division motor transport officer.
5. The division surgeon, under whom will serve the commanding officer of the sanitary train, the sanitary inspector and the division dental surgeon.

Under the second bureau, which includes enemy information, called "intelligence" after it has reached the man who can use it, a comprehensive development requires a good organization. The writer found it best under our present system to have reporting directly to the assistant chief of staff, G-2:

1. The first assistant, G-2, in charge of the reports section, for receiving all intelligence reports from the tactical units and for preparing reports for higher authority. This section maintains the enemy order of battle and issues the intelligence reports and bulletins.
2. The reconnaissance section, which should be preferably commanded by an officer with topographic experience. He will have charge of all maps, all divisional observations and reconnaissance, airplane photographs and will command such units of the air service as the division has for observation.
3. Next is the enemy section under the senior interpreter in charge of all interpreters, translators, examination of prisoners, handling of civil affairs in occupied territory and counter espionage.
4. The fourth section, that of censorship, under the second assistant, G-2, includes mail, press, correspondents and attaches.

The third bureau under the assistant chief of staff, G-3, worked out for the writer very efficiently with only three sections:

1. The first was the operations section under the assistant G-3, where all tactical reports were digested and reports prepared for higher authority. The daily situation map was kept in this section, and all tactical, training, march and battle orders were prepared.
2. The second section was under the divisional signal officer, who was in charge of all divisional communications. Under his orders are such parts of the divisional signal battalion as are not assigned to the brigades, the division message center and all liaison agents reporting from adjacent and higher organizations.
3. The third section, under the division machine-gun officer, in charge of training with particular attention to specialties and automatic weapons. Visitors from our army were placed under his orders for reconnaissance duty. Other than in action (and once during an offensive) the division machine-gun battalion was placed under his orders and was used as the division machine-gun center, forming the basis for the infantry school of arms.

The assignment of personnel can not be fixed nor can the exact framework within the staff be considered permanent. The personal equation in practice becomes almost the ruling factor and must be recognized in order to get the best results. Granting this, however, it must be remembered that the first principles of organization should be faithfully adhered to, that at no time should responsibility be impaired, should command be disregarded, or should any subordinate be required to work for more than one boss at the same time. As seen above, the division engineer is placed directly under the orders of G-1 where the greater part of the engineering work is performed. In the supply section, however, where the services of an engineer are required to handle the routine of engineer supply separate from the regiment, a junior officer is so detailed and this engineer officer's boss is G-1's assistant for supply. Under the G-2 office, the officer in charge of the reconnaissance section will probably be an engineer. His boss will be G-2 and no one else. If for personal reasons, any of these officers are shifted, the matter is simple—let the officer, his old boss and his new boss, know of the change. But at no time must he be required to report to, function under, or be commanded by more than one superior.

It is believed that the proper assignment for the division munitions officer, if there be one, is on the staff of the commanding officer of the ammunition train who serves under the artillery brigadier. Moreover, the proper assignment for the senior chemical warfare service officer is on the staff of the artillery commander. Defense experts in chemical warfare should serve with the infantry brigades and with the sanitary train, at least until the line and medical personnel become thoroughly instructed in this phase of warfare. The sooner, however, that this work is absorbed and handled in action by the line itself, the more efficiently it will fit in with the combat organization.

The question of relative rank immediately arises in the minds of engineers. The division engineer with the rank of colonel is, according to sound organization principles, placed apparently under the orders of a junior. He must not be under the orders of a junior. The assistant chief of staff, G-1, must be in every way capable of commanding the division engineer, and not only the engineer but the surgeon and the commander of trains, his own assistants for administration and for supply. This is a large order. It takes an able man to fill the job. He must not only be capable along executive, administrative and co-ordinating lines, thoroughly grounded in this G-1 work, but he must be capable of appreciating the tactical requirements of each situation that confronts the division commander. The G-1 officer should be picked as the best executive supply and service man who has had sufficient tactical training to fit him for the job.

The writer feels that too much importance can not be placed on the proper conception of the G-1 qualifications of the general staff. As warfare has developed and the entire strength of a nation is placed behind its combat forces, the duty of co-ordinating all this material strength becomes every bit as important as the making of sound military plans, gaining accurate enemy knowledge and conducting successful strategic operations. Moreover, no one of these operations can be performed with efficiency without knowledge of the capabilities and possibilities of the other parts. Unless the G-1 chief has a military mind, his work and the final result must fall short of its full possibilities. Unless the tactical chief appreciates the G-1 situation, impractical plans or incomplete operations are cer-

Digitized by Google

tain to result. In other words, the true mission of the general staff, not only for the division but for any military body, is the duty of fitting all military activities of supply (material and otherwise) into a soundly organized system for control by the superior commander. It furnishes the "members" of the military framework which positively connect the commander with all the agencies that supply the line and make its successful operations possible.

It must be distinctly recognized, however, that the staff members should not be considered in any respect as coming between the tactical commander and the tactical subordinates. That responsibility must be direct and uninterrupted. The tactical details of any operation should be worked out by tactical subordinates. For example, on the division staff, the division commander having made his decision, the chief of staff must see to it that the G-3 officer supplies a comprehensive order expressing the commander's wish to his tactical assistants and to the chief of staff. G-3's duty is to see that the order is quickly framed into language that can be understood, that it contains no inconsistencies, that the orders of the corps commander are complied with and that there are no omissions. It is not his duty to work out the details of the brigadiers' plans. That is interference. Such details must be left to each brigade commander and his tactical subordinates.

The matter of relative rank under this system would work itself out. We should not be seriously concerned with such details so long as infinitely more important matters are at stake. If it seems necessary to have the division engineer a lieutenant colonel, well and good. When such an officer's duties are important enough relatively to warrant his holding a higher grade, that will be apparent and can be met. The writer personally feels that the division engineer, the division surgeon, commanding officer of trains and assistant for supply in the G-1 office should, under our present system, be lieutenant colonels. The assistant for administration should be a major. The G-1 officer should have the rank of colonel as should the G-3 officer who, during the absence of the chief of staff in active operations, perform the duties of the senior staff officer of the division. The assistant chief of staff, G-2, however, should be a lieutenant colonel.

As for the chief of staff, his duties and responsibilities demand an officer of caliber at least equal to that of the brigadiers. His responsibility if anything is larger, and his training should have been even more varied than that of a brigade commander, while being in all respects thorough; he is the division commander's first advisor and should be a man in whom the commander and the brigadiers have confidence. It is not felt that he should be senior to the brigade commanders, but he should have the same relative rank. This, however, is a matter of relatively small importance. Colonels can command colonels when the regulations require it. But, of course, the commander must not be of junior grade to his assistants. It should be remembered, when discussing rank on the staff, that this system is economical. A capable G-1 and assistant for supply will release older quartermasters and ordnance officers for better jobs, turning over to a junior officer the Q. M. and ordnance work under efficient G-1 supervision.

What we need in our military organization is not a single theoretical mind to control the troops—but one single head, the real master mind, to command the organization. We must recognize the responsibility and command go hand in hand, and form the real foundation and framework of the military structure; that the chain of line command must be direct, positive and unmolested by the staff; that sound organization being as vital to staff success as it is to line success, then full responsibility and complete command must be given to staff chiefs over their subordinates; that the rudiments of organization, applicable the world over, must not be disregarded in such an essentially practical business as war. All this means getting the desired results in the easiest, best and quickest manner—the essence of efficiency.

We should not be satisfied with the remark that capable staff officers will make any system work out. We must have a system which will develop good staff officers—a system which will produce results with "the run of the mine" material, sorting it automatically, requiring every individual in authority to prove his worth.

When such a system as this is put into operation and is maintained, it will be the greatest possible eliminator of dead wood. Every man in the entire organization will have his job, will have somebody requiring him to produce, will have the necessary means to make good or to prove his inefficiency. This is not merely a theory. It has been done. Its application will be fought by reactionaries and by the inefficient, but the writer feels that, imperfectly as these principles have been stated, their truth will carry conviction to all practical men.

For Discussion, see Page 565

Making Wood Fire-resistant with Paint

The inflammability of wood may be decreased by: (*a*) keeping it wet; (*b*) injecting chemicals into it under pressure; (*c*) painting it with fire retardent paint. The U. S. Forests Products Laboratory finds the last method the most practicable for the economical treatment of small quantities of wood. For interior use, ordinary calcimine or white wash has proved as effective as any paints investigated. It rapidly loses its effectiveness when exposed to weather, and for such conditions the Forest Products Laboratory recommends a paint consisting of linseed oil, zinc borate, and chrome green. Numerous patented fire resisting paints have also been found satisfactory.—*Eng. News-Rec.*

A Defense of "Essayons"

One of the older officers of the Corps of Engineers writes as follows:

I have noticed with regret a lack of due consideration in the way in which a question of a change in the time-honored motto of the Corps of Engineers, "Essayons," has been discussed in the columns of THE MILITARY ENGINEER.

Of all things most needed in this country at present, cool and judicial conservatism in combatting hasty and ill-considered action is the most desirable. It is as necessary to check the ultra-radical as it is to prod the ultra-conservative.

The radical efforts of fanatical minorities in demanding the enactment of endless laws to cure moral defects and to effect changes in every conceivable relation of social, business and industrial life on the mere grounds that because it is, it is wrong, will lead us into an endless maze of half baked legislation and executive action, which will eventually terminate in contempt for both law and executive authority.

The proper significance of "Essayons" is "Let us undertake it," "Let us carry on" no matter what the task presented, the order given, the problems to be solved, the difficulties to be encountered, the fatigues and dangers to be incurred, the personal sacrifices involved. The answer of the Corps of Engineers in the past has aways been, and with proper guidance and handling in the future, will always be "Essayons," "Let us undertake it" for "duty, honor, country."

The Port of Mobile as a Factor in Foreign Trade

By

R. S. Thomas

Major, Corps of Engineers, U. S. Army; M. Am. Soc. C. E.

[*Note.*—Fundamental economic principles are of more importance and more interest than technical details. They bear the same relation to the latter that the *control* of a survey bears to the details which fill up the map. Without a good control we can not have a good map, however carefully the details may have been executed. Similarly a commercial project, however vigorously and efficiently it is carried out, will certainly fail to achieve the full measure of success if based on an incorrect conception of economic principles.

These remarks are also true of warfare. In war, however, there is often opportunity to retrieve a bad plan and poor preparation by vigorous execution. In fact, this has been America's invariable method of conducting war. And we have achieved success, or apparent success, but regardless of cost. A very moderate amount of planning and preparation would have avoided war or have greatly reduced its cost. We are now bearing the burden of the unnecessary cost of war due to deliberate refusal to make preparation, and we will bear it for many years to come. And the next great war will impose an even heavier burden than the late conflict.

The principles of economics are of general application, and the author of this article furnishes us an excellent example of their concrete application to the most important of man's activities—commerce. His clear statements can not fail to be interesting and profitable to any engineer, whatever his particular line of activity.—ED.]

CONSIDERATION of the commercial prospects of any port requires a detailed examination and discussion dealing with—

(*a*) The geographical location of the port with reference not only to the trade centers in the interior, but also to foreign ports;

(*b*) The question of railroad rates on export traffic from the producing centers to the port;

(*c*) Combined rail-and-water rates on exports;

(*d*) The effect of these factors on the commerce of the port;

(*e*) Commercial statistics;

(*f*) Steps that might be taken to stimulate the movement of traffic through the port, and

(*g*) Port facilities and the physical efficiency of the port.

The port of Mobile, Ala., is selected as a concrete example for discussion. Local features have been omitted where not essential to indicate the method of treatment. In the practical study of a particular port, however, the local features predominate and must of necessity be treated in greater detail than herein, while the more general economic features can be greatly condensed or omitted.

Geographical location

In commerce, as in any other competition, whether on the race track or in warfare, an important factor is position. On the race track, as everyone knows, the "inside track" gives the horse an advantage. In military history there often occur the phrases "a strategic position," "interior lines," etc. It is also well known that the horse having the inside track does not always win the race, nor does the army in the best strategic position always win the war. Position, then, is an important factor but not the only factor.

In considering Mobile as a port let us first examine the advantages and disadvantages that accrue by reason of its position. In the first place, what is the position of Mobile with reference to trade? The chart herewith shows the United States divided by broken lines into zones which may be called tributary zones to a certain seaboard on the basis of railroad mileage. It will be noted that on the chart near the intersection of the longitude line 85 degrees and the latitude line of 30 degrees there begins a broken line extending almost due north to near Lexington, Ky., thence northwest to St. Paul, Minn. Points east of this line are nearer by railroad to the Atlantic seaboard than to the Gulf or to the Pacific. Near the southern extremity of the boundary line between Arizona and New Mexico there begins another broken line extending in a northeast direction. Points west of this line are nearer in railroad distance to the Pacific seaboard than to the Atlantic or to the Gulf. Points east of this line and west of the line before mentioned are nearer the Gulf seaboard than to the Pacific seaboard, or to the Atlantic seaboard. For the purpose of comparing the position of Mobile to that of New Orleans, its competitor, there has been drawn a third line of dashes extending north and northeast from Gulfport, dividing the territory tributary to the Gulf seaboard into two parts, that which is nearer to Mobile and Pensacola and that which is nearer Galveston or New Orleans. In this discussion no attempt has been made to distinguish the tributary area of Mobile from that of Pensacola—the geographical position of these two points is for all practical purposes identical. It should also be pointed out that from such points as Kansas City and Omaha the distance to Mobile is less than the distance to New Orleans, but that on a distance basis only the logical port for these cities is Galveston, which is the nearest port.

Thus we see that in distance alone Mobile and Pensacola have the inside track on exports from a large area in the South and Middle West, including the entire State of Alabama and large portions of Iowa, Missouri, Illinois, Kentucky, Tennessee, the southwest part of Indiana and the eastern half of Mississippi. This area includes the most fertile agricultural section of the United States and the coal and iron fields of the Birmingham district.

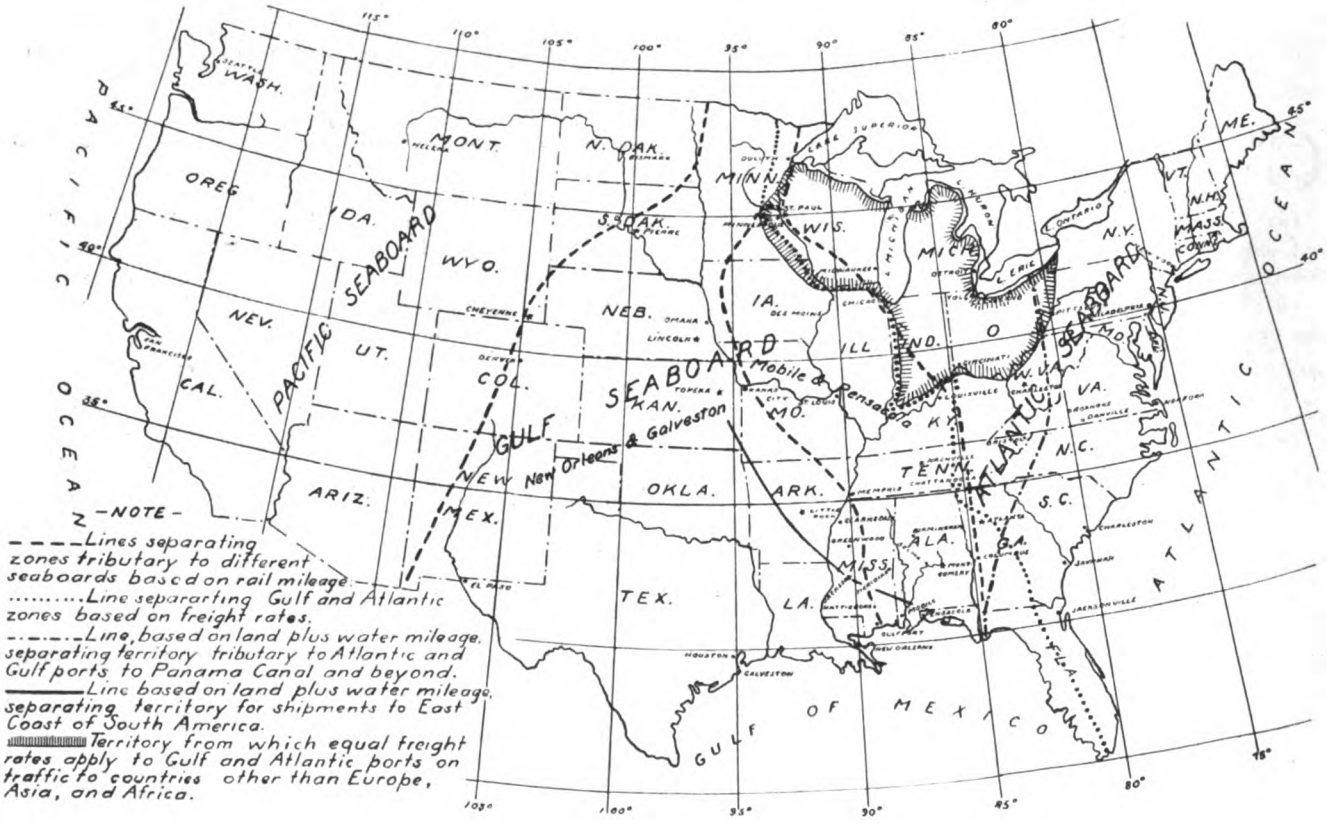
An idea of Mobile's geographical position with reference to these interior points may be obtained from a consideration of those cities which may be considered to lie within the "twilight" zone or near the border line of the tributary zone. For example, the following cities are slightly nearer the Atlantic seaboard, namely, Atlanta, Nashville, Cincinnati, Indianapolis, Chicago and Milwaukee. On the other hand, the following cities are slightly nearer the Gulf seaboard: Birmingham, Montgomery, Chattanooga, Louisville and St. Paul. These cities are said to be in the "twilight" zone inasmuch as the difference in distance to the Gulf and to the Atlantic seaboard is so slight that the matter of position alone offers practically no material advantage in

Digitized by Google

favor of either seaboard, and trade from these cities would result from such factors as storage and transfer facilities at the port, favorable schedules, direct haul, banking facilities and habits of trade.

As between the Gulf ports, Hattiesburg, Meridian, Memphis, Louisville, St. Louis, Dubuque, Des Moines and St. Paul are nearest to Mobile; Gulfport and Jackson, Miss., Chicago and Milwaukee are nearest to New Orleans, and Little Rock, Kansas City, Omaha and Denver are nearest to Galveston.

Positions with reference to foreign ports



In the competition between cities as exporting points the advantage of position with reference to producing centers is not alone sufficient to insure control of trade. Goods in transit have a point of origin, and a short haul from that point of origin to the seaboard is a material advantage; but these goods also have an ultimate destination, and therefore the distance from the port to that point of ultimate destination is also a matter to be considered. Let us now examine the position of Mobile with reference to the various ports of the world that receive the products of America. This is shown in the table on page 515.

Havana, Cuba; Cartegena, Colombia; the west coasts of Mexico and Central America via Panama Canal, and the west coast of South America via Panama Canal are all nearer to the Gulf ports than to the Atlantic ports, while Nassau, in the Bahamas; Port Au Prince, Haiti; Port of Spain, Trinidad; and the east coast of South America are nearer to the Atlantic seaboard than to the Gulf seaboard. As between the Gulf ports, Mobile and Pensacola enjoy a slight advantage over New Orleans and Galveston in having a somewhat less distance to Belize and points south, including the Panama Canal. This obviously gives Mobile and Pensacola a slight advantage in distance to all points on the west coasts of Central and South America. As for the west coast of Mexico the advantage lies with the Pacific seaboard.

Thus it appears that the "inside track," the logical trade territory for Mobile, consists of Cuba, Central America, Venezuela, Colombia, Ecuador, Peru, Bolivia and Chile.

Habits of trade

For the purpose of illustrating the functions of the ports of the Atlantic and Gulf coasts and for illustrating the various factors that determine the volume of trade through the several ports, let us imagine a small community situated in a fertile valley bounded on the east and south by a range of mountains through which there are several passes and beyond which lie good roads and the several markets for the products of this community. Now, let us consider Mr. Chicago who lives in the center of this valley and wishes to haul his products to the town of Liverpool situated to the east. Naturally he would haul his product by way of the east pass through the mountains. It so happens, however, that the road to the east pass is much more hilly than the road to the south pass, and it would be advantageous to go out by way of the south pass even if the haul is a little longer, but his grandfather and his father had always hauled by way of the east pass so Mr. Chicago continues to haul the same way. Now, suppose Mr. Chicago wants to haul his products to the town of Panama, lying south of him. The logical way, naturally, would be through the south pass, but there is a favorite merchant of his living near the east pass that will buy his wheat, corn, eggs and chickens, and sell his dry goods; so

Producing zones tributary to various seaboards on the basis of railway mileage

Digitized by Google

Mr. Chicago prefers to sell his stuff to this merchant rather than to haul it all the way to Panama, and this merchant at the east pass collects the produce from the various farmers in the community in large loads and ships out the produce to various markets in other communities.

Now, let us consider Mr. Meridian, a big cotton planter. He finds a better market for his cotton in the town of Liverpool than at Panama, but Mr. Meridian is nearer to the south pass than to the eastern pass. The southeast, however, has another pass over the mountains near Mr. Savannah's plantation, and the total distance to Liverpool by way of the Savannah pass is less than by the south pass, although he has a longer distance over bad roads to travel. If Mr. Meridian did his own hauling he would probably prefer to take the longer route and the better roads by way of the south pass. It so happens that Mr. Meridian doesn't own the necessary transportation, so he employs a truck company to do the hauling for him. The truck company charges a higher rate to go by the south pass than by way of the Savannah pass, and, of course, Mr. Meridian does not care what route the transportation company uses so long as he gets the cheapest rates.

In this parable one can see the advantage of nearness to the port; that is, the shorter rail haul or the shorter haul over the rougher and more expensive road. It will be seen also that nearness to the port is not necessarily the controlling factor, for the total combined distance from the point of origin to the point of destination must be considered. It will also be seen that where the producer does not do his own hauling that the combined distance from the point of origin to the point of ultimate destination is also not a controlling factor, but that the actual price that he pays for the service of transportation is what decides him. Generally speaking, the distance of haul naturally determines the price that he pays for his transportation, but the cost of this transportation is not always directly proportional to the distance over which the produce is hauled. There can also be seen in this parable the influence of that factor which may be called "Habits of trade." People follow the crowd and hold to well-established paths. This movement of commerce may be also compared with that of a river, once established in a definite channel it is very difficult to divert.

Total distance from point of origin to ultimate destination

How Mobile is situated as an outlet for commerce from various producing centers in the United States to the Panama Canal, can be determined by comparing the total rail-and-water distances from certain typical cities to Colon via the nearest Atlantic port and via Mobile. For example, Pittsburgh, Pa., is nearer to Colon via Philadelphia than via Mobile, the total distances by the two routes being, respectively, 2,702 and 2,594 miles. On the other hand, Cleveland, Ohio, is 82 miles nearer the Panama Canal via Mobile than via Philadelphia, its nearest Atlantic port. Charleston, W. Va., is 36 miles nearer by way of Mobile than by way of Norfolk; Danville, Va., is nearer via Norfolk. Knoxville, Tenn., and Atlanta, Ga., are, respectively, 163 and 186 miles nearer by way of Mobile than by way of Savannah.

These facts are shown graphically on the chart by the line of dashes and dots starting on the Gulf coast of Florida and extending northeastward and northward near Atlanta, Charleston and Cleveland. For the points east of this line, shipments to the Panama Canal would move by a shorter route by way of the Atlantic seaboard than by way of the Gulf. For the points west of this line, distances to the Panama Canal and to points beyond would be less by way of the Gulf than by way of the Atlantic seaboard.

For points north and east of the solid line that passes near Meridian, Jackson, Little Rock, toward Topeka, shipments to Buenos Ayres are nearer by way of the Atlantic seaboard. For example, the distance from Meridian, Miss., to Buenos Ayres via Savannah, Ga., is 22 miles less than by way of Mobile. It must not be forgotten, however, that these figures apply only to combined distance. As the cost of moving by rail is greater than the cost of moving by water, Mobile now draws shipments from territory north

of this heavy line, by reason of the shorter rail haul.

Freight rates

The advantages and disadvantages hereinbefore indicated are based solely on distance and are therefore more theoretical than actual. The actual cost of handling commerce on the present basis is the artificial but well-established railroad rate plus the somewhat fluctuating ocean freight rate. Where shippers own their own transportation they will generally take the shortest distance from their farm to their market, but where they have to pay a transportation company for the delivery of their product the distance is not of so much importance as the actual charges of the transportation company. We will suppose that when the first transportation company was organized they figured how much it would cost them to operate and charged prices that would enable them to make a profit. On such a basis the charges might be said to be based on the "cost of service."

But the transportation company may be supposed to have found later that they could raise the prices without reducing the volume of goods they handled and that the farmers would stand for it. They also found that a certain part of the community was not developing and therefore not producing much freight for handling by reason of its remote distance. The company therefore made cheaper rates for similar service to the remoter sections of the country, at the same time charging other sections as much as possible without discouraging production. The rates were then based on the rule called "All that the traffic will bear."

Let us suppose that other transportation companies were then organized. Then freight rates had to be adjusted to meet competition, and the rates were then placed on a "competitive basis." It was then found that people living in one section were getting a freight rate which made it uneconomical for the people living in another section to attempt to produce the same commodity. Freight rates were then "adjusted" so that one community could continue to produce in competition with the former and thus furnish freight to the transportation companies.

Now, let us suppose there were several farms in this community on the banks of a river, by means of which the produce could be hauled to market more cheaply than by the trucks or railroads of the transportation company. In order to meet this water competitor, the transportation company offered the farmer a price of transportation below that which it would cost him to haul by water, and, in order to make up this loss from the income of the transportation company caused by reduction in rates to the farms on the river, the price of transportation from the farms not situated on the water was increased correspondingly. This was a most usual practice.

This story shows in a general way the evolution of our existing elaborate and complicated system of freight rates. It is now easily apparent how far the basis of existing rates has departed from the original basis, *cost of service.*

Let us now apply these considerations to our local port. What effect would the return to the original basis of cost of service in the fixation of freight rates have upon Mobile?

First. Consider the topography of the eastern portion of our country. There is the Appalachian chain of mountains separating the Middle West from the Atlantic seaboard. Crossing these mountains involved a greater first cost in the construction of the railroad, a greater cost of maintenance of trackage and a greater cost of traction on the east and west railroads to the Atlantic seaboard as compared with the lesser cost of similar items on the north and south railroads following natural grade lines to the Gulf coast. This factor should have a tendency to enlarge the tributary area of the Gulf seaboard.

Second. The volume and density of traffic to the Atlantic seaboard is greater under present habits of trade and under existing freight rates than is the volume and density of traffic to the Gulf coast. The greater the volume and the density of traffic, naturally the less will be the proportionate charge per ton-mile of overhead expense and therefore the less the total cost per ton-mile. This factor would have a tendency to contract the area tributary to the Gulf. It is largely upon the theory of this latter factor, density of traffic, that existing freight rates are established. It is also claimed that the east and west railroads are better equipped and organized and more economically operated. than the north and south roads.

Referring again to the chart there will be seen a line of dots running through central Florida and Georgia, Tennessee, Kentucky; thence along the Ohio River to the western boundary of Indiana; thence to Chicago and St. Paul. This is approximately the line of equal freight rates between the Atlantic and Gulf seaboards on general freight. Points west of this line enjoy a differential in favor of the Gulf seaboard. The shaded area of Indiana and Wisconsin, Ohio and the southern peninsula of Michigan indicates neutral territory in which the freight rates to the Atlantic and to the Gulf are equal. On certain special commodities, however, there are special rates to which the foregoing remarks do not apply. The class rates applying on export traffic to countries other than Europe, Asia and Africa from Chicago, St. Louis, Indianapolis and Cincinnati are identical for Mobile and New Orleans, which cities enjoy a differential of about 12 per cent under the respective rates from the foregoing cities to New York. For shipments to Europe from the central territory, rates are favorable to the eastern and south Atlantic ports and unfavorable to the Gulf ports.

The data upon commodity rates that were available at the time of preparation of this article are not sufficient to permit of an exhaustive study of the influence of freight rates upon the commerce of the port of Mobile, but they are sufficient to warrant some interesting conclusions, among which are the following:

(*a*) Flour can be shipped from Kansas City, Mo., to Cuba or Liverpool via Mobile and New Orleans at less than via New York.

(*b*) Agricultural implements can be shipped from Chicago to Liverpool and to Buenos Ayres via Mobile or New Orleans at less than via New York.

(*c*) Cotton can be shipped to Liverpool from Memphis, Tenn., Montgomery, Ala., and even Meridian, Miss., at a less rate via Savannah, Ga., than via Mobile or New Orleans. The Interstate Commerce Commission has recently ordered a readjustment of these rates, declaring the present rates unfair and discriminatory.

(*d*) In general, the ocean rates on similar commodities from Gulf ports, except Key West, are the same, and these rates to Cuba and South America are also the same as the rates from the Atlantic seaboard, and the ocean rates to Europe are greater from the Gulf ports than from the Atlantic ports.

A glance at the rates reduced to a ton-mile basis is sufficient to show that actual mileage is not the controlling factor in the determination of present freight rates.

Competition between producing localities for trade in certain markets appears to exert the predominant influence in the establishment of the combined rail-and-water rate,

Digitized by Google

the railroad or ocean carrier absorbing the greater proportion of the rate, depending upon the principle of charging what the traffic will bear. Generally the longer the haul the less the cost per ton-mile, and the shorter the haul the greater the cost per ton-mile. This last principle is reasonable in that the shorter the haul, the greater the proportion of overhead expense to be borne per ton-mile of traffic, but the application of this principle has established some very unfair rates. This is especially noticeable in the rates for cotton, which are soon to be readjusted.

These rates on cotton have had a marked influence on the commerce of Mobile, although this city is located close to the center of the cotton-growing country and has connection with the interior by an improved water system and by five railroads traversing the cotton regions. The once large cotton trade has dwindled in recent years to an almost negligible figure. The combined rail-and-ocean rate on this commodity from Memphis, Tenn., a cotton center, to Liverpool, is $2.20 per hundredweight via Mobile and New Orleans and $2.05 per hundredweight via Savannah. Although the rail distance from Memphis to Savannah is about double the distance from Memphis to Mobile, the rail freight rate is 55 cents per 100 pounds to Savannah and 45 cents per 100 pounds to Mobile.

The effect of existing rail and ocean rates upon the commerce of Mobile

In general, the rail rates from the Middle West on like commodities are the same for New Orleans and Mobile; from points west of Chicago there is a differential in favor of the Gulf ports, and from points east of Pittsburgh and Buffalo there is a differential in favor of the Atlantic ports.

The minimum ocean rates established by the Shipping Board place the Atlantic and Gulf ports on the same basis for like commodities to Cuba and to South America. On account of the shorter haul the ocean rates to Europe are less from the Atlantic ports than from the Gulf ports. As between New Orleans and Mobile, on general merchandise, there is practically no difference in rail or ocean rates from the producing centers of the Middle West and to foreign markets.

Except for special commodities, and for products from certain producing localities, the *existing* rail-and-ocean rates are not the controlling factor in trade combination. *The volume of commerce through a port appears to be more largely influenced by the harbor facilities, banking and mercantile facilities and established habits of trade than by freight rates.*

With ocean and freight rates via two ports equal, the influence of a shorter mileage by way of one port than by way of the other is materially felt in the time element. For example, the ocean rate from Mobile to Havana is $0.51½ per hundredweight, and the rate from New York to Havana is also $0.51½. Although the rate is the same, an advantage lies in the nearer port, in that the time of passage is about one and one-half to two days less than from the more distant port. This factor increases the profits of the carrier and should encourage tramp steamers to come to the nearer port. This time factor should have a marked influence in favor of Mobile in the competition for future trade with Central America, west coast of South America and points via the Panama Canal.

Discussion of commercial statistics

Local details are here omitted. The discussion involves total tonnage by decades, the period of maximum and minimum total tonnage, trend of imports and exports of principal articles handled through the port, and a study of tendencies for certain articles to increase or decrease in volume, and, where data is available, a study of the causes for such increases or decreases in the volume of the principal commodities.

For Mobile the year 1907 was the banner year with 3,304,998 tons. In 1919 the total commerce was a little short of 2,000,000 tons, which is somewhat in excess of the average for the past decade. Present indications show a greater valuation than ever before and a marked increase in volume over recent years.

The principal imports are petroleum products (coastwise), bananas, iron ore, molasses and sisal grass. During the war and the Mexican disturbance, imports of iron ore, pyrites and sisal grass have fallen off.

The principal articles now being exported are lumber, cooperage, iron products from the Birmingham district, agricultural machinery and naval stores. Additional exports of the following products could be reasonably expected if proper steps be taken to improve existing facilities where lacking and to stimulate traffic: Coal, flour, grain and cotton.

Unbalanced commerce

A most unbalanced commerce through Mobile is noted. It is seldom that any vessel sailing from this port brings a return cargo. Generally speaking, sufficient cargoes have been assembled for export to fill available bottoms; but, as a rule, the ships loading at Mobile will bring a return cargo either for New Orleans, New York or some other port. This is not as serious a handicap as the figures would indicate, as may be explained by reference to the boats of the Munson Steamship Line. This company has regular sailings from Mobile for Cuba and Buenos Ayres. There is ample freight for export to fill their vessels. On the return trip from Cuba the boats generally carry sugar to New Orleans, returning light from New Orleans to Mobile. From Buenos Ayres the ships bring a return cargo of hide and quebracho, a tanning wood utilized by the Eastern shoe manufacturers. This return cargo is generally carried to New York, the ship returning to Mobile with only a partial cargo. These return cargoes, while not imported through Mobile, do at least enable the ships that sail from Mobile regularly to obtain a return cargo from the port of destination to some American port, thereby enabling them to continue profitably the export business from this port. Although, as stated above, the unbalanced commerce of this port is not as serious a matter as the figures would indicate, it is sufficiently serious to warrant a careful study and an effort by local interests to stimulate imports.

Recommendations for stimulating commerce of the port

It can be concluded that the foreign trade with the Pacific Coast and portions of the east coast of Central and South America should naturally be handled through the ports on the Gulf. Also it would be advantageous for a larger portion of the European trade to be routed by the Gulf if congestion of traffic is to be avoided on the east and west lines with the consequent tie-up of freight cars. This congestion is aggravated during the winter when snow and ice block the lines during a considerable period and at a time when the heaviest movement of coal is in progress in the eastern portion of the country. These causes of delay are practically unknown to the Gulf region.

It is believed that the Gulf ports would greatly profit by an adjustment of freight rates on the basis of cost of service. The shorter haul that would follow such an adjustment would allow the full cars to be moved to destina-

Digitized by Google

tion and then returned in less time than is now consumed, and this would require less equipment to carry existing traffic and would result in final economy to the public.

The creation of a body to stimulate the trade in certain definite commodities would result further to the port's advantage.

Special study of the import traffic to enable both the water carriers and railroads to handle nearer their capacity in both directions would effect further economy. Among the commodities that efforts should be concentrated on, and which could be economically handled through this port, are coffee, quebracho, bauxite, asphalt, dye woods, fruits, mahogany and nitrate of soda. These products are now handled in limited quantities, and any increase would greatly assist in reducing the present unbalanced condition.

Mobile's favorable location with respect to the Panama Canal is an advantage that should be utilized to the utmost. The logical trade territory of Mobile is Central America, Columbia, Venezuela, west coast of South America and Cuba. A concentrated, well-organized effort should be made by the chamber of commerce, or by some other commercial interests, to study the needs of this portion of Latin America, to provide for these needs, and to establish banking, mercantile and social relations that would attract the buyers from these countries to visit and market in and through Mobile.

Port facilities and physical efficiency of the port.—This phase of the problem is the kernel of the nut from the port engineer's standpoint, and local questions require their own special treatment. Some of the advantageous features of the port of Mobile are:

(*a*) Depth of channel of 28 feet to be increased 30 feet at an early date; (*b*) physical connection of railroads with warehouses, wharves and shipside; (*c*) highway connections to water terminals; (*d*) interconnection of railroads; (*e*) favorable port charges and expenses; (*f*) repair facilities up to 10,000 tons; (*g*) fresh water berths; (*h*) small variation in tides and floods; (*i*) ability to load from cars, wharves and water at same time; (*j*) adequate banana unloaders; (*k*) inland waterway to iron and coal fields.

The following are considered unsatisfactory conditions:

(*a*) Divided control of harbor facilities; (*b*) inadequate warehouse space; (*c*) high cost of stevedore services and labor disturbances among longshoremen; (*d*) absence of adequate mechanical appliances for loading and unloading and for handling in the pier sheds; (*e*) need for export coal terminal which, however, is now projected; (*f*) belt-line connections controlled by railways; (*g*) insufficient advertising and efforts to draw trade; (*h*) water front partially railbound; (*j*) inadequate depth in slips and lack of private dredging plant; (*k*) immediate hinterland undeveloped.

Recommendations and suggestions

(*a*) *Central control.*—There is need for all the facilities to be concentrated under one head or executive body, which should have the power, funds and *disposition* to initiate, plan and construct as well as to administer.

(*b*) *Additional warehouses* should be constructed, and existing warehouses should be improved and equipped with modern handling appliances.

(*c*) *Cost of stevedore service.*—Installation of labor-saving devices.

(*d*) (*e*) *Mechanical appliances* within reason and suited to the principal commodities handled through the port should be provided; these should include a stationary power derrick to handle steel containers of the Mississippi Warrior Service, belt conveyors or storage battery trucks at the wharves and sheds, and a coal terminal for bunker and export coal.

(*f*) *Belt-line connections* operated by a central harbor control are almost essential for efficient and equitable service.

(*g*) ***Mercantile and advertising facilities:***

(1) Establishment of a coffee exchange and facilities for grading and storing coffee.

(2) Improved and more efficient cotton warehouses.

(3) Establishment of large export and import company specializing in the needs of Latin America, affording credit and banking connections.

(4) An advertising campaign in the tributary area of the Middle West.

(5) Visits of commercial committees to Cuba, Central America and South America to study trade conditions and to establish trade relations.

(*h*) *Relocation of certain tracks.*—This is a delicate problem requiring vision, force, boldness, tact and perhaps ultimate drastic action.

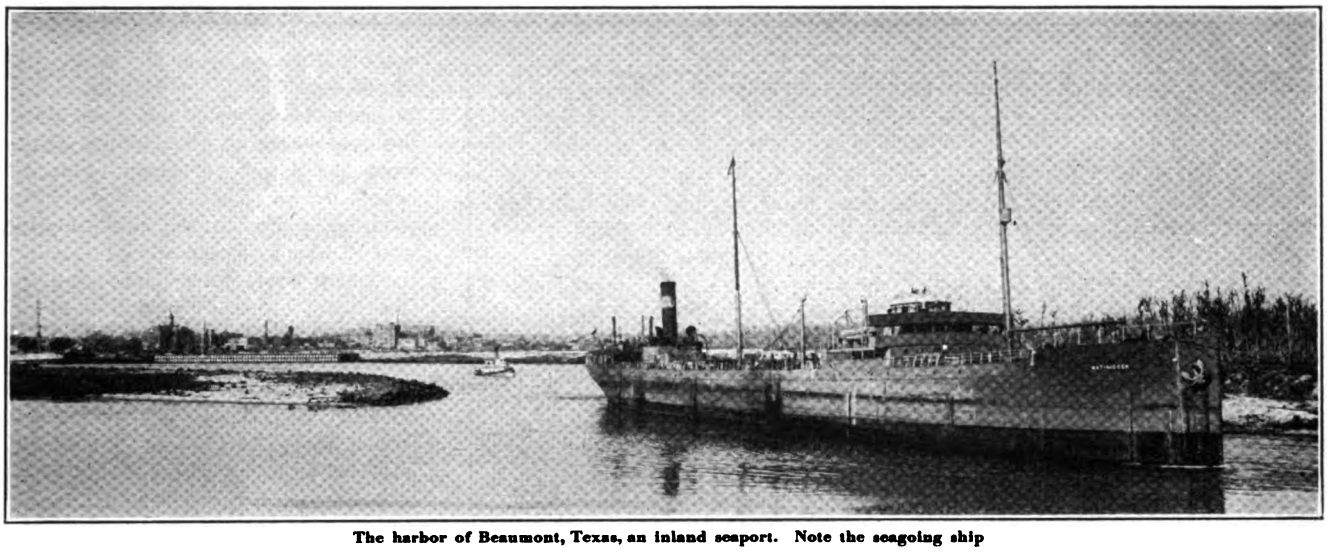
(*i*) Organize co-operative dredging company among private interests.

(*j*) *Development of surrounding country.*—This can be accomplished only by time, encouragement of immigration from other ports of the United States and other countries, cheap fertilizers, improved roads and general agricultural development.

A continuous and progressive development of the harbor, of its terminal facilities and of its storage and warehouse facilities and the installation of such labor-saving and cargo-handling devices as may be economical and practicable are essential if Mobile is to take the place among the world ports to which its strategic location and its natural advantages entitle it.

Light Creosote Oils in Wood Preservation

Light creosote oils properly injected into wood apparently will prevent decay until the wood wears out or until it checks so badly that the untreated portions are exposed. Such is the indication of service records collected by the U. S. Forest Products Laboratory on railway ties and telegraph poles preserved with low boiling creosotes.



Creosotes used in ties from 25 to 50 years ago were for the most part oils having 50 per cent or more distilling below 235 degrees Centigrade, with a residue not to exceed 25 per cent at 315 degrees Centigrade. The ties so treated lasted from 15 to 20 years, and failure was traceable in most cases to mechanical wear, such as rail cutting and spike killing. In no case was failure found to be the fault of the preservative.

Of 1,558 telegraph poles in the Montgomery-New Orleans line, which were pressure-treated with a light creosote oil, 1,049 poles were still sound after 16 years. In 91 per cent of the cases of decay the fungi had entered the wood through checks and shakes. Representative sections in the Norfolk-Washington line showed that after 17 years' service, of the 1,614 poles inspected, 1,469 were sound, 92 decayed at the top, and 105 decayed at the ground line. The decay at the top was caused chiefly by cutting off the poles. In those decayed at the ground line, the causes of failure, as determined in 88 per cent of the cases, were checks or shakes. Here, again, as in the ties, the preservative outlasted the mechanical life of the wood.

The following conclusions are from the Forest Products Laboratory "Technical Notes":

"Unless some other factor than protection from decay is considered important, therefore, there is apparently no need to specify high boiling oils. The important point is that any coal tar creosote which is not extremely low boiling or extremely high boiling will satisfactorily prevent decay, and in the selection of an oil, factors such as price, penetrability, and convenience in handling should receive greater consideration than moderate differences in volatility."—*Eng. News-Record.*

The harbor of Beaumont, Texas, an inland seaport. Note the seagoing ship

The Sabine-Neches Canal

An Example of a Successful Inland Waterway

By

A. H. Weber

U. S. Assistant Engineer

[*Note.*—The world is full of examples of unsuccessful inland waterway projects. Countless millions of dollars have been spent in this and other countries on projects which have never justified their cost. So great has been the waste that many economists, investigating these ill-advised projects, have been led to utter sweeping condemnations of improved inland waterways, and to assert that such waterways can never successfully compete with railroads. Inland waterways have accordingly fallen into a disrepute which is perhaps deserved in view of the carelessness and lack of study with which many of them have been planned.

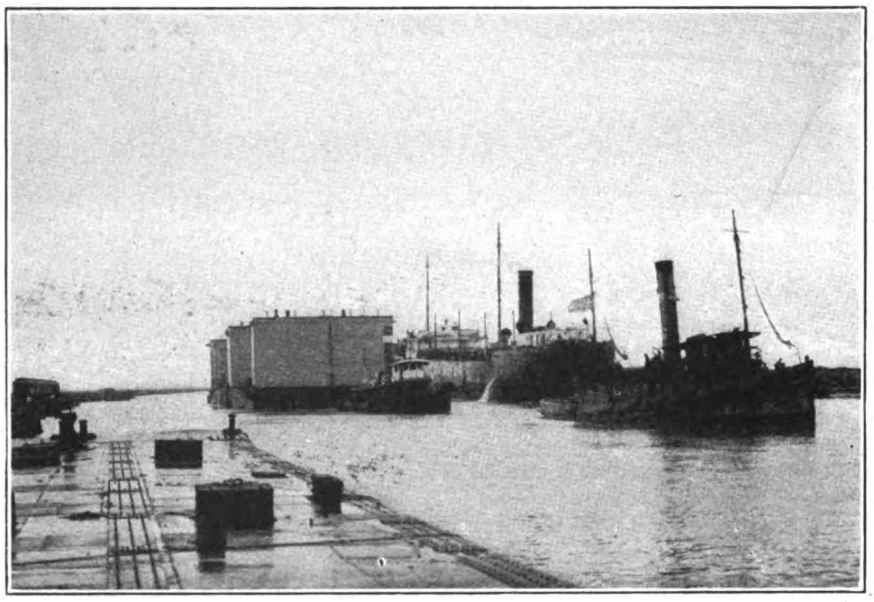
But we must beware of extremes. Transport by water is inherently cheaper than transport by rail, and when applied under favorable conditions and after careful study of these conditions, has been almost invariably successful. Of this there are many notable examples, chief of which is the water transport on the Great Lakes. The Sabine-Neches Waterway, described by Mr. Weber, is another successful example.

One of the most advantageous applications of inland waterways is to provide *deep-water access* from the sea to inland points, which are thus converted into seaports. The Sabine-Neches Waterway is an example of this form of economy, and the astonishing growth of its commerce is the proof of its success and of the skill and forethought with which it was planned.—Ed.]

THIS waterway extends from the Gulf of Mexico through Sabine Pass, Port Arthur Canal, Sabine-Neches Canal, the Neches River to Beaumont and the Sabine River to Orange. The entrance to the pass is protected by jetties. Beaumont is 51 miles and Orange 42 miles from the outer end of the jetties at Sabine Pass. Port Arthur, the principal shipping point, is at the head of the Port Arthur Canal 16 miles above the outer end of the jetties. (See map, page 521.)

The chief purpose of the present waterway is to provide a deep draft outlet to the sea from the oil fields in the vicinity of Beaumont, Tex. The project was favored by the existence of Sabine Lake and the "pass" connecting it with the Gulf of Mexico.

Originally, a bar extended for about 3½ miles beyond the mouth of the pass having an available depth over it of only 6 feet at mean low gulf level.* The original project, adopted in 1875, contemplated a dredged channel through this bar 12 feet deep and 150 feet wide. The jetty project was adopted in 1882, since which time the scope of the improvement has been enlarged by progressive steps until now it provides for jetties about 4 miles in length and a ship channel 25 feet deep, from the Gulf to Port Arthur, Beaumont and Orange. About 21 miles of this channel is artificial, having been cut through low lying prairie lands, at a moderate cost.



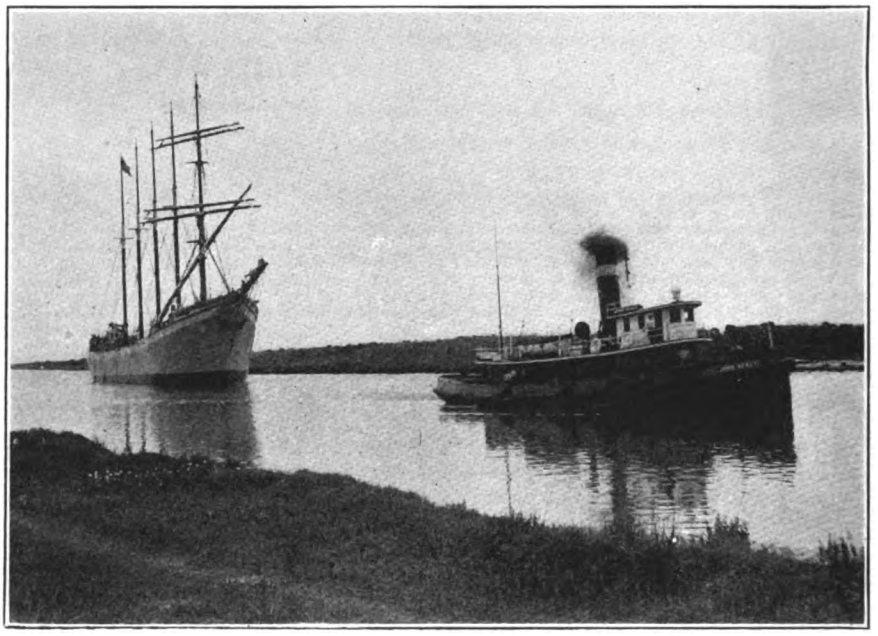
Commerce has taken full advantage of its opportunities here and has grown in proportion to the facilities afforded. It is well known that ever since the inception of the improvement vessel keels have dragged the bottom. The principal item of commerce is crude oil and its products, which now amount to about 7,000,000 tons annually. The total commerce on the waterway is about 8,000,000 tons. Of this, about 6,800,000 tons is loaded or unloaded at Port Arthur and the balance above. Modern oil tankers draw generally 25 to 28 feet, but some of them as much as 30 feet, and it is this class of vessels that is engaged in handling the business of this waterway. The splendid growth of commerce is shown by the following table of statistics:

1900	217,000 tons.
1905	1,779,000 tons
1910	2,304,000 tons.
1915	6,002,000 tons.
1918	7,261,000 tons.
1919	8,005,000 tons.

The total cost of the improvement to date is about $8,500,000. Interest on this sum at 5 per cent is $425,000. If to this be added $200,000 annual maintenance, the total government subsidy is $625,000 per year. On a basis of 8,000,000 tons commerce this amounts to less than 8 cents per ton. However, this does not take into account the distance over which this traffic moves. If it be assumed that 6,800,000 tons is loaded or unloaded at Port Arthur, 16 miles from the outer end of the jetties, and the balance at Beaumont and Orange, an average distance of 48 miles

*To the Board of Engineers for Rivers and Harbors.

Digitized by Google



Beginning of the Sabine-Neches Canal, showing dry-dock being towed out toward the Pass and vessel heading up to Beaumont

from the end of the jetties, we have the following annual ton-mileage:

1,200,6,800,000 × 16---	108,800,000
1,200,000 × 48--------	57,600,000
Total (ton-miles)----	166,400,000

The government subsidy per ton-mile is thus $0.0037; that is, 3.7 mils per ton-mile. This figure requires no comment—it speaks for itself.

The steady growth of traffic and the increasing size of ocean-going vessels has led to a request on the part of the business interests of the community for greater channel dimensions, and the Engineer Department has now under consideration a project looking toward a channel depth of 30 feet, with suitable width. It is thought that such a channel will meet present and immediately prospective needs of commerce. One of the interesting features of this improvement is the guard lock located a short distance below the mouth of the Neches Canal, its purpose being to check the inflow of salt water during low stages in the Neches River when the supply of fresh water is being drawn upon by the large pumping plants of the rice growers who at certain periods use practically the entire fresh water flow in irrigating their crops. Beyond a small degree of brackishness, salt water is very injurious to rice culture. The present lock has but one set of gates opening downstream. It was expected that these would be needed only during low stages when the flow was reversed, but experience in navigating large vessels through the lock in times of freshets, when the currents are swift, indicates the desirability of gates opening both ways, and this change is being considered in connection with the enlarged project.

Tests of aged cements in concrete mixtures

Owing to a shortage of cement in the District of Columbia for use on construction work being carried out by the Engineer Corps of the Army, the Bureau was asked to determine the strength of concrete made up from cement which had been in storage for about a year and a half. The cement as received was first put through a sieving process to remove the lumps. The cement after sieving, as well as the crushed lumps, were then made into separate concretes which were compared with concrete made from cement recently purchased in the local market. It was found that a 1 : 1¼ : 2½ mix of the old cement would give approximately the same strength as a 1 : 2 : 4 mix of the fresh cement, and it was recommended that the lumps be sieved out of the old cement before using. Similar tests were conducted on aged cements submitted by the U. S. Engineer Office at Vicksburg, Miss. The results indicated that a 1 : 2¼ : 4½ mix of the aged cements gave approximately the same strength as a 1 : 3 : 6 mix of fresh cement.—*Bureau of Standards.*

State highway work in Washington

The State Highway Department of Washington has located, prepared plans and estimates, secured right of way and let 113 contracts for the construction and improvement of 526.36 miles of new road at a total cost, not including engineering, of $10,378,000, and for the construction of 25 concrete and steel bridges at a total cost, exclusive of engineering, of $1,001,000.—*Eng. and Cont.*

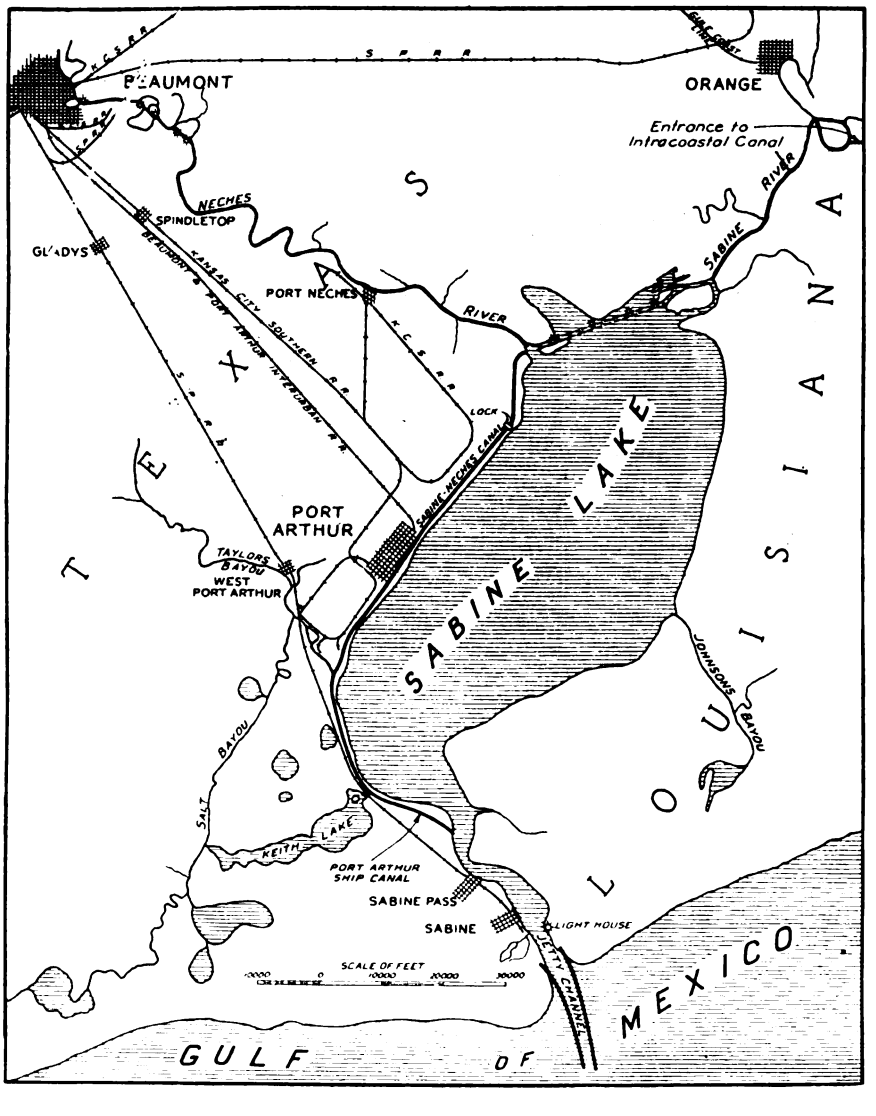
Hydraulic Control of the Red River of the North

TO convert Lake Traverse into a detention reservoir by a dam with permanent outlet, to straighten and improve the Bois de Sioux River for nearly 30 miles from this outlet to the Otter Tail River, and to construct main ditches to drain the land below the reservoir, are the preliminary steps of an interstate project for drainage and flood control in the valley of the Red River of the North. Minnesota, South Dakota and North Dakota are the three States concerned.

An annual run-off of 23,430,000,000 cubic feet was determined as a maximum for the drainage area of Lake Traverse. To control this by converting the lake into a detention reservoir, it is proposed to build an earth dam about 2¾ miles long and 15 feet high across the two outlets at the northern end, 4 miles south of White Rock, S. D. A concrete sliceway would provide for normal discharge. A spillway for maximum discharge would have its crest at elevation 983, with capacity for discharging 2,000 cubic feet per second when the lake level reaches elevation 985. The combined capacity of culvert and spillway would be 4,000 cubic feet per second, which is far in excess of any probable requirements. At the south end of the lake, levees would be built for protection of low lands. Reservoir capacity would be 9,840,000,000 and 12,035,000,000 cubic feet at the two elevations mentioned. Below the outlet a defined and direct channel would be built along or near the present winding course of the Bois de Sioux, with levees on each side, to retain flood discharge.



These proposed improvements are designed to control the run-off from the upper drainage area of 1,335 square miles above the dam. This control would be effected in three ways: By storing in the reservoir all the run-off during March and April; by storing after May 1 any flow in excess of the 1,000 cubic feet per second discharged through the control outlet; by storing all the run-off that occurs during any summer period when the run-off from territory below the dam fills the discharge channel.

To drain the reclaimed land on either side of this channel, or the straightened Bois de Sioux River, there would be main ditches practically parallel with the channel and having a fall toward the north. These ditches would serve also to relieve the upper part of the channel from the run-off of the adjacent land, below the dam. Drainage works under the plan proposed would provide outlets for water from 112,370 acres below the dam, this area having at present no adequate outlets. The lake and the Bois de Sioux constitute the drainage outlet for 1,200,000 acres, or 1,875 square miles, the drainage from which affects that of the smaller area served by the ditches. Of the 112,370 acres, there are 31,140 acres in Minnesota, 76,160 acres in North Dakota and 6,070 acres in South Dakota. The total cost of the project is estimated at $1,400,000, or $12.50 per acre directly affected.

In their annual report recently made public, the Harbor Commissioners of the Dominion of Canada state that the development of the northern districts of Manitoba is restricted, owing to the lack of proper dockage facilities on the Red River in the City of Winnipeg.

The report also indicates that the extensive dredging of the Red River is probable, especially in the vicinity of the present docks. It is fully realized that the utilization of the Red River as a traffic route connecting lower Manitoba with Lake Winnipeg is most essential. Locks, involving an expenditure of upward of two million dollars, have already been constructed for the purpose of making the river navigable.

Lake Winnipeg is one of the largest bodies of water on the North American continent. The upper end of the lake extends to the mineral deposits of northern Manitoba, as well as pulpwood area. The Red River has its source in United States.

Retirement of Brig. Gen. James P. Jervey

COLONEL J. P. JERVEY, Corps of Engineers, was retired September 21, 1920, at his own request under the provisions of the Act of Congress of March 4, 1915, with the rank of brigadier general in recognition of his services as one of the builders of the Panama Canal.

James Postell Jervey was born in Powhatan County, Va., November 14, 1869. He graduated from the United States Military Academy, West Point, N. Y., in 1892, number two in his class. All of his service has been with the Corps of Engineers, in which he rose through all the grades to that of colonel in 1920. Upon graduation from the Military Academy he served with the battalion of Engineers at the United States Engineer School at Willets Point, N. Y., for about three years, from 1892 until 1895. His first field duty in engineering work was as assistant to Major Mahan and Captain Flagler in the Montgomery, Ala., River and Harbor District. He served here from 1895 until 1898 and was engaged a large part part of this time in constructing the then modern fortifications at Fort Pickens, Pensacola Harbor. For six years, from 1899 to 1905, he was instructor in the Department of Civil and Military engineering at the United States Military Academy. In 1905 he went to Manila, P. I., with the 1st Battalion of Engineers and served there about two years, part of the time at Zamboanga, assisting in the government of that province. On his return from the Philippine Islands he was detailed as instructor at the U. S. Engineer School, which had then moved to Washington Barracks, D. C.

Brig. Gen. James Postell Jervey

Shortly after this Colonel Jervey was ordered for duty on the Panama Canal Zone and spent something over five years as resident engineer in charge of the construction of the great Gatun locks. The locks were sufficiently completed under his direction to enable him to make the first trip through them on a small vessel of the Isthmian Canal Commission. Returning from the Isthmus in 1913 he was detailed as District Engineer, Wheeling, W. Va., in charge of certain work on the Ohio and Great Kanawha Rivers, and a year later as District Engineer, Norfolk, Va., in charge of the rivers and harbors of that vicinity.

On the outbreak of the World War Colonel Jervey was assigned to the command of a regiment of Engineers, the 304th at Camp Meade, which he organized, trained and took to France in July, 1918, as part of the 79th Division. He commanded the regiment at the front until compelled by sickness to relinquish his command and go to the hospital. Upon his recovery he was assigned to duty as assistant to the Chief Engineer of the American Expeditionary Forces. He also served a short time as engineer of an army corps. For his services in France he was awarded the Distinguished Service Medal by General Pershing.

After the armistice he again resumed river and harbor work under the Chief of Engineers with station first at Wilmington, Del., and later as both district and division engineer at Baltimore, Md., on which duties he was engaged at the date of his retirement.

General Jervey has been appointed City Manager of Portsmouth, Va. His comrades in the Corps of Engineers regret the loss to the Corps of this efficient and popular officer, but congratulate him upon his appointment to an important position in civil life while still a young man.

The Passing of Permanently Emplaced Artillery?

[Summary of an article in the *Journal of the U. S. Artillery*, by Lt. Col. H. R. Oldfield, Coast Artillery Corps, with discussion by Col. J. C. Oakes and Majs. C. O. Sherrill and C. L. Hall, Corps of Engineers.]

SINCE early times armament has largely controlled strategy and tactics. Artillery is the most immobile part of an army. In early times, it was divided into three classes—field artillery, siege artillery and fortress artillery, each with separate personnel. Artillery is no longer so designated, but is now classed as mobile, fixed, anti-aircraft and trench.

At the Dardanelles the allied fleets reduced at will all old Turkish forts located near the seashore; guns hidden well back from the shore were never entirely neutralized. Italy made some use of mobile guns in the defense of her coast line. Germany, in her Belgian coast defense, finally ceased installing fixed mounts, using considerable numbers of large caliber railway guns in hidden and retired positions, with entire efficiency.

Fixed mounts were in elaborate emplacements; railway guns were successfully emplaced in entirely unprotected positions, concrete being sometimes used for their gun blocks and posts of command.

American railway artillery in the World War fired many rounds from open emplacements, but no guns were put out of action. All fire of this artillery was on the whole "truly remarkable. It was fully equal to that which can be expected of guns on permanent mounts." The rate of fire was slow, but this can be entirely remedied—can even be made to exceed that secured by our present fixed mounts.

Our army possesses a large number of 155-millimeter G. P. F. guns and 240-millimeter howitzers that can be advantageously used for intermediate coast-defense armament. The present heavy-caliber railway gun is limited in number, and was designed for land warfare. As a whole, however, it is a valuable addition in our present coast defenses. A more accurate 14-inch and 16-inch rifle will soon be produced, quite equal to those on fixed mounts.

The present coast defense is in reality harbor defense. The emplacements therein consist of well-designed elaborate concrete installations, but it is doubtful if they furnish sufficient protection to-day against modern guns. They are also located close to the sea, in a position that can be readily identified. Although very unsatisfactory, they are by no means obsolete, and can still be usefully employed.

In future, appropriations will be limited, and it will be an absolute waste of money to spend any of it on anything but 14 and 16 inch guns on railway mounts, where feasible, but no matter what type of mount is adopted, the position should be well back from the shore. Naval engagements will be decided at ranges above 15,000 yards in future; consequently, there is no advantage to be derived from placing guns in an exposed position simply to secure direct fire. The slight gain in range is more than counterbalanced by the increased accuracy of the hostile navy firing against these positions.

Guns emplaced on fixed mounts will probably still require elaborate protection even though located in such retired positions. Guns on railway mounts, on the other hand, do not need such protection, the railway tracks being established in time of peace without revealing their purpose. If the enemy should locate one of these guns, it will immediately be withdrawn to another position. It is, therefore, of the greatest advantage to have all mounts mobile, both tactically and strategically. In this way they can be moved from one strategic area to another, or from the Atlantic to the Pacific, in time to meet a probable attack. Even if all the fronts should be menaced at once, it would still be an advantage to have the armament in such shape that it can be redistributed as occasion demands in time of peace, as would be the case with railway mounts. Another advantage of these installations is that in case part of our coast should be evacuated, fixed emplacements would have to be blown up, whereas mobile guns could be moved, and if an important harbor is seized by the enemy, these guns could be turned upon the structures therein. These two considerations alone are sufficient to warrant the adoption of the railway mounts.

It is, however, in connection with the recently developed "Positive system of defense" that the railway guns' many advantages really become evident. The large-caliber guns will be of the greatest assistance in holding off forces that have obtained a footing, and when invasion has become a success these guns will destroy the lines of communication behind the invader, as was done at Verdun.

Of course, in order to use railroad guns, the railroads must be capable of transporting them; if they can not be so transported, they are of no use. This matter has not been fully investigated, but the 14-inch and 16-inch guns at least can be taken from the Atlantic to the Pacific Coast and can be used for the defense of all important points on the Pacific Coast and all of the important points on the Atlantic Coast north of Cape Hatteras; in fact, there are very few places on these two sections where they can not be used.

The question as to relative cost is important, and a detailed investigation indicates that the cost of fixed guns in fixed emplacements will be from 10 to 20 times as great as an equal number of emplacements for railroad mounts.

There should be provided as many of these railway mounts as of the fixed guns, because it is possible that we may some time have a war with all the rest of the world, in which case, they would be very useful. They will form the cheapest possible insurance in our system of national defense.

Summing up, it appears that one railway mount is strategically and tactically equivalent to and quite as cheap as several fixed guns, and that, therefore, fixed mounts should be limited to restricted and inaccessible positions, marking the end of the concrete fortifications in the course of time. However, mobile as railway guns now are, even their mobility is not sufficient, and it is desired to have "16-inch guns mounted in air vessels at the very earliest date possible."

Discussion

J. C. Oakes
Colonel, Corps of Engineers

I have read with interest the article by Lt. Col. Homer R. Oldfield, C. A., on "The Passing of Permanently Emplaced Artillery." It is interesting as showing the extreme views held by some artillery officers, particularly as such views are so greatly at variance with the ideas held by most officers of the artillery previous to the World War. In the past the artillery has demanded the greatest possible protection for guns and crew, massive gun platform built separately from the remainder of the emplacement and accurately leveled, magazines, and casemates fully protected by overhead cover, machinery for handling ammunition and elaborate measures for range finding, plotting and communication. Apparently, now these ideas have passed, and the most casual type of position with or without gun block, parapet, magazines or other permanent structures, and improvised range-finding apparatus and methods of communication appear to be sufficient.

Colonel Oldfield makes many statements of fact in his article which I question, and many statements of opinion with which I differ. In discussing an article of this kind, it is very difficult to present tersely objections to statements made, and perhaps the best method to present my principal objections is to quote a statement from the article and follow immediately by discussion. Adopting this method, the statements from the article will be placed in quotation marks with my discussion immediately following.

"In this greatest of all wars there was no example of permanently emplaced guns giving a good account of themselves against the heavy mobile artillery of the land armies."

The German attack on Liege was made on the night of October 5, and the town was captured on the 6th. The Belgian troops retired, leaving a small garrison in each fort. These small garrisons prevented the advance of the German army for thirteen days, and it was not until superior heavy siege artillery, of a type which these forts were never designed to resist, had been brought up and by its long range and heavy caliber projectiles broke down the defenses, that the forts were captured. This halt of the German army for thirteen days had the very greatest effect on the war in general, and, in my opinion, is a very good example of what even an inferior land fortification can accomplish against overwhelming odds. Of course, it is not to be expected that medium calibered guns will be able to hold out indefinitely against an overwhelming superiority of guns of greater caliber, but if the Liege forts had been supplied with as heavy artillery as the German siege artillery, the advance along the Aix-la-Chapelle Liege Railroad would have been stopped much longer, and if a mobile army had been available to reinforce the garrison, the advance along that line would have been permanently stopped. Therefore, I do not think the above statement is a fair one. Certainly, a number of permanently emplaced guns are more than equivalent to the same number of mobile guns of equal caliber, without emplacements, parapets, permanent magazines, or other necessary permanent equipment.

"The old-style fortress that could defy an army due to its heavy guns and its heavy defensive protection of stone and concrete . . . is no longer able to resist a mobile army with its masses of heavy artillery."

This statement, of course, is correct, if the number of troops and the number of superior guns brought against the fort are overwhelming, but it is possible for a fort even with inferior guns to stop the progress of an army until the mobile forces can be mobilized and rushed to the defense of the position. Certainly the fact that France had good permanent fortifications at Toul and Verdun, even if they were "old-fashioned," had the very greatest effect upon the decision of the German general staff in making its plans for the invasion of France. If Toul and Verdun had not been fortified, the line of advance into France would have been the direct one from Lorraine and Luxembourg to Paris, instead of through Belgium.

"At the Dardanelles the allied fleets were able to reduce all of the old Turkish forts located near the seashore."

This is exactly contrary to the tenor of the report of the American attache to Turkey which I have recently obtained from the War Department. In that report it is stated that the principal armament in the five land fortifications consisted of five 15 cm. (6-in.) guns, nineteen 25 cm. (10-in.) guns and six 35 cm. (14-in) guns. Of these the only ones with telescopic sights were the 15 cm. guns. The bombardment which took place on March 18, 1915, by fifteen ships of the line, later increased to nineteen, at ranges of from 8 to 10 miles, did very little damage to the forts. The 15 cm. turrets were hit three times with no gun damage. Another fort had one carriage destroyed, with no gun damage, although the embankment was hit a number of times. One battery had two guns temporarily disabled. All other damage was slight and the fleet was driven off. It seems to me that the land batteries with their inferior guns, inferior personnel and without the necessary range-finding apparatus, performed their function very satisfactorily.

"Italy made use of mobile guns in the defense of her coast line."

I have been unable to verify this statement, and can not positively controvert same. I am informed, however, that the only mobile gun used for such purpose was a gun mounted on a barge, or boat, which, therefore, was more of a naval than land auxiliary.

"Germany in her defense of the Belgian coast finally ceased to install fixed mounts and used large-caliber railway guns in hidden and retired positions in lieu thereof."

It is true that railway guns were used, but I think they were not used on the railway mounts. The guns were brought up to the coast, dismounted from their trucks and placed on improvised emplacements with as much protection as could be given with the labor at hand. More permanent emplacements could not be provided on account of the time limit. The guns, therefore, were nothing more than temporarily emplaced guns, fixed in position exactly as the more permanently emplaced guns, and can not properly be considered as railway guns, except that they were taken to and from their positions by rail.

"American-manned railway artillery was under fire on the western front approximately 1,500 gun-days, and probably received about 25,000 large-caliber enemy shells." (No gun being put out of action.)

What is meant by "received?" Were 25,000 aimed shots fired at our railroad artillery? If so, the practice was evidently very bad. Does the author mean to convey the idea that while the enemy's practice was exceedingly bad our practice was better? If an enemy, having had four years' previous experience in the practical school of actual war, fired from improvised batteries and railway mounts 25,000 long-range shots at our batteries without effect, does the author think that is an argument in favor of the use of similarly located guns for our harbor defense? To me this statement proves the general inaccuracy of long-range fire and the need of carefully selected positions with guns placed on fixed platforms, and permanent range-finding

Digitized by Google

systems, including everything that will increase the accuracy of long-range firing.

"A 14-inch 40-caliber rifle on an all-round fire railway mount has recently been fired at a moving target with most excellent results."

It would have been very interesting if greater detail had been given. I understand that this rifle was mounted on a concrete gun block, constructed by the Engineers, that the gun was dismounted from its railway trucks, placed thereon, and therefore was fired exactly as any permanently emplaced gun would be, except that the ammunition was handled by hand and the range-finding apparatus was more or less temporary. It would be interesting to know at what range this rifle was fired, how fast the target was moving, whether it was moving at uniform speed parallel to the shore, or whether its direction and speed were non-uniform to simulate the movement of a ship attacking a battery.

The Christie wheel-caterpillar mount adapted to the 155-mm. rifle. The latest development of tractor artillery

"It is asserted that it would be a waste of money as well as a serious mistake, from a military point of view, to permanently emplace any such mounts (*i. e.*, 14-inch and 16-inch) in any locality accessible to railway mounts."

I disagree with this assertion for reasons which I will state later.

"To-day, however, battle ranges will be nearly twice this great" (*i. e.*, 30,000 yards).

This statement might be correct, if any method of range finding had been devised by which the position of a ship 30,000 or more yards from the shore line could be determined. Up to the present time, however, ranging beyond 15,000 yards is practically impossible, except in the very clearest weather, owing to poor visibility. I know that the artillery proposes to spot shots by use of aeroplanes, but if a fleet be strong enough to seriously attack one of our harbors for the purpose of capturing same and making it a base of operations, the fleet will necessarily be extremely strong, and it must be assumed that the enemy commander will provide an overwhelming force of aeroplanes. It is not to be expected, therefore, that a harbor which will be attacked by surprise, and ordinarily, be found in a more or less partial state of defense, will have superiority in the air, and the result will be that our aeroplanes will promptly be dispersed and the enemy will have the advantage of the use of his planes. Another advantage the fleet will have is that certain landmarks will enable him to fire on areas marked on the map by simply determining his positions with reference to the landmarks and measuring his azimuth from such landmarks. In my opinion, therefore, it is doubtful whether the seacoast defenses will have very great success at ranges much more than 15,000 yards. Certainly, during the recent war the only determined attack upon land fortifications, that at the Dardanelles was made at approximately that range which would seem to mean that even for the Navy a serious attack on land fortifications must be fought under present conditions at ranges not greater than from 15,000 to 20,000 yards.

"Guns emplaced on fixed mounts will probably still require elaborate protection even though so located in such retired positions" (*i. e.*, retired from the shore).

The tractor will negotiate a 100 per cent slope. Maximum speed as tractor, 10 miles per hour; maximum speed on wheels, 15 miles per hour. Total weight, 44,000 pounds

I see no reason why fixed mounts need more protection than railway mounts. If the guns be located where it will be difficult to spot the shots, a fixed gun needs no more protection than a gun on a railway mount. Even if the enemy knows its exact position on the map, long-range fire under battle conditions is so inaccurate that there is little probability that a gun will be put out of commission. The test firing at Mobile a few years ago, where the battleships were given the exact range from shore and the exact spot

Digitized by Google

hit before another shot was fired, and also the attack at the Dardanelles, prove this fact.

"If mobile guns are adopted, the total 150 guns (the total number available for coast defenses) can be assembled in one locality if the condition demands."

This is, in my opinion, one of the principal objections to change from our present system of fixed guns to the proposed system of having all guns on railway mounts. It is apparent that an enemy fleet can move more rapidly than guns can be transported by rail, and if the guns should be congregated at one locality for defense against an enemy attack, it would be extremely simple for an enemy fleet to feint at some important port, such as New York, carry on a bombardment until information was received that all of the railway artillery in the United States was being concentrated at New York, and then, leaving a few ships to continue the bombardment, the remainder of the ships could steal away and within a short time appear at Cape Henry, make its way into Chesapeake Bay and Hampton Roads practically without opposition. If we consider political conditions in this country, it is apparent that if the people of New York felt that a serious attack was being made at that point, the government could not resist the urgent demand for all of the artillery that could be furnished, and it is therefore apparent that all the mobile artillery would be immediately rushed to that port, leaving other ports at the mercy of the fleet, when the objective was suddenly changed. Consequently, in my opinion, a certain amount of artillery should be fixed at each important place, and considered as the absolutely essential minimum for the temporary protection of that place, and such artillery should never be moved under any conditions. Therefore, in my opinion, the less mobility such guns have the better they will serve the purpose for which they are emplaced.

"The collapse of the German defenses around Verdun was due in no small measure to the serious interruption of their railroad service because of the long-range fire of railway artillery. . . ."

This statement does not agree with my understanding of what actually occurred. It has been stated by numerous writers, and even by General Ludendorff himself, that the loss of men by the Germans in front of Verdun was so great that the German nation could stand it no longer, and the attempt had to be given up. It would be interesting to know just what damage was done by the railway artillery to the German lines of communication, not only at Verdun but at other places.

"This comparison showed that the mobile guns could be emplaced for slightly less than 5 per cent of the cost of the latest type of emplacement for fixed armament."

It would be interesting to see the estimates of cost upon which this statement is based. If the author means that the railway gun and its carriage, without appurtenances, will cost 5 per cent of a similar gun on fixed mount with all of the auxiliaries and complete protection to gun by parapet, and magazine and casemate thoroughly protected by overhead cover, the statement is perhaps approximately correct, but I believe that the author has left out of consideration the cost of the railway train and equipment that must be supplied with each railway gun of 14 and 16 inch caliber. Such a gun must be accompanied by a full train load of equipment and personnel. This means that there must be provided besides the gun on its trucks, an extra car for base rings, a locomotive, probably not less than six ammunition cars, a heavy crane (120 tons or more), rolling machine shop, a car for range finding apparatus, a car for engineering supplies and tools, and at least three cars for the personnel. The cost of extra track leading to gun positions, including extensive new construction to reach the seashore, must not be forgotten. The equipment must be furnished in time of peace and must be maintained at some base in full operating condition, else under the proposed method it would be impossible to defend the coast at any point.

Furthermore, the cost of maintaining a battery for defense is not dependent in the long run upon the cost of the gun and its emplacement alone, or the gun with its railway train. By far the greater part of the cost of such ordnance in times of peace is due to the maintenance of the personnel necessary for operating same. In my opinion, the fixed gun will require less personnel than the railway gun to maintain the equipment and to be ready to operate same Again, a practical method of reducing the expense of maintenance of our seacoast defenses is by the use of the National Guard, assigning guard companies or regiments from localities near seacoast defenses as reserve troops and have them understand that in time of war they will be used only to man these batteries. If this idea should be adopted, it would only be necessary to maintain at the fixed emplacements a small personnel to take care of the property and to act as instructors, and to fill the more important non-commissioned and commissioned positions during active operations. This suggestion would not be practicable if railway guns alone are used, because such guns with their equipment must be concentrated at certain bases for administrative purposes, and consequently, would be far removed from most of the National Guard troops that could be used for coast defenses in time of war. Nor would there be any assurance that the guns would be used in any specified localities.

Summing up in a few words my ideas on this subject, I feel that the article in question emanates from an enthusiast, who has lost sight of a number of practical considerations, and who pointing out the favorable characteristics of railway artillery has failed to point out at the same time the disadvantages of that type, or the advantages of the fixed guns as opposed to the mobile guns. It seems to me that there is and will be a distinct need for railway artillery; that it has a peculiar function to perform, and that there is no necessity for attempting in the discussion of the development of the railway artillery to make light of the peculiar functions of the fixed seacoast batteries on the one hand, nor of the mobile field artillery on the other. In my opinion, at each important point on the seacoast where good harbors exist that might be used for bases of operation by an enemy, or where important cities lie within long-range fire of naval vessels, a certain number of permanently fixed rifles of the largest caliber should be emplaced and should be provided with every protection, both to gun and to men, that is possible to give; that such guns will provide temporary defense which will delay the enemy and prevent his accomplishing his mission, until additional artillery can be concentrated sufficient to insure the enemy's defeat. This supplementary artillery must be transported to the point where needed by rail, and after the artillery reaches the point endangered, it may be temporarily emplaced on fixed platforms or fired from railway trucks, dependent on conditions as they develop. In any case, I believe that both fixed emplacements and railway artillery are needed, and that the latter will supplement the former and is an economical method of increasing the defense at threatened points, while the use of a minimum number of fixed emplacements insures the delay of the enemy sufficiently to enable the railway artillery to reach the point of attack.

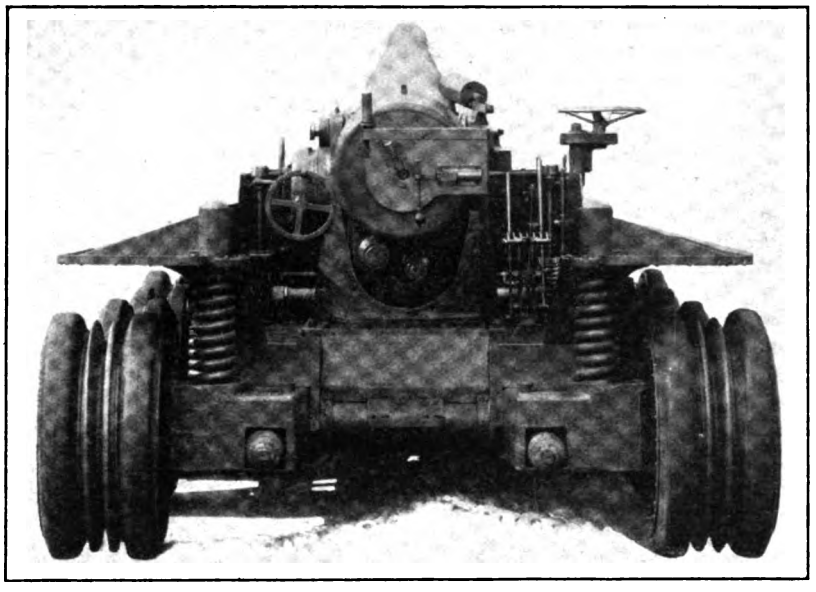
C. O. Sherrill
Major, Corps of Engineers



Colonel Oldfield concludes that railway artillery in open and unprotected emplacements must be the reliance for the coast defenses of the future as opposed to fixed emplacements. In arriving at this conclusion, he makes some fundamental errors which should be corrected. In the first place, he assumes that railway guns are easily camouflaged, whereas those on fixed mounts are difficult to camouflage. The contrary is really the case. A board of French officers, in planning works of defense for one of France's most important harbors, Toulon, recently came to the conclusion that fixed emplacements were preferable for a number of reasons, among others that they can be more easily camouflaged than can railway emplacements, on account of the impracticability of camouflaging the tracks leading up to the firing positions.

Colonel Oldfield states that many rounds were fired by railway guns during the World War, but that none were put out of action, and uses this as an argument for this type of armament. As a matter of fact, the reason these guns were not put out of action was because of their great distance back of the line, at which distance no target of so small a size as a single gun could be hit by hostile artillery, except by a remote chance. He also cites the accuracy of their fire as truly remarkable. The facts in this connection appear not to bear out his contention, for the targets upon which these guns fired were in practically every case large areas, such as cities, extensive railroad yards and supply depots; and even in these cases the actual damage done appears to have been very limited. Railway artillery with a field army is useful only in stabilized warfare, where it is fired by map at ranges in excess of 25,000 yards, under conditions making spotting impossible. So it is very doubtful if even for land warfare purposes these guns accomplish any useful purpose that can not be better and more cheaply accomplished by field artillery on wheel and tractor mounts, or by bombing planes.

Even if we assume that these guns were highly accurate and extremely effective in field warfare, it still would be unwise to deduce from that fact the conclusion which Colonel Oldfield arrives at, namely, that they will be highly effective against the rapidly moving targets presented by naval vessels. Nor has it yet been established that any type of mobile guns, including the 155 G. P. F. are as effective against rapidly moving targets as are guns on fixed and accurately adjusted mounts.

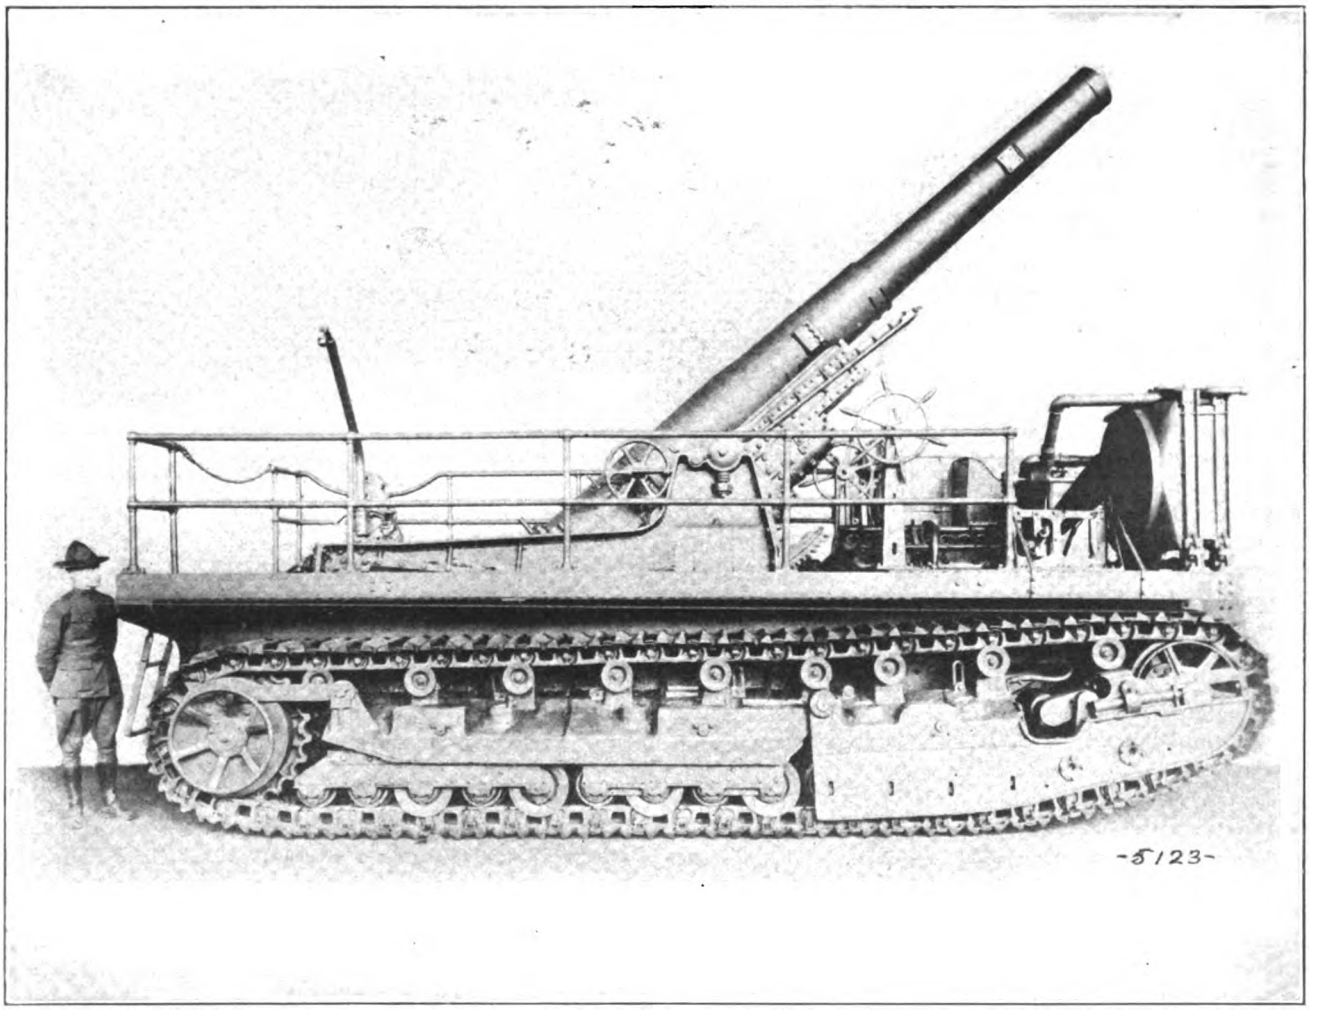
The suggestion that major-caliber guns on railway mounts will be serviceable, not only for the defense of our important harbors against naval vessels, but also as adjuncts of the mobile army in preventing a hostile army from landing on our open beaches, is believed to be fundamentally unsound. If major-caliber railway artillery should be found worthy of use in our army, it will be due solely to its utility as a harbor-defense gun, for it certainly has little value in connection with the mobile army against an invader, under conditions to be found on this continent. This matter is discussed at some length in comments by the undersigned on an article by Lieutenant Colonel Jarman, in the September-October issue of THE MILITARY ENGINEER, pp. 441-6.

Colonel Oldfield appears to draw some erroneous conclusions as to the late war, especially in reference to the vulnerability of fixed emplacements to naval fire, even in the case cited by him as to the fortifications at the Dardanelles. The official reports clearly indicate that even in the case of the inadequate, exposed and unsupported batteries at the entrance to the Dardanelles, although they were subjected to such a terrific fire that all front protection was destroyed, only one gun of the whole number was entirely put out of commission by the ships' fire, and this was caused by a lucky shot passing through the apron of the gun block and detonating there. Very little damage was done to the forts at the points nearest to the entrance, which were heavily attacked at a range of about 11,000 yards. The board reporting on this matter states "in no instance was the damage sufficient to keep any gun out of action permanently. The battery reported to have done the most firing was a 15 cm. battery. This battery had been heavily shelled, and the front slope was covered with shell craters. The only damage done to the pieces was by shell fragments."

Rear view of Christie mount for 155-mm. gun

While this was true as to the batteries entirely exposed to view and without protection, those batteries placed some distance away from the coast line were almost entirely undamaged. This result agrees completely with the experience along the Belgian coast, where the battery positions were located on and back of a small line of sand dunes, and although subjected to repeated shelling were scarcely damaged at all. This applies as well to the unprotected as to the protected batteries, whether fixed emplacements or railway guns. There were, in all, 113 guns installed on the Belgian coast for the defense of Ostend and Zeebrugge; of these 76 were visible to ships at sea and 37 were invisible behind the dunes. In spite of the fact that a majority were located thus, in plain view of the sea, and their positions exactly known from air photographs, yet they were practically undamaged by the most severe and protracted bombardments.

In this connection, it should be borne in mind that the railway guns, so called, on the Belgian coast, were complete fixed emplacements, requiring several months to construct,



Digitized by Google

and were elaborate concrete mounts upon which barbette carriages were installed by use of railway trucks. They can hardly be classed as railway mounts in the ordinary acceptation of the term, as used by Colonel Oldfield, ready to be moved at a moment's notice to a new position. Of the 113 guns employed only 8 were true railway mounts. In reference to his statement that Italy used mobile guns in her coast defenses, it should be noted that no major-caliber railway guns were so used. A board investigating the defenses gave a tabulated list of the artillery commonly employed in coast defense. This list shows *only one* mobile gun thus employed, and that one was *mounted upon a barge,* so that the statement that Italy made use of mobile guns in the defense of her coast line appears to be misleading.

Colonel Oldfield's cost data is based upon a comparison between the elaborate fixed emplacements heretofore used in our seacoast defenses, with all the bombproof auxiliaries, on the one hand, and the simplest type of railway mounting with only improvised auxiliaries, on the other. Even in this comparison, it is believed that he has failed to take into consideration all elements of the two cases, very much to the advantage of the railway guns. If, however, a comparison is made between fixed installations, approximating in character those used by the railway artillery, the relative cost is decidedly in favor of the fixed emplacement for a given amount of defensive power, on account of the many expensive auxiliaries required by the railway guns, such as locomotives, ammunition cars and personnel cars, in addition to the large expense of necessary railway construction.

There seems to be a determined effort on the part of some coast artillerists to develop a mobile railway service at the expense of an adequate system of fixed harbor defense, for the protection of our most important naval bases and cities, and it is my opinion that such an effort can lead only to disaster if carried to the extreme advocated by these enthusiasts. The adequate protection of our leading harbors and naval stations is of such vital importance to the country as a whole as to render these efforts to secure an inferior type of armament *that will fairly well serve both field army and coast defense purposes, a serious menace to the safety of our country.*

The urgent need of this country for adequate defense is an efficient Navy, free to act aggressively; a limited number of most powerful guns of not less than 16-inch caliber, on accurate fixed mounts, located at the right places for the protection of our important cities, harbors and naval stations. These, supplemented by a moderate-sized mobile army with adequate wheel and tractor artillery, and provision for rapid expansion of the mobile army in time of war, will assure our safety in any emergency.

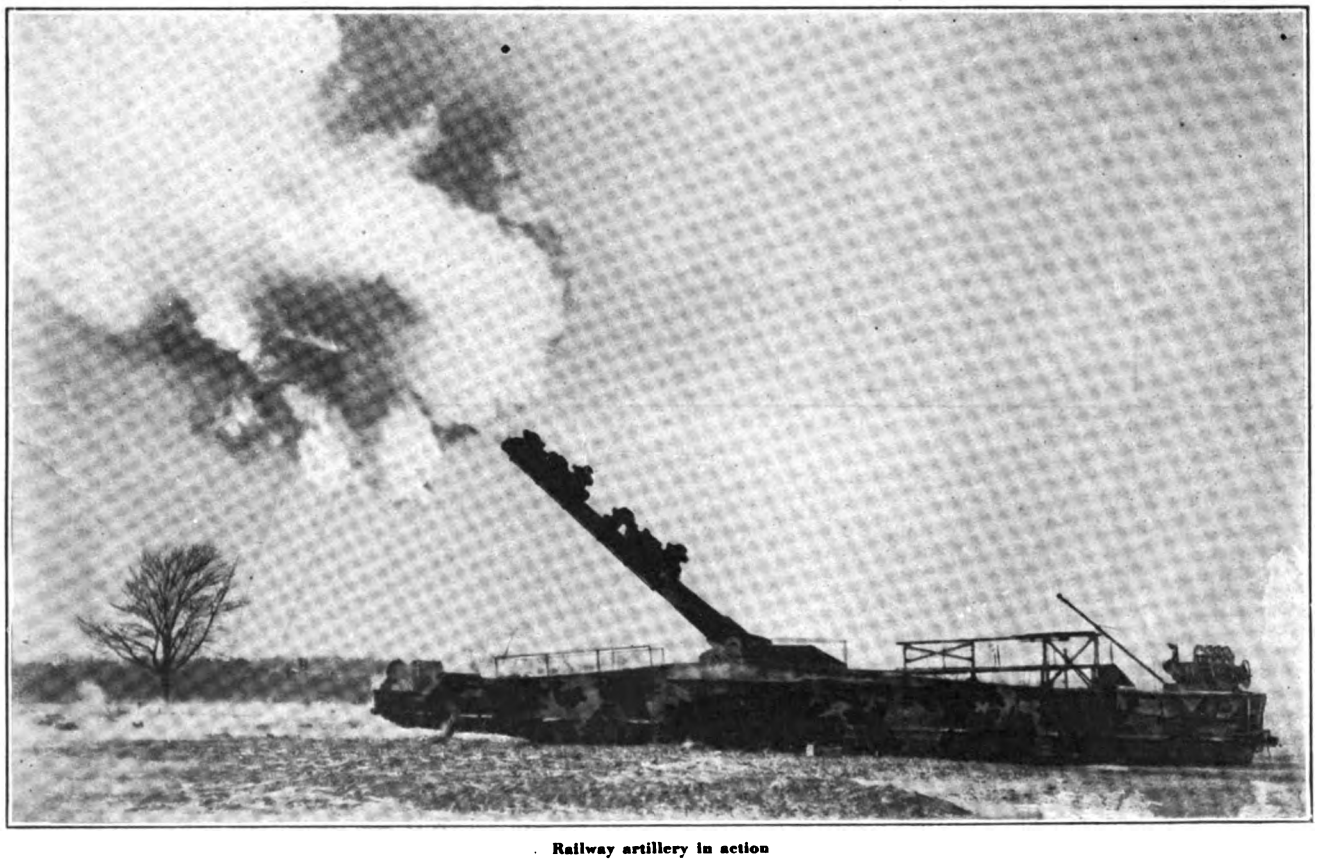
C. L. Hall
Major, Corps of Engineers

Colonel Oldfield's well-written article presents three propositions of fact:

1. For the same number of guns, the effectiveness of fire at the critical point will be greater when the guns are mobile.

2. The advantage of invisibility due to the withdrawal of weapons more than balances the loss of range caused by such withdrawal.



3. Permanent fortifications are obsolete.

The first proposition is merely a truism. Everyone knows that material of war can only be used at the place of battle. If the battle occurs at some place to which the fixed material can not be transported, the said fixed material will be of no value. If a critical point in a defensive system is of such overwhelming importance that it is advisable to defend it with the most powerful weapons known to science, and if these powerful weapons are not capable of transportation, it is nevertheless necessary to use fixed weapons.

The second proposition that the advantage of withdrawal of guns balances the loss of range, is at least arguable. This idea can be reduced to an absurdity, for, by placing the guns where the shells from them, fired at extreme range, would hit the 30-foot-depth curve, we can make them entirely immune to naval attack. At the same time the hostile fleet could get close enough to destroy the port structures.

The third proposition has been regularly advanced after almost every war in history, and has almost invariably been analyzed by the historian as merely indicating that if a fortification has not altered during a generation of peace, and the gun has improved during the same period, the war finds the fort out of date. If warfare were continuous, no one would ever hear of the proposition. If fortifications could be modernized every two weeks, as they were during the World War, everyone would concede their utility. The writer emphatically dissents from the notion that fortifications upon land are entirely obsolete. If we could be sure that tactical operations on a grand scale would take place in a terrain subject to fire from our forts and supplied by land routes of communication covered by the said forts, then all of us would shortly become partisans of permanent fortifications. In coast defense we are sure of just exactly that. The critical operations of ships against a coast must take place in front of a large harbor where captured shore facilities can be utilized by the invader and where the direct damage from ships' fire is appreciable. Such harbors are the places where coast defenses are now installed, and we would be foolish to throw away the enormous advantage which our possession of the ground for years in advance of hostilities gives us. If the forts are not modern, let them be modernized, not scrapped.

The lessons drawn by Colonel Oldfield from the Dardanelles campaign appear somewhat unusual. It has hitherto been the writer's opinion that the battle of the Straits, like the campaign of Santiago de Cuba, indicates that land fortifications have retained their moral and material ascendancy over sea power, and can only be taken in reverse.

Railway artillery in action

The Campaign of Marengo

By

C. L. Hall

Major, Corps of Engineers; Assoc. M. Am. Soc. C. E.

[*Note.*—This article was originally prepared as the first lecture in a course in Military History at the Engineer School. The time available permitted but one short study of the battles of the great master of the art of war. Marengo was selected for study. It is a fine example of "open warfare" as conducted in Napoleon's day."—ED.]

NAPOLEON BONAPARTE returned from Egypt in the fall of 1799, and, in a few brief days, by the Revolution of 18th Brumaire, seized the political power of France, and, establishing himself as First Consul, became, to all intents and purposes, the nation's dictator. But the land of whose destinies he thus became the arbiter, was by no means the same land that he left in 1798. Then, as a result of his victories, French troops guarded the Cisalpine Republic of North Italy and the Parthenopean Republic of Naples. The Rhenish states supported French garrisons. But, during the two years of his absence, terrible disasters had overtaken the French arms. Everywhere the French troops had been driven back. The military frontier on the north was the Rhine. On the south, as we shall soon see, only a few thousand troops were left in Italy. Napoleon, by his very political success, had become a liquidator of disaster. His consular chair would last until the first great battle. If successful, he could exchange it for a crown; if defeated, for a guillotine.

During the winter the First Consul busied himself with negotiations for peace and plans for war. The former came to nothing; the latter were, indeed, crowned with laurels.

In the latter part of March, 1800, there were two main French armies in being. Covering the Rhine and holding the German-Swiss Passes, which had been preserved for France out of the wrecks of the preceding year, was Moreau, with the Army of the Rhine. Holding Genoa, a little fringe of the Appennines, and the Savoy passes, was Massena, with the Army of Italy. Moreau had about 120,000 men, and so did his opponent, Kray. Massena, who was probably the ablest of Napoleon's generals at that time, had about 40,000, of whom 10,000 under Suchet were guarding the Alpine Passes. Against him was the Austrian general, Melas, a man 70 years old, with about 100,000 men, of whom 80,000 were in Piedmont, and the other 20,000 on garrison duty in the west of North Italy.

It was certain that the French Republic could never retrieve the losses of 1799 with forces such as these. Accordingly, it was decided to organize an Army of Reserve in Switzerland. This, Napoleon intended for himself. However, as the new constitution forbade him to command troops in the field, Berthier, his old chief of staff, was designated as its commander, and the First Consul merely accompanied it. Of course, this was camouflage, Napoleon was the real commander.

Consider the sketch, page 532. It will be noted that between Moreau and Massena was what I have here called the Swiss Bastion, a mountainous land that the Austrians could not get into, and which they did not think the French could get out of. It was entirely in the hands of the French. Troops quartered in South Switzerland, near the lake of Geneva, could be used as re-inforcements for either army, either in attack or defense..

The Anti-French coalition was more or less committed politically to an offensive, but it could not be foreseen whether the main attack would come via the upper Rhine or via Savoy. Those who have seen the maritime Alps may smile at the idea of an offensive in that direction, but it must be remembered that the British controlled the seas absolutely; and that southern France was a hotbed of royalism, where the invaders could find many friends.

Napoleon had no intention of awaiting the coalition's moves, however, and planned to strike first, as he always did. His first idea was to combine Moreau's and Berthier's armies under his personal command, strike from Lake Constance, against Kray's communications, and, after defeating Kray, move on south and cut off Melas.

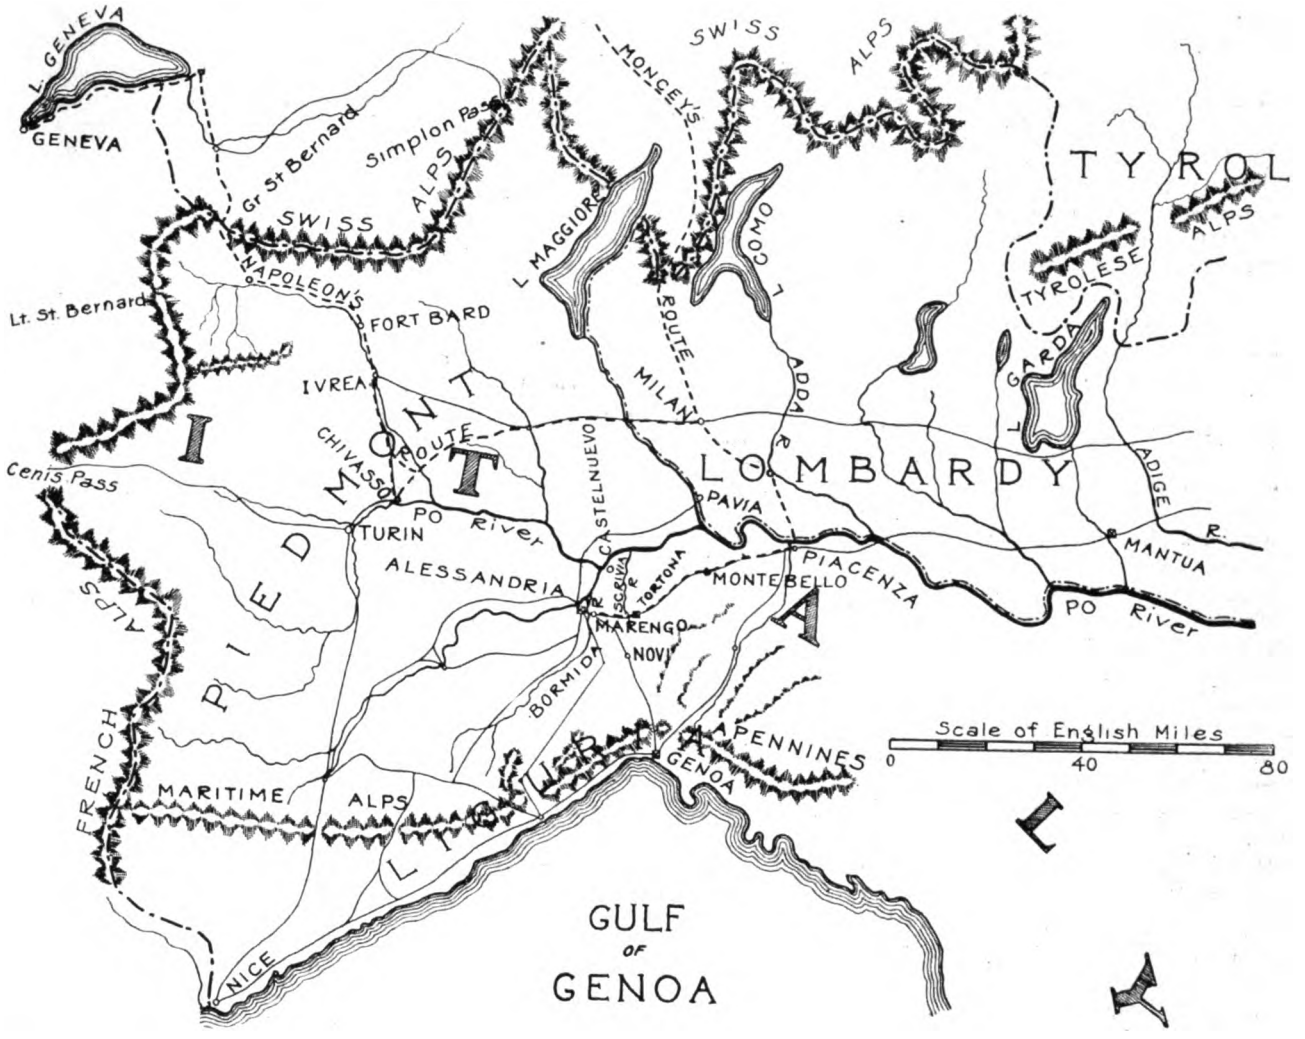
In the execution of this move he ran into a snag. Moreau disapproved of the plan and refused to be a party to it. In the rather shaky political situation, Moreau could not be relieved; moreover, his talents were so high that it was difficult to replace him by a professional equal.

So a different plan was evolved. Before explaining it we may examine the tactical and topographic situation of the moment.

It was wholly impossible to keep secret from the Austrian spies the creation of the Army of Reserve. But the army itself was concentrated around Lake Geneva, whereas it was given out that it was organized near Dijon. Great publicity was given to a review of the Army of the Reserve by the First Consul in person, which was held at Dijon, a locality familiar to many Americans. For this review there were turned out three or four thousand men, all either superannuated or recruits. The spies immediately reported the non-existence of the Army of the Reserve, and Napoleon was able to attack with an army whose existence was unsuspected.

From Switzerland Napoleon had three or four passes, all very difficult, though not exactly impossible, as Hannibal had proved. They were, however, impossible as lines of supply, and the French armies would have to live on the country. Melas had the broad valley of the Po as his line of supply, and did not think that elements, whose very existence he doubted, could debouch from the Swiss Passes.

Napoleon's modified plan of campaign was as follows:



(*a*) To cross the Alps via St. Gothard or Simplon Pass.

(*b*) To move thence on Turin, forming a junction at that point with Massena (if possible).

(*c*) With his forces combined with 25,000 men whom Moreau had promised him, to attack Melas and drive him out of north Italy.

On April 7 Massena was sent his orders. These directed him to remain strictly on the defensive until the Army of

Digitized by Google

the Reserve debouched into Switzerland. Then he was to attempt to form a junction with its right wing at Turin.

In the meantime Melas had taken the offensive on his own account (April 6). He adopted the very style of fighting which Napoleon had foreseen, namely, he advanced concentrically, enabling Massena to attack him an element at a time. His forces were, however, so superior that Massena, in spite of most brilliant troop-leading, was invested in Genoa on April 18. Of these events Napoleon received only sketchy information, as Massena's communications with France were soon cut off. However, he concluded that the Army of the Reserve could not lose a minute. Hence, the great St. Bernard was chosen instead of the more easterly passes. This was the first change in the plan of campaign.

On May 1 Berthier arrived at Geneva. On May 6 Napoleon left Paris and reached Geneva two days later. On May 10 the Army of the Reserve was organized into an advance guard under Lannes, two corps under Duhesme and Victor, and the cavalry under Murat. Its total strength was 42,000 men. At the same time Thurreau, who held the Cenis Pass, was transferred out of Massena's Army. Moreau's contribution of 15,000 men under Moncey was marching toward St. Gothard.

Malas' army was for the most part either besieging Massena or trying to enter France from Nice. The rest of his men were scattered all over north Italy, including 8,000 men watching St. Gothard.

On May 15 Lannes crossed the pass. The journey was very difficult, but Napoleon had made all possible arrangements to supply the troops en route, and they were exceedingly cheerful as "Successors of Hannibal."

Lannes had hardly crossed when he was delayed by the impregnable post of Fort Bard. It was impossible to take it directly, but a foot-path was found to get the infantry around it; and the artillery stole by at night. Lannes continued forward, and on May 22 attacked Jurea, but without success. Two days later more artillery had been brought up, and the town was taken by assault. On May 26 Napoleon entered the town himself.

The opening maneuvers had been brilliantly successful. Napoleon had placed a first-class army, by pure surprise, on the flank of Melas' line of communications, and had made the invasion of southeastern France an impossibility. He now took a very bold attitude and adopted the following plan of campaign:

1. To abandon Massena to his fate.

2. To march on Milan, seize the crossings of the Po, thereby cutting off Melas, and attack and defeat him in detail. An army defeated at its rear is, of course, no army at all.

The abandonment of Massena was a master-stroke. For even if he surrendered (as he later did) so many more Austrians would be absent on the critical day. If the Austrians abandoned the siege, he was released any way.

On the 27th of May Lannes, after some fighting, reached

Digitized by Google

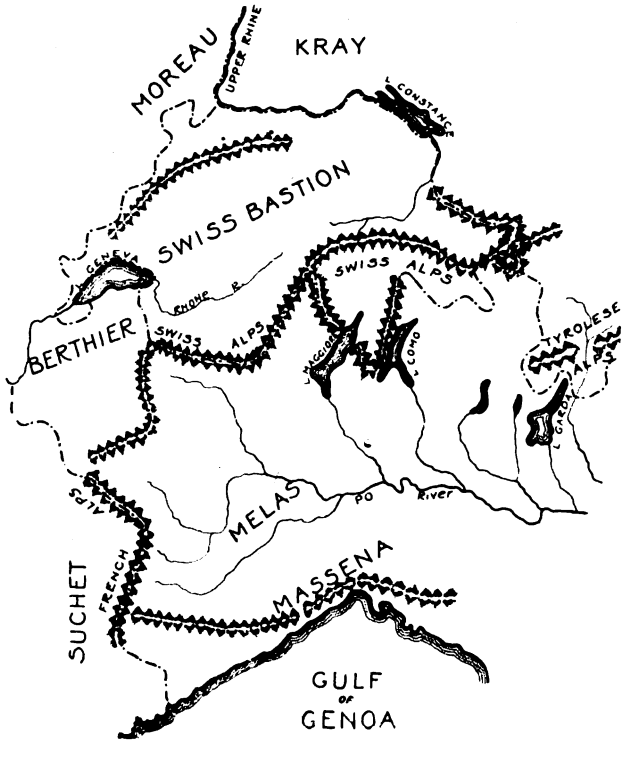
Chivasso. Moncey crossed the St. Gothard on the 26th and 27th. Leaving Lannes as rear guard, the French on June 1 entered Milan. On June 3 Lannes entered Pavia. Suchet, who was in command of the troops in southeastern France, had, in the meantime, driven back the Austrians in his front.

By the night of May 31 Melas became aware of his critical situation, and ordered a concentration at Alessandria. Ott, in front of Genoa, was negotiating with Massena for its surrender. The latter was, of course, wholly unaware of his prospective relief, his supplies were exhausted, and he surrendered with all the honors of war on June 4. His defense ranks as a classic of military history, and proves that the most hopeless defense, protracted to a sufficient extent, may have far-reaching influences on the success of a campaign elsewhere; Stoessel, at Port Arthur, 105 years later, had apparently forgotten this. Ott, on June 6, withdrew toward Alessandria.

The same day Moncey entered Milan. Lannes and Murat had crossed the Po. Ott had received orders to move on Piacenza instead of Alessandria. Lannes met him on June 9 at Montebello and drove him back to Castelnuevo.

We should pause here and observe the tactical situation. Ott, with the beaten advance guard, was at Castelnuevo about a day's march west of there. Napoleon had 34,000 men south of the Po ready for action, 23,000 too far away to be of immediate use.

According to the books, Napoleon should have concentrated his 34,000 and prepared for immediate battle. Most authorities are agreed that this is what he ought to have done.



His estimates of the enemy's intentions conceded him three plans:

(*a*) To cross the Po and move to the north of, and parallel to Napoleon's line of communications back on Mantua.

(*b*) To retire, via Genoa, to friendly Tuscany and prolong the campaign indefinitely.

(*c*) To attack.

To meet the first plan, two divisions were sent to the vicinity of Chivasso. On the 12th, the French advanced on Alessandria. On the 13th, the French crossed the Scrivia. Here, finding no enemy, Napoleon became worried that the Austrians might adopt the second plan, and sent Desaix, who had just joined from Egypt, to Novi to cut off Melas' retreat. The first and second of the enemy's plans were, indeed, well discounted, but the First Consul was badly weakened if the enemy should attack.

Late on the afternoon of June 13 Victor encountered the Austrian rear guard at Marengo and drove it back to the Bormida bridgehead. This made Napoleon safe in case of a prospective retreat, and he slept in peace that night.

Melas' troops crossed the Bormida early in the morning of June 14 and attacked Victor's advance troops. Napoleon was completely surprised and sent post haste for Desaix at Novi. Desaix reported that he would arrive at 4 o'clock. In fact he started without orders as soon as he heard the fire of guns. All of Napoleon's efforts were thus bent on gaining time. The attacks of the Austrians were more and more successful, and by noon the French were almost routed. At this time the aged Austrian general became physically exhausted and turned his command over to the chief of staff. The latter formed the army into one great column and marched on down the high road.

At 5 o'clock Desaix came up. The fugitives were rallied, the French lines re-formed. Marmont managed to turn some reserve artillery on the Column, Desaix attacked the right front, and Kellerman, with a cavalry brigade, the left rear. The Austrians, thus threatened, broke and ran, and that night all but their rear guard crossed the Bormida. On the morning of June 15 Melas sent a flag of truce and the Marengo Campaign was finished.

Let us sum up some features of this great campaign.

Napoleon chose a line of communications, which would preserve his own line of retreat in case of failure, but which would cut off the enemy entirely in case of success.

He deliberately abandoned a portion of his army (Messena's), which he could have relieved, but only by forfeiting his chances of a smashing victory.

His dispositions were so taken that if the Novi detachment had been led by a lesser man than Desaix, his violation of the principles of concentration for action would have been fatal.

Melas, however, committed about every known mistake. The successful defense of Fort Bard gave him every chance to cut off Lannes before the rest of the army could get over the St. Bernard. Had he concentrated all his troops, even as late as May 30, he could certainly have prevented the disaster which overtook him.

The campaign which opened when Napoleon crossed the Alps on May 15 and ended when Melas' parlementaire appeared on June 15, settled the fate of north Italy and gave permanence for fourteen years to a Bonapartist dynasty. It has been studied and restudied by every staff officer in Europe. If Napoleon's principles were not followed in the Great War, it was not for lack of effort.

American shipbuilding during 1919-1920

During the fiscal year ending June 30, 1920, according to the U. S. Department of Commerce, the total shipping built in the United States and officially numbered by the Bureau of Navigation, aggregated 2,241 vessels of 3,860,484 gross tons as compared with 2,158 vessels and 3,734,741 gross tons for the preceding fiscal year. The peak of production was reached in the autumn of 1919 and the following winter when, from September, 1919, to February, 1920, the output was at the rate of 4,250,000 gross tons per year.—*Eng. The Mental Processes of the Military and the Non-Military Mind

As Applied to the Design of Army Wagons

By

Ernest Graves
Major, Corps of Engineers

[*Note.*—The spirited attack by Colonel Graves and the active defense by Major Keesler are most encouraging signs, as indicating the virility which characterizes our Society and all the members thereof. Our readers will much enjoy these comments, which combine technical information and human interest in so graceful a manner.

In his letter submitting these comments, Major Keesler says: "While I do not know Colonel Graves personally, I know he enjoys the reputation of being a good engineer officer and accustomed to speak his mind plainly, which I consider more praiseworthy than otherwise." And again he says, by way of warning: "I could submit much more favorable comment, but the attack does not force me to call out *all* of my reserves at this time."

This lively discussion on the "processes of the military and non-military mind" seems in a manner to epitomize the aims and purposes of our Society of American Military Engineers. For the defense of our country the best thought of both the military and non-military mind is needed. To bring the military and non-military mind together on a common ground and for a common purpose, to profit by the best that each can do, to let each perceive by contrast with the other its own strength and its own weakness, and finally to adjust differences of opinion and cause the two to pull together as an unbeatable team, is the reason for our Society, and for its Journal.—ED.]

IT has been frequently stated that civil and military engineering are identical, or nearly so; that military engineering is merely an application of the civil art. Aye, but there is the rub—in the application. The details of practice are very similar to be sure, but the fundamental principles differ widely. The term "military engineer," as here used, does not mean simply a person who carries a title as military engineer. It means one who really follows military mental processes, or, in other words, thinks on a military basis.

The civilian engineer receives from a client an idea of what is desired, and he figures to design and erect a structure that shall fulfill those desires. His mission is to satisfy his client. As a rule, appearance, facility of operation, convenience, first cost, etc., are the most important considerations. There must be produced a finished product which is all that the client desires as to efficiency and ease of operation. The engineer has the markets of the world at his disposal and, within reason, such time as he needs to accomplish his results.

The conditions under which the military engineer operates are as different from this as possibly could be, in almost all respects. What is demanded is a structure to accomplish certain necessary results in a minimum of time. The engineer first takes stock of his materials, supplies and labor, and then decides how the bare necessities of the case can best be met with the facilities available. His designs are based upon, in fact entirely subservient to the resources available. Time is always limited. The engineer has generally to accept anything that can be used, regardless of whether it is really suitable to his purposes.

During the great war most of the failures of the engineers resulted from designing ideal structures, and then sitting back and waiting for somebody else to supply the facilities with which these ideal structures were to be erected. This somebody else never appeared. Usually the engineer in charge did not even put his most efficient assistant to the task of obtaining supplies. This point of view is all wrong. Anybody can build an ideal structure when somebody else furnishes him all the labor and materials that he requires, but it takes a real man to provide necessities on time with nothing to work with except what he "rustles" for himself; to feed a multitude with 5 loaves of bread and 3 fishes. Military engineering is a thoroughly practical art. There is little time for theorizing.

The real military engineer has only two essential things to do. He must fit his designs to the facilities he thinks he can obtain, and he must be the chief instrumentality in obtaining these facilities. In other words, he must go out and get what he wants. Most of the time, brains and energy, even of the chief engineer, must be devoted to supply of material. He should familiarize himself with the available resources and methods by which they may be exploited. His designs must be adapted to the situation. Not infrequently their features will be determined chiefly by the available labor. To prepare such designs may look like rough and ready work—actually it requires a nimble and resourceful mind, which must be able to determine promptly which designs are most economical as applied to given conditions, as to available materials and labor.

The mental processes to which we refer are not limited to the engineer. They are characteristic, or should be characteristic of all those directing all classes of military operations. For example, if a movement by road is contemplated, the military mind will select the motor trucks that will probably keep going on the roads that must be used for the movement; the non-military mind is too apt to become befogged with a number of incidental matters, such as economy of operation under ideal conditions, trusting that somebody else will create the ideal conditions. This somebody else is usually conspicuous by his absence.

The foregoing remarks find some application to the question of proper equipment for troops, and in particular to an article in a recent issue of THE MILITARY ENGINEER by Capt. A. A. Keesler, of the Watson Wagon Co., with reference to a design for a wagon for engineers.

It is believed that incorrect mental processes resulted in the evolution of our present wagon for engineer tools, and that these were the processes of non-military minds.

Without doubt Captain Keesler is a capable man in his own line, which is the designing of wagons, but he is not a professional soldier, and therefore not as familiar as

Digitized by Google

a professional soldier with military needs. During the war he was engaged in studies which resulted in the design of a wagon, but the result proved quite conclusively that he had not sufficient supervision by military experts. He understood only half his problem, worked on false hypotheses, and if his wagon is adopted, the army will be saddled with an abortion.

Captain Keesler states, "it is generally true that to do a special task most efficiently you must have a special tool therefor. The task may be done with a general purpose tool, but can be done quicker, better and with immensely more satisfaction to one's self and one's superiors with the proper tool designed for that particular work." This is not correct. In engineering, both civil and military, it is extremely undesirable to be saddled with special tools. These have their use in factory production, but in engineering, and especially military engineering, special tools should be avoided. We must not allow ourselves to be led astray by any such specious arguments as this.

In attacking this problem the practical military mind would first be concerned with the question as to whether the vehicle *can be kept in operation*. The next question would be whether a fairly efficient wagon could be obtained. The limber and caisson type requires two drivers and a man to operate brakes, or three men; it uses four to six horses; it is easy to obtain access to its contents; it will undoubtedly travel over very rough roads; and it can be divided into two carts. However, it is believed that this device does not fulfill as well as a wagon the prime military requisite that it can be *kept in operation*, because it wears out horses which, in any event, are harder to keep going than mules, and because in campaign broken tongues, bolts, wheels, etc., could not be quickly and easily replaced. Another serious defect is that such a wagon is not adaptable to general hauling. It might be satisfactory for tools, but if something more bulky were to be hauled, it might prove quite unsatisfactory. The engineer is called upon to haul all sort of things in his wagon, and he has need of a general purpose wagon for general hauling.

The military mind would reason this thing as follows: "If I have an escort wagon, one man does all the driving, including operation of the brakes; I have mules, harness and wagons that can be easily replaced, either in whole or in any broken part, anywhere that there are other troops, because this equipment is standard throughout the army. If I have a limber and caisson wagon, possibly I can reach a certain tool therein a little quicker; but if a piece of harness, a tongue or a wheel breaks, I probably will have to leave behind the wagon with all my tools. If this should happen to an escort wagon, I simply go to the nearest quartermaster, and while I am requesting his help, if he does not give it to me, one of my enterprising soldiers will steal the necessary spare part from some wagon train in the locality.* In any event I shall keep my tool wagon moving."

On the punitive expedition into Mexico a wheel on one of my tool wagons broke down. A sergeant stayed up all night wiring it together with wire from a nearby fence. Knowing this would not hold for long, I sent an officer back to Columbus to get a wheel. Next day on the road I passed a wagon train leaving behind a wagon with a broken wheel. When I stopped that night I sent a pack mule to get the good wheel of this broken wagon. My lieutenant also obtained a wheel in Columbus, put it in a truck and started toward the outfit. As he neared the broken wagon some officer took the wheel away from my lieutenant, but even so the quartermaster's wagon had only three wheels. I proceeded with four good wheels. If I had had a limber and caisson wagon, I should have been forced to leave my tool wagon behind.

Practical questions like these are of far more importance than theoretical efficiency. Practical military equipment can be designed only by practical military men. That they should have the assistance of expert civilian designers is, of course, desirable, but the military mind and not the civilian mind is qualified to fix the requirements, and make certain that they are met by any device it is proposed to adopt.

*[This merely indicates how results *may* be achieved. Major Graves believes that such practices should not be wanton, nor even habitual. They should be limited to cases of really dire necessity. But in such cases the end justifies the means, and an *undetected* theft becomes a really commendable act.—ED.]

Comment

A. A. Keesler
Major, Engineer Reserve Corps

Colonel Graves seems to be so much in earnest that I rather hesitate to disagree with him, but after a careful perusal of his article I can not help but wonder whether he has ever had occasion to give *any* type of engineer tool wagon a fair test under actual service conditions. I might add that I have been advised that no such test was made with the Pershing Expedition to Mexico as that expedition very soon became a test of motor equipment.

He makes the point that there is a great difference between military engineering and military hauling, and civilian engineering and civilian hauling. In both cases, I take it, the idea is to move certain material of various kinds from the place where it is to the place where it will be wanted. In both cases it must be done often under adverse conditions as to weather, vehicles and motive power.

I admit that twenty-five years of designing, building and supervising the use of haulage vehicles of all kinds, from a two-wheel cart to a seven-ton truck, may not have fitted me adequately to compete with Colonel Graves in designing vehicles, but over two years' service in the army, which included the inspection of and remedying of defects in horse-drawn transportation, from Camp Green to Coblenz, gave me a fair opportunity to judge the quality of design which military minds of the Regular Army turned out.

It may be true that the civilian mind does not function in a way to allow it to understand the military mind, if judged solely by the product of its brains, as shown by the horse-drawn vehicles in use. In a lifetime association with general contractors who have developed this country from one ocean to the other, in building roads, dams, irrigation systems and railways, wherein they must haul supplies of every conceivable nature that is or could be handled by the army, I am convinced that I could not induce them to use the vehicles which army men are forced to use for their transportation.

If "incorrect mental processes" resulted in the evolution of the proposed general service limber and caisson wagon, then I wonder what would be said of the mental processes of the military mind which conceived the Brill type of engineer tool wagon. I will leave the characterization of that military mind to any of the officers or men who trained with it in this country or used it overseas. It is certain that if this is a type of the working of the military mind in designing vehicles, then it would be better to intern all engineer officers while they were being provided with transportation equipment.

Undoubtedly, Colonel Graves must consider that "suffi-

Digitized by Google

cient supervision by military experts" must mean his own supervision. The officers under whom the writer served during the designing of the wagon in question were all Regular Army officers who had had all of the usual experience of the Regular Army officer and some of whom had had extended overseas experience and had been returned, that the benefit of their service overseas might be obtained in the equipment of the army. If the officers and men of the 1st, 2d and 3d Divisions were not experienced military experts, I fear the army is without them. When the wagon as designed and presented was remodeled on the Rhine, under the supervision of the Chief Engineer, 3d Army, the division engineers, 1st and 2d Divisions, and after conference with several higher and experienced engineer officers who had served as corps engineers, the experience of the officers who served throughout the war in these Regular Army divisions was taken advantage of, as well as the criticisms of the non-commissioned officers and men. If this is not sufficient to produce a wagon which meets with Colonel Graves' approval, at least it was sufficient to produce the high recommendation of many able officers who have commanded troops in the field and met the problems which Colonel Graves refers to. I will quote from reports which I suspect were not far from Colonel Graves' elbow at the time he was slinging ink on my poor little wagon and using such epithets as "incorrect mental processes" and "abortion":

"The wagon as it stands modified will take the platoon equipment anywhere two animals can go. Once there, a usable piece of transportation is available, ready to go for rations, additional tools or a load of rock."

"This limber and caisson type wagon, as modified, is considered by far the best unit of its kind yet developed. With the two changes indicated below, its adoption is strongly recommended."

"I believe the wagon as brought to Europe by Captain Keesler is a great improvement over any tool wagon I have ever seen. As modified by him, I believe it to be well nigh ideal for engineer uses."

"Subject to above comments, the new type of wagon has my enthusiastic endorsement."

It is deemed regrettable that the Colonel should excavate in his own fertile imagination rather than in the records on file in the office of the Chief of Engineers, but that possibly may be the manner in which his military mind functions.

I do not mention the names signed to these reports because I know these officers are amply capable of defending their own opinions. They are brilliant officers of the greatest fighting divisions of the Regular Army.

As to the matter of special tools for a special task, if nothing but a general purpose tool must be used, I should like to ask Colonel Graves why it is that the equipment table for the engineer tool wagon provides for several hundred different tools. Probably wire may be cut with an axe, which is a general purpose tool, but the wisdom of some one has provided wire-cutting pliers.

As to the point he makes, "However, it is believed that this device does not fulfill as well as a wagon the prime military requisite that it can be kept in operation, because it wears out horses which, in any event, are harder to keep going than mules, and because in campaign, broken tongues, bolts, wheels, etc., could not be quickly and easily replaced," it must be pointed out that the breakage on the limber and caisson type would be considerably less than on the stiff reach type and that if adopted, spare parts would be as easily obtained.

As to the statement "another serious defect is that such a wagon is not adaptable to general hauling," it is pointed out that this wagon is adaptable to all kinds of general hauling and is capable of carrying any material, with the exception of lumber or timbers, which can be carried in a stiff reach wagon, It will go over country without damage where it is impossible to take the escort wagon, and under certain circumstances, it has the great advantage of becoming two vehicles, thereby doubling the efficiency of the transportation for certain purposes. If a company commander wanted picks and shovels and also wanted a shell hole filled, it is quite possible that he might have to go in different directions.

As to the complaint that it requires four horses, while the escort wagon requires two, I am astonished that Colonel Graves has not noticed that the four horses were to pull a load. I am surprised to find that he is the kind of military engineer who has overlooked the fact that the motive power, namely, horses or mules, is the most valuable part of his equipment, and that the commonest fault in the army is overloading. It is less necessary to use four horses on the proposed limbered wagon than it is on the escort type.

In conclusion, it is believed some discussion should be had regarding the uses, the excellent points and the defects of both the limbered type and the stiff reach type of wagon, in order that a correct decision might be arrived at. There must be points in favor of the limbered wagon, or else the British Army was entirely mistaken in their equipment. If the stiff reach type is adopted exclusively, the writer would be glad to assist in helping to redesign it, so as to eliminate some of the defects of the escort wagon in order to make it more serviceable and easier of procurement.

Highway bridges inadequate for motor truck traffic

Eng. News-Record points out that one of the weakest elements of our road system is the insufficient strength of highway bridges under motor truck traffic. The number of commercial motor vehicles in America is increasing rapidly. Five years ago there were 70,000 on our roads, to-day there are 7,000,000. Even the smaller of these vehicles often attain a gross weight (truck and cargo) of 5 tons, whereas the larger attain to 15 or even 20 tons. All are free to pass over any of our highways. A survey made by one state highway department during the war revealed the fact that a large number of highway bridges could not carry a load beyond one ton without exceeding what are ordinarily regarded as safe limits of stress. Accordingly the dangerous combination of a weak bridge and a heavy truck is daily becoming more frequent.

Until our bridges can be reconstructed a close regulation of truck loads and speeds will be necessary if frequent accidents or failures are to be avoided. This is a more critical matter than that of wear on road surfaces.

Incentive is so fundamental to success wherever human effort counts, that to provide this incentive must be regarded as the third commandment.—Railway Age.

Should Engineer Troops Be Trained in Peace As They Are in War?

By

H. A. Finch

Major, Corps of Engineers

THE discussion of the article, "Some Practical Points on the Training of Troops," in the May-June (1920) number of THE MILITARY ENGINEER developed an interesting difference of opinion that is believed to be worthy of further investigation. This difference of opinion is that concerning the best system of providing for the engineer instruction of our troops.

In the original article an argument was made in favor of the principle of providing expert, specialized instructors or supervisors for the engineer training (other than general pioneer instruction) of the various platoon units throughout our regiments—these instructors being drawn from the officer personnel of the regiment. This method was followed with success in our preparation for participation in the World War. In the discussion of the article referred to certain officers of long experience took the ground that this method of instruction had been forced upon us through necessity for hurried preparation for war; that the need of such a system no longer exists, and that we should therefore revert at once to the method of holding the company officers directly responsible for the complete instruction of their units.

In the original article this subject was treated very briefly, and the writer may have failed to make clear that he advocates holding the company officers accountable for the general pioneer instruction of their organizations (recommended for the entire regiment), and for all infantry training, except perhaps rifle practice. However, the statements made verbally and through correspondence by certain engineer officers indicate that they would be much better satisfied to have the captain and his lieutenant assistants assume the burden and the responsibility for all instruction of whatever nature given the men under their charge.

At the outset the writer is forced to confess that he has never met a company officer versatile enough to meet all the demands that such a system imposes upon a captain of engineers and his lieutenants. Therefore, with due deference for the opinions of the advocates of "direct responsibility," the writer submits that much may be said in favor of providing special supervision over much of the technical engineer training given any unit of an engineer regiment.

Perhaps the best method of approaching this subject is to establish first, as clearly as may be, the object of a training schedule for engineer troops. If, as some officers hold to be the case, the training of troops in the American Army has as its main, if not its sole object the development of competent officers and non-commissioned officers; if the instruction of the men in the ranks is a matter of secondary importance in that they are to be handled or mishandled simply in order that officers and non-coms may learn by making mistakes—if this theory is accepted, then more may be said for the system of making the efficiency of the company entirely dependent upon the ability and versatility of its officers. But there is another conception of the purposes of military training in our army which must be considered on its merits. This is the theory that the object of all our army training is to provide correct military instruction for as many men as possible in this "unmilitary" nation, to the end that each man turned back on the country may have benefited to the fullest extent through his army experience. This idea contemplates that discharged privates shall leave our service, not with a muddle-headed wondering of "what it was all about," but with certain clearly defined lessons in mind—lessons that will prove of benefit to the country in time of stress whether or not the man ever rises higher than the grade of private.

The writer believes that in the future, even more than in the past, will it be difficult to fill the ranks of our regiments unless the army can be shown to provide worth-while training, vocational as well as military, for the eligible young men of this country. To the writer's mind this implies that, far from placing the training of 100 to 200 young men in the hands of a captain and his lieutenants, who by reason of limited experience can not be expected to do full justice to the immense engineering field to be covered, it is much wiser, as a general policy, to provide the very best technical and vocational training that it is practicable to obtain by utilizing any expert knowledge that may be possessed by any of the regimental officers, or that may be developed in these officers in schools established for the training of instructors. It is believed that not only may this be done with marked benefit to the men in the ranks, but also to the officers of the company who, as observers, learn the correct methods of imparting instruction in various subjects in which they were not fully grounded.

It seems certain that men will not in the future enlist for military service in sufficient numbers to fill our peace-time quota unless the army can be brought to mean something desirable to the man who wants to serve and at the same time is ambitious to learn, but who does not find the chances of his being promoted to a non-com's grade sufficiently attractive to tempt him into the army. But even if recruits were plentiful, the writer holds that the field of engineering instruction is now so wide that the average captain, busy as he is drilling, disciplining and administering his company, can not be expected to do justice to all the subjects in which instruction is required. And this does not mean that the average young officer is believed to be incompetent, but simply that he is *bound* to be inexperienced in some of the many lines of instruction over which he (under one theory) must exercise control. It takes time and study to

Digitized by Google

become a competent instructor, and the captain and his assistants have not the time to qualify in all subjects. The best they can hope for is to graze superficially over what they don't know until by observation of some one who *does* know they gain knowledge enough to act as real instructors. And unless that "some one" is provided by the system under which they work they may go for years in their ignorance. This is said from experience. Such a system may accustom an officer to assuming responsibility, but it is more likely to habituate him to bluffing his way—until the day when his bluff is called, as it nearly always is. In any case this system fails to furnish correct instruction for the privates in the ranks while their officers themselves are learning.

The writer speaks feelingly on this point because he has the handicap of a memory that will not forget the many mistakes he has made while floundering around with the millstone of platoon or company responsibility about his neck. Too often has he scratched his head (and watched others do likewise) over the distribution of a company for engineer instruction, only to end after all other practicable training was provided for, by consigning the twenty or thirty remaining men to "Knots an' lashin's." (It would be an interesting but perhaps a distressing task to calculate the number of years in actual elapsed time that have been devoted in our engineer service to the grand old game of "Knots an' lashin's," and to compare this figure with the benefit derived from such instruction.) Too often, as a captain, has the writer wished that he could find the time and that some one would produce the knowledge to clear up his hazy ideas as to the correct method of teaching *soldiers* to make a quick and worth-while road sketch. As for rifle shooting, there is no forgetting the hours wasted on inefficient methods and useless drills designed to teach this all-important subject—methods hammered out separately by groups of company officers acting without expert guidance from their superiors. Perhaps these senior officers did not realize that only one out of four companies was fortunate enough to include a competent rifle practice instructor among its officers, or perhaps they believed that there was no better way of developing instructors in this line than by insisting that each company group struggle for its own salvation; but contrast this haphazard, "direct responsibility" experience with the system which provides an expert possessing exact knowledge and enthusiasm for his subject to supervise the target practice for an entire division. Under this system the expert, such as Colonel McNab, assembles an entire regiment at one time for a series of talks on rifle shooting. From these talks both officers and men learned the purpose of the course, and they also learned what is to be emphasized and what to be ignored in the well-padded pamphlets issued by the War Department. A representative of the general supervisor is attached to each regiment to direct the instruction of each company in turn, the company officers being developed as instructors (so far as their other duties will permit) and employed as subordinate assistants. The writer has seen this system applied in several regiments and always with success—if teaching men to shoot be counted a success. It has proven itself. In no case were company officers allowed to "get away with mistakes." Nor have temporary officers been the only ones to secure benefit from the course, for it is a matter of record that under such a system many officers of the Regular Army with years of service learned for the first time the *real* way to implant a knowledge of rifle shooting in the head of any soldier.

Economical Loading of Seagoing Dredges

By

G. S. Phelps

U. S. Assistant Engineer, Cleveland Engineer District

The correct determination of the relative amount of time to be spent in dredging and in running to and from the dumping grounds is a matter of some importance. It may be investigated from a theoretical standpoint, and the ideal practice for particular cases determined, but judgment is essential when it comes to applying practically some of the theoretical conclusions.

Investigation was made as to the number of loads per day which should be dredged at Cleveland Harbor with the seagoing hopper dredge *Burton*. At this harbor dredged material running overboard with the overflow is a waste of money, as it settles within the dredged area. The material was a fine silt, which settled slowly in the bins. Time required for one round trip to the dumping grounds, about 30 minutes. The total time available for dredging and dumping is assumed at 9 hours per day. Two loads per day could be dredged with a pumping time of 4 hours each, which with the two trips to the dumping grounds consumed the 9 hours. While the dredge worked on that schedule, it was found that a fairly constant average of about 720 cubic yards of settled material in the bins was secured with each load, or at the rate of 3 cubic yards of settled material per minute of dredging time. Capacity of the bins was 935 cubic yards. The dredging time per load was varied from 30 minutes to 4 hours, and it was found that the amount of settled material in the bins was practically constant at 3 cubic yards per minute of dredging time, irrespective of the length of the dredging period. Thus when 6 loads per day were taken, the total time dredging was 6 hours, 3 hours were spent going to and from dumping grounds, and the quantity of measured settled material in the bins was about 1,080 cubic yards for the day, still 3 cubic yards per minute of dredging time. The question arose as to whether the solids held in suspension in the water above settled material in the bins were sufficient to justify the greater number of loads per day. The settled material had fallen from 1,440 to 1,080 cubic yards per day. It is apparent that volume of dirty water carried to the dumping grounds was increased from 2 (935)—1,440=430 cubic yards with 2 loads per day, to 6 (935)—1,080=4,530 cubic yards with 6 loads, an increase in volume of water carried of 4,200 cubic yards. The loss in settled material was 360 cubic yards. If the water contained 8.76 per cent solid material held in suspension, then the loss in settled material was exactly balanced by the gain in suspended solids; if less than 8.76

Digitized by Google

per cent, 2 loads per day gave the greater total of settled and suspended material; if more than 8.76 per cent, the shorter dredging period and greater number of loads were better.

It appears then that in this case, 8.76 per cent is the critical percentage of suspended solids at which economy definitely demands a change from a policy of full loading of bins to one of many loads per day, the more the better, limited only by the time required to fill bins with muddy water. Satisfactory sampling of the water held in bins has not been made, since the dredge left the work before this was done. It is believed, however, that in a great many cases where the material consists of fine silt, the solids held in suspension will considerably exceed this critical percentage, and that in such cases the dredge would better become a "water wagon" and take as many loads as possible of water to the dumping grounds, in spite of the humorous criticisms of those who assert that we spend the government's money dredging water, and reporting it as solids.

Plate No. 1 shows graphically, for varying number of loads per day, the total yardage which would be obtained under conditions as outlined for Cleveland dredging, with varying percentages of suspended solids. The importance of taking this suspended matter into account, when considering the total quantity of material carried, is strikingly illustrated by this diagram.

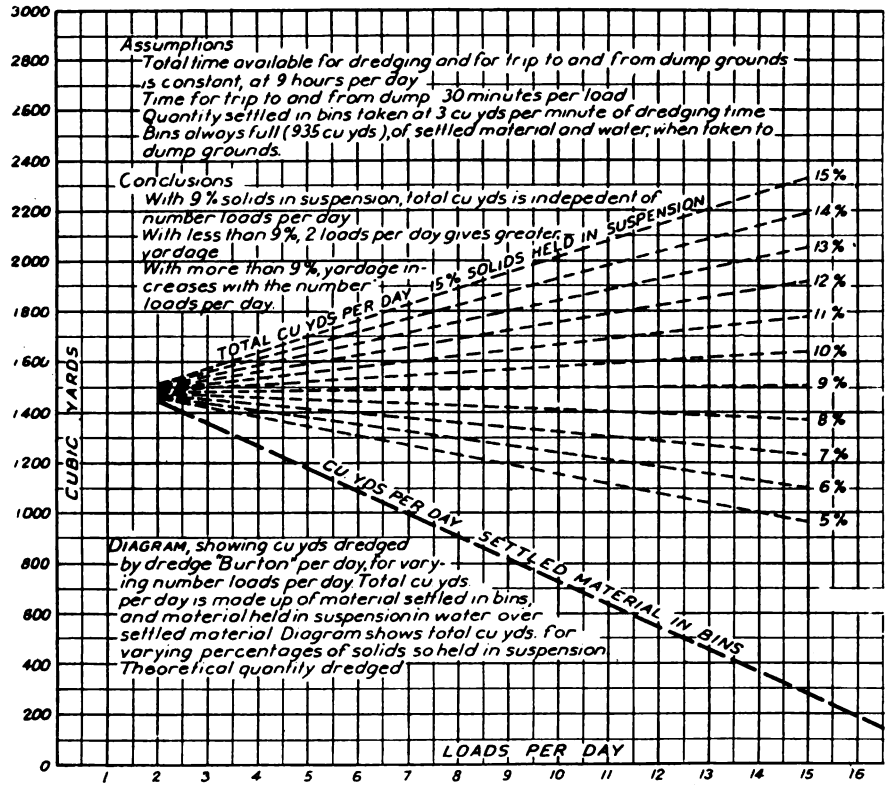

Plate 1

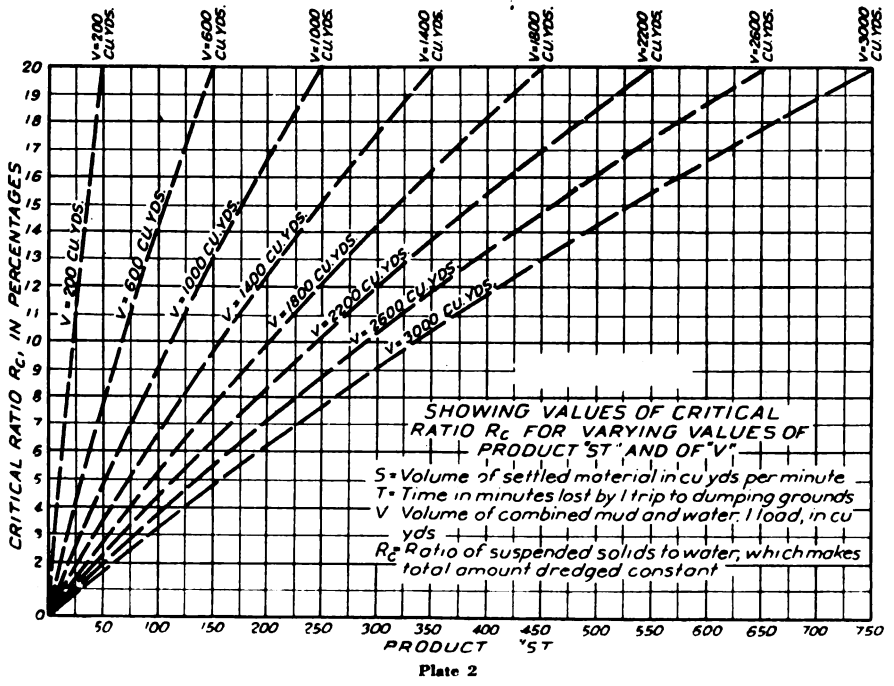

Plate 2

A more general solution of the problem is now to be considered. If V=Volume of bins in cubic yards, S=Cubic yards of settled material per minute of dredging time, R=ratio of suspended solids to volume of muddy water, Rc= critical ratio at which total yardage is constant, and T=Time in minutes consumed by one trip to the dumping grounds, then

$$Rc = \frac{ST}{V+ST}$$

The quantity ST is the cubic yards of settled material which might have been obtained in the bins by dredging for T minutes, or, expressed otherwise, the amount of settled material lost by taking time off for one trip to the dumping grounds. The denominator, V plus ST, is the increase in volume of water carried, caused by increasing the number of loads by one. It is evident that Rc (V plus ST) must equal ST, in order that the increase in suspended material may equal the loss in settled material and the total remain constant. The product of S and T, together with the capacity of the bins, V, determine this critical ratio Rc. The time required for one trip to the dump grounds and the rate of settlement in the bins per minute of dredging time are each of equal importance. If one is doubled and the other halved, the result is the same. Plate 2 shows graphically the critical value Rc, expressed in percentages, for varying values of the product ST and the quantity V.

The foregoing is all predicated upon a constant rate of settlement in the bins, per minute of dredging time, and no credit or account taken for agitated material not car-

Digitized by Google

ried to the dumping grounds. The general principle holds true even though these conditions do not obtain. If the quantity S is a variable for different stages of loading, and decreases as loading progresses, T a known constant and R determined for the class of material being dredged, the loading might economically be stopped at that stage where the product ST would give a value for the critical ratio Rc as low or lower than R. If the material agitated but not retained in the bins is of value, due to currents which may carry part of it away, the increased volume of suspended solids must balance not only the loss in settled material but also the loss in agitated material, in order to justify reduction of total dredging time by more frequent trips to the dumping grounds. If A represents the estimated valuable portion of the agitated material not retained, expressed in yards per minute, then

$$Rc=\frac{T(S+A)}{V+ST}$$

The numerator is the amount of both settled and agitated material "lost" by one trip to the dumping grounds. The denominator, as in the first case, is the increased volume of water carried by increasing number of loads per day by one. It is very probable that any reasonable value assigned to A, would so increase Rc as to be above any probable value of R, and would show that in this case economy lies in large loads and reducing the time lost by trips to the dumping grounds to a minimum.

It is assumed that capacity loads of settled material and water are taken out on every trip. Since the bin gates are not water tight, this involves the deposit of sufficient settled material to seal the gates. The quantity V is the total volume of mud and water actually carried away.

No account is taken in the foregoing discussion of other factors which might enter into the problem, such as relative consumption of coal while dredging as compared with that while running to and from the dump grounds, difficulty in disposing of the entire load of muddy water, changes in amount of time lost from causes other than going to dump grounds, difficulty in closing bin gates frequently, etc. It is believed, however, that a theoretical analysis of a given case will indicate at least in which direction the greater efficiency may be obtained.

Territorial reorganization of the Army

Under the provisions of the Army Reorganization Act of June 4, 1920, the former territorial departments of the army are replaced by nine corps areas, as shown on the accompanying map. The headquarters of each area is also indicated. These corps are also grouped into armies, as follows: 1st Army, 1-2-3 Corps; 2d Army, 4-5-6 Corps; 3d Army, 7-8-9 Corps.

Electrification of railroads

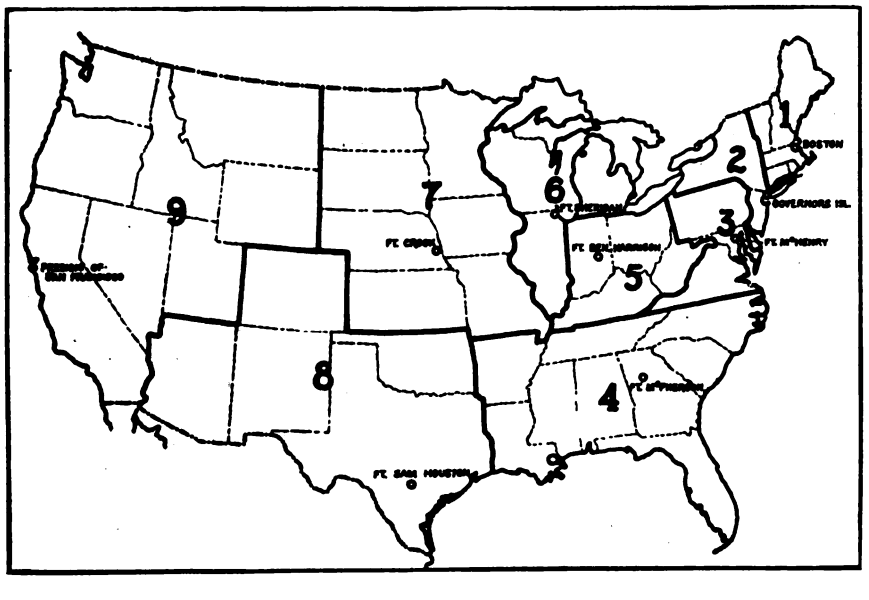
Electric manufacturers believe that there will be a pronounced movement toward electrification of railroads. Railway men say they are striving to accomplish two things, before turning their attention to this—relief of the shortage of rolling stock and the restoration of former operating efficiency.

Manufacturers of electrical equipment are endeavoring to make the railroad companies realize that it would be far better to start a program of electrification right now, as operating efficiency can undoubtedly be greatly increased thereby and the railroads also would not be obliged to scrap new, though obsolete, equipment.

Reasons for the tremendous impetus which will be given electrification as soon as the money situation is easier are:

Success of installations now in operation despite troubles which attended the experimental stage.

Gradual realization on part of efficiency engineers that the days of the reciprocating steam engine are numbered where electrical operation is practicable.



Present enormous coal consumption, the need for reducing which has been made doubly pressing by the critical fuel situation now confronting the industries of the country.

Recent passage of the Jones waterpower bill which opens the way to intensive development of all available waterfall on both navigable and non-navigable streams.

Statistics relating to the possibilities of electrification, compiled by electrical engineers, show:

Of total ton-miles of all railroads in 1918, amounting to 1,215,400,000,000, approximately 12 per cent or 146,000,000,000 would be totally eliminated with electric haulage, due to elimination of tenders, a large amount of railway coal and a portion of the non-driving weight of steam locomotives.

Of total coal used by all railroads in 1918, amounting to 176,000,000 tons (after reducing oil consumed to equivalent in coal), saving by electrification would have been 122,500,000 tons, according to result of General Electric Co.'s study of Chicago, Milwaukee & St. Paul. This saving amounts to one-quarter of total bituminous production in the country.—*Business Digest.*

New amphibious airplane

A new type of amphibious airplane, manufactured by Vickers, of England, and known as the Viking, was shown at the International Aeronautical Exhibition at London. The plane when fully laden weighs 4,545 pounds and is designed to start from or alight on either land or water. To this end the body resembles that of a flying boat, and is fitted with landing wheels that can be drawn up to the side when the machine is being used over water. The engine is a 360-horsepower Rolls-Royce "Eagle," and drives a pusher type airscrew. Accommodation is provided within the body for five people, but by removing three of the seats seventy-six cubic feet of space are made available for commercial freight. The machine has an overall length of thirty-two feet and an overall height of thirteen feet. Its span measures forty-six feet, the gap between the wings seven feet, and the chord of the wings six feet.

VOL. XII NOVEMBER-DECEMBER, 1920 NO. 66

List of Charter Members of the Society of American Military Engineers published in this issue

THE growth of our Society has been so rapid that we have heretofore been unable to publish a complete list of our charter members. In this issue, however, such a list appears.

This list of *charter* members was held open up to the instant of going to press, by decision of the Board of Directors. It is therefore a complete list of charter members, except for such as may have been inadvertently omitted.

The list is divided into two sections—first, those whose applications have been passed upon by the Committee on Membership, and who have been elected; second, all applicants whose applications were received prior to the closing of the list, but have not yet been reviewed by the committee. *All members whose names appear on this second list will become charter members as soon as their applications are passed.* A preliminary examination indicates that practically all are qualified for membership.

From this list our members may judge the high quality of our membership and identify friends and comrades who have joined the Society.

It is intended to publish as soon as possible a "year-book" of our members, giving their complete addresses, their present business connections, a brief of their military or civil records and other pertinent data.

In handling so large a number of names it seems almost inevitable that some omissions should occur. We ask the indulgence of our members in this matter, and request that we be promptly notified as to any names inadvertently omitted. Such errors will be corrected by a supplemental list in our next issue.

Action on applications for membership

SOME concern having been expressed by certain members regarding the delay in acting on applications and issuing membership cards, the following is published "for the information and guidance of all concerned."

Due to the fact that all the officers of the Society have been exceedingly busy with their own affairs or official business, and to the fact that the growth of the Society has been very rapid, we have been unable to complete action on all applications thus far received. More than half the applications have been passed upon by the Committee on Membership, and membership cards in such cases have been issued by Captain Weart, Secretary of the Society. The remaining applications are receiving attention as promptly as possible. The applications have not been reviewed exactly in the order in which they were received, which will account for apparently unreasonably long delays in certain instances.

All applications on hand have been given a preliminary examination, which indicates that the number of applicants who are not qualified for membership is practically nil. All may feel therefore reasonably assured that they will soon receive their cards of membership.

In order to relieve the minds of such members as have not received formal notification of their election, we are publishing in this issue a list of all members to date.

Why you have received so many circulars

THE immediate aim of our Society up to the present time has been to increase our membership to such a point that our financial success would be assured, and with it the perpetuation of our Society and its ability to carry out the purposes for which it was organized. We feel sure that all of our members will appreciate the tactical importance at this time of building up our membership, as the first prerequisite of success.

Accordingly during the summer and fall we have been conducting an almost continuous "membership drive." During this period there have been sent out something in the neighborhood of 100,000 letters and circulars. All must appreciate that it was impossible that these should have been personal communications, as such a task would have been manifestly beyond the capacity of our very inadequate office force. The work has been done by machinery as far as possible. In sending out, for example, a lot of 12,000 circulars to former emergency officers of Engineers, the clerical labor that would be involved in culling from this list all those who had already joined the Society, would have been almost as great as the labor of preparing the 12,000 circulars. Accordingly, the circulars have been sent to *all*, regardless of whether they were already members. In some instances this has naturally aroused some doubts on the part of charter members of comparatively long standing who thought that it indicated that there was no

Digitized by Google

record of their membership. It is hoped that this explanation will clear up any such misunderstandings.

The excellent results that have been obtained will compensate all of our members for any incidental annoyance to which they may have been subjected. As this goes to press the number of paid subscribers to THE MILITARY ENGINEER exceeds 3,500, which means that our Society is now on a sound financial basis, and its growth still continues. Thirty-five hundred members, all of them men of standing and influence, joining our Society in a space of nine months is a most remarkable result, and plainly indicates that the aims of the Society are heartily endorsed by the American engineering profession.

Society of American Military Engineers has successful year. A message from our President to all members

THE PLAN FOR ORGANIZING A SOCIETY OF AMERICAN MILITARY ENGINEERS to perpetuate the friendships and profit by the experiences of the World War, and to assist in the promotion of "preparedness," was conceived in the fall of 1919. The first positive steps in the organization of the Society were taken in February, 1920, during which month a few members joined.

The active campaign for membership opened in March, 1920. At that time it was decided that 3,000 was the smallest membership that would justify the existence of the Society and enable it to achieve the objects of its organization. At the close of September the number of paid subscribers to THE MILITARY ENGINEER, the great majority of whom are also members of the Society, was 2,872, and the number was increasing at a more rapid rate than ever before.

In seven months of active campaigning, therefore, our "first objective" is already attained. By the close of the year our membership will be well in excess of 3,000—a strong and influential body. Our "second objective" is accordingly placed at 5,000, which it is hoped to attain before next summer.

But it is not the number of our membership so much as its quality which affords us great satisfaction. The list of our charter members, published elsewhere in this issue, is splendidly representative of the American Engineering profession. It includes the names of men of national, even international prominence in engineering affairs. Every branch of engineering is represented. We number in our membership officers and former officers of nearly every branch of the service, including the United States Navy, the Construction Division, the Quartermaster Corps, the Air Service and Tank Corps, the Geological and Geodetic Surveys, and the Forestry and Reclamation Services, etc. As to former rank in the Army our membership ranges from private soldier to major general.

So representative, able and distinguished a body of men cannot be otherwise than a power for good in national and human affairs. The voice of the Society of American Military Engineers will receive respectful attention in all matters pertaining to the national defense and the public welfare. Membership in such an organization is a privilege, a distinction and an honor. More and more as time goes on will our members be identified by connection with the Society, as the best class of patriotic citizens.

Beginning in June, of this year, the organization of local posts, chapters or sections, was inaugurated, and at the present time our Society has flourishing branches in most of the larger cities of the United States.

It is hoped also that THE MILITARY ENGINEER may become the medium through which the members of many former military organizations which have added lustre to the time-honored emblem of the Engineers (the castle), shall keep in touch with one another, thus maintaining the spirit of comradeship born of privations shared and perils met and overcome.

With the issue of November-December, 1920, the journal of our Society, THE MILITARY ENGINEER, closes its first successful year. Born under conditions most discouraging and difficult from a financial and other points of view, it has been a worthy organ of our Society, a strong bond of union between our members. Probably more than any other single influence it has contributed to the healthy growth of the organization. Its columns have included handsomely illustrated articles on a wide variety of civil and military subjects, of great interest to all engineers. The contributors to its pages have included many men who won undying fame in the World War, as well as many who have achieved national distinction in civil engineering. But in particular our journal has fulfilled its mission and earned the praise of all who have seen it, because it has truly interpreted and represented the *spirit of service* of the engineer to his country. Its columns have breathed enthusiasm and devotion to duty. No periodical can have a higher aim than this.

That advertisers have appreciated the influence of THE MILITARY ENGINEER is indicated by the growth in the number of its advertising pages from thirteen in its first issue to thirty-five in the issue of November-December, 1920.

All of our members, whose support alone has rendered possible our progress, should feel a just satisfaction and pride in the excellent results thus far achieved and the bright outlook for the future. Less than one year from the time when our Society first took form in the minds of a few men, finds it a strong and flourishing organization of some 3,500 members, supporting and publishing its own journal, solvent financially, with local sections established in most of the leading cities, and growing at a rapid and steady rate. Truly this is a most satisfactory result for so short a period. I offer my heartiest congratulations to all our members, and I look confidently forward to greater progress during the coming year.

W. M. BLACK,
Major General, U. S. Army (Retired)
President, Society of American Military Engineers.

Improvements in our floating bridge equipage

IN an early number of THE MILITARY ENGINEER will appear two illustrated articles descriptive of the experimental work being carried on in both the French and American Armies, with a view to effecting improvements in the ponton equipage, based on the lessons of the War.

These articles will be written by the officers best qualified to present the information, and being on a subject of great importance to the engineer service can not fail to interest our readers.

Following the policy of this Journal it is desired to publish with the articles a discussion by others having knowledge of the subject. Any of our readers who may desire to comment on our equipage and its development, from any point of view, are requested to advise the editor by letter, when advance copies of the articles will be sent them for that purpose.

APPOINTMENT OF RESERVE CORPS OFFICERS HAS BEEN RESUMED

THERE is no limit by law to the number of officers in the Engineer Reserve Corps. Accordingly there is a place for every engineer who wishes to join and who fulfills the requirements.

Recently the issuance of commissions in the Reserve Corps was temporarily suspended pending the enactment of new legislation and not subsequently resumed because of the pressure of work incident to filling vacancies in the Regular Army.

This suspension of procedure was the cause of a good deal of uneasiness among engineers desiring to join the Reserve Corps, as evidenced by the large number of letters of inquiry that have been received. There is, however, no occasion for concern.

On June 4, 1920, the President signed the Act of Congress amending the National Defense Act, June 3, 1916. Certain provisions of the new law with respect to appointments in the Reserve Corps differ from those of former legislation and until recently no definite information on these matters has been available.

In a letter dated October 4th, however, the Chief of Engineers is directed to appoint a board of officers for the purpose of considering applications for commission in the Engineer Reserve Corps. This board has now been appointed and is proceeding to pass upon applications already on file.

All engineers desiring appointment in the Reserve Corps should submit their applications promptly in the form of a letter to the Chief of Engineers, setting forth briefly the qualifications which entitle them to appointment. Any additional data required will be called for.

Under the new regulations there are four classes eligible for appointment, as follows:

1. All persons who served in the United States Army at any time between April 6, 1917, and June 30, 1919.

2. Former officers of the Regular Army

3. Officers of the National Guard in Service on June 4, 1920.

4. Graduates of Reserve Officers' Training Corps at educational institutions.

Appointment of former officers may be made in the grade held at the time of discharge, or in any lower grade. No appointments will be made in the case of applicants whose average rating under the new rating rules falls below 53.

How Reserve Corps Officers may keep in touch with the Service

ONE of the desirable, if not the best, means by which Engineer Reserve Officers may keep in touch with the activities of the active engineer forces is THE MILITARY ENGINEER. The first endeavor of this magazine is to bring them together and to keep them together. News of the active engineer forces is printed freely, and important items of the inactive forces are of great interest to those who are in active service. The rendering of monthly reports by mail by officers on the inactive list is not required, excepting those that may be called for from time to time in connection with the correspondence courses conducted by the Engineer School at Camp A. A. Humphreys, Va.

Steel centers for concrete arches of Georgetown Bridge over the Potomac River

The views herewith illustrate the method being used in erecting steel centers for the concrete arches of the Georgetown Bridge, D. C. (formerly called the Key Bridge and described in the January-February issue of THE MILITARY ENGINEER).

The spans of the bridge are: Channel spans, one 208 foot, two 204 foot, two 187 foot; shore spans, one 152

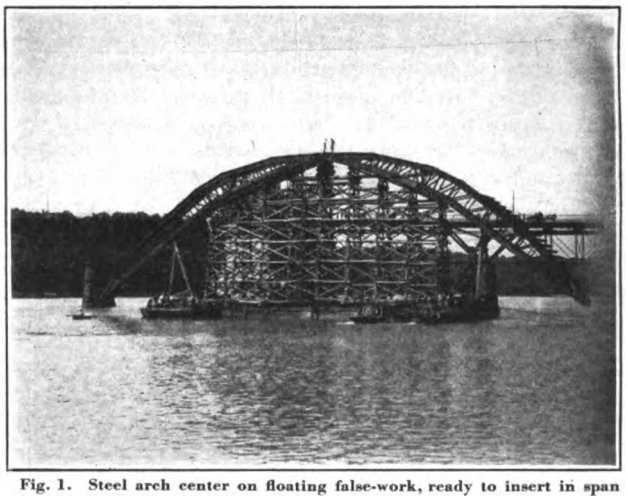

Fig. 1. Steel arch center on floating false-work, ready to insert in span

foot over Water street, one 85 foot over the C. & O. Canal. Each span consists of three arch ribs, spandrel columns and arches and reinforced concrete deck. The center arch rib of each span is 22 feet wide while the up and down stream ribs are each 11 feet wide.

The steel centers were furnished by the Blaw-Knox Co., of Pittsburgh, shipped to the site in sections and are bolt connected on the field by the construction force. For the 208 and 204 foot spans all sections are required, but for the shorter spans certain sections are omitted. Each set of centers will support one of the narrow ribs; for the center rib both sets are required.

The illustrations show one set of centers erected for the 208-foot span. Fig. 1 shows steel erected on floating false-work prior to being placed in span. Fig. 2 shows steel in place before falsework was floated out. Fig. 3 shows false-work removed, and Fig. 4 is a close-up view of shoes, wedges and supports.

The false-work is carried by three barges securely fastened together by steel beams and tie rods so as to distribute load uniformly. The center barge lies lengthwise

The Sword of Peace

By

HERBERT KAUFMAN

MERE PAPER CHAINS CAN NEVER BIND THE WORLD TO PEACE! Steel will slake its thirst as long as men itch for power and force advises opportunity.

National necessity, international jealousy and racial ambitions will be served regardless of agreements.

The struggle for markets is the first skirmish of conquest. Trade fights with a calculation sheet, then powder and ball. Wherever commerce crosses a frontier, regiments wait to follow. The wars of business and the business of war are inspired by the same motive — the aggrandizement or defense of power.

Might and Must eternally write red history.

We are now universal providers; our ships are headed toward every port, and wherever American wares are sold, America's strength will some day be challenged. We shall have tranquil dealings just as long as we are able to enforce tranquillity. Ruthless and rowdy states will respect our determination to evade difficulty only as far as they may expect reprisal for violating our rights.

If we insist upon living pacifically, we must be ready to discourage affront. In this sudden, resourceful century, it is impossible to predict when and from what quarter the next hostile will strike. We could once measure the human content of a country, count its arsenals, shipyards and barracks and fairly estimate its combative quality.

But to-day when every test-tube nurses a potential devastator and every obscure inventor's laboratory possibly houses a resistless engine of holocaust, we dare take nothing for granted.

We are no longer safe within walls or behind fleets. Caution screams at us ceaselessly to search imagination for stronger weapons than others can bring to bear against us.

Years soon forget their scars. Coming generations will recompose present alliances. Shishak and Xerxes and Alexander and Bonaparte and the Hun shall rise again from the dust to foray and plunder. Hate and greed and fanaticism and autocracy will have their grudge.

The nations that can rely upon their arms can alone rely upon their treaties. Peace must wear a longer sword than war.

of span, the two end barges across the span, so that the float is very steady. The range of tide is about three feet. One set of centers weighs about 200 tons and puts the float down one foot more that its light draft. High tide gives about one foot clearance of shoes above supports, and low tide gives about one foot clearance between steel and falsework.

It is proposed also to move the steel from one location to another on the work by this method.

The bridge is being constructed by hired labor and government plant by the Washington Office. Captain L. E. Oliver, Corps of Engineers, is in immediate charge of the work.

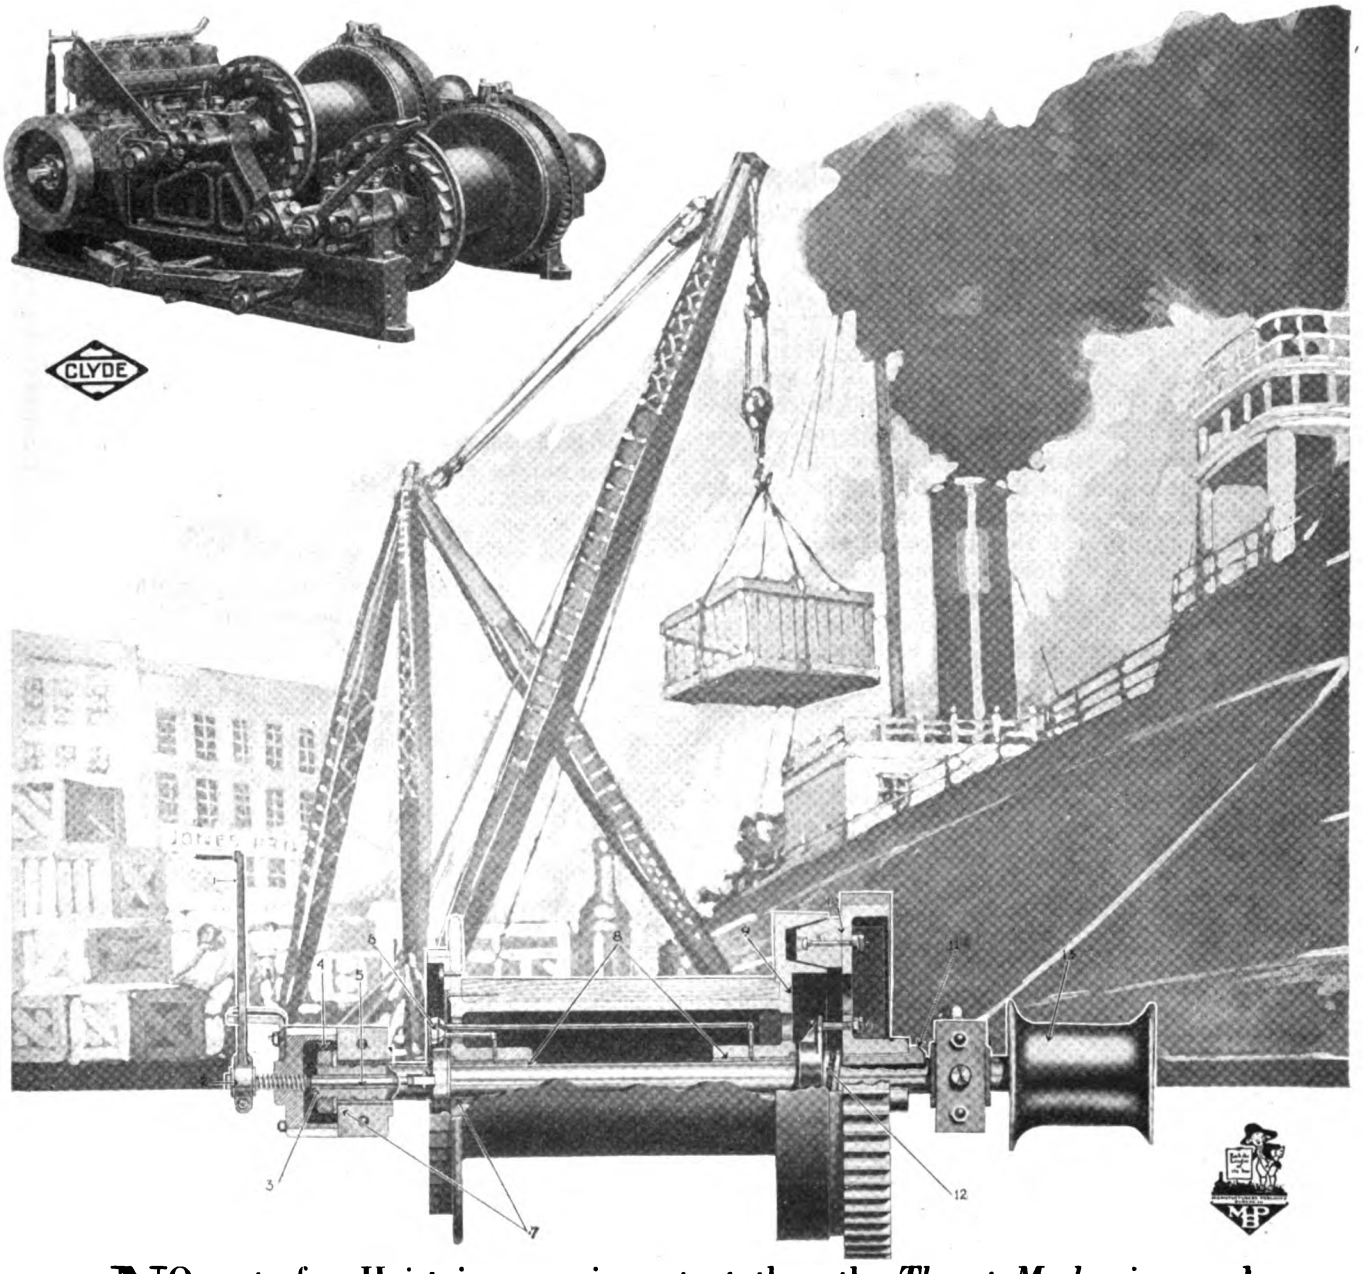
Bridge vs. tunnel for the proposed Hudson River crossing at New York City

That eminent authority on all things pertaining to bridges, Dr. J. A. L. Waddell, in *Proceedings Am. Soc. C. E.*, favors the profession with an entertaining discussion on the relative advantages of bridges and tunnels.

Dr. Waddell considers this matter not only from point of view of cost, but from every other point of view, in particular the convenience, comfort and pleasure of the traveling public. He states that for some years it has been his opinion that the best economic solution is to carry all street car and subway traffic under water and all strictly highway traffic above, and that his recent investigations have confirmed this opinion.

With reference to the cost of operation, the tunnel requires a dip of 90 feet below high water, whereas the bridge requires a rise of 180 feet above, accordingly, so far as expenditure of energy is concerned, the tunnel is decidedly preferable. Dr. Waddell points out that this is a matter of considerable moment in the operation of street cars, but of much less importance to motor trucks and practically none at all to the pleasure automobile. The automobilist seldom considers the cost of gasoline in climbing a long, heavy grade; on the contrary he enjoys the climb, whereas the electric railway officials endeavor to reduce this item of expense to a minimum. Another important consideration is the pleasure of traveling. People, especially the ladies, who now have the vote, usually prefer travel over a bridge affording a good view of the surrounding country, to shooting through an underground tube. Nevertheless, they have become quite accustomed to the latter so far as the street cars are concerned, but a pleasure automobile will certainly always prefer a bridge affording good air and light and a fine view, to a long, cramped, dingy tube.



With reference to the question of public health, the tunnel is as satisfactory as the bridge so far as street cars are concerned, but the proper ventilation of a tube carrying automobile traffic, says Dr. Waddell, is yet an unsolved problem. Even should ventilation be feasible it would certainly be very expensive. Regular daily passage through such a tube would tend to undermine one's health; a blockade in the traffic would result in an excessive quantity of gas being discharged in the tunnel and might result in a holocaust. Nevertheless, Dr. Waddell believes the experiment of automobile transportation through long tunnels worth the making inasmuch as such traffic will probably be necessary, and the experiment would give information of great interest and value to the engineering profession and to the public. If the tunnels prove unsatisfactory they could still be used for electric railway cars.

It is interesting to note that while modern practice in long span bridges appears to have tended toward the cantilever type, Dr. Waddell has adopted the suspension type for his estimates. The maximum length of the main span which he contemplates exceeds that of any cantilever bridge yet constructed. For such very long spans the suspension type is the only one practicable.

From the point of view of cost the tubes lend themselves particularly to electric railway traffic, whereas the bridge favors highway traffic. This conclusion, confirming that arrived at from the foregoing considerations of policy, must have been very pleasing to Dr. Waddell. The reason for this is that two single-track tubes, whether for highway or electric railway traffic, are cheaper than one double-

What The Clyde Thrust Mechanism Means To You

NO part of a Hoist is more important than the *Thrust Mechanism*, and upon its unfailing operation depends the service rendered on your jobs.

Note points listed below:

1. Forged thrust lever
2. Large head to avoid slippage
3. Renewable special bronze point
4. Oil collar thrust nut
5. Tool steel pin and cross key
6. Accessible grease cups for both ends of drum
7. Bronze liners on larger sizes
8. Long bronze bushings
9. Lagging pocket
10. Smooth turned hard maple friction blocks, grain circumferential
11. Gear pressed against gib head tapered key to prevent lateral motion
12. Bridled spring to release drum from friction
13. Large turned winch head

track tube. A single track tube is entirely satisfactory for electric railway traffic inasmuch as the breakdown of a vehicle blocks only one line and is thus no worse in a single-track tube than it would be in a double track, except that it is possible that a longer time might be necessary to remove a broken-down car. But when we come to automobile traffic, the breakdown of a single vehicle in a one-track tube may entirely block traffic, whereas in a two-track two-way tunnel the breakdown of an automobile would delay but not block traffic, therefore the double-track or four-track tunnel is essential for highway traffic whereas the cheaper one-track tunnel may be used for electric railways.

The figures at which Dr. Waddell ultimately arrives, assuming a main span of 2,900 feet for the North River Bridge, are as follows:

Highway bridge	$32,500,000
4 highway tunnels	49,000,000
Electric railway bridge	34,500,000
4 double-track electric railway tunnels	48,000,000
8 single-track electric railway tunnels	30,000,000

This indicates a saving in favor of the highway bridge of $16,500,000 and a saving in favor of single-track electric railway tunnels of $4,500,000. While the cost of right-of-way and property damages for the bridge will be somewhat greater than those of the tunnel it will by no means equal the above figure. Accordingly, concludes Dr. Waddell, from every point of view it would appear that the bridge is to be preferred for automobile traffic and single-track tubes for electric railway traffic.

The lowest price at which a combination of bridge and tunnel for both kinds of traffic could be built he estimates as follows:

Highway bridge	$32,500,000
2 single-track tunnels	7,500,000
Total	$40,000,000

These estimates do not include right-of-way, property damages, or administration. The author concludes with the sage observation that in view of these considerations some further study may be advisable before committing the public to the policy now contemplated.

Germany returns to piecework rates

Stronger incentive to work than mere sense of duty appears to be needed.

One of the first economic effects of the German revolution was the refusal of German workers to work at piecework rates, and the consequent general decrease in output. At first the abolition of piecework was warmly welcomed, as it was thought that in a state in which all the people were imbued with a sense of duty there would be no necessity for any other incentive to work. Now the disappointment is great when it is realized that the sense of duty is not equal in all sections of the community. It seems that a change of mind has taken place with regard to piecework. *Vorwarts*, the organ of the Social-Democratic Party, advocates piecework and a bonus system, not only as an expedient measure in the railway shops, where decline in output was a big factor in last fall's coal crisis, but as an industrial principle. It states:

Piecework, if reasonably applied, is the most just method for determining wages.

In addition to the piecework system, consideration should also be given to the bonus system, which has been opposed in Germany while in Russia it has been advantageously adopted.

And *Soziale Praxis* stated as long ago as last September that:

In some instances workers are returning voluntarily to the piecework system. One firm, Bergmann in Suhl, had given notice of dismissal to all its salaried employees and workers because the diminution of output had made it questionable whether operation could be carried on at a profit. The notices were, however, withdrawn because the workers declared that they were prepared to accept the piecework system.

A new piecework system in operation in a government railway repair shop is described in *Vorwarts* of October 4, 1919, as follows:

A new system, which is of the nature of profit sharing, has led to increased production in the government's railway repair shops at Golm-Mark. A commission, composed of a works manager, a delegate of the workers, and a railway official, calculates the number of hours necessary for the performance of a certain piece of work, on the basis of actual experience and average production.

While aiming at the highest possible technical perfection, the workers try to carry out the prescribed task in the shortest possible time. By a special scheme the saving in cost resulting from the difference between the actual number of hours worked and the calculated number is shared between workers and employers. Each individual worker is paid according to output and capacity on a scale arranged between the management and the workers.—*Business Digest.*

The largest concrete ship

The concrete ship is evidently no longer an experimental device. On June 12, the *Cuyamaca*, 7,500-ton concrete oil-tanker, was launched at the yards of the Pacific Marine and Const. Co., at San Diego, Cal.

This vessel is 420 feet long, 54 feet beam, and 36 feet deep. The hull is entirely of reinforced concrete up to the quarters on the bridge deck. It is described as beautifully proportioned, with lines as clean as those of a yacht.

The concrete has a burned clay aggregate which saves 40 lbs. weight per cubic foot. The shell is from 4 to 5 inches thick. There was required for construction 9,400 bbls. of cement, 2,800 cu. ft. of baked clay, and 1,500 tons of reinforcing steel. The deadweight of the vessel is 5,800 gross tons, and its carrying capacity 50,000 bbls. of oil.

This vessel was built on designs prepared for the Engineering Fleet Corp., six vessels of this type being constructed.—*Concrete.*

The possibilities of our oil shales

Will they ever be able to take the place of oil wells as a source of petroleum supply?

That the oil shale which is found in large quantities in Colorado, Utah, Nevada and Wyoming will eventually have a large commercial value is the opinion of the British *Board of Trade Journal.* For not only are all our underground reserves of oil being rapidly exhausted but the demand is as rapidly increasing year by year. Increased consumption in old industries and the discovery of new uses to which it may be put, make it certain that the manufacture of oil from shale is destined soon to assume a more prominent place than it now has.

Use of Oil in Motor Transport

The consumption of mineral oil and its derivatives is increasing rapidly. In the automobile industry alone it was estimated that there would be 7,602,000 automobiles, either passenger or commercial, officially listed in this country on December 31, 1919, which would be an increase of about one and a quarter million above those of 1918. The

number of motor trucks is estimated between 600,000 and 700,000.

Conversion of Ships to Oil-Fuel Consumption

In addition to the use of oil in motor transport, we must take into account the extent to which it will be used by ships, as a motive power in factories, farm-tractors, motor-boats, etc.

According to the *Annalist* of November 17, 1919, the use of oil as fuel for ships is also rapidly increasing. The United States Shipping Board has abandoned the coal-burning ship, and 636 out of 720 vessels under construction for the Emergency Fleet Corporation will be oil-burning. Almost all vessels now building for private or government account in the United States are to burn oil, and it is estimated that one-third of the tonnage on British ways will not be entirely dependent on coal. The United States Government has quite recently acquired or opened oil-fuel storage centers for its navy at Panama, St. Thomas, Azores, Biserta and Manila, whereby its numerous warships, almost all of which are oil-burning, will have fuel stations independent of the available supplies and bases of other nations.

Probable Date of Exhaustion of American Supplies

The United States Bureau of Mines states that the underground reserves of the United States are 40 per cent exhausted and that production from drilling has probably nearly attained its maximum.

It is also estimated that the demand will reach 800,000,000 barrels per annum by 1927, and all known, and probably all existing underground reserves in the United States will be exhausted in 1928.

Shales in the Western States

The probability that the oil-bearing shales of the United States will serve to take the place, in due time, of the oil wells which are now responsible for the entire output of this country is emphasized by the action of our government in reserving 132,000 acres of shale country in Colorado and Utah for naval purposes. These shales, including those of Wyoming and Nevada, are richer in recoverable oil and more easily mined than those of Scotland.

The oil-bearing stratum in Colorado is estimated by the United States Geological Survey to be, on an average, 1500 feet thick, although one cannot assume that this is all commercial shale. "Commercial" shale is counted as producing about one barrel of oil to every ton of rock, and shale capable of producing on this basis has been variously estimated to range from 30 feet to several hundred feet in thickness, though a conservative average would probably be around 50 feet. This would mean that each acre would contain 110,000 tons of commercial shale, equivalent to the same number of barrels of oil.

How Oil is Produced from Shales

None of these shales, which are known as the Green River Formation, contain free liquid oil. They contain altered organic matter from which the crude oil must be produced by heat, the process known as destructive distillation. The oil leaves the shale as a boiling liquid rapidly passing into the form of vapor, which must quickly pass out of the retorts, otherwise there would be an undue formation of permanent gas at the expense of oil, owing to decomposition of the latter.

The distillation must be carried on at the lowest temperature consistent with the complete eduction of the oil and its conversion into vapor, so as to ensure the maximum amount of oil and the minimum of fixed or permanent gas.

Ammonium sulphate will be a valuable by-product—probably about 10 pounds per ton from some of the shales—and it is expected to use the spent shales (the disposal of which has always been a difficulty in Scotland, and an item of expense) as fertilizer, as they contain from 0.5 to 6 per cent of nitrates and small quantities of potash and phosphoric acid.

All this, however, is in the future, for the matter has never passed the experimental stage, and there are not at present any commercial oil-shale plants operating in the United States.—*Business Digest.*

Cost of hauling gravel with motor truck

In a paper presented recently at a meeting of the Provincial District Engineers of British Columbia, Mr. G. B. Whitehead, District Engineer, gave the following particulars of his experience in hauling gravel with motor trucks.

The truck operated in District No. 3 this past season was of 3½-ton capacity with 4-yard gravel box. This truck worked in conjunction with hired trucks. As it arrived late in the season, as the driver was only getting used to it at the end of the work, and as the road traveled over was not in the best shape, the cost will probably be bettered next season.

The trucks were loaded from bunkers and eight hours constituted a day's work. The initial haul was 2.3 miles, on which 10 trips a day were kept up until 2.9 miles were reached, making an average return trip of 5.2 miles a day. From 3.4 to 3.7 miles eight trips were obtained, the average return trip being 7.1 miles, or a total of 56.8 miles a day. From 3.7 to 4.5 miles seven trips were obtained with an average return trip of 8.3 miles or 58.1 miles a day.

The costs given below will be based on the work of this truck for 15½ days on an average haul of 4.15 miles or 8.3 miles return trip.

Driver's wages, 15½ days at $6	$93.00
Gasoline, oil and grease	93.30
Minor repairs	20.00
	$206.30

Material hauled, 432 cubic yards, field cost per yard hauling, $0.48.

These figures do not go into interest charges, depreciation of truck, or renewal of tires; but are simply data gathered as a basis for the contracting of gravel work next season.

This season $26 a day was paid for the rented trucks, everything found. The rented trucks had a capacity of only 2½ yards, and on the average haul of 4.15 miles the material delivered cost $1.48 per cubic yard, as against $0.48 with the district truck. The difference of $1.00 is too much as a charge for depreciation and profit and is due to two reasons, one of which can be rectified. First, the capacity of the trucks; second, the fact that the other truck owners felt that when they made the same number of trips as our slower and heavier-loaded truck they were fulfilling their contract. This could have been overcome in the rental agreement by calling for the speed for which the particular truck is catalogued.

Care should be taken to balance the number of trucks used so as to insure economical loading. For example, at one time it was found that the bunkers could not be supplied with one slip team, but that in employing two teams they both stood idle about a third of the day. By putting on two extra trucks both teams could be kept busy and the extra trucks worked without extra loading cost.

The difference in time between mechanical dumps and hand dumps averaged about 3 minutes. On short hauls this would become a factor that would have to be considered.—*Eng. and Cont.*

Annual Election of Officers of the Society of American Military Engineers

Under the provisions of Article VIII, Par. 4, of the Constitution of the Society, the Nominating Committee met in October and nominated a President, two Vice-Presidents and eighteen Directors for the year 1921. The annual meeting for the transaction of business and the election of officers will be held in Washington on Friday, January 14, 1921, when ballots will be opened and canvassed.

The following provisions of the Constitution and By-Laws of the Society of American Military Engineers (see Vol. XII, No. 62, page 233, THE MILITARY ENGINEER) govern the election of Officers and Directors of the Society.

ARTICLE IV.

Government.

1. The government of the Society shall be vested in a Board of Directors consisting of a President, a First and a Second Vice President, and eighteen active members. The President and the two Vice Presidents, all of whom shall be directors, shall be elected to serve for one year and until their successors shall have been duly elected: Provided, That no one of the three officers herein first named shall be eligible to immediately succeed himself in office.

The eighteen directors, other than the three officers above named, shall be elected to serve for three years: Provided, That six of their number shall be chosen from the regular army, six from the other military forces of the United States subject to active service, and six from the active members at large, exclusive of the foregoing two sub-classes of members: Provided further, That the term of office of two directors of each such group of six shall expire each year.

2. The Board of Directors shall elect from its own number a Treasurer to serve for one year and shall elect from the active members, though not necessarily from its own number, a Secretary whose term of office shall be one year.

ARTICLE VIII.

3. The President, the two Vice Presidents and two directors in each group of six representing the three sub-classes of the active membership, to wit: the Regular Army, the other military forces of the United States and the membership at large exclusive of the foregoing two subclasses, shall be elected by a written ballot at each annual meeting of the Society to serve for the appointed time of office or until their successors shall be elected: Provided, That a plurality of all votes cast shall be necessary for election, and Provided further, That at the first meeting of the Board of Directors after the first election held under the provisions of this constitution, two directors of each group shall be selected by lot to serve for one year only, two others of each group to serve for two years only and the remaining six to serve for the full term of three years.

5. In addition to the nomination so made by the committee, nominations may be made by a 'nominating letter" signed by not less than ten active members: Provided, That such nominating letter shall be received by the Secretary not later than the first day of December. The Executive Committee shall verify the eligibility of all nominees and their acceptance of nominations, and all nominees found eligible for election shall be included in the printed election ballot which shall be mailed to all active members between the first and fifteenth days of December. The names of candidates for each vacancy shall be arranged in alphabetical order with such data as to place of residence, civil and military record of each candidate, a the Board may deem pertinent or desirable: Provided, That no person shall at any one election be a candidate for more than one office or position.

The nominees for director herein listed, are grouped according to the class in which they belong, i.e.: Regular Army, active or retired; Reserve Corps and Membership at Large not of the foregoing classes.

NOMINEES

For President

Maj. Gen. W. M. Black, U. S. Army, Retired. Formerly Chief of Engineers; at present engaged in civil practice with Black, McKenney & Stewart, Washington, D. C. Born in Pennsylvania, December 8, 1855. Graduated U. S. M. A. in 1877. Stationed at Willets Point, N. Y.; Washington, D. C.; Havana, Cuba; Portland, Me.; New York City. Served in Spanish-American War and in the World War. Retired October 31, 1919, on his own application after 46 years of service. (See frontispiece.)

For First Vice-President

Colonel William Barclay Parsons, E. I. C. Served as senior member of Railway Commission in England and France. Commanded 11th Regiment of Engineers during the War. Also served as Brigadier General of the New York National Guard in Spanish-American War. Graduate of Columbia College, New York, A. B. degree and C. E. degree. Engaged in mining and civil engineering since 1881. At present senior member of Parsons, Klapp, Brinckerhoff & Douglas, Engineers, New York City. (See frontispiece.)

For Second Vice-President

Colonel Charles Keller, C. of E., U. S. Army. Born in New York February 13, 1868. Graduated from U. S. M. A. 1890. Brigadier General National Army during World War. Stationed at Montgomery, Ala.; Rock Island, Ill.; Charleston, S. C.; Portland, Me.; St. Louis, Mo.; Grand Rapids, Mich.; Manila, P. I.; Detroit, Mich.; Mobile, Ala.; Washington, D. C. At present member of River and Harbor Board, Washington, D. C. (See frontispiece.)

For Directors

Regulars

Maj. Gen. W. C. Langfitt, U. S. Army, Retired. Born in Virginia, 1860. Graduated from U. S. M. A. in 1883. Stationed at Cincinnati, Hawaii, Fort Stevens, Ore.; Portland, Ore.; Havana, Cuba; Washington, D. C.; Savannah, Ga.; etc. During the War he was the Chief Engineer, A. E. F. Retired May 31, 1920, after more than 40 years of service. At present located in New York City.

Col. Mason M. Patrick, C. of E., U. S. Army. Born in West Virginia, 1863. Graduated from U. S. M. A., class of 1886. Stationed at West Point, Cincinnati, Washington, D. C.; Havana, Cuba; Norfolk, Va.; Detroit, Mich.; Fort Sam Houston, Tex.; New Orleans, La. During the War he was Chief of the Air Service in France with the rank of Major General; director of Construction and Forestry and of Engineer Construction, A. E. F. Present station, Office of the Chief of Engineers, Washington, D. C.

Colonel William V. Judson, C. of E. Born in Indiana, 1865. Graduated from U. S. M. A. in 1888. Brigadier General in National Army during the War. Stationed at Rock Island, Ill.; Galveston, Tex; New York City; Porto Rico; Milwaukee; Montgomery, Ala; Canal Zone; with Russian Mission in 1917; Washington, D. C.; present station Chicago, Ill.

Col. Harley B. Ferguson, C. of E. U. S. Army. Born in North Carolina 1875; graduated from U. S. M. A. in 1897. Brigadier General National Army during the War. Stationed at Charleston, S. C.; West Point, N. Y.; Manila; China; Fort Leavenworth, Kans.; Montgomery, Ala.; Havana, Cuba; Washington, D. C.

Lieut. Col. Gilbert A. Youngberg, C. of E. Born in Minnesota, 1875. Graduate from West Point 1900. Principal stations Fort Leavenworth, Kans.; Chicago, Ill.; Havana, Cuba; Washington, D. C.; West Point, N. Y.; Charleston, S. C.; in France from August, 1917, to June, 1919. General Staff, A. E. F. Assistant Chief Engineer, A. E. F. Highest Rank Colonel in National Army. At present in Washington, D. C.

Major Richard Park, C. of E., U. S. Army. Born in Massachusetts, 1883; graduated from West Point in 1907. Stationed at Boston, Mass; Vancouver Barracks, Wash; Washington Barracks, D. C.; Manila, P. I.; San Francisco, Cal.; Ft. Leavenworth, Kans.; Camp Humphreys, Va. Rank of Colonel N. A., during the War. Present station, Portland, Ore.

Reserves

Major Percy E. Barbour, E. R. C. Served with 150th and 212th Engineers during the War. Born 1875 in Portland, Me.; graduate of Worcester Poly. Inst.; 17 years mining experience; 2 years on the editorial staff of "The Engineering and Mining Journal," New York City. Assistant Secretary American Institute of Mining and Metallurgical Engineers. Mexican Border service. At present in New York City.

Lt. Col. J. H. Finney, E. R. C. Born in Virginia 1863. Served during the War 105th Engineers, on joint Army-Navy

A Trench Raid

As demonstrated at the Infantry School, Camp Benning, Georgia*

THE raid described herein was recently demonstrated at the Infantry School at Camp Benning, Ga., before the Staff Class from the Service Schools, at Fort Leavenworth, Kans.

It was conducted by a company of infantry, supported by machine-gun one-pounders and trench mortars upon the system of trenches constructed on the reservation, as shown on the map herewith.

While raids were of very frequent occurrence during the World War, there were many officers who never participated therein, and this demonstration of exactly how such an operation is conducted will be of interest to our readers. Such raids are mysterious and confusing affairs to any who have not taken part therein, and possibly even to the majority who have.

There is a very general impression that raids were conducted in a more or less haphazard fashion, and consisted of a grand scramble into the enemy's trenches while he was asleep and out again before he could recover from his surprise. This is far from being the case, at least for raids as large as the one herein described. They were actually planned in advance in the minutest detail and thoroughly rehearsed by the troops who were to take part therein. Very often a piece of ground was selected in rear of the lines where existing or simulated trenches similar to those actually to be raided were utilized, and the participants were drilled like the chorus of a ballet.

These raids were conducted for very definite purposes. They, of course, served the general purpose of keeping up the interest and morale of the troops; they were also intended to harass the enemy and interfere with his rest. But in addition to these general purposes, the raids had each a very specific purpose, such as the capture of prisoners and documents for the purpose of identifying the hostile units in line and obtaining information as to their plans. Sometimes the raids were executed for the purpose of wiping out troublesome machine-gun nests, or to seize certain localities in preparation for operations on a larger scale.

Such raids are characteristic of modern war under the conditions that obtained in Europe, and accordingly training in them is essential. Engineer troops nearly always take part in raids of any magnitude, for the purpose of removing obstacles and destroying enemy works. It is of the highest importance that engineer officers should be familiar with the methods of conducting such operations.

Raids being highly active operations are very much to the liking of American troops. Even the Germans will admit that the Americans developed considerable skill in raiding. This raid, planned by well-informed officers, may be said to be based upon our experiences in the late war. In the absence of any proof to the contrary we must assume that it would have been a very successful raid.

The following brief "Primer of Raids" will serve to make the demonstration more intelligible:

Definition—

A raid is an entrance into the hostile position, usually for a brief period of time by a relatively small force; in other words, overcoming the enemy locally and temporarily.

A raid and an attack are similar in that they are both offensive in character; but the attack differs in that it aims to hold its gains, whereas the raid ordinarily does not.

Raids are incident to a situation where the opposing forces are in close contact, and are thus distinct from reconnaissances made to discover the enemy, or regain contact which has been lost.

Object—

As a rule, raids are primarily to gain information; secondarily, in some cases, to effect destruction and cause losses, to perfect or maintain training, and to raise the morale of our own troops and lower that of the enemy. However, it may be noted that *unsuccessful* raids have the reverse effect, especially when duly "camouflaged" in the daily communique.

Classes—

a. Unsupported raids, in which the raiding troops operate without fire support from the special weapons, such as machine guns, trench mortars, tanks, artillery. These are sometimes called "silent raids."

b. Supported raids, in which the raiding troops are supported by some or all of the special weapons.

Unsupported raids usually are conducted at night, supported raids by day; although this is not always the case. Supported raids may be launched with or without a preliminary fire preparation.

Unsupported raids—

When the object of a raid is simply the capture of prisoners, our experience indicates that the small patrol is the most effective method. Ordinarily, a few prisoners suffice as well as a greater number. A small patroling operation well planned and skillfully executed, will usually accomplish the desired result; and the method is simple, direct, rapid and economical in point of effort and men.

Supported raids—

If the situation requires that the raid be carried out by a force of infantry stronger than a small patrol, such a force can hardly expect to find protection in concealment. If it is discovered early enough, it almost certainly will sustain heavy losses, and will risk failure in its mission. Accordingly, these larger raids are supported by the auxiliary arms.

The supporting weapons are used, in general terms, to neutralize as completely as possible all of the defensive power which the enemy can bring to bear on the raided point, either in the form of men or fire power. Under this protection the raiding troops carry out their mission and withdraw. If the protection is complete, as it should preferably be, the raiding troops operate with relatively little fighting and with slight losses.

It was a raid of this type that was sustained by the 1st Division on November 3, 1917. The raiding troops numbered 200 to 250 men, with 5 officers. They were sup-

The Strength of the Pyramids

For centuries the Pyramids have stood with an endurance founded on solid, rugged strength. As these inanimate structures have endured through strength, so must an organization of men endure; and of the elements of strength, Service is the greatest, the most rugged, the most imperishable.

The strength of the American Association of Engineers lies largely in the service it renders to engineers. The 154 chapters of the Association supply non-technical educational courses, means for properly directed citizenship duties, opportunity for one to acquire experience in organization direction, business offices with interests of engineers as their principal endeavor, compensation and employment service, and the stimulating fellowship of other engineers.

Among such national activities as the publishing to the profession of a Code of Ethics, written for A. A. E. by the late Isham Randolph, the maintenance of a Practice Committee to enforce the Code, a great compensation service conducted in accordance with professional ethics, the Service Department stands in the forefront.

The positions filled during July saved members $35,000 which commercial agencies would have charged to place them in the same positions. This is more than two times the total monthly dues of the 21,000 members of the Association. Furthermore, the department did not fill all the positions on its list. It has 200 vacancies a month for mechanical engineers.

You should know more about the service rendered by this young, virile society. Send the coupon for a copy of our handsome new booklet entitled "An Ideal Which Has Become an Institution."

ported, according to reports, by 16 batteries of artillery. They were in the American position about 10 minutes. The Americans lost, 3 killed, 5 wounded and 12 prisoners; the Germans, as far as known, lost 1 killed and 1 wounded. A board of officers, convened to investigate this raid, stated in part as follows:

"Such a raid, elaborately prepared, made by picked troops and supported by heavy and accurately placed artillery fire, will almost certainly succeed in obtaining some prisoners."

As between the patrol raid and the supported raid, it can be stated only that the former is preferable when it will accomplish the desired results; some officers maintain that this always will be the case. The supported raid, however, has been found necessary in the past, and it hardly seems warranted to assume that there will be no occasion requiring its use in the future.

General situation—

The Red system of trenches is as shown on the accompanying map.

The Blue outpost is shown by the broken line near the bottom of the map.

The two forces have been stabilized for about a week.

Special situation, Blue—

The following is known of the enemy's dispositions: A platoon garrisons ABCIJ. A platoon holds the trench CDE. A platoon, probably intended as a garrison for HKFG, is in the trench GHI. A support platoon occupies the head of the draw 300 yards northeast of HKFG.

The Blue battalion commander of the sector has ordered Company A, 29th Infantry, which is in battalion reserve, to raid the closed sector of red trenches the afternoon of July 22, 1920, for the purpose of capturing prisoners and gaining general information.

Plan of raid—

I. Demonstration by Artillery.

Along entire division front from H—5 to H+30.

II. Neutralizaton by Artillery.

From H—5 to H+5.

(1) The trench FGHIJA.

From H—5 to H+30.

The battalion reserve line for ½ mile on each side of Gilbert Creek.

(2) The adjacent hostile works on each flank of the sector to be raided.

III. Neutralization by machine guns.

From H to H+30.

(1) The large hill northeast of sector to be raided.

(2) The Red Bone Road west of 403 for 800 yards.

(3) The east side of Gilbert Creek opposite the sector to be raided.

(4) The ravine east of the sector to be raided.

From H to H+5.

The trench EDCBA.

IV. Chemical Warfare Service (4-inch Stokes.)

(1) From H—5 to H+30, smoke demonstrations along division front.

(2) From H—5 to H+30, smoke screen on the area shaded on the map.

(3) From H—5 to H+5, smoke screen on area to be raided.

V. Light mortars.

(*a*) From H—5 to H.

(1) Make gaps in wire at B, D and E—one mortar to each gap.

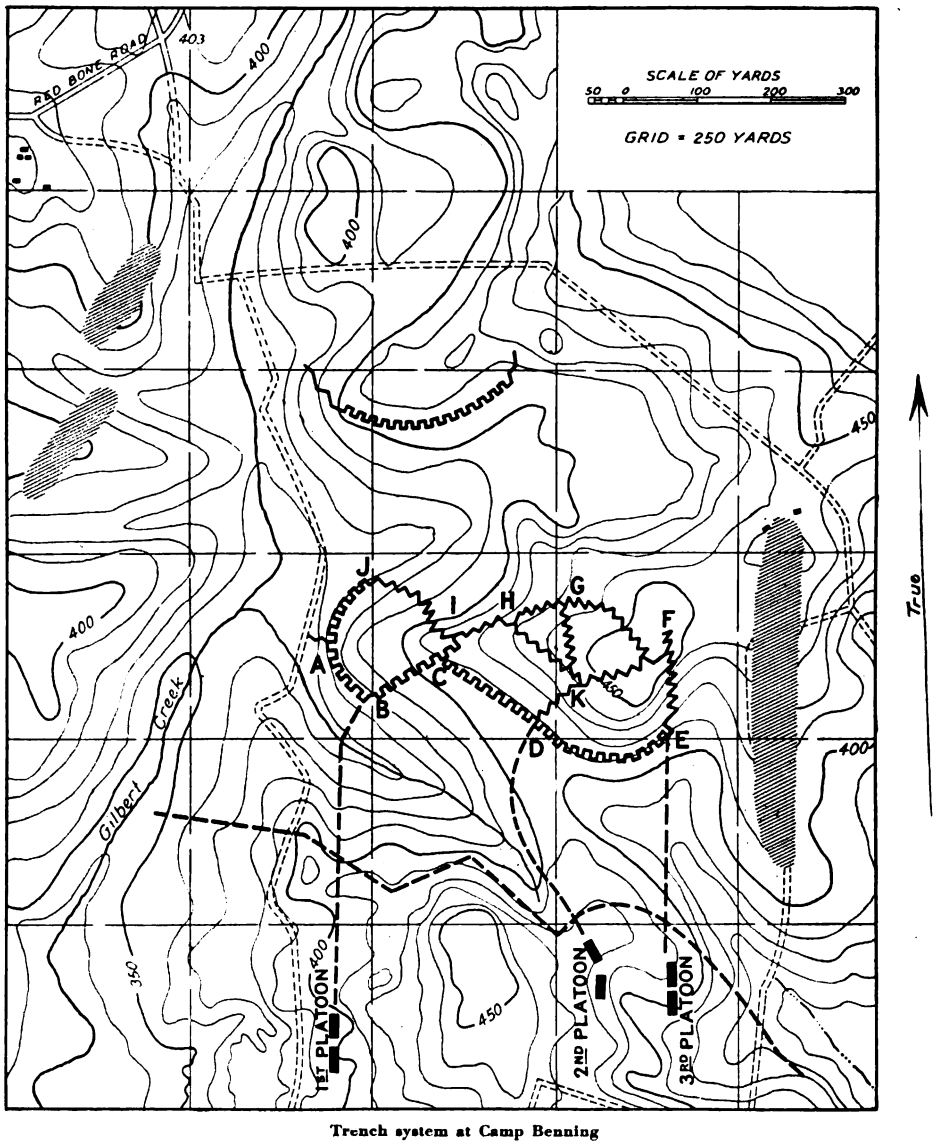
(2) Remaining mortars of regiment shell forward area of sector to be raided.

(*b*) From H to H+5.

All mortars shell trench FGHIJ.

(*c*) From H+5 to H+30.

1. Two mortars shell Gilbert Creek where it crosses battalion reserve line.



2. Remaining regimental mortars maintain a barrage on a line 200 yards northeast of and parallel to trench FG from house to northwest for 200 yards.

VI. One-pounders.

Fire on known hostile machine-gun emplacements and machine guns discovered during the raid.

VII. Infantry plan.

1. The 1st platoon will raid the area ABCIJ.

Trench system at Camp Benning

Digitized by Google

(*a*) The platoon will be formed at H—5 in the woods 150 yards southwest of hill 450 in section column, in two waves without distance. The front rank men of the 1st squad will be equipped with wire cutters. The rear rank of the 1st squad will be at the tail of the platoon.

The 2d and 3d squads will be equipped as bombing squads.

(*b*) At H hour the platoon leader will lead his platoon north down the small draw on the west end of hill 450, crossing No Man's Land at a double time, to the gap at B.

(*c*) The front rank of the 1st squad will complete the gap begun by the light mortar. It will then remain at the gap, collect prisoners and conduct them to the rear.

(*d*) The 2d squad will clean up trench BAJ.

(*e*) The 3d squad will clean up trench BCIJ.

(*f*) The 2d section will deploy after passing through the gap B and advance over the top of the ground to the rear of the area to be raided with its center marching on J.

(*g*) The rear rank of the 1st squad will take post at A and protect the left flank.

2. The 2d platoon, re-enforced by the 1st and 2d squads of the 4th platoon, will raid the area CDKGHI.

(*a*) The 2d platoon will be formed at H—5, 100 yards east of hill 450, in section column in two waves without distance. The front rank of the 1st squad of the 4th platoon, equipped with wire cutters, and the 2d squad of the 4th platoon, equipped as a bombing squad, will be formed in the order named at the head of the 2d platoon. The rear rank of the 1st squad of the 4th platoon will be at the tail of the 2d platoon.

(*b*) At H-hour the platoon leader will lead his re-enforced platoon down the first draw to the east of hill 450, crossing No Man's Land at a double time to the gap at D.

(*c*) The front rank of the 1st squad, 4th platoon, will complete the gap begun by the light mortar. It will then remain at the gap, collect prisoners and conduct them to the rear.

(*d*) The 2d squad, 4th platoon, will clean up trench DE until it meets a squad coming in the opposite direction from E.

(*e*) The 1st squad, 2d platoon, will clean up trench DC and IH.

(*f*) The 2d squad will clean up trench DK and KF until it meets a squad coming in the opposite direction from F.

(*g*) The 3d squad, 2d platoon, will clean up trench KG.

(*h*) The 4th squad, 2d platoon, will clean up trenches KH and HG.

(*i*) The 2d section (less 4th squad) will deploy after passing through the gap and advance over the top of the ground to HG with its right on trench DKG.

(*j*) The rear rank of the 1st squad, 4th platoon, will report to its corporal at the gap D to assist in collecting prisoners and conducting them to the rear.

3. The 3d platoon, re-enforced by the 2d section of the 4th platoon, will raid the area DEFGK.

(*a*) The 3d platoon will be formed at H—5, 200 yards east of hill 450, in section column in two waves without distance.

The front rank of the 4th squad, 4th platoon, equipped with wire cutters, and the 5th squad, 4th platoon, equipped as a bombing squad, will be formed in the order named at the head of the 3d platoon. The 6th squad and rear rank of the 4th squad, 4th platoon, will be formed in the order named at the tail of the 3d platoon.

(*b*) At H-hour the platoon leader will lead his re-enforced platoon down the second small draw 150 yards east of hill 450, crossing No Man's Land at a double time, to the gap at E.

(*c*) The front rank of the 4th squad, 4th platoon, will complete the gap begun by the light mortar. It will then remain at the gap, collect prisoners and conduct them to the rear.

(*d*) The 5th squad, 4th platoon, will clean up trench ED until it meets a squad coming in the opposite direction from D.

(*e*) The 1st squad, 3d platoon, will clean up trench EF and establish a block 25 yards north of F.

(*f*) The 2d squad, 3d platoon, will clean up trench FK until it meets a squad coming on the opposite direction from K.

(*g*) The 3d squad, 3d platoon, will clean up trench FG.

(*h*) The 2d section, 3d platoon, will deploy after passing through gap with its right at E, advance over the top of the ground and occupy FG.

(*i*) The 6th squad, 4th platoon, will take post north of E and protect the right flank.

(*j*) The rear rank of the 4th squad, 4th platoon, will report to its corporal at the gap at E to assist in collecting prisoners and conducting them to the rear.

(*k*) The section sergeant of the 1st section will organize the two squads which meet about half way between D and E as a support wave for the 2d section.

Signals.

"Position occupied," yellow smoke rocket, by each platoon leader, as soon as his position is occupied.

"Withdraw, first phase," star red rocket, by captain.
"Second phase," green very light, by platoon leaders.

Plan for withdrawal.

At the signal (1 star red rocket) the first phase of the withdrawal will be executed

First phase—

Squads and sections will return independently under their leaders to their own trenches with the following exceptions:

1. The half squad at A will remain in position.

2. The leader of the 2d section, 1st platoon, will designate one squad to remain at J.

3. The leader of the 2d section, 2d platoon, will designate one squad to remain at G.

4. The squad at F forming the block will remain in position.

5. The squad at E protecting the left flank will remain in position.

6. The groups at the gaps will remain in position All the squads left in position are to protect the first phase of the withdrawal.

Second phase—

As soon as the part of his platoon designated to withdraw at the signal one star red rocket have cleared the gap in the wire, each platoon leader will signal the second phase (green, very light). At this signal the squads left in position to cover the first phase of the withdrawal will return independently under their leaders to their own trenches.

Company headquarters.

At the gap in wire at D.

The Big Work of 1921

Aside from Railroad Betterments, for which you will need Western Dump Cars, the big work of this year will be Concrete Road Construction. Now is the time---between seasons---to investigate the merits of the

Western Industrial Railway and Batch-Box System

You can work more days, regardless of roads and weather.
You can get along with from 15 to 20 fewer men.
You can keep material off the sub-grade and free from dirt.
You can back-fill inexpensively with loose dirt, instead of concrete.

Read what this New York Contractor says about it:

"We have had the Western Industrial Railway Equipment, consisting of 24-inch gauge track, with trucks and batch-boxes, in operation for a very short time, here on our contract at Whitney Point, near Binghamton, N.Y. Already its reputation has spread through this part of the country and hardly a day passes but what contractors and the State Engineers, in charge of the work, visit us to see the efficiency of its operations. It is efficient, and after their visit they leave us convinced of its merits. *We are convinced that no State Road Contractor should be without the Western Industrial Railway Batch-Box outfit.*"

(Signed) Rosoff Engineering Co., Inc.
S. R. Rosoff, President.

Upward Pressure on Floor of Lock on Porous Foundation

By

Malcolm Elliott

U. S. Assistant Engineer; formerly Lieutenant Colonel, Engineers
M. Am. Soc. C. E.

THE following gives the results of observations as to upward water pressure, with and without relief holes, on the floor of a lock built on a porous foundation. The observations were taken on an actual structure and are therefore not subject to the criticisms which may be made against such observations when based on a small scale model and artificial conditions. More observations with more complete data would have been obtained but for the fact that this would have interfered with important construction work at a time when labor of all kind was difficult to obtain, and a rising river was threatening to submerge the work.

The observations were made at Lock No. 43, Ohio River, 26 miles below Louisville, Ky. The lock is built on a porous foundation, the material being a mixture of firm sand and gravel reasonably free from silt. The concrete lock walls and floor are supported by piles. Rows of sheet piling surround the area inclosed by the lock walls and miter sills.

Considering the river wall as a dam excluding the water from the lock when the latter is pumped dry, it was believed that the flow through the porous foundation under the wall would endanger its stability unless some protective measures were taken. The ordinary means for protecting dams on porous foundations consist of long aprons, either upstream or downstream from the dam, and sheet piling so as to increase the distance traveled by the water percolating from the upper to the lower levels. In this way the velocity of the percolating water can be "killed" or reduced to a point where it will have no eroding action.

The above principle was applied to the river wall of Lock No. 43. Upstream from the dam the outside of the wall was protected by a crib, 20 feet wide, and a blanket of riprap, 12 feet wide. Downstream from the dam the crib was omitted, but the riprap was used. Rows of sheet piling, 25 feet deep, were placed under the inner and outer edges of the wall. A concrete floor was placed in the lock.

When this type of construction was adopted it became important to know what would be the upward pressure on the floor and what means should be provided for resisting it. If the floor were watertight, it was believed that the lock would be practically the same as a boat, and that the upward pressure head on the floor would be equal to the height of the river above the bottom of the floor. In this case, when the river reached a certain stage, the upward pressure would lift the floor unless measures were taken to reduce the pressure or hold down the floor.

It was apparent that this excessive pressure could be greatly reduced by providing holes or vents in the floor. The flow through holes would convert part of the excessive static head into velocity and friction heads, thus relieving the pressure on the floor. One 6-inch diameter hole for each 100 square feet of floor surface was provided. As an added precaution the floor was made 4 feet thick, counteracting about half of the maximum head, and was anchored with hold-down piles with enlarged butts at the rate of one pile for each 25 square feet of floor surface.

Figure 1 shows a typical cross-section of the lock. Due to accidents of construction and perhaps to unusual hurry to get the floor in before the lock was flooded by high water, most of the holes in the floor were omitted. Some of them perhaps became stopped up by collecting silt. At any rate, when the lock was pumped out only a very few of the holes were open. Some of those that were open "boiled" vigorously, but the water did not bring any appreciable amount of sand or gravel into the lock, indicating that the flow had no eroding action. The holes which flowed most freely are shown in Figure 2.

During the fall of 1919 the lock was pumped out for the purpose of installing the lock gates. It was decided to take advantage of this opportunity to measure the upward pressure on the floor and determine, if possible, the reduction in same effected by the holes. Iron pipes, 3 inches in diameter, were set in three 6-inch holes (P-1, P-2 and P-3, Fig. 2), and the annular spaces between the outsides of the pipes and holes were plugged with wooden wedges and oakum, as shown in Figure 3. Very tight joints were obtained.

The height of water in the pipes was sounded daily for a period of over a month. The readings in the pipe and the gauge readings in the river are given in the following table and plotted in Figure 4. During the entire period the movable dam was down, and there was a difference in elevation between the upper and lower pools of only two or three inches. The heights in the pipes and the river are referred to the bottom of the lock floor, elevation 358.0 above sea level. The observations covered a period of one month (Sept. 16-Oct. 16).

16	22.6	14.21	14.32	11.13	

Figure 4 shows clearly how the pressures were influenced by the fluctuations of the river and the relief afforded by opening adjacent holes. The observations were started September 16, 1919, on which date pipes were placed at P-1 and P-3. The initial reading in pipe P-1 was 0.17 foot less than the elevation of the river. During the next two or three days the river fell slowly, and the pressure head in the pipe also decreased, but not so rapidly as the elevation of the river. On September 17, 18 and 19 the head in the pipe was slightly greater than the height of the river. It is probable that the pressure in pipe P-1 came from the ground water rather than from the river.

The height of the river, of course, controlled the height of the outlet of the ground water, and thus the head in the pipe would follow more or less the fluctuation of the river, even though the water causing same came from a spring in the bank. The theory that the water in hole P-1 came from the bank is supported by the fact that the flow left traces of discoloration about the edge of the hole, due to iron content of the water, similar to that caused by the water from a well that had been driven on the reservation adjacent to the lock. To make sure that the head in the pipe was actually greater than the head from the river, the pipe was bailed down well below the elevation of the river surface. It promptly filled up again to the original elevation as soon as the building was stopped.

The effect of placing the pipe in hole P-1 was, of course, to stop the flow of water through the hole and thus increase the static upward pressure on the floor in the vicinity of the hole. This effect was shown on September 19 when the hole H-1, 15 feet away from pipe P-1, started to "boil" vigorously. Previous to this there had been no evidence of flow through hole H-1. Evidently some obstruction which had prevented flow through the hole was removed by the increased pressure due to placing the pipe in hole P-1. The static pressure in P-1 immediately fell after hole H-1 began to flow, as shown by the abrupt drop of the curve P-1 (Fig. 4), on September 19. Hole H-1 continued to flow after it had once started, notwithstanding the decreased pressure head. The opening of hole H-1 did not produce any visible effect on the pressure at hole P-3, which is 225 feet downstream from H-1.

On October 3, hole H-1 was stopped with a wooden plug and well calked. As was expected an immediate rise occurred in pipe P-1. The observation on the morning of October 4 showed a height in the pipe 0.4 higher than the river. The purpose in closing hole H-1 was to increase the pressure and start more holes flowing, if possible, so as to increase the number of observations. The immediate effect, however, was merely to start percolation through several of the floor construction joints near by, but this percolation continued only a few hours and then stopped, probably by drawing sand and silt in the joints. No new holes were

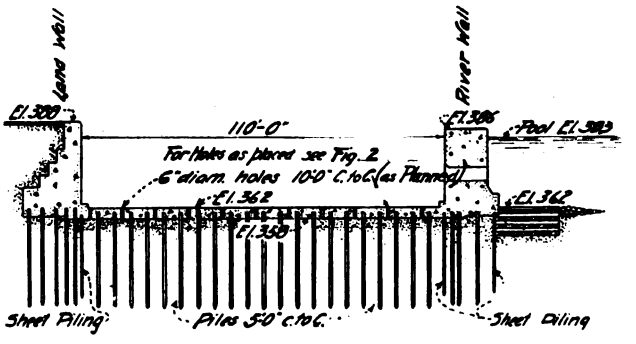

Fig. 1. Lock No. 43, Ohio River. Typical cross-section.

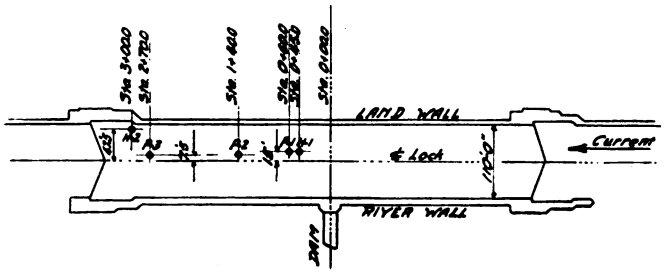

Fig. 2. Lock No. 43, Ohio River. Plan of lock showing location of pipes and holes. Holes P-1, P-2 and P 3 were fitted with pipes for measuring pressures. Holes H-1, H-2 were not fitted with pipes.

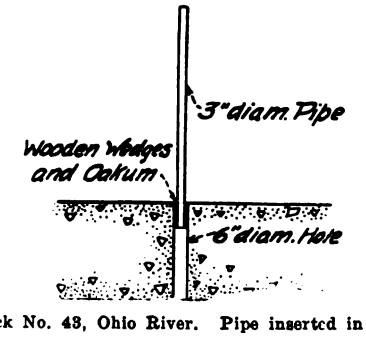

Fig. 3.—Lock No. 43, Ohio River. Pipe inserted in hole in floor.

started. Contrary to expectations, the closing of hole H-1 caused an increase in the pressure in pipe P-3, 225 feet away, as shown by the abrupt rise in curve P-3 on October 4.

On October 2 a pipe was placed in hole P-2. There had been a very slow flow of water through this hole, indicating almost complete stoppage. Efforts were made to clear the hole, but these did not result in increased flow. It was apparent that the hole could not be opened without drilling. When the pipe was inserted it filled slowly until on the morning of October 3 its head showed a pressure over a foot greater than the head in the river. Thereafter the

Digitized by Google

head in pipe P-2 followed the fluctuations of the river quite closely until October 14.

On October 14 hole H-1 was purposely opened, and there occurred an immediate drop in pipes P-1, P-2 and P-3. The drop in pipe P-3 was greater than that in pipe P-2, notwithstanding that the former was more remote than the latter from hole H-1. On October 15 hole H-1 was again stopped, causing an immediate rise in pipes P-1, P-2 and P-3. The water now began to run over the tops of pipes P-1 and P-2, and it was impracticable to extend the pipes to continue the readings. It is believed that if the pipes had been long enough, the readings would have paralleled closely the height of water in the river. On October 16 the water was still running over the tops of pipes P-2 and P-1, and the reading in pipe P-3 was 11.13 feet, corresponding to a river elevation of 22.96 feet. At this point the lock was flooded, and the readings were discontinued.

The readings in pipe P-3 were always considerably less than the heights of the river. This was due, no doubt, to the relief effect of hole H-2, about 60 feet distant from pipe P-3. This hole, flowing freely, was in a pump directly under one of the pumps used for unwatering the lock, and it was not possible to close the hole without more expense than was considered justifiable under the circumstances. It is believed that if hole H-2 had been closed, the pipe at P-3 would have shown a head about equal to the height of the river surface.

These observations agree with theory as ordinarily applied to the design of locks and dry docks on porous foundation; for example, the theory that upward pressure, if not relieved, will correspond to the full head acting on the outside of the lock and that substantial relief from this upward pressure can be obtained by providing vents in the floor. Sheet piling has little, if any, effect in reducing the pressure if vents are not used, but probably cuts off considerable pressure and flow into the lock when vents are used. With this particular foundation the effect of a vent is felt at a distance of over 200 feet, indicating that the number of holes need not be large. For a less permeable material perhaps closer spacing of holes would be required. It is advisable, however, to use no more relief holes than the number required to relieve the pressure, because a surplus of holes increases the amount of water entering the lock and adds to the expense of pumping.

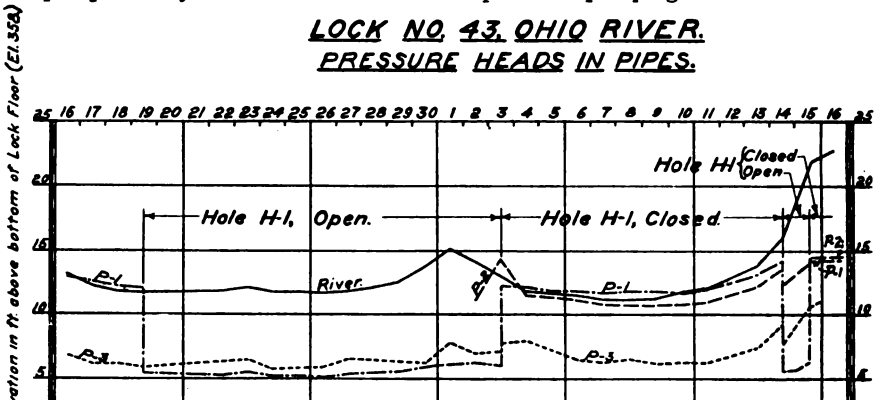

Fig. 4.

Changes in Personnel in the Corps of Engineers

Contributed by Mr. J. A. EGAN, Office of the Chief of Engineers.

Col. FREDERICK W. ALSTAETTER has been retired from active service, effective August 21, 1920, due to physical disability incident to the service. He remains on active duty as district engineer, Savannah, Ga.

Col. HERBERT DEAKYNE has been assigned to duty as division engineer, Pacific Division, and district engineer, 1st San Francisco District, thereby relieving Col. E. Everth Winslow, who has been ordered to Governors Island, N. Y., for assignment to duty as engineer, 2d Corps Area.

Maj. FREDERICK B. DOWNING has been granted sick leave for three months. Maj. Creswell Garrington will act as district engineer during the sickness of Major Downing.

Maj. JOHN J. KINGMAN has been granted a leave of absence for two months, effective on or about October 1, with permission to leave the continental limits of the United States.

Capt. EVERETT B. MURRAY has been relieved from duty at Yale University, Sheffield Scientific School, where he had been serving as assistant professor of military science and tactics, and ordered to duty as assistant in the Galveston, Tex., Engineer District.

Maj. FRANCIS B. WILBY has been detailed as a member of the board of officers appointed for the purpose of examining the records of applicants for appointment to the grade of warrant officer, and to assist in arranging an eligible list for that grade.

Capt. HOEL S. BISHOP has been relieved from duty at Camp A. A. Humphreys, Va., and assigned as assistant professor of military science and tactics at the University of Alabama, University, Ala.

Capt. EDWARD G. BLISS has been relieved from duty in the office of the Quartermaster General, this city, and directed to report in person to the Chief of Inland Waterways Service for duty in his office.

Capt. THOMAS D. FINLEY has been transferred, at his own request, to the Infantry Arm, Regular Army, in accordance with the provisions of the Act approved June 4, 1920.

Capt. BENJAMIN F. VANDERVOORT, Engineers, has been assigned to duty as constructing quartermaster, Savanna Proving Ground, Savanna, Ill.

Capt. ARTHUR P. VON DEESTEN has been relieved from duty with the 4th Engineers, Camp Lewis, Wash., and assigned to duty as assistant to the district engineer, 1st Portland, Ore., Engineer District.

Capt. CHARLES S. WARD has been assigned to duty as secretary and disbursing officer for the Board of Road Commissioners for Alaska, with station at Juneau, Alaska.

Capt. JOHN W. STEWART, having been found physically disqualified for active duty, his retirement is announced in War Department orders.

1st Lieut. THOMAS NORTH, Engineers, has been relieved from duty at Headquarters, American Expeditionary Forces, this city, and assigned to duty with the 81st Field Artillery, Camp Knox, Ky.

The following-named officers of the Corps have been ordered to report to the Commanding General, American Forces in Germany, for assignment to duty:

Capt. Edwin A. Bethel
Capt. Hugh J. Casey
1st Lieut. Henry G. Lodge
1st Lieut. Randolph P. Williams.

Capt. JOHN S. BRAGDON has been assigned to duty as assistant professor of military science and tactics, Carnegie Institute of Technology, Pittsburgh, Pa.

Capt MERRIFIELD G. MARTLING, recently returned from overseas, has been assigned to duty in the office, Chief of Engineers. Capt. Martling has since been appointed in the Corps of Engineers, Regular Army, with the rank of first lieutenant.

Capt. LEHMAN W. MILLER has been relieved from duty at Camp A. A. Humphreys, and assigned to duty at West Point, N. Y.

Capt. WILHELM D. STYER has been assigned to duty in the Militia Bureau, this city.

Col. WILLIAM J. BARDEN has been assigned to duty at Florence, Ala., in charge of the construction of the Wilson Dam.

Col. HENRY C. NEWCOMER has been assigned to duty as Division Engineer, Gulf Division, vice Col. Hubert Deakyne.

Maj. EDMUND L. DALEY has been detailed as professor of practical military engineering, at the U. S. M. A., West Point, N. Y.

The following-named officers of the Corps have been promoted to the grade of major:
Capts. Philip B. Fleming, David McCoach, Jr., Joseph C. Mehaffey, Paul S. Reinecke and Raymond A. Wheeler.

Maj. J. FRANKLIN BELL has been assigned to duty as district engineer, Pittsburgh District.

Col. WILLAM W. HARTS has been assigned to duty as division engineer, Central Division, vice Col. M. L. Walker.

Maj. HARRY F. CAMERON and Capt. Edward N. Chisholm, Jr., have been assigned to duty as assistants to the district engineer, Florence, Ala., in connection with the construction of the Wilson Dam.

Maj. CHARLES W. COCHRAN has been ordered to Camp Benning, Ga., for assignment to duty as camp engineer.

Maj. RICHARD T. COINER has been assigned to duty as district engineer, New Orleans, La.

The Fundamentals of Staff Control

(Continued from Page 508)

Discussion

Fox Conner
Brigadier General, U. S. Army; formerly Chief of Staff [G-3] G. H. Q., A. E. F.

The article, "Fundamentals of Staff Control," is valuable not only intrinsically as a simple and clear exposition of the relations which should exist between staff and bureaus, but as symptomatic of the gradual "getting together" of staff and bureaus, which is essential to efficiency.

The general staff in our service is comparatively new, and it is natural both that it should have encountered much criticism, and that a great deal of this criticism should have been well deserved.

After the Spanish-American War it was evident that our military organization was vitally inefficient because of the impossibility, for the higher command, of exercising efficient control under the then existing system. A few of our officers and a few distinguished civilians saw that the only remedy for the chaos which had existed lay in the establishment of a general staff. But this staff had hardly been conceived when the embryo encountered the most violent opposition from the old established bureaus. This was but natural, for our bureaus had grown accustomed to the idea that they were supreme and that the remainder of the army existed at and for their convenience. Now, however, in the establishment of the general staff the bureaus saw this supremacy menaced by the creation of a body which, whether in the War Department or in the field, would have more immediate access to the ultimate authority than had they.

This attitude on the part of the bureaus was strengthened, and to some extent justified, by the early functioning of the general staff. While a few officers had correctly conceived the principle, we had, when the general staff was created, no officers who were properly trained in general staff duties, and we were therefore unable to install a working system which would put into effect the correctly conceived principles. An earnest attempt was made from the beginning to select efficient officers for the general staff, but since we had had no general staff experience, there was no criterion for such selection, and the choice too often fell upon men whose only qualification was success in duties pertaining to some one of the established bureaus. Confronted by the hostility of the bureaus, forced to fight for its existence, and knowing little beyond ordinary routine, the general staff turned to what has not inaptly been described as pernicious meddling with the internal working of the bureaus. Notwithstanding constant development, especially in the schools for instruction of future general staff officers, it was patent to all that our general staff was not fulfilling legitimate general staff functions. Consequently, it was not surprising that shortly before our entry into the World War the quarrels between staff and bureaus found their way to the Congress, with the result that drastic legislation was enacted with the avowed object of clipping the wings of the general staff.

The intent of the law of 1916 was good, but in enacting it, no account was taken of the fact that the fundamental difficulties were the lack of qualified general staff officers and the absence of the essential conception that both the general staff and the bureaus are the servants of the commander in the supply, development and employment of the line of the army, which alone wins battles, and is thereby alone entitled to special consideration.

The experience of the A. E. F. did much to bring about a proper realization of this fundamental conception and of the proper relationship between the bureaus and the staff. Although a few traces of the old quarrels remain in the late reorganization of the Army, we may hope that the hitherto insurmountable difficulty in the development of a capable general staff will soon be removed by the enactment of a law which will require adequate training as the *sine qua non* of the general staff eligible. Once this training is assured, and with our A. E. F. experience behind us, our general staff development will be rapid, and bureaus and line will join in securing the repeal of any remaining fragments of unnecessary legislative restrictions.

Restrictions on the duties and powers of general staff officers can only be put into effect by the proper training, experience and selection of general staff officers. The general staff is not only the *adviser* of the commander, but above all it is the *mouthpiece* of the commander, and the body which formulates and issues in the name of the commander the orders and instructions necessary to carry out his policies and his decisions. In advocating a purely advisory general staff we would forget the lessons of history, and we would in effect be seeking to establish a staff modeled on the lines of the Aulic Council; and one which would be as useless and as much of a nuisance as was that body. The general staff must issue orders and make decisions, and it must be reiterated that only by the adequate training and proper selection of general staff officers is it possible to settle the daily questions as to where general staff functions should properly cease. Training, experience and proper selection (and not the incorporation in unalterably rigid rules of words such as "administer" and "coordinate"—which may and often do have diametrically opposite meanings when applied to concrete cases) will soon place proper and effective limitations on the exercise of general staff functions.

The development of the general staff will certainly be along functional lines. There must of necessity be a certain "overlapping" between the sections of the general staff just as there must be an "overlapping" of general staff functions over the duties of bureaus. Thus the functions of the general staff as a whole embrace the broader phases of all those things which affect the employment of troops in battle, and the exercise of those functions must entail authority over a limited amount of detail when such detail affects more than one arm or service. The principle that the general staff should interfere in no matter of detail which pertains solely to a single bureau is unquestioned, but we must recognize that there is a twilight zone in which it is not always easy clearly to distinguish between legitimate general staff functions and meddlesome interference.

The internal organization of a general staff body along functional lines is essentially the same in all armies. That this is true has perhaps not always been grasped by those to whom words mean more than ideas. In the English service, for example, staff functions are assigned virtually as they were in the A. E. F., and yet the British terminology has given many people quite a contrary opinion. In the British Expeditionary Forces the term "general staff" included our G-2 and G-3 sections only, but the English title "Quartermaster General" properly connotes G-4, and not at all an individual with duties similar to those of our own Quartermaster General; similarly the British Adjutant General had duties practically identical with our G. H. Q. G-1. To carry this point to the *reductio ad absurdum* it may be noted that the fact that Ludendorff bore the title

Digitized by Google

of "First Quartermaster General" does not indicate that he issued either beans or socks, or that he was especially trained for those important duties.

Functionally divided, the duties of the general staff, in all armies, then, classify themselves naturally: (1) Personnel; (2) Intelligence; (3) Operations and Training, and (4) Supply. Special conditions in the A. E. F. made it desirable to separate Operations and Training, but such a separation should not exist in developing a permanent system. On the other hand, one of the most important lessons to be drawn from our A. E. F. experience is that, following our terminology, the system of the four G's is necessary at every headquarters from the battalion to G. H. Q., inclusive. Each of these headquarters should therefore be organized with a chief of staff and the four G's; in the smaller units the G-4 might fulfill the actual functions of issue and accountability. The same thread of organization would thus be preserved throughout; we would avoid some confusion which existed in France, and each lower echelon would be constantly preparing officers for higher staffs.

It should be observed that while the classification of general staff duties into personnel, intelligence, operations and training, and supply makes a most distinct functional division, there are, as already mentioned, "twilight zones" which can only be suppressed by such a hearty co-operation between sections as existed in France. In one thing I can not agree with the author of this article; his apparent assumption that it is necessary to continue the present Adjutant General's Department. It is believed that a much more economical and efficient organization would result by merging the officers of The Adjutant General's Department with the General Staff Corps and the creation of a Central Records Service whose only duties would be concerned with the care of dead records, individual records of soldiers, routine reports and returns, etc. Under such a system each bureau and each section of the g neral staff would keep its own live records, and correspondence would be addressed to the office which must initiate action with a consequent saving of time, money and effort.

Geo. V. H. Moseley
Brigadier General, U. S. Army; formerly Assistant Chief of Staff [G-4] G. H. Q., A. E. F.

Order is the basis of military efficiency, and this is true whether it be order in troops on the march or deploying for battle, or order in the arrangements of staff organization. Disorder in the office of the commanding officer or his staff is reflected all the way down the line and shows itself finally in the way troops operate against the enemy. All successful business is organized into certain orderly sub-divisions with a control post over each, and in this way administration is decentralized and responsibility fixed. Successful industrial enterprises have these control posts called vice-presidents, directors, general managers, etc., and every good army must have them also, and it matters not whether they are called general staff officers, adjutants general, executive officers, or what not, provided the organization has been well laid out fundamentally. In a military organization, order is a characteristic of a high state of discipline. Disorder is a characteristic of raw, undisciplined, or defeated troops.

America, noted for its efficiency and enterprise in business organization, has also been equally noted for its inability to establish sound military organization. Why is this? In business, all are united upon the accomplishment of the single mission of making money. In a peace-time army, there is not the common mission of defeating the enemy, so that many adopt the mission of their own ambitions. In business, the inefficient or disloyal can be discharged, while in the army they generally have to be carried along, often in high places, much to the embarrassment of their superiors. Again, in business, the control posts are filled by men hired for their particular talents, while too often in the army, these positions have been held by men not properly educated for their tasks, or perhaps inherently incapable of rising to the high standard necessary.

Some of our successful commanders have been criticized because they wanted a certain group of assistants around them. But this is perfectly natural, for they want men who have been tried out and found fit, and they do not want some substitute detailed by roster and reported "just as good."

The system of staff control discussed in the article on "Fundamentals of Staff Control" is practically that which formed the basis of the organization of the A. E. F. in France. It proved to be sound throughout, and it well withstood the stress of modern war. In going to France, we had the advantage of starting with a clean slate. The A. E. F. was given a sound fundamental setting and a framework or organization was adopted which could absorb, in an orderly manner, the various units as they arrived. Each such unit had a logical place in the machine which it took upon arrival. Efficiency governed and not political considerations or peace-time conditions. A "wet ditch"—the Atlantic Ocean—protected the A. E. F. from harmful interference. The setting was for team play and not individualism.

On the other hand, at home, there were enormous difficulties to be overcome. Archaic systems had to be uprooted, often involving the removal of men who were well intrenched. To-day, the victory at home is not generally understood or fully appreciated. Considering the handicaps which were overcome at the outset and the scarcity of trained general staff officers, the results obtained by the War Department were no less than miraculous.

Little is to be gained, as the author of this article points out, in quibbling about whether the general staff should have the power only to co-ordinate or advise or control, or what not. In any system we must start first with a trained general staff officer fully qualified professionally and temperamentally for the position in which we are going to use him. No machine can be made so perfect as to be independent of the human element. Men with the proper qualifications must be assigned to all critical points. Each general staff officer in charge of a subdivision of the work, must have the *power* to make all decisions necessary and to require the proper agencies of the government to execute his will; but after his decisions have been made they should be executed, as far as possible, by existing non-general staff agencies organized for the purpose.

In considering the whole question of reorganization and staff control, we should go to the very root of the matter. The conditions of future wars will require closer and closer unity of action between the Army and Navy, and these two arms, which are organized and maintained for our national defense, must be merged into one great organism for that purpose. The Army must not be allowed to develop at the expense of the Navy, nor should the Navy be developed and our land forces neglected. In theory the President is the co-ordinator of these two services, but in practice he has no time for such duty, and as a result each Secretary

Digitized by Google

goes independently to Congress and secures from that body all he can for his own service. All this can be avoided by replacing the Secretary of War and the Secretary of the Navy on the Cabinet by one secretary for national defense. As assistants to this single Cabinet officer there should be a secretary for the Army, a secretary for the Navy and a secretary for Munitions. With such a plan in operation the objections to a separate Air Service would pass away, and a secretary for Air could be authorized, co-ordinate with the secretaries for the Army, Navy and Munitions.

Whatever plan is adopted should be simple, fundamentally sound and then adjusted in an orderly manner throughout the Army. No plan, however perfect, will produce satisfactory results unless excellent discipline exists throughout the Army. We expect to find good discipline throughout the line of the Army, but we do not always find it as we advance to higher staff organizations. Commanding generals should be given the greatest freedom in selecting their staffs and in removing those found unsuited for any reason. In the same way the Chief of Staff of the Army should have the power to remove any officer on duty in the War Department, and all officers there should hold their positions at his pleasure. We should not charge any officer with such a great responsibility unless we are willing to give him the maximum amount of freedom in the organization of his office as well as in the selection of his assistants.

E. S. Hartshorn
Lieutenant Colonel, General Staff, A. E. F.

The Act approved January 21, 1903, creating the general staff, is an exceedingly well-drawn enactment, and as the organic instrument or constitution of the general staff, it is susceptible to little, if any, improvement. It is difficult to state to what extent by-laws in the form of added legislation or regulations are necessary to supplement this constitution.

A proper interpretation of this Act by officers thoroughly trained in general staff procedure should result in the discharge of staff duties in a manner satisfactory to all elements of the service. To prescribe a rigid method of procedure, or as the author states a "doctrine in plain words" for the general staff, appears inadvisable, since the conditions existing in the winter of 1917-1918 may repeat themselves in the future, and in such times of stress the Chief Executive and the Secretary of War should be accorded the utmost freedom of action as to the means to be employed in solving the difficult problems confronting them. In this connection attention is called to the fact that it was necessary very shortly after the beginning of the period of mobilization to remove many restrictions placed upon the general staff in time of peace. Lieut. Col. E. Requin, of the French general staff, with reference to the influence of our general staff, states (page 23, "America's Race to Victory") " . . . but considered as a general staff it did not exist. Its Chief of Staff was, by the laws and regulations then in force, deprived of that high authority which he ought to have exercised over his own staff officers, as well as over the several departments of the Army."

Under "What does the general staff do?" the author credits the staff with two functions, *i. e.*, "Advice, or to give orders." I beg leave to add another function, "to render service," both to the commander and to the troops, since a good staff is the servant of both. The red tabs of the British general staff officer have been described for many years by the faculty of the British Staff College as a "badge of servitude," and throughout the course every effort is made to inculcate in the student personnel this doctrine with respect to staff procedure.

The relationship of the commander and his general staff section, with respect to the channels of command, requires most careful consideration, since the danger of building up what may be termed a "staff officer's command" exists at all times. It should be clearly understood that there can be but one commander and that the necessary decentralization of functions incident to the performance of general staff duties should never constitute an excuse for departing from the prescribed channels of command through responsible commanders.

The author's conception of functional control by the staff, under the supervision of the commander, is based upon sound principles. If bureaus or corps reported to any *one division* of the general staff, it would be obviously necessary for that division, or "G," to exercise within itself the functions of the entire staff and to maintain sections corresponding to those which now constitute the four coordinate primary administrative subdivisions, that is to say, administration, intelligence, operations and supply. The solution of a replacement problem, for example, by these proposed subsections, or sub-G's, would be interesting and instructive and would at once indicate the impossibility of any co-ordinated effort under this system.

Our recent association with our Allies and a critical examination of European staff procedure indicates that the organization of our general staff does not require extensive revision. On the part of the general staff there should be a sympathetic appreciation of the needs of the troops, a highly developed sense of service and a clear understanding of general staff procedure, and on the part of all a keen desire to play for the team.

LeRoy Eltinge
Colonel, Cavalry; formerly Brigadier General, Deputy Chief of Staff G. H. Q., A. E. F.

I think the author has made a good analysis, and that it should be helpful. I would, therefore, suggest the following addition, to clarify the conception of the relations between the Commanding General and his general and technical staff:

The Commanding General may in a sense to be said himself to give all the orders that emanate from the general staff; for he keeps his staff constantly and fully advised as to his policies, and the staff simply applies these general policies to all particular cases that arise. As a practical matter this is done in two ways: (*a*) By personal conference with all or part of his staff; (*b*) by the approval or amendment of proposals submitted to him by members of his staff, issued in the form of staff memoranda.

As an example of (*a*): The Commanding General says, "I desire particular attention given to the prompt completion of the road from X to Y." It is then the duty of G-1 to arrange the work of the engineers, quartermaster corps and motor transport corps toward the end desired, and to inform them what work each must postpone or abandon, in order to accomplish the desired result.

As an example of (*b*) G-2 sends a note to G-3 stating that identifications of enemy troops opposite are badly needed. G-3 adds to this that a raid on such a part of the hostile trenches appears most feasible. The Commanding General approves or amends this proposal and returns same, or calls in G-2 and G-3 and goes over the situation with them. The Commanding General having decided upon the operation to be undertaken, it is up to G-3 to give all

Digitized by Google

the necessary detailed orders and to supervise their execution.

Geo. P. Tyner

Lieutenant Colonel, General Staff; formerly Colonel, G. S., Assistant Chief of Staff [G-4], 2nd Army, A. E. F.

The article on "Fundamentals of Staff Control" bears on a subject of great importance to the service. Fundamentals of general staff control have often been misunderstood and often incorrectly applied, this due both to absence of knowledge of correct principles and disregard of established policies by officers occupying general staff positions.

The laws governing our military establishment distribute the supply and technical staff functions of the army amongst different bureaus, departments and services. Each is responsible for its own operation and performance up to 100 per cent efficiency. But as a team they must have a "quarterback" to insure that the policies of the "captain" run smoothly and effectively. If anyone attempts to work independently, they are all "downed" and the "play" is stopped.

The author of this article exhibits an intimate knowledg of his subject and unhesitatingly hits the nail on the head. It might be clearer to the uninformed if his description of staff control were applied to the activities of other services as well as to the engineers. The point is properly emphasized that none of the services work exclusively with any particular general staff section. The action of any general staff section is the action of the Chief of Staff. The sections are merely his assistants, and the division of their duties does not coincide completely with the activities of any particular service. This applies in the War Department and applies in an infantry division as well.

Occasionally a general staff section must jump in and actually operate a service. This, however, should be confined to those rare cases where the responsible representative of the service fails, and it is known that those of his assistants who are present are equally inefficient. Such operation by the general staff should never extend beyond the time necessary to install an efficient replacement officer in charge of the service. In the meantime the local responsibility for that service rests upon the staff.

As stated in the article the question of rank between the chief of a general staff section and the representative of a service is of no importance. If the chief of the general staff section is a trained general staff officer, and if the service representative knows his work, there will be no friction which will not be promptly "nipped in the bud" by their common commander.

John S. Fair

Lieutenant Colonel, General Staff

This article is a very clear and concise exposition of the duties and functions of the general staff and will help materially in creating a better understanding of what staff control is. Ever since the creation of the general staff there has been a persistent misconception, both on the part of general staff officers and others, as to the functions of such a staff. The World War has helped to clear the situation. From the beginning of the war there was an imperative need in the War Department for an organization to control as well as "supervise and co-ordinate" war-time activities in the name and by authority of the Secretary of War.

The present organization of the War Department General Staff was not finally established until early in 1918. The final organization into four divisions, viz:

1. Operations,
2. War Plans,
3. Purchase, Storage and Traffic, and
4. Military Intelligence,

was the result of evolution.

The assignment of duties to the divisions was along functional lines except in those cases where other considerations prevailed. The utilization of a Chief of Staff presiding over a War Department general staff, and acting as the agent of the President and the Secretary of War, not only in the matter of carrying out adopted policies but also in the determination of policies, is absolutely necessary for proper administration. Without such an agency adopted, policies will not be executed, and new policies will be presented to the Secretary and secure adoption on a one-sided presentation of the case.

There is one special function that peculiarly belongs to general staff officers which is not fully emphasized in the foregoing discussion. I refer to the exercise of supervisory power in the matter of seeing that orders are carried out after they are issued. The War Department has recognized the necessity for the better instruction of officers in general staff duties by the establishment of the General Staff College. Congress has recognized the principle that only officers thoroughly trained in general staff functions should be eligible for detail to general staff duty by including in the bills for the reorganization of the Army a provision for a general staff eligible list and restricting details to the general staff to those officers whose names are borne on this list.

Jno. C. H. Lee

Major, Corps of Engineers; formerly Colonel, General Staff, Chief of Staff 89th Division, A. E. F.

I think that our general staff system, as it worked out, needs material adjustment, first, as regards its relation to the bureaus and staff department, and, secondly, as regards its relation to the line. Colonel Young has dealt very forcefully with the first problem and has presented the clearest view of the existing system I have ever read. His war experience was near the fountain head—G. H. Q. Mine was with a division. Almost he convinces me, until I remember the low-brow's saying about general staff orders: "Beaucoup are issued—but damn few obeyed."

Colonel Young says "There are only two things the general staff can do—advise or give orders." But who exacts compliance with the orders? The Commanding General? Must he go about crawling junior subordinates? Or the Inspector General? He was at one time, in fact, vested by G. H. Q. orders with responsibility for discipline. Right here is where the "theoretical single mind" with all its magnified G-lobes failed in active operations: too many orders, many conflicting orders, nobody really held responsible that orders were obeyed. Take, for example, a case: G-1 orders the division engineer to keep his entire regiment on communications and handling engineer supplies. G-2 sent out orders for the construction of O. P.'s (two-platoon jobs) and for map work requiring another platoon of men. G-3 ordered engineer supervision sent to each infantry brigade to stake out and wire the position of resistance, also wire cutting details to train with the infantry for the coming advance, and a detachment to report to the artillery brigadier for getting up his guns. Later G-3 sent orders

Digitized by Google

for engineer detachments to report to each brigade commander to construct the successive brigade P. C.'s. And *reports*—each G demanded a report! G-1 happened to see the report with only half the regiment working on roads and bridges. He protested. The engineer remonstrated and finally went to the general with the question: "Who is my boss, anyway?" Can we blame him?

Under a system where twenty or more staff heads are considered responsible to the commander, but where there are between him and them four or more G's, each giving orders to all, any incompetent man can ride along with the excuse that the other "G" told him "differently." If the engineer can't know definitely what his job is, how can anyone else know and see that he does it?

At a stationary headquarters it may be possible to assure results by the functional control system. I am sure that it is most difficult if not impossible in a division staff. The functional theory is like higher mathematics. Highly trained minds "hive"* it, talk it, think it, and seem to get results with it. A mathematics student thinks he hives it too—as we did at the Engineer School when we heard Dr. Steinmetz talk electricity in terms of the calculus. But when we start to explain that to, and apply it with the low-browed soldier—it can't be done. To a combat soldier the functional system seems to require an ideal condition among the commander and his general staff—ideal in temperament, training, and well-nigh telepathy—if the theoretical single mind is going to function over the line and the staff. Also it requires ideal subordinates, capable and willing to obey all orders, or to report the facts when orders are not obeyed.

In war we must make our work *simple,* so that each man can know clearly what his job is, what he has to do his job with, and who is his boss to hold him up to it. I feel that this is the basis of sound staff organization, and without sound organization we can't expect results in hard campaign.

[The Discussion of Major Lee's article follows in the next column.]

Cost of Levee Construction in Louisiana

The earth utilized in building the levees of Louisiana, by the levee districts, and the state, during the past two years, has continued to be moved mostly by power-driven machinery, the latter still standing first in place of volume of work performed; that performed by scrapers drawn by mules, second, and by men with wheelbarrows, third. The percentages, according to the recently issued report of the Board of State Engineers, were as follows:

By power-driven machinery, 65 per cent; by scraper drawn by mules, 30 per cent; and by men with wheelbarrows 5 per cent.

The average cost of the levee work performed by the levee districts and by the state, by all methods, during the past two years was $0.30 per cubic yard; and by the three methods named, as follows:

By power-driven machinery, $0.215 per cubic yard; by scrapers drawn by mules, $0.46 per cubic yard, and by men with wheelbarrows, $0.31 per cubic yard—*Engr. and Cont.*

Working Speed of Tractor

It is an established fact, states the April report of the Nebraska Department of Public Works, that the working speed of horses is from 1½ to 2 miles per hour, while the working speed of a tractor is from 2½ to 3½ miles per hour.

*"Hive"—West Point slang: to discover, appreciate, or understand.

Staff Organization and the "Theoretical Single Mind"

(Continued from Page 512)

Discussion

Douglas MacArthur
Brigadier General, U. S. Army; formerly Chief of Staff and Division Commander, 42d Division, A. E. F.

The purpose of organization is one of the most important and interesting of subjects, and yet one of the least understood in the service. Too many even of our brilliant officers believe that it means merely the accumulation of personnel and releasing to that personnel the authority to write "By order of . . ." It, of course, should be the means whereby a single controlling head makes known and puts into effect his ideas and policies. Unfortunately, however, the average commander, instead of outlining definite policies to his subordinates and relying upon them to carry out the details thereof, delegates to them the authority to determine the policy itself. Having "decentralized" to this extent, the commander too frequently begins to interfere with many of the minor details which are properly the functions of the subordinate. Most of the mistakes that the American Army has made in the last thirty years, both before and during the World War, can be traced to a wrong conception and application of organization. There has been no mechanical framework which made it possible for the ideas of the commander to be translated down through all ranks, the substitute therefor being the conglomerate ideas of dozens of men speaking in his name with conceptions frequently unknown to him and generally unco-ordinated. For success, there can only be one head to any one organization.

John H. Parker
Colonel, Infantry (A. E. F.).

The theory of a composite directive mind, "a theoretical single mind," composed of a general and a selected group of staff officers, is German, is utterly discredited by the German debacle, and could never find a supporter except on the hypothesis that competent commanders will not be available.

The fundamental error is that responsibility cannot be fixed upon individuals under such a system. The very theory of titled figureheads to be carried to success by technically trained assistants was the origin of that doctrine in the German army. The results require no comment. From conception of war aims, through selection of the time to strike, and conduct of operations during the war, down to the pitiful "bluffing" of inability to maintain public order in Germany with a force that the Junkers claim was not whipped, the same thread of error runs all the way.

The value of the mark is eloquent testimony that the Germans were "whipped." To the end of the fighting their forces were not only numerically superior at all points of contact—in the Argonne my single National Army regiment met and licked and took prisoners from four different regiments of the Prussian Guards, and our experience was typical—but also better trained, better equipped, and better managed in every element of staff service than ours. The men we captured were real soldiers, "Veterans of fifty victories," as they boasted at Seicheprey. The failure of German arms did not result from any failure of the German soldier as a fighting man. At Gesnes on the 29th of Sep-

Digitized by Google

tember, when my regiment, that got its machine guns, automatic rifles, trench mortars and hand grenades within 200 yards of the German line on the 26th of September, ten minutes before zero hour, broke the German line, the bayonets flashed into the machine gunners of two German machine gun nests within 24 paces, as I fell. The German soldier fought his guns until he was bayonetted at his post.

This rule was general.

Their failure, then, cannot be ascribed to their soldiers, and must be placed on their system of command, which was based on the vicious idea of "A theoretical single mind."

The essential weakness of structure in this theory is the utter impossibility of *fixing responsibility.* It is a system cunningly devised for the very purpose of enabling "titled figureheads" to avoid all responsibility for erroneous decisions, but enabling them to claim all credit for success, and to ruthlessly "break" and discredit any individual who threatens to become prominent enough by his success or superior intelligence to endanger the credit to be allotted to these "titled figureheads." The German system was designed for just that purpose, and it failed because it was fundamentally, inherently, viciously, fatally defective. The same defect ran through their social, political, and diplomatic structures.

The German system was fastened upon Fort Leavenworth years ago, at a time when German propaganda had convinced many American officers of the correctness of the German claims that all the military knowledge and science in the world had been absorbed and predigested by the German General Staff, and that this German prepared military pabulum was the only possible diet that could be digested by the American School for Staff Officers.

I have very often heard distinguished Leavenworth graduates expound the theory that the "titled figureheads" of the German Army would find their prototype in "Political incompetents" in the American Army in time of war.

The proponents of this idea were very much in earnest about it. They were convinced that they were right. Their motives were beyond criticism. Their desire for American success was beyond question, and they were most eager to do all in their power to promote that success—even to sacrificing themselves in the obscure performance of the ungrateful duty indicated for such staff officers in the German plan. And many of them graduated from successful performance of such duties to the command of troops, as replacements could find opportunities for such service, thereby illustrating the true American spirit which always seeks the post of danger and of opportunity, and which could not be wholly destroyed even in those who were betrayed into acceptance of a false and dangerous doctrine by German propaganda.

The Leavenworth schools are now busily engaged in preparing a purely American doctrine.

The doctrine of a "theoretical single mind" finds its best illustration in that hoary military anachronism called a "Board"; that useful device for avoiding individual responsibility under the form of collective action. When the conclusions of "Boards" are not the action of a single dominant mind they are invariably compromises, and compromise action always represents the minimum of right, the maximum of delay in reaching a conclusion. A board is a long, narrow, wooden object. Is it possible that the term "Board" came into military use by analogy?

The system of a composite directive mind, "a theoretical single mind," has all the advantages and all the drawbacks of a "Board."

In point of fact, our tactical blunders in France were usually the blunders of staff officers, actually "functioning for and in the name of" their chiefs.

I do not recall a single case within my personal knowledge where an American general officer ordered in person an operation that was a tactical blunder. I know personally of various incidents where zealous staff officers, invested by this hideous and pernicious doctrine with authority to give orders of their own motion, but in the name of chiefs ignorant both of the conditions and the orders being thus given in their names, either consummated egregious blunders at the cost of human lives or were prevented from doing so by the sounder judgment and wiser action of regimental and brigade commanders, their seniors in rank and experience, their superiors in every way as soldiers and officers, from every standpoint except the erroneous assumption that the staff officer, as a member of the "composite" "theoretical single mind," was in some way thereby made superior.

The true "operations staff" of a commander is composed of his unit commanders, and not of clerks and messenger boys.

These commanders are responsible. Any theory that makes them in any manner subordinate to any staff officer, that makes them serve two or more chiefs, that leaves in their minds the least doubt that every order received by them is in very truth and very fact an expression of the single and individual will of their immediate superior—and of no other person—any such theory is based on false premises or false deductions, and will lead to disaster in our service, as it did in the German service, if made the foundation of our organization.

When orders received do not cover a situation, and where action must be taken before the will of the commander, in person, can be known, it is *the responsible unit commander himself, and no other person, who must make a decision and on that decision must act.* No staff officer, no matter how high in rank, no matter what his position, can divest the unit commander of this *responsibility.* The only means of escaping it are death, and devolution of command; and in either case the same responsibility passes to the successor in command. It cannot, under any conceivable circumstances, devolve upon any staff officer. If the staff officer actually knows the will of the commander and conveys that will to the unit commander, then the decision is that of the superior. But if the staff officer assumes to give orders when he does not know the commander's will, then he is guilty of the most damnable crime possible—that of attempting to destroy the lawful organization of military administration in time of war, during a critical tactical situation, in the presence of the enemy. For this offense any staff officer who commits it should be summarily shot.

With these few comments interpret my attitude as a rather earnest endorsement of the views expressed by Col. Lee.

Chas. E. Kilbourne
Lieutenant Colonel, Coast Artillery
Lieutenant Colonel, Chief of Staff, 89th Division, A.E.F.

Major Lee's presentation of this important subject, is of course, entirely sound. Success depends upon each responsible officer from the division (or higher) commander down to the corporal having a definite job. And it devolves upon each responsible officer so to allot the work among his subordinates that nothing important will be overlooked. In my opinion, nothing makes more greatly for success than for each officer to anticipate, as far as is practicable every contingency and place the responsibility upon a subordinate, thus leaving the higher commander free to

Digitized by Google

to meet, with a clear mind, the new emergencies which are certain to arise and which it is impossible to anticipate.

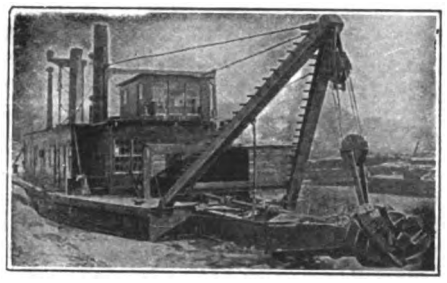
I do not believe there is any great difference between the doctrine of the service schools and that stated by Colonel Lee. The General Staff officers are practically part of the commander's mind, in that they relieve him of all the fatiguing study, laying before him all information in such thoroughly digested form as will permit him to come to a wise and prompt decision without having to consider an infinite number of details, and seeing that his decision is carried through to conclusion. I believe, also, that occasions will arise where the staff officer, knowing the commander's plans not only to the extent published, but also beyond the point it may be advisable to announce them, must give orders "in the name of the commanding general." All general officers I have served under have expected this of their staff officers.

Stephen O. Fuqua
Lieutenant Colonel, Infantry, A. E. F.; Chief of Staff 1st Division

The principles enunciated in this article are seemingly sound, particularly those on Organization. In fact, most of them are military axioms which have long been accepted and advocated by military men. However, the application of these principles is necessarily varied. The author, in this article, builds a staff structure at variance with the very principles enunciated as his foundation stones.

It is difficult to get the author's ideas of the function of a chief of staff. He says, "The division commander holds his tactical assistants (brigadiers) responsible for the tactical details of the work, while holding his staff assistant (chief of staff) responsible for all staff details." From this one draws the idea that the author believes that the division commander drives, metaphorically speaking, four reins—three tactical and one staff. Further on in the article we find the author appreciating the intended mission of the chief of staff, but only to a limited degree. He says, "The division commander having made his decision, the chief of staff must see to it that the G-3 officer supplies a comprehensive order expressing the commander's wish to his tactical assistants and to the chief of staff." Still further on the author states the true mission of the chief of staff. "As for the chief of staff, his duties and responsibilities demand an officer of caliber at least equal to that of the brigadiers. His responsibility, if anything, is larger, and his training should have been even more varied than that of a brigade commander, while being in all respects thorough, *he is the division commander's first advisor and should be a man in whom the commander and the brigadiers have confidence.* The italics are those of the commentator and are made use of to emphasize that this is exactly the function and qualifications of a chief of staff in capsule form, and with which the Staff Manual and the Leavenworth doctrine are in accord with the author. This principle announced by the author and given structural form would not place the chief of staff as one of the four "assistants" to the division commander, but would make him what all military students, including the author, intended him to be—the principal advisor to the division commander. The author's idea in the first pages of this article is seemingly to separate the chief of staff from operations, the division commander dealing directly with the three brigade commanders. This idea of divorcing the chief of staff from operations is very wrong and certainly antagonistic to the very best thought on staff organization. It is true that the division commander should deal directly with his brigadiers—his three tactical assistants as the author refers to them—whenever practicable; but, if possible, the chief of staff should be present at these conferences to advise his division commander whenever called upon in matters pertaining to disposition of troops, supplies, ammunition, relation of movement or plan to neighboring troops, etc. However, the normal case will be in those fleeting moments when rapid decision and quick execution are demanded—when the "tactical assistants" are not available for conferences, or when they are out "on the job," when reports from the "tactical assistants" are local in character and require proper interpretation and co-ordination—then the chief of staff functions as a gatherer of information from the sources available at his command, formulates an estimate of the situation and constantly keeps his commander confronted with that situation, being prepared at all times to present a true estimate and a sound plan. The chief of staff should be the executive officer of the division and the medium for the transmission of the will of the commander to staff or troops as well as a co-ordinating agency which insures the proper functioning of the whole machine.

I believe that in campaign there is a certain amount of detail work, especially in the G-1 section, which should be taken up directly with the corresponding G section in the next higher unit without first addressing either the commanding general of the division or the commanding general of the corps. This would apply, however, only to details of working out a plan which had been adopted by the corps and communicated to the division in which the division commander was aware. I believe that the division G-1 should not be allowed to deal with the corps G-1 on anything which would change the principle or plan which had already been adopted. It seems, however, to me not to be expected that a division G-1 having a question, for example, of additional facilities for supplying his division be taken up with the corps commander through the division commander. The question can be settled by direct communication between the division G-1 and the corps G-1 so long as the principle involved is not altered.



I do not agree with the author's statement to the effect that a staff officer's responsibility ceases after delivering an order to a tactical command. His next immediate duty after delivering such an order is to follow it through and see that it is executed, and if not executed, advise the division commander of what has or what has not been done.

With reference to the author's subdivision of the duties of the G-1 section, it does not seem feasible to me to have any officer actually in command of troops an assistant in the staff section, such as the author proposes in his third, fourth and fifth subdivisions of the G-1 office. The G-1 office should have in it an assistant who would coordinate the work of the engineers, commanding officer of trains and the division surgeon, but these officers themselves should not be assistants.

I believe that the subdivision of duties as indicated in the Provisional Staff Manual is an improvement on Major Lee's ideas.

With reference to the division munitions officer, I do not agree at all with the author and am firm in my conviction that the division munitions officer must be in the G-1 office and that the motor train of the division must function under the G-1 section through some immediate line officer, such as the commanding officer of trains or the M. T. O. If the Field Service Regulations are to be followed, I would say that the munitions officer must be on the staff of the

field artillery brigade commander and not, as the author states, in the ammunition train.

The Chemical Warfare Service officer is now a chief of technical service as well as a staff officer, and should have the same relative position on the staff as the division quartermaster.

With reference to the author's remarks concerning relative rank of officers on the staff, I do not believe that the best interests of the service warrant the use of a colonel in that capacity. As a matter of fact, the way G-1 and G-3 and G-2 will function will depend, first, upon the chief of staff, and, second, upon the personality and ability of his three assistants and not on their rank. The assumption is, of course, that if a colonel is placed in G-1, it means that G-1 office will be in command of an officer who is of greater experience than would be the case if it were in charge of a lieutenant colonel. Still I believe that a lieutenant colonel has had sufficiently varied service to insure a successful G-1 section. As a matter of fact, I believe that a level-headed and capable, well-balanced major could perform the duties satisfactorily. There should not be any friction between the G-1 section and the engineers, for example, simply because the engineers are commanded by a colonel and the G-1 section by a major or lieutenant colonel. It is essential that both understand the difficulties and desire each to co-operate with the other. Sympathy, co-operation and understanding between the G-1 section and the technical services is the essential point. It is not a question of relative rank. Probably, one reason why general staff officers are said to interfere in the line of command and to handle matters in their own names, is because of their high relative rank in organizations.

In the division of intelligence duties I think that the reconnaissance section should be divided into a topographical section and an observation section. The topographical section should come entirely from the engineer regiment to division headquarters, subject to call, and its duties should concern maps only. The observation section should be in charge of air and ground reconnaissance; this would make five subsections instead of four subsections in the intelligence section. In Major Lee's fourth subsection in the intelligence section is included "mail," this duty is generally handled by the division adjutant. If any mail seems subject to censorship, it is turned over to this section for action. The routine of handling mail, however, should not fall under the intelligence section.

There is no question in my mind but what the present organization, outlined in our Staff Manual, intends that the commander should command in every sense of the word. It is certainly not contemplated that the general staff officer shall assume any command nor that he should issue any orders of great importance without either tacit consent of his organization commander or a complete understanding of his organization commander's mind that would cause him to assume the responsibility to act for his commander during his absence. I am sure that all of the principles of organization outlined by Major Lee are considered in our Staff Manual, and that our present organization, with some slight changes, admits of the carrying out of all of these principles. A great deal depends on the subdivision for assignment of duties by the division commander and the chief of staff.

W. Goff Caples
Major, Engineers; formerly Colonel, Division Engineer
1st Division, A. E. F.

Staff relations are important matters. The system of giving what amounts to a command to the G's, is indefensible and insufferable. As a rule the G's will be found younger than, and junior to, the other staff officers. This case was particularly aggravated in the recent war where many of the G's of the divisions had practically no experience at all. No man can keep his self-respect and be under the command of an officer many years junior to him both in age and rank. If the G's are to exercise command, they must be the officers next in seniority to the chief of staff, who, in turn, under such a system, would have to be next in seniority to the general. If the system, as it existed in some divisions, is to be continued, there is no choice left an officer except to get on the general staff himself, or throw away his last vestige of self-respect. A division staff officer, and particularly the division engineer, must have dealings with every one of the G's. Without early and thorough knowledge of the G-3 plan it is frequently impossible to make the best use that could be made of the engineer troops. The liaison with G-2 should be an especially active one. Under a system where the G's are co-ordinate with, and not commanders of the other staff officers, there would be no necessity for G-2-C section, which amounts generally to nothing more than a duplication of the work that should be done by the engineers. In matters relating to administration and supply, the engineer has to deal with G-1. In a properly organized system all staff officers should report direct to the chief of staff. The G's should be what they were formerly designated, assistants to the chief of staff, and not assistant chiefs of staff. There is a marked difference.

G. R. Young
Captain, Corps of Engineers; formerly Lieutenant Colonel, G. S. (G-4)
G. H. Q., A. E. F.

Major Lee's article is a valuable and entertaining contribution to our knowledge of its subject. But I believe that, mathematically speaking, he exterpolates his curves too far from a limited number of known points. What will answer for a group of 20,000 men will not do for a group of 2,000,000. On this basis I offer a few comments on his article.

Elsewhere in this issue I have given my conception of existing theories of staff control. Major Lee proposes a revision of these theories.

The essence of the proposal appears to be that we abandon the functional division of staff duties, the so-called "theoretical single mind," composed of the commanding general and his general staff, and adopt an organizational system where certain divisions of the general staff have complete control over certain organizations or elements of the army. Coupled with this is the removal of tactical fighting units from staff control.

Major Lee's article was evidently written from the point of view of the division. My own staff service was entirely with general headquarters of the A. E. F., and it is natural that I should criticise the article from that point of view rather from the divisional.

It then appears to me that while Major Lee's system may be perfectly workable for a division, which is the smallest unit having a general staff, it would present grave difficulties when applied to larger units. To illustrate briefly, consider the analogy of Major Lee's proposed system as applied to the highest command in the A. E. F., namely, the General Headquarters of the C. in C.

The C. in C.'s immediate tactical subordinates commanding fighting units, during active operations, were the commanding generals of the 1st and 2nd Armies. His supply chiefs were grouped at Tours, under the C. G. S. O. S. (an arrangement made necessary by local conditions, and which

Digitized by Google

would probably not be repeated in a normal campaign). Major Lee's arrangement would have called for a chief of staff with five G-sections at G. H. Q. G-1 and G-4, which divided between them the functions of supply, transport, administration, equipment, shipping and overseas requisitions, would one or the other have been in direct command of The Adjutant General, Judge Advocate General, Inspector General, Chief Quartermaster, Chief Ordnance Officer, Chief Engineer, Chief Surgeon and certain minor activities. G-3 would have been in direct command of the Chief Signal Officer. This does not cover all the activities which would thus be controlled, but will serve as an illustration.

G-2 and G-3 would be responsible for the collection of information and for the translation of the C. in C.'s commands into effective tactical orders. The functions of G-5 may not be considered here.

But none of the G-sections, nor the chief of staff, would have any control over the commanding generals of the first or Second Armies, nor over any organizations or echelons of those armies. No one would be interpolated between the Commander-in-Chief and the commanders of the 1st and 2nd Armies.

The functional difficulty of this arrangement would lie in the size and complexity of the units dealt with and the extent of territory covered by them. The 1st Army at one time controlled territory covering probably two or three thousand square miles, in which were a tremendous complexity of supply functions and organizations handling supply matters. It was out of the question that a commanding general of the 1st Army should have an intimate knowledge of the details of the operation of this great machinery; and in fact Major Lee's thesis is specifically that he should not; such matters being delegated to his chief of staff and G-sections. But this supply machinery of the 1st Army tied in, over a line of scores of miles in length, crossed by many roads and railroads, with an even more complex supply organization under the control of General Pershing's chiefs of services in the S. O. S. It was equally impracticable that the C. in C. should be familiar with the details of this latter supply organization, as again is admitted in Major Lee's thesis—and equally essential that it be controlled by the appropriate G-sections at General Pershing's Headquarters.

Now, this line of demarkation between the S. O. S. and the largest fighting army was the most critical point in our entire war machinery from a supply point of view. In order to keep things moving across this line, and to keep the activities on one side co-ordinated with those on the other, it was found essential that the activities on one side be controlled by a single man, namely, the Commanding General, S. O. S., and the service chiefs under him; on the other side by a single man, namely, G-4, of the 1st Army; *and that the two together be controlled and co-ordinated by a single man, namely, G-4 of G. H. Q.*

And this arrangement at once involved the necessity of G-4, G. H. Q., issuing orders, in the name of the Commander-in-Chief, but in most cases quite without the Commander-in-Chief's personal knowledge, to the subordinates of the Commanding General of the 1st Army, issued quite without the knowledge of the Commanding General of the 1st Army. And these subordinates were frequently the very tactical fighting unit commanders, whom Major Lee insists should be removed from the chain of staff control and should receive orders only down the line of direct tactical command.

This variety of absolutely necessary staff "interference" in the chain of direct tactical command often went down several degrees, not simply as between G. H. Q. and an army, but as between G. H. Q. and a corps or division. To illustrate:

On a certain occasion (which might be multiplied a great many times) it was necessary to move a division, belonging to an army, by trucks. It takes many more trucks than are normally assigned to a division to move its personnel wholly by truck. Due to the shortage of trucks in the A. E. F., the greater part of all reserve trucks were held under the control of G. H. Q. What actually happened was that the order went out through due military channels, via army and corps, for the division to move. G-4, G. H. Q., was then notified that it must find the trucks to move it. That office directed a subordinate of the C. G., S. O. S., to have the trucks at a certain point at a certain time. It then directed G-1 of the division to arrange to have his division at that point at that time, and put them on the truck. The orders were carried out, and the division was duly moved. But what actually happened was that a sub-sub-assistant of the C. in C. issued direct orders to a sub-sub-assistant of the C. G., S. O. S., and other direct orders to a sub-sub-sub-assistant of the C. G., 1st Army; and by the latter procedure injected himself into the sacrosanct area of the fighting tactical command; and this without any reference to the Commanding General of the 1st Army, or Commanding General of the corps in question, or the Commanding General of the division in question.

Putting the thing in general terms, I believe that the clear-cut division which Major Lee draws between the fighting tactical units and all other units, as applied to the division, is not applicable at the other end of the line, where one must consider hundreds of thousands of men instead of thousands. In the control of these very large units I believe that there must be a chain of direct staff control from the subordinates of the commander of one unit to the subordinates of the commander of the smaller unit. I believe, further, that this chain must often involve the fighting tactical units, so that instructions will be issued to them, or to echelons of them, by members of the general staff, even of the supply and transport portions of the general staff. It is worth noting in this connection that the fighting tactical units to which Major Lee refers in his article are brigades; and a brigade is exclusively a fighting unit. It has no strictly non-combatant troops of any importance which are an integral part of it. But an army of a million men, though it also as a whole is a fighting unit, has hundreds of thousands of troops forming an integral part of it which are essentially non-combatant, and which must, in the nature of things, be under a dual control, the control of tactical command from the army commander, and the service or staff control from the higher supply staff.

All this, however, is not really intended as a criticism of Major Lee's thesis as applied to a division, but only to the rigid extension of that thesis indefinitely upward. I have heard criticisms and suggestions regarding our staff system, similar to this one, from many officers serving with divisions or even with corps; though I have never seen the matter presented in such a clear-cut way, nor with the essentials so clearly stated, as in Major Lee's article.

I think the conclusion to be drawn is that the strictly functional division of staff duty is proper at the upper end, with the supreme command of a very large force; and that as one proceeds downward through armies, corps and division, its outlines become more and more blurred, until in the division an arrangement is found in effect very similar to that outlined by Major Lee, implying a combination of organizational and functional control, with the former

predominating. Organizational control is much more apt to come about automatically in a small unit, where each *chief* deals directly in such matters with the *chiefs* under him; instead of an office subordinate of one chief dealing with an office subordinate of the lower chief. In the former case the personalities are always the same and work along the same lines; and if Smith is always giving a certain kind of orders in a certain way to Jones, no theory of organization ever written will prevent Jones from considering himself as in effect the direct organizational subordinate of Smith. But where Smith has twenty juniors in his office and Jones has fifteen, and any one of one set is likely to be talking to any one of another set—as happens with the large units—the personal element largely disappears. And where personal contact and personal understanding weaken, there must be an increase in system, theories of organization, military channels, and the other necessary parts of red tape.

It is then my belief that Major Lee's thesis contains material, so far as I am qualified to judge of the matter, for an excellent staff manual for a division or possibly a corps; but that it would hardly be safe to apply it in toto to an army, or army group, and hardly justifiable to revise our staff theories for the higher commands along these lines.

Final Discussion by Major Lee

When the writer prepared his article he realized that some criticism and perhaps even some acrimonious discussion would result. He trusts he is betraying no confidence when he now recalls that such acrimonious discussion was desired by ye editor in order to draw attention, stimulate interest and perchance increase the circulation.*

The writer has only praise for the foresight and courage of the Leavenworth Schools and for the way in which Leavenworth men on the whole developed the A. E. F. organization for General Pershing. Surely, however, even "Leavenworth" learned something during the World War. Without Leavenworth, America would truly have been in a bad way, but this fact does not necessarily mean that the Leavenworth doctrine is perfect. True greatness admits of advancement and progress, admits of scrapping worn-out ideas for newer and sounder ones. Is it not possible that the time has come to consider replacing the German general staff principles by sound American organization? True, all European staffs felt the influence of and in the past have largely followed the German School, the dominant military influence of the past generation. But that is now history. The Kaiser's wish is no more the most rousing and convincing way of expressing an order. Europeans will cling longer to the influence of royalty, the wish of the king, or the command of the general. With us Americans, however, this hero worship carries relatively little weight among efficient men. We prefer to get our orders from our immediate boss himself, the man who best knows what he is talking about.

It is not easy to express oneself in a single article on such a broad subject. For example, there is no intention of divorcing the chief of staff and G-3 from operations. They are, of course, the commander's tactical advisors. And G-3 does the tactical hack work for the general and attends to details so far as the division is concerned (but not brigade or regimental details). The main point at issue is that *neither* G-3 nor the chief of staff can *control the troops*, the line troops, the troops that are commanded by the brigadiers. To see this, the reader should try to picture himself in the brigade commander's position. Both at home and in the A. E. F. the writer saw a strong tendency for the division commander and staff to assume the brigade commander's prerogatives, to give him detailed orders, to undercut him by dealing with his colonels. This wasn't done so much with the artillery, for usually the staff knew relatively little about the artillery. The old army tendency was that of the colonel meeting the company commanders at officers' call, undercutting the majors, just as the division commander began to undercut his brigadiers. A good brigadier can do a lot for the division commander in a fight, but no one can tell whether the brigadier is good or not unless he is given full responsibility and is held up to it.

The second principal point at issue is that the staff chief *commands the staff*. He doesn't have to give staff orders in the name of the commander. In all the foregoing discussion no question is raised about this. If such is accepted, the writer is very glad, for he considers it to be of importance secondary only to the aforementioned: viz, that the staff does not control the line.

The writer believes in all that General Moseley says and also admits the points made by General Conner, except it is felt that sound American staff development should be along clear-cut organization lines—not functional. General Conner's plan of four G's in every staff from battalion to G. H. Q. is very thorough. While he is eliminating The Adjutant General's Office the writer would also eliminate the Inspector General and make the true inspector, the unit commander, the Inspector General for each unit all the way down.

The writer can not agree entirely with Colonel Tyner, Colonel Fuqua and Colonel Eltinge. They express certain ideas that seem fundamentally opposed to sound organization built upon responsibility and command. The writer first wishes to say, however, that he agrees fully with Colonel Fuqua regarding the general duties of the chief of staff, his advisory duties to the commander. The writer regrets that his article is capable of such misinterpretation.

When Colonel Fuqua says that the staff officer after delivering an order must next "follow it through and see that it is executed," he is, in the writer's opinion, gravely undercutting the brigadier. The writer is glad that Colonel Fuqua thinks that all the principles of organization mentioned in the article can be admitted into our present staff system.

In Colonel Eltinge's example (*b*) he cites a typical case where, as the line sees it, the G's "frame up a show" and put it over on the brigade commander. To quote Colonel Eltinge: "It is up to G-3 to give all the necessary detailed orders and to *supervise their execution*" (!?!)

Colonel John Henry Parker speaks feelingly as a line soldier, even if he is a graduate of Leavenworth. The writer believes that many other line commanders of the A. E. F. feel the same way about it.

The writer has derived much of his staff knowledge from Colonel Kilbourne. As he says, many times will come when the staff officer will have to give orders in the name of the commander because the staff officer through his closer association knows better the commander's plan, intentions and responsibility. The staff officer is merely expressing then the commander's will as he best understands it. If in doubt he should discuss it with the brigadier, who will know more about the immediate situation in front. As loyal subordinates to the commander they will try to arrive at the decision he would make, and then carry it out.

*Major Lee betrays no secrets. To "increase the circulation" is, or should be, the aim in life of every editor. Differences of opinion, especially if tinged with good-natured sarcasm, not carried too far, *appear* to produce the desired result.—*Ed.*

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

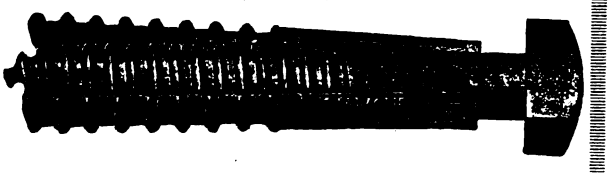
Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.



When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

But always it is the commander, his will, that controls the troops.

The writer has already commented on Capt. Young's excellent article. He makes no claims to knowledge of higher units, but sees no reason why the G-4 of G. H. Q., who should command the S. O. S., should not be able to deliver to the Army G-4 at the distributing points (advance depots or rail heads) just as dependably as a divisional G-1 delivers his supplies to the regimental supply officers at their distributing points. The principles are the same, and the writer would think that the higher the echelon and therefore the more complex the plan, all the greater need for clarified organization, responsibility and control. As to army truck moves, the writer saw the other, the "bitter," end of them. They were far from smooth, usually confusing and often chaotic.

As General MacArthur says, "The purpose of organization is one of the most important and interesting subjects, and yet one of the least understood in the service." Our army generally has failed to develop and maintain real interior organization. Our regulations talk of squad control, but on the very next step (the sergeant's command) the system breaks. True, in garrison, there seems to be no need for it. We become victims of expediency. We get immobilized and drift into stationary habits of peace time. It is feasible for one company supply sergeant to hold the clothing and equipment memo-receipts for all the company. One officer in the troop can be responsible for all the animals; one for all the guns and materiel of the battery. Platoons are recognized only at drill, and then are changeable. It is "easier" and therefore excused as "more efficient." Post headquarters deals with a dozen or more subordinates directly—or through the loose paper reins of the adjutant. Within the limits of the reservation and the Regulations, the quartermaster, the range officer and a dozen other staff officers can't go far wrong, and it is "easier" for the post commander to handle them directly. Similarly it is "easier" for the regimental commander and staff to deal directly with the company, troop or battery commanders. But witness the confusion when the garrison takes the field. There is no flexibility to meet the constantly changing condition of campaign. There is no sound organization.

Thus did war find the Regular Army. For the large part we had to forget the way we were accustomed to, realize that we had been blind to the demands of war, and start over again. Instead of the crisis finding us with strongly organized military character, based on years of sound habit, so that in full stride we could lead forward the men who joined us to learn—we had to stop, reconstruct and then stumble forward, trying to teach that which we were really learning ourselves for the first time. And the result was that the great new American Army had most of the faults of the old Regular Army—and the greatest of these was disorganization. Young company and battalion commanders wore themselves out, broke down and even committed suicide, because they were doing the N. C. O.'s work. They didn't know and didn't use their interior organization.

There has been much talk about handling men—and about West Point methods. Here is a definite fact. The cadet in the past has lived through four character-forming years with no true example of sound interior organization ever shown him. There has been no squad organization in the Corps of Cadets. In ranks, squads were formed for appearance at parade, and for as trivial reasons broken up. The squads never lived together, going on guard as squads, the corporals having no responsibility, nor the sergeants, nor the lieutenants, as such! The "tac"* really did it all. For four years, the cadet wasted a splendid opportunity to learn as second nature the true value of interior organization. The first principle of efficiency in handling men is to give the man a job he can handle and then know how he does it, and let him know that you know how he does it. It is little wonder that cadets never learned this. They should learn it by four years of habit so that it becomes as lasting a characteristic as honor and industry. If this were done, if true interior organization were recognized throughout the service to be worth the price of effort, if not, indeed, as essential to training and character making, we would take a long step forward and earn the compliment we used to feel we deserved—"good organizers" and "able to handle men."

Simple Plant Makes Good Record in Dam Construction

With a force of approximately 21 workmen, aggregates have been excavated, hauled, crushed and screened and concrete has been mixed and placed at the rate of 300 cubic yards in an 8-hour shift at the Devil's Gate Dam, one of the structures being built by the Los Angeles County Flood Control District.

About 17,000,000 cubic yards of gravel, sand and rock had to be removed in preparing the foundations for the dam proper and in excavating the spillway. About 9,000 cubic yards in the dam foundations were handled by a guy-derrick having an 85-foot boom and operating 1 cubic-yard skips loaded by hand. One foreman and 12 to 16 men loaded about 100 skips in an 8-hour shift. The spoil was piled just above the upstream face of the dam and will be leveled off to form a fill against the masonry. A high promontory, against which one end of the dam abutted, was selected for the site of the crushing plant, material bins and concrete mixer.

Suitable materials for concrete were found in the bed of the arroyo about 1,500 feet above the site of the dam. The sand and gravel, and boulders up to 16 inches in diameter, are loaded by steam shovel, having a ¾-cubic-yard dipper, directly into dump trucks to be hauled to the mixing plant. A gyratory crusher that will handle rock up to about 16 inches in diameter is located beneath the truck dumping platform and all materials from the trucks go through this crusher. From the crusher the materials are taken by a 70-foot elevator to screens on top of the bunkers. These screens separate as sand all material up to ¼ inch in diameter. That which falls through the screen, with 3-inch perforations, is classified as rock, and larger material passes on to another gyratory crusher which reduces it to 1-inch size for use in the tunnel, or elsewhere where reinforcing is used. The supply of over-sized rock from the big plant is quite uniform and well within the capacity of the small crusher, and after passing through this crusher the rock is taken to bunkers by a conveyor.

From the screens the sand and rock drops into bins located above the hopper of a 45-cubic foot mixer which, in turn, delivers to a spouting system running out over the dam. Three cables span the gorge directly over the dam. Concrete chutes are suspended from the cables by block-and-tackle, so that they can be adjusted to the desired height or swung to position over any portion of the dam. About 75 per cent of the total concrete yardage can be poured directly from the mixer into the dam.—*Eng. News-Rec.*

---

*"Tac"—West Point slang for the army officer assigned to supervise the instruction of a company of cadets—a "tactical officer."

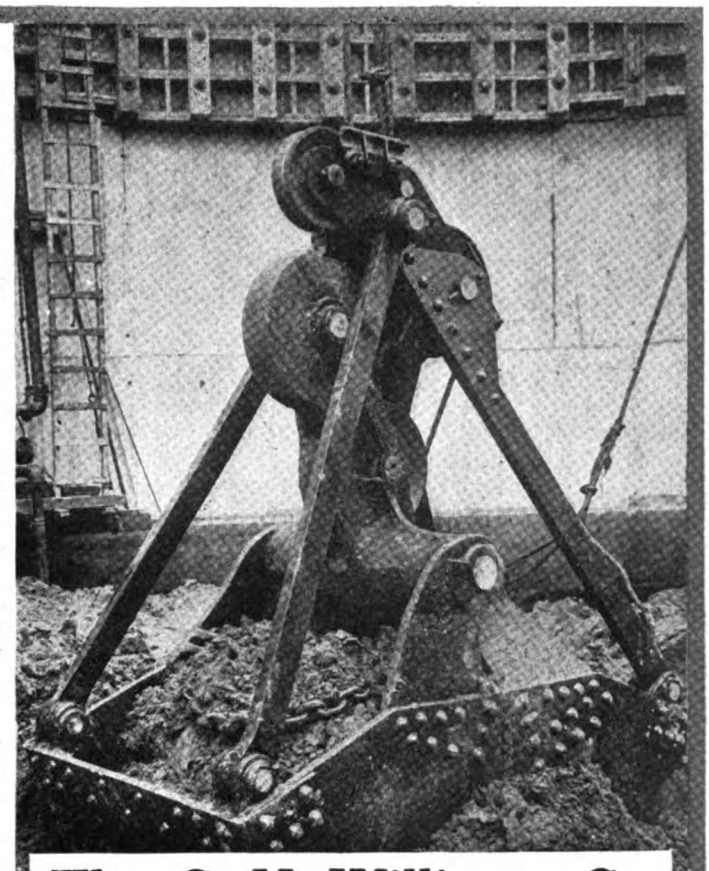
Williams Buckets

Simple, Speedy, Efficient and Easy to Operate

WILLIAMS BUCKETS are built to meet any condition. That is one reason why you will find them in use by all large steel plants and contractors in the world, by the United States and French Governments.

Note its sturdy, all-steel triangular construction—that insures rigidity and perfect alignment of all parts. Large bearings and fewest parts are other features. These with perfect lubrication reduce friction to a negligible quantity.



And remember we build them to dig—in addition to economy of operation, long life and *low cost of upkeep*.

Let us send you *full* details, including catalog.

Wanted! Back Numbers of "The Military Engineer"

Because of the great demand for No. 62 (March-April, 1920) of the MILITARY ENGINEER by our new members, the supply of this issue is exhausted, but the demand continues.

We will pay 40 cents plus postage for each copy of No. 62 returned to this office with the name of the sender.

Address

The Military Engineer, 423-425 Gee Street, Northwest Washington, D. C.

WESTERN

In War or In Peace

Two factors of civilization can be depended upon absolutely, *in War or in Peace*---Military Engineers and Western earth-handling equipment. Developed in Peace, both have been tried in the furnace of War, *and they made good.* Working together, there is nothing in the field of construction which they can not accomplish.

Many of you Military Engineers, in action yourselves, saw Western Dump Car Equipment in action. Did you have time to note why Western Air Dump Cars made good so superbly?

They are conscientiously built, of the best material obtainable
Their superior mechanical design gives them a steeper dumping angle and larger discharge opening
Their simplified air-dumping device gives them more than 30 per cent greater dumping power than cars of other makes, with no greater consumption of air

These are a few of the reasons. Others will be found in our new Dump Car Catalog, No. M E 51, just out. We very much want every Military Engineer to have a copy on file. *Send for it!*

Working together, Miltiary Engineers and Western Equipment can reconstruct the World

Western Wheeled Scraper Company

Austin Road Rollers are Everywhere

IT is a significant fact that wherever roads are built, Austin Rollers are high in the favor of the builder. They have proven themselves to be safe and dependable and entirely satisfactory for every phase of road roller operation. They are built in three types, Motor---Tandem---Steam, and each is a leader of its line.

Illustration shows a group of nine Austin Rollers used at Camp Kearney, California, during the late war. It is an interesting fact that during that period the United States and Allied Governments purchased over 700 Austin Motor Rollers, more than ten times their combined purchase of all other rollers and at higher prices.

Wickes Blueprint System

FOR DISTINCTNESS

Above all else a blueprint must be distinct—a single decimal point or figure misinterpreted may result in a catastrophe.
Protect your job, your workmen and yourself by getting absolutely distinct Prints.
Use the WICKES SYSTEM. It is consistently reliable in accuracy, distinctness and clearness. No blotches or faded lines, to mar its strength of tone.

Let us send you our catalog

BAYER Valves

BAYER Valves are made in heavy-pattern regrinding globe, angle and check types, screw and flanged ends—all good for working pressures up to 225 lbs. Each one is guaranteed to meet the metal composition requirements of U. S. Navy Department specifications 46-B-8, June 20th, 1913, covering valve bronzes or composition "M."

Body walls are of liberal thickness, with a uniform distribution of metal. Valve seats are radial, and can be ground continually, thus prolonging the life of the valve indefinitely. Discs are made of a hard bronze composition; stems are unusually heavy with a greater number of accurately cut threads than usually found in valves of this type.

Naturally, continued satisfaction is the only logical result that can follow adherence to the BAYER standard. Send for our book "The BAYER Valve."

BAYER VALVE COMPANY

LOCOMOTIVE CRANES
CLAM SHELL BUCKETS - SHIPBUILDING CRANES
CAR DUMPERS PILE DRIVERS
THE McMYLER INTERSTATE CO.
CLEVELAND OHIO

THE LARGEST CRANE AND THE LARGEST STIFF-LEG DERRICK

The crane shown, which lifted 505 tons at one time, is in operation in the Philadelphia Navy Yard, where it was erected by the aid of the largest stiff-leg derrick ever constructed.
The height of the crane is 235 feet, while the derrick is equipped with a boom 252 feet long.
Both the crane and the derrick were designed and built by THE McMYLER INTERSTATE CO.
By those who are uninformed, this crane installation may be accepted as an index to our possibilities.

THE McMYLER INTERSTATE CO.
CLEVELAND, O.

The Field Artillery Journal

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bi-monthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

Address—

The Secretary
United States Field Artillery Association
War Department, Washington, D. C.

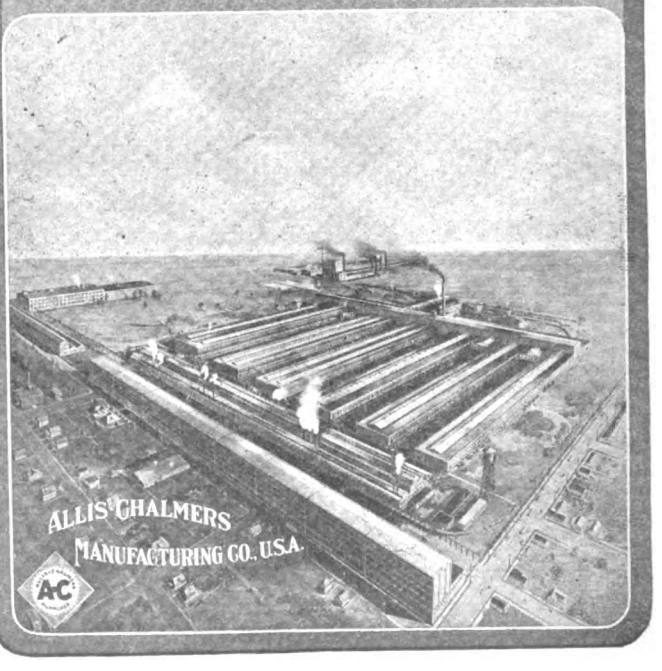
Allis-Chalmers

ORGANIZATION



Principal Products:
Air Brakes
Air Compressors
Cement Machinery
Centrifugal Pumps
Condensers
Crushing Machinery
Electric Hoists
Electrical Machinery
Farm Tractors
Flour Mill Machinery
Forgings
Gas Engines
Hydraulic Machinery
Oil Engines
Reciprocating Pumps
Rolling Mill Machinery
Steam Engines
Steam Hoists
Steam Turbines
Sugar Machinery

The Allis-Chalmers organization is so interlocked that all its functions work as a unit toward obtaining maximum results. The engineering and commercial organization is divided into the following departments, each department having its own manager and engineering specialists:

Electrical, Steam Turbine and Pumping Engine, Engine (Steam, Gas and Oil), Mining Machinery, Crushing and Cement Machinery, Hydraulic Turbine and Centrifugal Pump, Milling Machinery, Farm Tractors.

These departments are interlocked by a standardization department, for the purpose of keeping each group of engineers in touch with developments of design, of inter-department apparatus, in order to minimize the development expense and bring about the use by all departments of the design of standard accessories.

ALLIS-CHALMERS
MILWAUKEE, WIS. U. S. A.

The Roads of Alaska

Work of the Alaska Road Commission

By

James Gordon Steese

A. M.; F. R. G. S.; Major, Corps of Engineers
President of the Commission

[NOTE—In this entertaining article Major Steese, President of the Alaska Road Commission, gives a vivid picture of the road construction in our far off territory, the difficulties under which the work has been done, and its great influence over the development of a new country where, as always, transportation is the most urgent need.

To the military man the article will be of special interest, for it will be observed that the roads of Alaska are built on strictly military principles—built to meet a situation, which has been well met.

The striking characteristics of the roads of Alaska, as brought out in this article are: first, the adaptation of road building methods to actual conditions; second, the *intensive use* of roads, the few crude roads of Alaska mean more to her economic life than those of any other state; and third, the astonishing economic results from a very small expenditure, an example and inspiration to all builders of roads, not as roads alone, but as vital routes of transport.

In a later issue it is hoped to present another article on Alaska's roads, describing the methods of construction and some of the difficulties that have been met and overcome.—ED.]

THE development of Alaska, as of any other pioneer country, is dependent primarily upon facilities for land transportation. Without trails, roads, and eventually railroads, there can be no progressive economic development. Unlike large areas in the western United States, where wagon, or even automobile travel can pass almost without hindrance, in Alaska wheeled transportation is, in almost every locality, quite impossible until roads have been constructed. That lack of transportation, more than any other agency, is retarding the development of Alaska, is conceded by all who are familiar with Northern affairs. In the interior, the great cost of moving freight by teaming or packing, together with the difficulty and uncertainty of moving it at all, constitutes the main obstacle to the growth and development of the district.

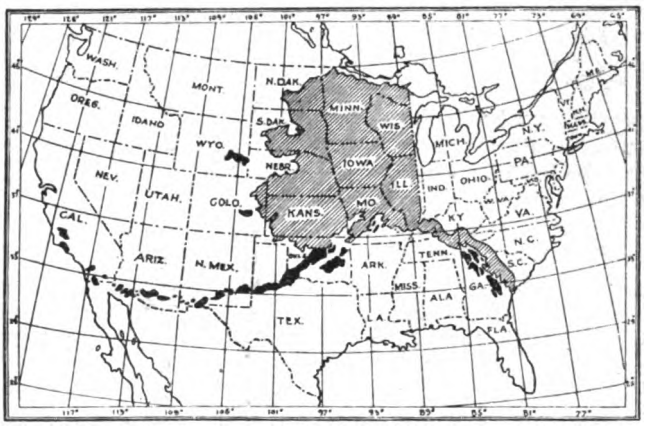

Fig. 1. Alaska super-posed on the United States

The bulk of the road and trail work in Alaska is concentrated under the control of the Alaska Road Commission. In addition to its own funds, it expends the major portion of the appropriations of the Territorial Legislature for roads, bridges, and trails. Considerable money appropriated for the Department of Agriculture, and limited in its application to the Chugach and Tongass Forest Reserves, has been expended by the Alaska Road Commission. By close co-operation between it and the above two agencies, having limited funds for road work, the entire road and trail program is co-ordinated, and all money is spent upon a consistent system without duplication of effort and only slight increase in overhead expense.

Board of Road Commissioners for Alaska

Gen. Wilds P. Richardson, U. S. Army, was the first President of the Alaska Road Commission, and remained at its head from the time of its first organization, in 1905, until December, 1917, when he was called to overseas service in the Great War. As reorganized since the close of the War, the Commission is now composed of three officers of the Corps of Engineers of the United States Army; Maj. James G. Steese, President; Maj. John C. Gotwals, Engineer; Capt. C. S. Ward, Secretary and Disbursing Officer. The Commission reports to the Secretary of War through the Chief of Engineers, U. S. A., under whose direction River and Harbor improvements and other public works are constructed and maintained.

Location and Description

The principal office of the Commission is at Juneau, Alaska. District offices are maintained at Valdez, Seward, Fairbanks and Nome. The work committed to it by law is the location, construction, and maintenance of wagon roads and pack trails from any point on the navigable waters of the Territory of Alaska to and between towns, camps, and settlements therein.

Alaska has an area of 590,880 square miles, which is more than twelve times the size of New York State, or practically one-fifth the size of the entire United States. At its southern point it is 700 miles from the northwest point of the State of Washington by the usually traveled route. Thence the southeastern Alaska Archipelago and a strip of mainland lying west of the Canadian boundary extend northwesterly for about 520 miles to the major portion of the Territory which lies west of the one hundred and forty-first meridian, and has a dimension of approximately 900 miles north and south and 700 miles east and west, with the Alaska Peninsula and Aleutian Islands reaching out from the southwestern portion nearly 2,500 miles toward Siberia. The comparative areas of Alaska and the United States are strikingly shown in Fig. 1 above.

Digitized by Google

Though Alaska is often loosely referred to as an Arctic province, nearly three-quarters of its area is within the north temperate zone. The climate of the coastal section is comparable with that of Scotland, but somewhat warmer. That of the inland region is not unlike the climate of Alberta and Manitoba in Canada. The northerly section, bordering the Polar Sea, is the only one in which Arctic conditions prevail. In Fairbanks (latitude 65 degrees, same as northern Norway), in the summer time, the same clothing is worn as in New York City.

There is little level area in Alaska, except the moss-covered tundra of the far north and northwest. The coastal region as far west as Cook Inlet is wet, extremely rugged, and covered with a dense growth of medium-sized timber, especially on the seaward slopes. The valleys of the interior or central portion are fairly well timbered near the streams; elsewhere they are covered with a thick growth of underbrush, and the ground is overlaid with a blanket of moss, beneath which the soil is usually frozen to a great depth. In summer these valleys are transformed by the melting snow and by the surface thawing into morasses and swamps, through which travel on foot or on horseback is a slow and laborious process. As one leaves the stream valleys the timber becomes lighter, and on the hill slopes fairly good ground may be found. In a few places considerable areas of dry gravel bench exist, but nowhere is it possible to use wheeled vehicles over any considerable distance except on the roads.

Resources

The agricultural resources of Alaska are just beginning to be developed. Local markets are now supplied with potatoes and other root crops, garden truck, hay, berries and limited amounts of cereals. Two grist mills have been taken into the interior. When more attention is paid to agriculture, particularly to the selection of suitable varieties, the Tanana, Susitna and Matanuska Valleys and several smaller districts can be made to supply the markets for a greatly increased population. The backward state of agriculture is partly due to the fact that the present population is made up of miners rather than of farmers. The agricultural output will probably never exceed the local demand.

The timber resources of Alaska are very extensive and important, especially in spruce and hemlock in the southeastern section. Extensive stands of birch suitable for furniture are found in the interior. In spite of the inferior quality of Alaska timber, it not only answers for local use but is being exported in increasing quantities; 50,000,000 feet were cut in 1919. About an equal amount ($1,600,000 worth) of lumber, principally Douglas fir, was imported from the United States. Recent water-power legislation favorable to the wood pulp industry has already resulted in several projects. It is estimated that Alaska can furnish indefinitely one-third of the pulp paper used in the United States.

Moose, caribou, reindeer, mountain sheep, goats, ducks, grouse, etc., furnish considerable food supply to the present population in the interior, but there is little revenue from the exportation of game. The reindeer herds have increased sufficiently, however, to justify the expectation of the exportation of an increasing amount of frozen meat. Attention is now being given to the possibility of handling musk-oxen in substantially the same way. Marten, mink, bear, muskrat, lynx, ermine, fox, etc., are exported in gradually decreasing amount but in increasing total value. Seal has produced large amounts, but it has been, until recently, completely protected. Beaver is still protected. Furs produced about $4,175,000 in 1919.

Salmon is the principal product of the fisheries, but large quantities of halibut, cod, herring and whales also are secured. The fisheries have been the principal support of the south and southeast coast population to date. The output was $52,000,000 in 1919.

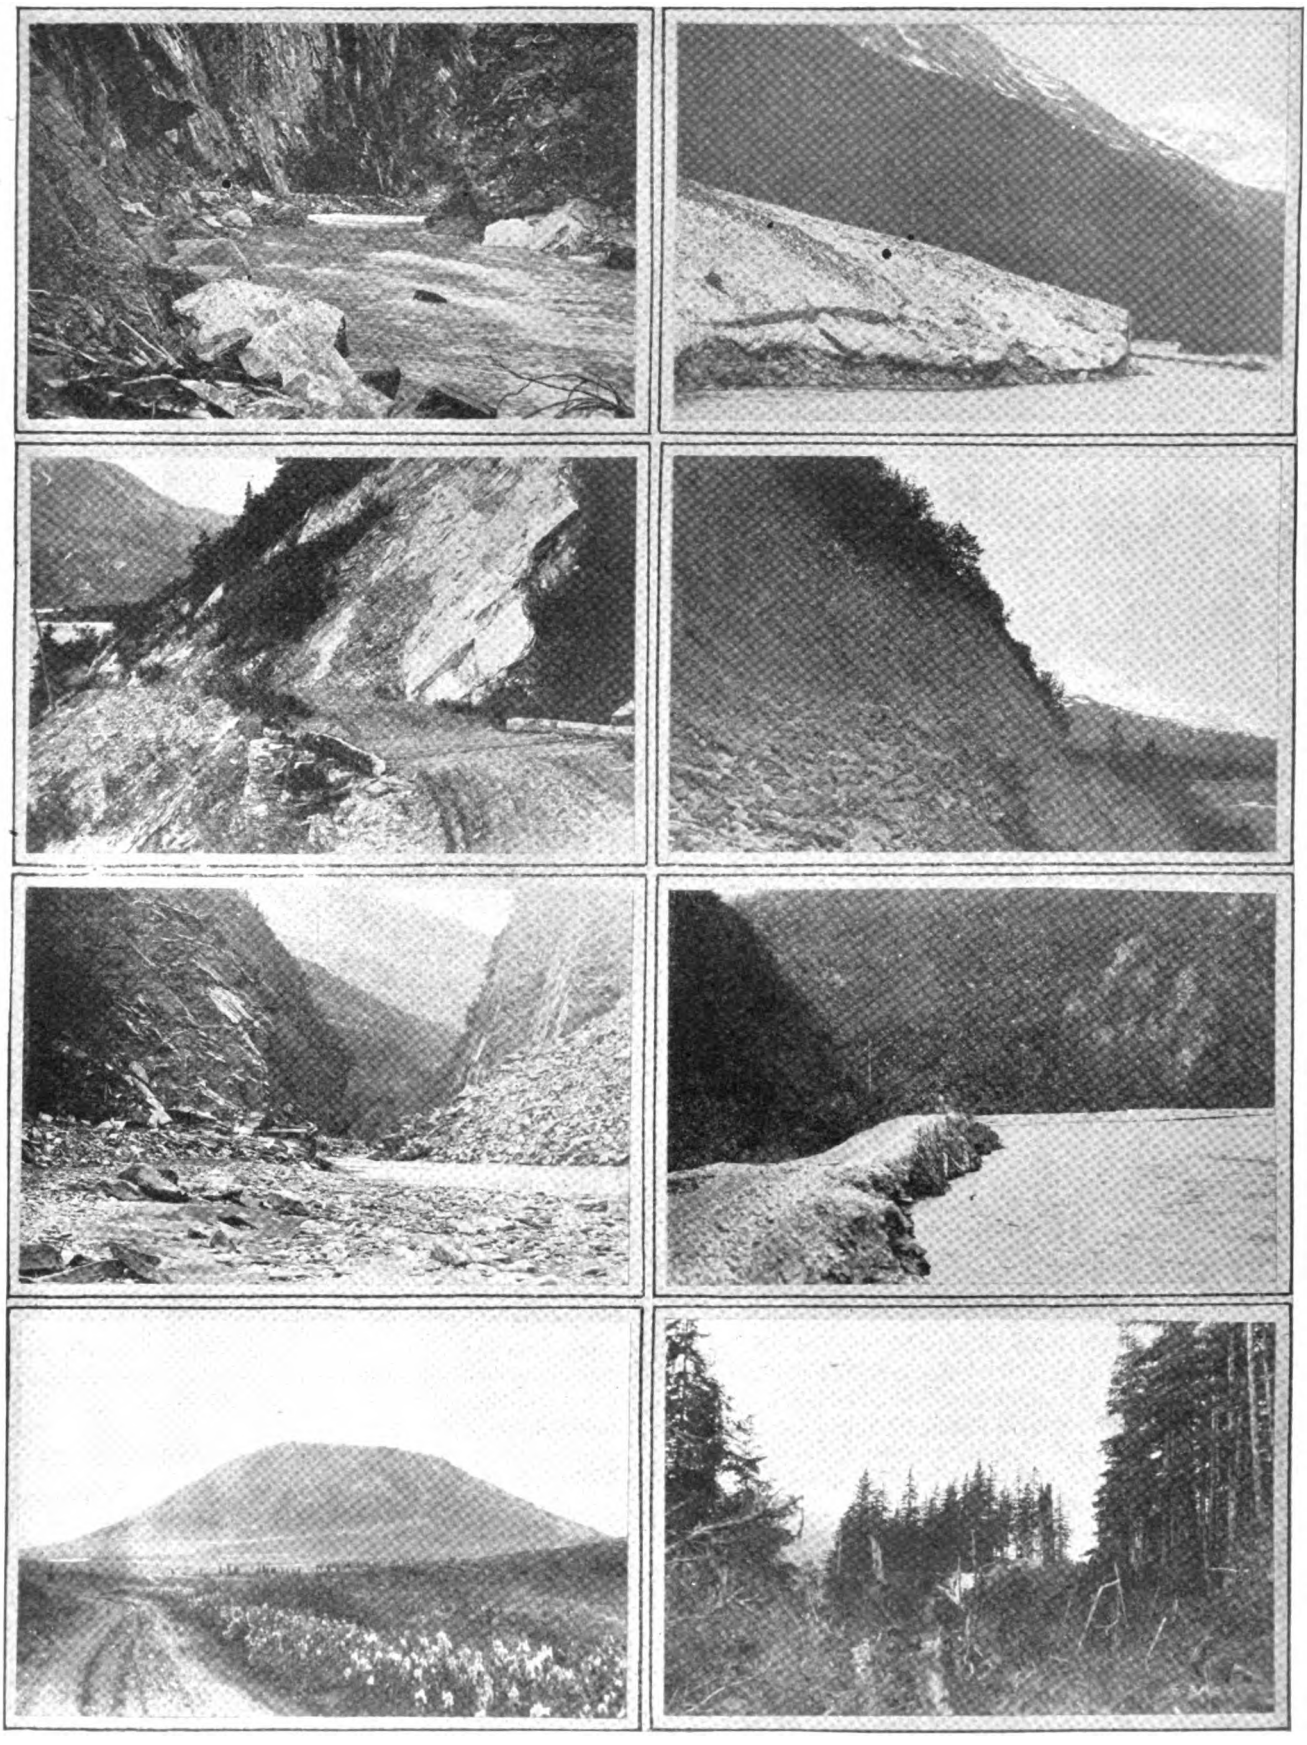
The following minerals are developed and producing in order of value: Gold, copper, silver, coal, lead, tin, platinum, palladium, marble, gypsum and petroleum. The following have been discovered but are undeveloped owing to the high cost of transportation or to government restriction: Zinc, antimony, quicksilver, peat, asbestos, graphite, as well as low grade deposits of all of the preceding list. Output for 1919 in gold, $9,000,000; in other metals, $10,000,000.

Total Production

	To 1919	1919	Total
Total mineral production	$418,000,000	$19,250,000	$437,250,000
All products, to include 1920	----------	----------	$1,000,000,000
Total commerce for 1919	----------	----------	$120,000,000

Original condition. Prior to the organization of the Alaska Road Commission, there were, in the whole of the Territory, less than a dozen miles of what might be called wagon road, with a few hundred miles of pioneer trail, mostly constructed by expeditions under the War Department. Travel was largely confined to the open waterways in summer and to their frozen courses in winter. When mining machinery and other supplies were to be transported from the coast or river landing, they were in most cases hauled over the snow during the winter, with some preliminary clearing of the route when necessary. Travel across country in summer, generally speaking, was possible only on foot or with pack-horses. It was difficult always, and frequently dangerous on account of the numerous swift and deep streams, fed by the ice-cold waters of mountain glaciers.

Previous projects. In the summers of 1898 and 1899 War Department expeditions under Captains Abercrombie and Glenn and Lieutenant Herron made explorations which collected much valuable data regarding the country and the best natural routes of travel. For the fiscal year, 1901, Congress appropriated $100,000 for roads and trails in Alaska, to be expended under the War Department. Practically all of this was spent on the route leading from Valdez to Eagle, but was sufficient only for the construction of a crude pack trail through sections otherwise impassable and the building of some of the most necessary bridges along the route. In the summer of 1904 an appropriation was made for a survey and estimate for a wagon road along this route. The survey was made under the direction of the Chief of Engineers.



Existing project. The existing project began with an act of Congress approved January 27, 1905. It requires primarily the maintenance and improvement of the present system of roads and trails, aggregating about 4,890 miles in length, and such new construction as funds will permit.

Inland travel and transportation. Inland travel and transportation are by means of:

(*a*) Wagon in summer and bob-sleds in winter where road conditions will permit, usually only on "wagon roads" or "sled roads" constructed by the Commission.

(*b*) Pack trains in summer and double-enders in winter where road conditions will permit, but where other traffic cannot be accommodated. A large number of trails for these classes of traffic have been constructed over short distances to individual mines, usually as tributaries to the Commission roads or trails, or to natural watercourses.

(*c*) Summer packing on men's backs or dog teams in winter are used where little or no work has been done, or where extremely unfavorable snow conditions are encountered. The former is employed only in isolated localities in summer. Except where river surfaces are used, some work is always necessary to permit the use of dog teams.

In the classification of the Alaska Road Commission, *wagon roads* are any roads cleared, grubbed, ditched and graded and drained sufficiently to accommodate wagon traffic. *Sled roads* are cleared and graded like wagon roads, but not grubbed. They are drained only sufficiently to prevent their destruction by the summer rains. Their wearing surface is of snow. *Trails* include any construction less than the above suitable for summer or winter pack traffic.

Railroads, completed and projected. Several railroads have been projected and operated for short distances. Exclusive of the Government railroad, the total mileage constructed is 466 miles. The only lines operated in 1920 were the White Pass & Yukon, 110 miles (only 20.5 miles in Alaska, the balance in Yukon Territory), and the Copper River and Northwestern, 195 miles. This does not include private tram lines connected with some mining developments.

The Government railroad. During the investigations which led to the construction of the Government railroad there were three problems to be considered: 1st, to open up the Alaska coal fields; 2d, to develop Alaska by providing a trunk line from the coast to the interior (Yukon River); and, 3d, strategic questions with reference to military control of the Pacific. The Alaska Railroad Commission made a preliminary examination in 1912 and submitted its report to Congress in February, 1913. The Alaska Engineering Commission was authorized in March, 1914, and started operations that same summer. The final route was selected by the President early in 1915 and active construction began that year.

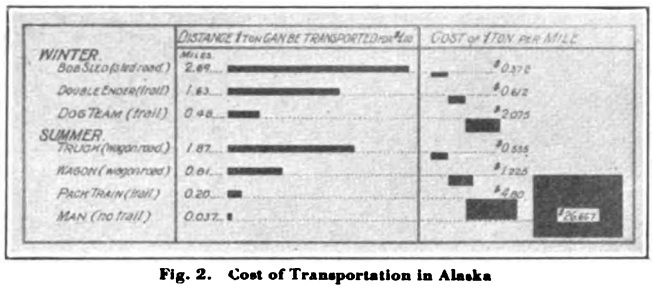

Fig. 2. Cost of Transportation in Alaska

The Government railroad, as at present projected, contemplates a main line of 471 miles from Seward, an open all-the-year port on the south coast, to Fairbanks in the Tanana Valley, the center of distribution for the interior. In December, 1920, this was completed except for about 90 miles, between miles 265 and 358 over the Broad Pass section. In addition the following bridges for the completed section have not been built: Susitna River, mile 264; Nenana River, mile 370; and Tanana River, mile 411. These are all important structures costing in the neighborhood of a million dollars each. It is expected that this 90-mile gap, upon which considerable clearing and grading have already been done, will be completed by December, 1921. The total cost will be between 50 and 60 million dollars.

In addition to the main or trunk line, branches are in operation from Matanuska Junction, mile 151, to Chickaloon in the coal fields, 38 miles, and from Fairbanks to Chatanika in the mining district, 39 miles. Of the total of about 550 miles, all is new construction except 115 miles which were purchased and rehabilitated at considerable expense; 71 miles from Seward to Kern Creek from the old Alaska Northern Railroad Co., and 44 miles around Fairbanks from the Tanana Valley Railroad Co. (narrow gauge).

Last summer passenger trains were operating three times weekly between Seward and Anchorage, mile 114, and twice weekly between Anchorage and Talkeetna, mile 227; also three times weekly between North Nenana, mile 412, and Fairbanks, with a gas car on alternate days. An irregular service as required was maintained in other completed sections and branches, and passengers were also carried on freight trains. The passenger fare was about 6½ cents per mile with an additional 1½ cents per mile for chair car when available.

Tourist routes. Scenic Alaska has already become a tourists' paradise for those travelers who are willing to leave the beaten track of Pullman cars and resort hotels. There are comfortable ocean and river steamers, good hotels in all important towns, and no real hardships or even serious inconveniences need be feared. But Alaska is still a pioneer country, its greatest charm to a great number of travelers, and one must expect to experience delays while waiting for boat connections, to get out of an automobile sometimes to walk around a bad spot in the road, and be satisfied with modest accommodations at the roadhouses in the interior.

From among the great variety of trips that may be made, the following typical ones have been selected. In all cases, the time and cost are figured from Seattle, the usual port of departure.

(*a*) To ports of southeastern Alaska as far as Skagway, circular tour of about 10 days, 2,300 miles, cost $87 to $97. (*b*) Same, extended to Southwestern Alaska as far as Seward and Anchorage, including Government Railroad, one way between Seward and Anchorage, and side trip from Cordova to Childs Glacier on Copper River Railroad, total tour about 21 days, 4,600 miles, cost about $175. Fairbanks from Tanana Valley R. R. Co. (narrow gauge). Seattle direct, tour 60 days, 7,500 miles, cost about $750.

(*c*) Additional three to five days will permit continuing on Copper River Railroad from Cordova to Chitina and then by automobile over Government road to Valdez, catching next boat to westward, or original boat on return trip eastward, 250 miles, $60.

(*d*) Trip (*a*) extended to Lake Atlin and Whitehorse, total tour about 21 days, 2,600 miles, cost $140 to $150.

(*e*) Midnight Sun Special Excursion—to Fort Yukon, inside the Arctic Circle, via Southeastern Alaska, Whitehorse, Dawson and return by same route, about 24 days, 4,200 miles, cost about $295.

(*f*) Trip (*e*) continued down the Yukon and up the Tanana Rivers to Fairbanks, automobile over Government Road up Tanana and Big Delta Rivers, across Alaskan Range, down Gulkana River Valley to Willow Creek, and then to Chitina and Copper River Railroad to Cordova, or on up the Teikhell and Tsaina River Gorges, over the Chugach Range and down the Keystone Canyon to Valdez, in either case then west and return as in (*b*) or (*c*), total tour about 40 days, 5,000 miles, cost about $500.

(*g*) *The complete Alaska tour.* To Southeastern Alaska, Lake Atlin, Dawson, Fairbanks, Valdez, Seward, as in (*f*), and then overland again via Government Railroad and road to Nenana and Fairbanks, down the Tanana and Yukon Rivers to St. Michael and Nome, and ocean steamer to Seattle direct, total tour about 60 days, 7,500 miles, cost about $750.

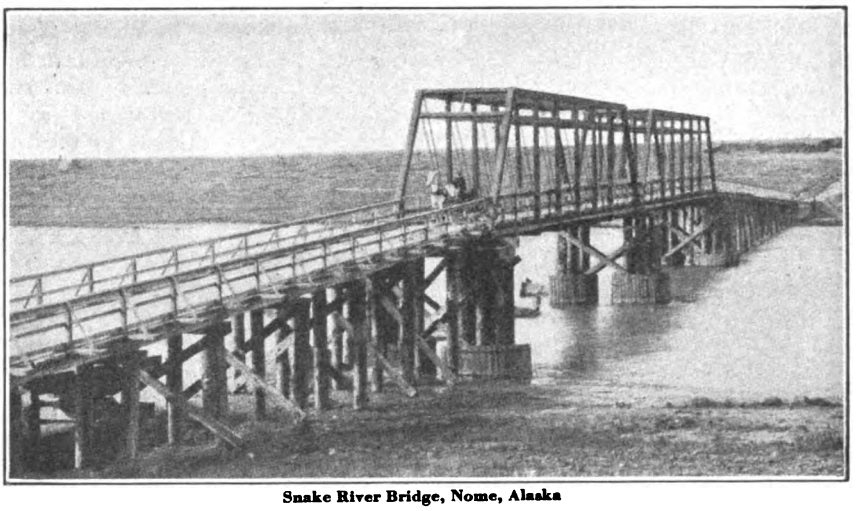
Costs of transportation. Fig. 2 indicates graphically the costs of transportation by the usual modes of transport in Alaska. Railroad transportation cannot yet be regarded as a usual form for Alaska, and steamship rates are entirely arbitrary, depending upon competition. They, like the existing railroad rates, have been fixed by two factors only: 1st, the cost of hauling on some competing wagon road, sled road, or trail, where such competition exists (or, in the case of steamships, sometimes by competing steamer line); and, 2d, by the highest rate the freight can stand and be shipped at all.

The diagram shows the actual costs at the rates for teams, labor, food, forage, etc., prevailing in the great interior regions of Alaska. They are based also on the costs of hauling large quantities. On the south coast the comparative values are the same, but actual values are about ⅓ less because of lower costs of above controlling elements.

During the opening of new diggings in the Chisana region a few years ago, beans, coffee, sugar, hay, candles, bacon, grain etc., was sold $1.50 per pound. The freight charges were almost a dollar a pound, so that the original cost of the article was of relatively little importance. And even at that, the supply could not keep pace with the demand. Last summer, the freight charges for transporting supplies from Dawson in the Klondike to some mines about one hundred miles away in the American 40-Mile District were greater than the original cost of the supplies plus the freight from U. S. to the Klondike. (Dawson is 1,700 miles from Seattle.)

The following table shows the expenditures under the Alaska Road Commission and the mileage of roads and trails constructed by it up to June 30, 1920:

Fiscal year	Funds appro. U. S. Treas	Alaska Fund	Total	Road Wagon	Road Sled	Trail
1905-6	$ ----------	$ 170,379.47	$ 170,379.47	----	---	133
1907	150,000.00	196,745.70	346,745.70	76	132	----
1908	250,000.00	111,972.32	361,972.32	90	252	119
1909	250,000.00	113,617.65	363,617.65	286	12	13
1910	350,000.00	10,396.79	360,396.79	268	25	206
1911	100,000.00	166,777.95	266,777.95	39	86	201
1912	150,000.00	167,303.72	317,303.72	56	74	710
1913	125,000.00	228,118.29	353,118.29	47	36	794†
1914	155,000.00	168,862.31	323,862.31	5	---	34
1915	125,000.00	159,755.12	284,755.12	35	---	40
1916	165,000.00	135,720.62	300,720.62	18	6	323
1917	500,000.00	76,747.90	576,747.90	60	---	81
1918	500,000.00§	97,020.18	597,020.18	26	13	155
1919	100,000.00	199,024.26	299,024.26	25	---	147
1920	100,000.00	157,416.69	257,416.69	----	---	267
Total	$3,020,000.00	$2,159,858.97	$5,179,858.97	1031	636	3223
1921‡	350,000.00	160,000.00	590,000.00*	---	---	----



§ Available for two years.

† This figure includes 257 miles heretofore staked temporarily, but not classified as trails. The actual new construction for the year would be 541 miles.

‡ Appropriated for fiscal year ending June 30, 1921.

* Includes $80,000.00 from the Territory.

In addition to its own funds ($5,179,858.97 in above table), the Commission had supervised up to June 30, 1920, the expenditure of the following co-operative funds: (*a*) from the Department of Agriculture, to be expended only in the Chugach and Tongass Forest Reserves, $249,500.00; and (*b*) from the Territory of Alaska, $101,000.00. Grand total, $5,530,358.97. Expenditures have been distributed as follows, including maintenance:

Snake River Bridge, Nome, Alaska

For wagon roads	$4,433,300.00
For sled roads	286,200.00
For trails	402,875.00
For examinations, reconnaissance, etc., not followed by construction	57,483.97

The annual cost of maintenance of routes in Alaska varies considerably with the locality, the range of climate being greater than that of the United States and the cost of labor also varying greatly. The experience of the Road Commission indicates that for all Alaska proper, average construction and maintenance costs, including bridges, are about as indicated in the following table:

Classification	Cost of Construction Per Mile	Annual Maintenance	Total Cost Per Mile 1905-1920
Wagon roads	$2500*	$250*	$4300
Sled roads	300	25	450
Trails	100	10	125

*Note. For earth roads only. Higher classes of construction cost more but have proportionately much less maintenance charges. As the mileage increases, the total maintenance charges increase, so that smaller proportionate amounts are available each year for new construction.

During the sixteen years of the Commission's existence slightly over one thousand miles of road (besides much greater lengths of sled roads and trails) have been constructed and maintained at a cost of about five and one-half million dollars. Two policies of the Commission, through all this period, have shown the highest wisdom; first, that of building successively trail, sled road and wagon road, as the traffic along a communication line justified; second, building largely with local labor. These two policies assured sound development, resulting in roads carrying traffic as soon as completed. To import labor to construct roads would make possible the building of roads away from centers of present or even prospective population and serving, when completed, only as monuments to the builders. The soundness of the Commission's policy is further emphasized by a survey of roads now in use. Under no possible conception would the abandonment of any part of the present road and trail system be justified.

A careful traffic census was begun by the Commission in 1911. Comparing the expenditures for freight on each route at the present rate with the cost of transporting the same amount of freight at the rates prevailing before the road was constructed, a figure is obtained which represents the economic saving to the community served by the construction of the particular route in point.

Combining the saving for all the routes built by the Com-

Digitized by Google

mission, the following table for 1911, 1912 and 1913, has been compiled:

Year	Expenditures for the year	Total expenditures for roads to end of year	Economic saving to shippers
1911	$266,777.95	$1,908,460.70	$1,981,677.00
1912	317,303.72	2,225,764.42	2,141,688.00
1913	353,118.29	2,578,882.71	2,144,667.00
1911-1913	937,199.96	2,578,882.71	6,268,032.00

From this table it is seen that the saving in these three years alone was almost three times the total expenditure for roads to the end of 1913. For 1920, the saving will be even more notable.

Operation and results during fiscal year 1920. The work of the last fiscal year has been largely maintenance of the existing mileage of wagon roads, sled roads and trails. Substantial progress was made in this respect, with the result that two-thirds of the length of the Fairbanks-Chitina road has been given a gravel surface. During the early summer of 1920 an automobile drove over this 320-mile road in twenty-two hours actual running time. In August, 1920, an automobile made the trip over the Fairbanks-Valdez road in 25 hours actual running time for the first 352 miles. The remaining 18 miles were made in two hours, including three miles on foot around the relocation through Keystone Canyon.

The winter of 1919-1920 was followed by a very late spring, and although a mantle of heavy snow fell in February and March and was late in disappearing, the spring break-up occurred with but little damage. The Commission took advantage of this favorable condition to work upon several new projects. Labor conditions have been slightly improved although the scale of wages is still rising.

Condition at end of year. The total mileage of roads and trails constructed by the Commission is 4,890 miles, consisting of 1,031 miles of wagon road, 636 miles of sled road, and 3,223 miles of trails. The main element in the road system, the Valdez-Fairbanks Road, has been kept open from Chitina, on the Copper River Railroad, to Fairbanks. Extreme high water from Lowe River damaged the Valdez end of this road between mile 8 and mile 17 to such an extent during July, 1919, that the funds available would not permit the reopening of this road. However, this work was taken up vigorously during the present season and there is every prospect of rehabilitating this road in time for use next season.

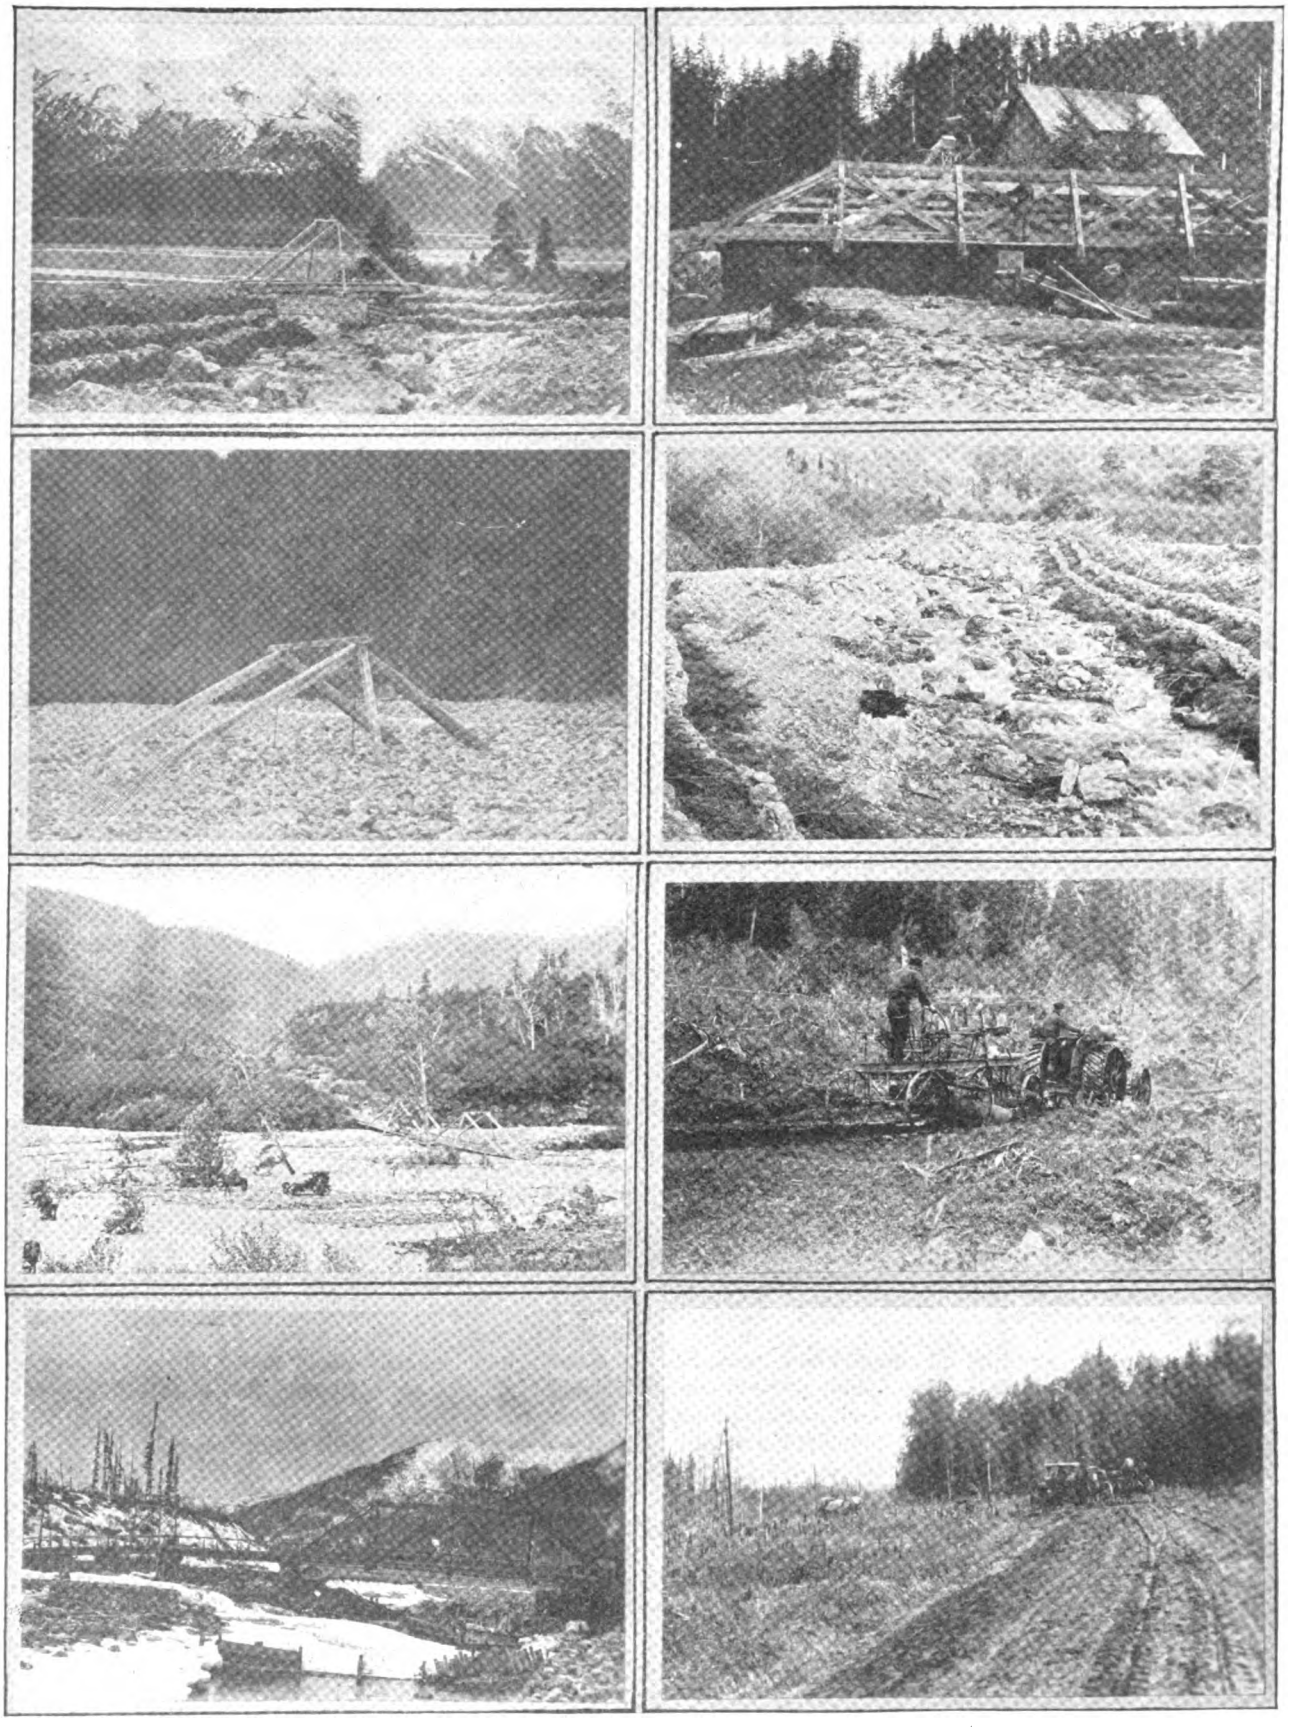
The progressive improvement of the remainder of the Fairbanks Road has continued through the fiscal year. The remaining mileage of roads and trails was carried through the year with ordinary repairs. A small mileage of new construction was carried out partly under co-operative agreements. 4,600 miles of the route form a connected system reaching from the open coast ports to the Arctic Circle and to the Kotzebue Sound country above Behring Straits, affording communication by road or trail with practically every settlement in Alaska, except those in the southeastern part and isolated coast towns.

Local co-operation. The funds disbursed are obtained from an appropriation "Construction and maintenance of military and post roads, bridges and trails, Alaska," and from receipts from the "Alaska Fund" by act of Congress approved January 17, 1905, and amended by act approved May 14, 1906. More than 40 per cent of the total cost of the road and trail system has been paid from the Alaska fund. Beside the above sources of funds, co-operation was had with both the Department of Agriculture and the Alaska Territorial Road Board wherever possible.

The most extensive co-operative work was that performed on roads in southeastern Alaska by agreements with the Territorial Road Board and the Department of Agriculture. The methods of the Commission, worked out through long years of successful experience and applied to as great extent as was possible under the agreements drawn up, greatly aided the Department of Agriculture and the Territorial Road Board in the rapid prosecution of this work.

Effect of Improvement. The roads and trails constructed by the Commission have not only opened up to development nearly all sections of the Territory, but have effected large savings in freight charges. Data collected by the Commission in 1913 indicated that the direct saving in cost of transportation of freight in that year, due to the construction of roads by the Commission, was $2,144,667. It is doubtful, however, if anything like that amount of freight would have been transported without the roads, and the indirect loss which would be occasioned by the restriction on output and development if the roads did not exist, can not easily be estimated, but is certainly very great.

Mail was handled by automobile on 160 miles of the Richardson Road between Chitina and Fairbanks during the entire winter. The use of automobiles has not been encouraged by the Commission, but their number is increasing rapidly. Approximately 90 per cent of the traffic on the main wagon roads is handled by motor, which has greatly increased the cost of road maintenance.



Alaska's future. The close of the fiscal year, June 30, 1920, marked the end of the war period in the work of the Alaska Road Commission. The road system has been kept open during the period of the war and some slight improvements made. The economic situation now met in Alaska and the plan of the Commission for future road construction will now be reviewed.

Alaska has suffered economically from three main causes by reason of war conditions: First, increased prices and wages made the mining of gold, the chief industry, unprofitable except from the richest claims; second, high wages in the United States attracted many prospectors and settlers from Alaska; third, and most important, a greater percent than from any state, of the young men of Alaska, variously estimated at from three to five thousand men, entered the service of the United States. Taken together, the result has created a shortage of the vigorous, virile miner and prospector upon whom finally the prosperity of Alaska rests. Already signs are seen that the tide is turning and that a few years will see the return to Alaska not only of these men but also of many ex-service men to whom the development of Alaska offers a promising field for endeavor.

Alaska's commercial development and its future embrace both hard facts and fascinating dreams. The former must be held to, and the sound common sense of the point of view presented in the report of the Alaska Road Commission for 1917 is worthy of reiteration.

As stated in a former report, "The truth about Alaska is good enough." Any information disseminated on the subject, by exploitation through newspaper articles and other publicity agencies, which tends to give a wrong impression of the true conditions can only result in injury to the Territory in the end. Alaska is for the present, aside from the fisheries, essentially a mining country, and with encouragement and support to the miner and prospector and to capital as well, which is sorely needed to open up its resources, and with reasonable aid in the construction of wagon roads and trails, the Territory will develop and grow in population and in home building along normal lines; but slowly and with much labor. The truth must be faced in the end, in spite of enthusiastic reports and glowing predictions and books of romance written on the subject. These latter are frequently interesting and doubtless well intentioned, but serve rather to entertain the tourist and sightseer than to aid the investor and home seeker. The natural resources as they are developed can

be levied upon to assist in bearing the expense of road building and eventually to carry it altogether.

Alaska's present important industries are mining, fisheries and fur. High hopes exist for paper, oil and coal production. All may materialize. Important reserves of pulpwood exist, and with the rise in price of print paper in the United States, developments are possible. Oil, under the new leasing law, is being sought both on the Alaskan Peninsula and in the Controller Bay District. The oil is of an unusually high quality but no large producing wells have been found thus far. As to coal, while both the Matanuska and Behring River coals are of high quality, until such time as a shortage of native coal exists in our Pacific Coast states no export market for this coal can be found. The presence of this local coal, however, greatly aids local Alaskan consumers. Important advances are being made in agriculture, and again the production of limited quantities of garden truck, root crops and grain, for local consumption, is the evident future of agricultural effort.

Altogether, the present and future industries of Alaska offer opportunity for a livelihood for a substantial population. It must be remembered that about one billion dollars in wealth have been extracted from this country and little more than one-tenth of this value left in Alaska is in the form of federal or private improvement. To provide for this future, to facilitate the ready exchange of goods between Alaska and the United States, to provide channels through which goods may be exchanged within Alaska, reduces in the end to a problem of securing adequate transportation facilities.

Commercial statistics

Total commerce of Alaska for the fiscal year ended June 30, 1919.	
Shipments of:	
Domestic merchandise from the United States to Alaska	$ 35,544,034
Domestic merchandise from Alaska to the United States	71,594,966
Foreign merchandise from Alaska to the United States	473,193
Domestic gold and silver from the United States to Alaska	98,523
Domestic gold and silver from Alaska to the United States	9,224,759
Foreign gold and silver from Alaska to the United States	83,360
Total	$117,018,835
Shipments of:	
Merchandise from foreign ports to Alaska	$ 1,334,403
Merchandise from Alaska to foreign ports	1,074,367
Total	$ 2,408,770
Grand total	$119,427,605
Total mineral production up to include 1919	437,250,000
All products to include 1920	1,000,000,000

The number of men entering the armed forces from this territory almost eliminated the possibility of new commercial development. The rise in general prices also has greatly handicapped the gold mining industry. However, there is every evidence of rapid recovery in all commercial lines, and Alaska, with great potential possibilities, faces the future with confidence.

Work upon the government railroad from Seward to Fairbanks is gradually opening up a new area of interior Alaska. Numerous requests have been made from this area for road construction contiguous to the railroad. Careful consideration has been given to these requests and work will be done wherever funds are available and the project warrants.

Transportation system. First in importance in Alaska's transportation facilities are the splendid existing coastal and interior waterways. Essentially an overseas country from the United States, the open waters of the Gulf of Alaska and southeastern Alaska are virtually Alaska's richest possession. After these come the easily navigable (although open but five months of the year) rivers of the Yukon, Tanana, Kuskokwim, Kantishna, Iditarod and Koyukuk. The water-borne commerce upon these rivers and ocean waters are, and always will be, the chief life giving element in Alaska's commerce.

Next to the water-borne commerce in importance comes the land transportation connecting up base ports and waterways. Two means exist, of course, railroads and wagon roads. As to railroads, with the completion of the Government Railroad from Seward to Fairbanks, about $100,000,000 will have been invested from public and private funds in railroads. For both railroads and wagon roads the function must be, in the present state of Alaska's development, to cross divides and connect up lines of water communication. For railroad development, the expenditures already committed are such as to take care of the development of Alaska for a long time.

As to wagon roads, the nature of the commerce existing and expected in Alaska is such as to make them especially necessary. The Government Railroad, now nearing completion, will be of little value until the commerce of the country passed through is brought to the railroad upon tributary highways. But in providing such roads, the immediate construction of numerous feeder roads constructed to fit only the topographical features of the Territory, even if the fabulous cost could be met, would give but meager return. These feeder roads must be built with a careful consideration of both the topography of the country passed through and the economic return to be expected. Finally, before the tonnage which the Government Railroad can carry materializes, it will be found that an amount equal to that spent upon its construction must be invested in tributary wagon roads. To enable a substantial development of this generous federal project to take place, to aid in the balanced development of all parts of Alaska, a modest but thoroughly considered program of wagon road construction has been presented.

Terminal and harbor facilities. All ports in southeastern and southwestern Alaska, as far west as Cooks Inlet, are open to shipping all the year round. All Alaskan ports, except Nome and St. Michael, are well equipped with docks at which ships may lie in almost all weather. Anchorage is frozen up for about five months in the year, and Nome and the Yukon and other river ports for about seven months. All cargo must be handled by ship's tackle. Skagway, Cordova, Seward, Anchorage, Nenana and Fairbanks have rail connections from the docks to the interior.

Alaska compared with other states. From the best statistics available it would appear that Arizona, the poorest State in the United States in wagon roads, has about 35 times as many miles of road in proportion to its area, as has Alaska. Connecticut, the State with the best showing, has about 1,800 times the proportionate mileage of Alaska, and the entire United States has over 500 times as great a proportion. Of eighteen foreign countries, Australia, the poorest, has 50 times as much, and England and Wales, the greatest, have 185 times as much.

In a sparsely settled country, since individuals must travel relatively greater distances in the processes of commercial communication, the necessary mileage per capita must be very great. On this basis, taking the States west of the Mississippi River, Alaska has less roads per capita than any. Nevada, the State whose conditions of topography, population, age and industries are most similar to Alaska, has seven times the mileage of roads per capita.

In the matter of expenditures, Nevada is the only State

Digitized by Google

spending as small an amount per square mile for roads as Alaska, while New Mexico, with the next smallest expenditure, spends nearly six times as much, or allows for about nine times as much road work per square mile, if we consider the cost of labor, etc. It should also be noted, that over large areas of Nevada, New Mexico, etc., wagon or even automobile travel can pass almost without hindrance, while in Alaska wheeled transportation is in almost every locality quite impossible until roads have been constructed.

Future road development. The Alaska Road Commission has, up to the present time, undertaken work on fifty different routes. About 4,600 miles of its 4,890 miles of roads and trails form a connected system reaching from the open navigation of the south coast to all inhabited sections of the Territory. The maintenance of these routes requires an annual expenditure of about $200,000.

In 1913 the Commission drew up a comprehensive program of road construction and development to cover the succeeding ten years. This project was based upon (*a*) the maintenance and improvement of the existing projects, (*b*) the completion of projects already undertaken, (*c*) the completion of projects already approved but not then undertaken, and (*d*) the completion of projects likely to arise with the development during the ten-year period. This program called for a total expenditure during the ten years, 1914-23, of $7,250,000 and would have resulted in providing Alaska with a complete road system such as its immediate needs seemed to justify, and probably sufficient to meet all reasonable demands until the Territory became sufficiently developed to take over all internal public works as a part of its own government.

This program was also based upon the assumption that governmental restrictions and red tape would be removed and the Territory allowed to develop normally as in the case of our other great western territories. The enormous expenditures contemplated that same year for a Government railroad seemed to augur a more liberal attitude on the part of the Government. Seven years of that period have now passed by and three factors have arisen to derange those calculations: First, the Great War; second, the lack, until this year, of any indication of a change of attitude on the part of the Government looking to a rational policy of Alaskan development; and, third, an average expenditure per year of only $375,000, instead of $725,000 for the past seven years for road and trail work. For the two years of the war the total appropriations were only $370,000, or $185,000 per year, only one-fourth the average required.

As to the importance of road and trail work, the following is quoted from the report of the Alaska Railroad Commission:

With one or two notable exceptions, these roads are not comparable with the best highway construction in the States, but for the money expended in their creation and maintenance they have shown a remarkable return, and have assisted greatly in development. The

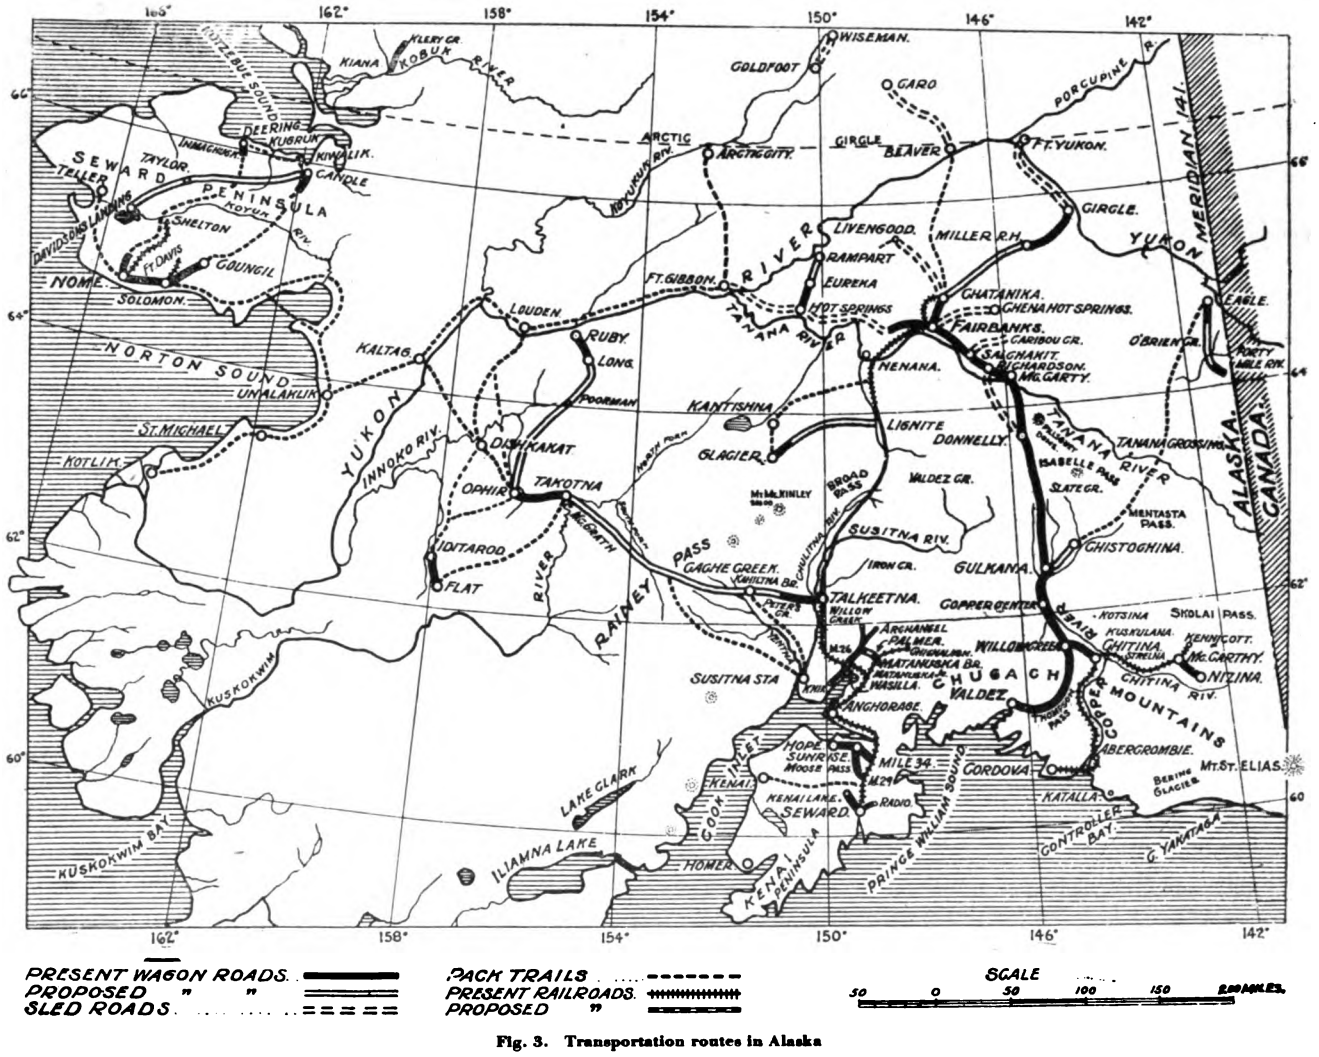

Fig. 3. Transportation routes in Alaska

Digitized by Google

immediate commercial value of the expenditures of the Board can be shown in the reduction in summer and winter freight costs wherever they have been built. The Alaska Railroad Commission desires to record itself as greatly impressed with the work accomplished by the Board of Road Commissioners, and to express its belief that, *in guiding lines of future railroad construction* in Alaska, work along the lines developed by that Board should be continued and enlarged upon.

The new Commission, feeling that the War is sufficiently past to permit of the United States taking up again its work of interior development, has drawn up a new program involving an expenditure of a million dollars a year for a period of ten years. This program is based upon the same general considerations as the 1913 program, but takes into account also the following new factors: 1st, the damages and deterioration of the existing project during the lean war years; 2d, the increased cost of labor, materials and supplies; 3d, the provision of a system of feeders for the Government Railroad; and, 4th, the necessity of providing a more substantial type of construction to withstand motor traffic.

With the knowledge based on sixteen years' experience in Alaskan road construction, this Commission, with the proud record of achievement through all its existence as a guarantee for the future, sets forth a ten-year program of road construction that will carry forward substantially the reviving industries of this Territory and will provide the Government Railroad with a generous contribution of traffic.

Initial considerations. To prepare any program of road construction, both the topography of the region traversed and the economic return expected must be studied. In topography alone, the glaciers, glacial streams, swamps, elevated snow covered mountain ridges, frozen soil and dense vegetation offer obstacles of remarkable obstinacy. As to economic returns, the traffic existing and prospective must be estimated. The building of roads through known mineralized, but undeveloped areas, to reach developed areas is sought.

To be considered at the same time is the location of projected roads in relation to other lines of traffic; that is, waterways and railroads. In the present state of Alaska's development, it is unwarranted to parallel such lines of traffic with wagon roads. It is especially aimed to build as feeders and in a few cases cross divides and link together existing lines of traffic. Roads planned upon such a conception will give the greatest return with the minimum of cost.

Of almost equal importance to the above considerations is the adjustment of the program to the funds that are requested. This modest program can be constructed within the estimated cost and time. It would require only a draftsman's service to cover the map of Alaska with a network of roads that could not be constructed with any reasonable appropriation within less than fifty years. This estimate is, therefore, made with a view to being a practicable program with the funds and time that may be reasonably expected. This program of road development covers that desired during the next ten years, 1921 to 1930, inclusive. The new road mileage which is projected totals seven hundred miles. These roads are termed 1921 roads. This will call for a rate of construction of seventy miles per year. The cost of these roads, to construct and maintain through this period, will average ten thousand dollars per mile. This cost is an average for all districts. The roads selected for construction during this period are along well defined lines of travel which have received previous development as trails and sled roads and whose worth is unquestioned.

In the work proposed for the next ten years, three classes of road building operations will be carried on. First, the new construction planned as arterial or feeder highways and totalling seven hundred miles for the period, will be carried out. These roads will, in the main, follow old lines of development. These are described in detail below. Second, roads, termed development roads, the value or location of which is not yet fixed, will be constructed from time to time with a limited apportionment of funds. A number of roads of this type are described hereafter. Construction of roads of this type provide the necessary flexibility to meet new conditions. At a later time these development roads may become arterial roads. Third, the present road and trail system must be kept up. This requires an expenditure for maintenance which is estimated, from past expenditures of the Commission, to be $200,000 per year.

Physical features of Alaska. In presenting the program in detail, it is necessary to outline briefly the physical features of Alaska and the lines of communication already established. The portion of the territory now under development naturally divides into the following districts:

1. *Southeastern Alaska*, embracing the islands and coastal mainland east of the 141st meridian. This district is served almost entirely by water-borne commerce and no new construction is planned under this program. The necessary short tributary roads to settlements not already constructed can be built as development roads.
2. *Copper River Valley*, embracing Cordova, Valdez and Kennecott and served by the Copper River Railroad, extending to the summit of the Fairbanks Road.
3. *Susitna Valley*, embracing the country traversed by the Government Railroad in the Susitna Valley, including Seward, Anchorage and Matanuska. The Alaskan Peninsula and Kodiak Island are closely related in development to this district, and are included therein.
4. *The Kuskokwim*, embracing the lower Yukon Valley and the valley of the Kuskowkim west of the Alaska Range. This district is very meagerly provided with transportation facilities and the most important project of this program aims at its relief.
5. *Yukon District*, including Fairbanks and the Yukon and Tanana Valleys. This region is of high importance for development as here must originate the most important tonnage for the Government Railroad.
6. *Nome District*, Seward Peninsula and Kotzebue Sound Country.

Program proposed. The "1921 Roads" included in the proposed program and a number of possible "Development Roads" will now be described in detail.

1921 Roads

Project "A." Susitna and Kuskokwim Districts. Talkeetna, Takotna, Ophir and Ruby Roads. Total mileage, 280.

These roads reach from Ruby, on the Yukon, through the most promising mining district of the Kuskokwim, through Mt. McKinley Park, to Talkeetna on the Government Railroad. Sixty miles of this route are already under construction. The most promising mineralized region of the Upper Yentna Valley is reached.

Project "B." Nome District. Davidsons Landing, Kugarok and Candle Roads. Total mileage, 135.

This road runs from tidewater through the Kugarok mining district to Kotzebue Sound at Candle. It is of the highest importance for the further development of the Seward Peninsula.

Project "C." Yukon District. Roosevelt, Glacier and Lignite Roads. Total mileage, 75.

These roads connect the important Kantishna Mining District with the head of navigation on the Kantishna River and with the Government Railroad near Lignite.

Project "D." Yukon District. Eagle and 40-mile Boundary Roads. Total mileage, 50.

This is an extension of an existing road and improvement of a sled road to the 40-Mile mining district from Eagle. Connection will be made at the Alaska-Yukon Territory boundary with the Mile Creek Road to Dawson.

Digitized by Google

Project "E." Yukon District. Chatanika and Miller House Roads. Total mileage, 80.

These roads connect two old Road Commission projects, enabling traffic to pass from Circle on the Yukon to the Fairbanks District and serving as a very important feeder to the Government Railroad.

Project "F." Yukon District. Rampart and Hot Springs Roads. Total mileage, 21.

These roads connect two old projects, connecting Rampart, on the Yukon, with Hot Springs, on the Tanana.

Project "G." Copper River District. Gulkana and Chistochna Roads. Total mileage, 40.

These roads are important tributaries to the Fairbanks Trail, and are a part of a future main artery road from the Copper River Valley to the Yukon at Eagle, making accessible the promising Slate Creek mining district.

Development roads

Under Development Roads the most important possible projects are noted below:

Alaskan Peninsula—

Wide Bay—Oil Fields; 25 miles.

Reaches from tidewater at Wide Bay to the old fields now being prospected near Cold Bay.

Iliamna Lake—Lake Clark; 20 miles.

Serves as a portage from Iliamna Lake to Lake Clark.

Kenai Peninsula—

Kenai—Homer; 70 miles.

This road, with the completion of the Kenai Mile 29, will give a system of roads to the Kenai Peninsula reaching every district and making connection with the Government Railroad at Mile 29.

Susitna Valley—

Talkeetna—Iron Creek; 45 miles.

This road will connect an important mining district in the Susitna Valley with the Government Railroad.

Government Railroad—Valdez Creek; 50 miles.

This road makes accessible to the railroad the important Valdez Creek Mining District. This district is now reached only by a seventy-mile trail from Meiers on the Richardson Road.

Copper River Valley—

Abercrombie (Copper River R. R.)—Katalla; 45 miles.

Makes accessible the Katalla oil field to the Port of Cordova, and especially necessary in case a railroad extension is not made.

Katalla—Cape Yakataga; 80 miles.

Reaches a new oil field now being prospected and otherwise inaccessible for development.

Nizina River to Nizina; 10 miles.

This will include the Nizina River Bridge and make accessible the upper Chitina Valley to the Copper River Railroad.

Strelna to Kuskulana River; 16 miles.

This comprehends the improvement of existing roads built by mining operators and makes accessible an important mining district in the upper Kuskulana Valley.

Chistochina—Chisana; 45 miles.

This makes accessible the upper Chistochina Valley workings to the road projected on this year's program from Gulkana to Chistochina.

Yukon Valley—

McCarty to 40-Mile; 135 miles.

This road would complete a through road from Dawson and Eagle to Fairbanks and would pass through a very promising and undeveloped agricultural region in the upper Tanana Valley.

Circle to Fort Yukon; 80 miles.

Makes accessible both winter and summer the important trading post of Fort Yukon. This settlement of fifty whites and five hundred natives is now reached by water in summer and with difficulty over the ice on the Yukon in winter.

40-Mile to Tanana Crossing; 60 miles.

An extension of the Eagle—40-Mile Road passing through an important mining district and reaching the valley of the Tanana.

Chatanika—Livengood; 56 miles.

This road makes accessible the important mineral developments around Livengood.

Beaver—Caro; 75 miles.

Provides a line of traffic between the Chandalar mining district and the Yukon.

Fort Gibbon—Arctic City; 100 miles.

Connects the valley of the Koyukuk with the Yukon Valley.

Eagle—Seventy Mile; 40 miles.

Connects the Seventy Mile mining district with Eagle.

Nome District—

Nome—Kugarok; 60 miles.

Connects the Nome District with the Kugarok mining district and with the Davidsons Landing—Candle Road projected under this year's program.

Southeastern Alaska—

Skagway—White Pass; 13.5 miles.

This is an important international road and by co-operative effort on the part of the Canadian Government would make travel by road from Skagway to White Horse possible.

Taku Landing—Boundary; 22 miles.

This road, if prolonged by the Canadian Government into the Lake Atlin region, would permit travel from Juneau to Lake Atlin.

The map (Fig. 3) indicates the program proposed by the Commission, exclusive of isolated projects in southeastern Alaska and in the Alaska Peninsula. It will result in giving Alaska, in addition to short spurs and development connections between the producing communities and water or rail transportation, the following through routes by road or trail:

Result of proposed 10-year program

Season	*Vehicle*	*Roadway*	*Mileage*		*Through Routes*
Summer	Automobile or Wagon	Wagon Road	573	"a"	Valdez or Chitina to Fairbanks, Chatanika and Circle.
do	do	do	469	"b"	Government Railroad to Cache Creek, Tacotna (Kuskokwim District), Ophir, Long, Ruby (Yukon District).
do	do	do	97	"c"	Eagle to Forty Mile and International Boundary (connects with Canadian Road to Dawson).
do	do	do	159	"d"	Davidsons Landing to Kugarok and Candle.
do	Pack Train	Wagon Road,	2887	"e"	Route "a" connected
do		Sled Road, or Trail.			to Routes "b," "c" and "d."
do	do	do	3802	"f"	Route "e" extended to Ft. Yukon, Caro, Livengood, Rampart, Arctic City, Iditarod, Kotlik, St. Michael and Nome.
Winter	Bob-sled	Wagon or Sled Road	1353	"g"	Same as Routes "a," "b," "c" and "d."
do	do	do	988	"h"	Route "a" extended to Fort Yukon, Livengood, Rampart and Ft. Gibbon.
do	Double-ender or Dog Team	Wagon Road, Sled Road, or Trail	3802	"i"	Same as Route "f"

Mileage, Entire project	*Wagon road*	*Sled road*	*Trail*	*Total*
Through routes above	1298	470	2034	3802
Miscellaneous routes	567	630	1266	2463
Total	1865	1100	3300	6265
Existing system	1031	636	3223	4890
New construction	834	464	77	1375

The Government Railroad, as planned at present, will be completed in December, 1921, at a total cost of between $50,000,000.00 and $60,000,000.00. An Alaska Advisory Committee (federal) reported on June 11, 1920, that:

The construction of wagon roads and trails is one of the most important and urgent needs of Alaska. Without the construction of a large mileage of wagon roads and trails the resources of the Territory cannot be made available. Nothing will contribute more to development of tonnage for the Government Railroad than a system of tributary wagon roads. The Committee recommends that Congress be asked to make an annual appropriation of not less than a million dollars for the construction and maintenance of wagon roads and trails in Alaska.

Conclusion

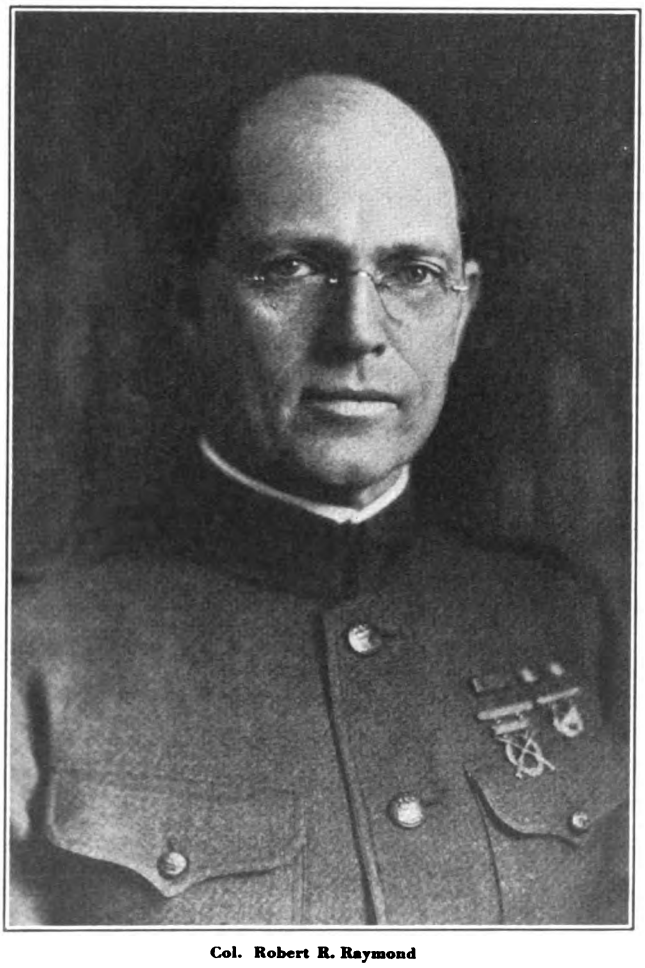
Alaska has been slowly developing for twenty-two years.

Digitized by Google

Sixteen years ago the first steps in road construction were taken. The first steps in railroad building were made even earlier, but so far all have been unsuccessful, chiefly because the railroads could land freight only at their freight platforms and had no road feeders to distribute their tonnage. No railroad can be successful without roads as branches or feeders, any more than a tree can grow by its trunk alone without branches and leaves.

A railroad must have large tonnage, and trunk-line railroads, such as proposed for Alaska, cannot hope to succeed except as they become arteries of trade supplying large areas. Such areas must extend some distance from the railroad line and terminals, and they can be made tributary thereto only by means of branches. In a highly developed country the larger of these branches may be small railroads or even small systems, but the last connecting line between the railroad and its customers, the mine, the farm, and the factory, is wagon or truck.

Great natural riches can make a country productive even without the assistance of roads, as Alaska proved before 1906. Since that time, however, the evidence of the value of the few existing roads has been demonstrated, and the necessity of completing the road systems has been made manifest.



If left to itself Alaska will continue its slow rate of development, and by building its own roads and creating industries sufficient to warrant private enterprise, it will, in half a century, become an empire in spite of all hindrance. No rapid or general development has or will follow the construction of the Government trunk line railroad to the interior unless preceded or accompanied by the construction of numerous wagon roads and trails as feeders. By the construction of highways as the development of the country demands them, this period may be shortened to one-half. The railroads and highways should shorten it to one-quarter. The experience of Alaskan railroads already constructed is a strong indication that without road systems no Alaskan railroad need be expected either greatly to stimulate the development so much to be desired, or to be anything but a financial failure itself.

Retirement of Engineer Officers

Col. ROBERT R. RAYMOND, a well-known and popular officer of the Corps of Engineers, on December 21, 1920, was retired from active duty, at his own request after more than 30 years' service.

Colonel Raymond was born March 5, 1871, in New York, the son of Gen. Charles W. Raymond, a distinguished officer of the Corps of Engineers. He graduated from West Point in 1893, and his entire service has been with the Corps of Engineers, in which he reached the grade of Colonel in 1920.

Colonel Raymond's principal service to the government was in connection with the development of our seacoast defenses to which, being of great inventive ability, he contributed many notable improvements, including the ammunition hoist for seacoast batteries. His aptitude for invention and for the improvement of construction methods found application in many situations both within and even without the scope of his own duties. He was directly responsible for some of the most important features of the novel and successful plan for uncovering the wreck of the *Maine* in Havana harbor. Amongst many other activities Colonel Raymond was the first editor and creator of PROFESSIONAL MEMOIRS, the predecessor of this journal.

Col. Robert R. Raymond

During the late war he organized and trained the 313th Engineers, 88th Division. His last assignment on active duty was as District Engineer of the Cleveland District.

Col. FREDERICK W. ALTSTAETTER, an officer widely and favorably known in the Corps of Engineers and the Army generally, was retired from active duty on August 21, 1920, on account of physical disability.

Colonel Altstaetter was born December 11, 1875, in Ohio, and graduated from West Point in 1897. He reached the grade of Colonel in the Corps of Engineers in 1920.

His service included a wide range of activities, both civil and military. He served many tours of duty with engineer troops, including the Philippine Insurrection; and was in charge of a number of important river and harbor improvements, including the districts of Wheeling (W. Va.), Grand Rapids (Mich.), Savannah (Ga.).

During the Philippine Insurrection, Colonel Altstaetter, then a Lieutenant, was taken prisoner by the insurrectos and remained in their hands for several months, which resulted in injury to his health from which he never entirely recovered.

The government is fortunate in being able to retain his services as District Engineer of the Savannah District.

Prize Map Problem

Duties of Divisional Engineers in an Advance

[The solution of practical problems, such as that which follows, is conceded as the best method available in time of peace for the instruction of officers in the duties that will fall to their lot in time of war.
This problem is based on a situation in "open warfare"—which makes the greatest demand upon combatant engineer troops.
Officers of all ranks should be familiar with the general duties of the engineers in campaign, and it is recommended that all who are interested solve this problem.
For solutions submitted in competition THE MILITARY ENGINEER offers the following prizes:
In case 30 solutions are received, 3 years' subscription to THE MILITARY ENGINEER (or 3 years free membership including the journal, to members) for each of the 3 best solutions received.
In case less than 30 solutions are received a similar prize will be awarded to the 2 best received.
The competition is *not* limited to members of the Society of American Military Engineers.
All solutions should be submitted to the Editor of THE MILITARY ENGINEER, 423 G Street, N. W., Washington, D. C., not later than March 1, 1921. A letter of transmittal should accompany each solution, but the name of the competitor should not appear on the solution itself. Manuscripts should be typewritten if practicable. Sketches may be submitted if desired.
The solutions will be passed upon by a board of three engineer officers, who will determine the winners. These will be announced in a later issue, at which time also, if practicable, the winning solutions and a solution by the author of the problem, will be published.—ED.]

THIS PROBLEM is intended to exemplify the use of Engineer troops in open warfare, and the issuance of orders based on small scale maps. The physical data is based on a very general knowledge of the region, but will be assumed as correct in the solution of the problem. (See map, page 15.)

General Situation

War has broken out between the United States and the Red Nation, and the latter has attained sea supremacy. On September 25 a Red force has landed at SAN DIEGO, Cal. No other landings are as yet effected. The 8th and 10th U. S. Divisions, which have been mobilized at LOS ANGELES, about 125 miles north of SAN DIEGO, are advancing southward to contain or drive out the Red force. Each has 1 regiment of cavalry and 10 heavy tanks attached. The 8th Division is moving down the Coast Highway, which passes through OCEANSIDE-ENCINITAS-DEL-MAR-LA JOLLA. On September 28 its cavalry gained contact with Red forces along AGUA HEDIONDA CREEK, about 5 miles south of OCEANSIDE. The 10th Division is moving down the interior highway which passes through ESCONDIDO, POWAY and MERTON. Both divisions are at full strength (1918 organization), and completely equipped. While the Red navy has occasionally shelled the single-track railroad and highway, the fire was not effective, and these are open to OCEANSIDE.

The composition of the 8th Division is:

Division Headquarters.
16th Brigade (32d and 33d Regts. Inf. and 24th M. G. Bn.).
17th Brigade (34th and 35th Regts. Inf. and 25th M. G. Bn.).
8th Artillery Brigade [24th and 25th F. A. (75s, horse-drawn); 26th F. A. (155-mm. howitzer, tractor-drawn)].
18th M. G. Bn.;
8th Regt. Engineers;
8th Engineer Train;
Signal Corps troops, trains, field hospitals, etc., complete.

Attached:

6th Regt. Cavalry;
101st Tank Co.

The Engineer Regiment consists of:

Regimental headquarters,
Colonel, lieutenant colonel, 4 captains, 1 lieutenant,
18 master engineers,
45 other grades, mounted,
101 other grades, dismounted, including band of 19 men.
2 Battalions, each of
Battalion headquarters—major and captain,
3 companies, each of 5 officers, 250 enlisted.

Regimental headquarters has 1 motor car, 4 motorcycles and 6 tool wagons, containing map reproduction, surveying, drafting and miscellaneous equipment.

Each company has 4 tool wagons in addition to field wagons.

The Engineer train (2 officers, 85 enlisted), has 23 technical wagons, 13 loaded with picks, shovels, axes, saws, etc.; 6 with small arms ammunition and 4 with sand bags, barbed wire, pickets, etc., and 12 motor trucks similarly loaded; all in addition to the necessary field wagons.

A water tank train of 12 water tank trucks, each of 500 gallons capacity, has also been furnished the Division Engineer for the operations.

Physical Features

The country is generally treeless, except that some timber is found in the river bottoms, and there are occasional plantations of eucalyptus. Much of the land is uncultivated, and such is generally covered with a dense growth of brush. It is toward the end of the dry season, and water is found only in the largest streams. There are a few scattered wells in the river bottoms. The streams lie in narrow, deep cut valleys or canyons, and at the mouth of each is a wide marsh, intersected by small meandering channels. The coast highway is a concrete road. It crosses the stream outlets on embankment, with bridges from 50 to 300 feet in total length, of various construction. The other roads, which are quite numerous, are generally dirt, and the location of many have changed since the date of the map.

Special Situation

On September 29 the advance guard of the 8th Division, consisting of the 32d Infantry, 1 Bn. of the 24th F. A., and Company E, Engineers, reached the north side of AGUA HEDIONDA Creek late in the afternoon at the end of a long day's march. The division has halted for the night along the highway, and extends as far north as OCEANSIDE. The trains are just north of OCEANSIDE. The tanks are held up by an unsafe bridge about 40 miles to the north, and the 1st Battalion of the Engineers is strengthening bridges from that point on to OCEANSIDE. Division Headquarters is in the hotel at OCEANSIDE.

Digitized by Google

At 5:00 P. M. Colonel A, the Division Engineer, is summoned by the Chief of Staff to a conference, at which he finds the three assistant chiefs of staff, and the division artillery commander, signal officer and machine gun officer. The following instructions are given: "The Air Service report small forces of the enemy moving south toward SAN DIEGO this afternoon. The few prisoners taken by our cavalry are all from the 149th Red regiment, belonging to the 40th Red division. The force in front of us is probably small and already withdrawing. A civilian just arrived from San Diego states that 15 Red transports have so far arrived. We estimate that not more than two Red divisions have landed. The 32d Infantry is in contact with enemy outposts along AGUA HEDIONDA Creek, and the cavalry are patrolling up the north side of the Creek as far as the branch railroad. The advance cavalry of the 10th Division has gained contact with the enemy in the hills just south of ESCONDIDO, and the advance guard of the 10th Division had reached MOOSA at 4:00 P. M.

"We advance at 5:30 A. M. tomorrow; the 16th Brigade leading, the 17th in reserve. DELMAR is the day's objective. The cavalry will operate on the left flank and will endeavor to cut off retreating Red detachments. The division will be ready at all times to take up a defensive position if superior enemy forces are encountered. Division Headquarters moves to ENCINITAS as soon as this is cleared by the 16th Brigade."

Colonel A informs G-3, in charge of operations, that he will submit his proposed disposition of engineer troops to the latter within an hour, and informs G-1, in charge of administration and supply, that he will submit the proposed arrangements for water supply by 7:00 P. M. G-1 grants Colonel A's request that the Engineer Train, heretofore under the orders of the Commander of Trains, be placed under Colonel A's orders. G-2, in charge of information, strongly urges that the correction of the maps as to roads, etc., in the zone of the division operations be continued by the engineers.

As he leaves the conference, Colonel A receives the following messages:

From Captain Z, Company E, Engineers, dated 3:30 P. M., by runner: that the bridge across HEDIONDA Creek is intact and that E Company P. C. is in a ravine about 2 miles east of CARLSBAD.

From Major Y, 1st Battalion Engineers, dated 3:00 P. M., by motorcyclist, that the 1st Battalion has been relieved and is proceeding in trucks to OCEANSIDE, where it will arrive about 6:30 P. M. Wagon transport of the battalion will follow by road tomorrow.

From the Corps Engineer, at LOS ANGELES, by wire; that the corps troops have taken over all work as far as OCEANSIDE; that Colonel A is to report fully on the condition of the railroad south of OCEANSIDE as uncovered by our advance; and that a division of heavy ponton equipage, horse-drawn, is leaving LOS ANGELES the following morning to report to Colonel A.

Further Information

There is a small lumber yard at OCEANSIDE, well stocked with ordinary building material, such as can be expected in a town of a few thousand inhabitants, and there is a small supply of railroad bridge timber and ties in the railroad yard. There is ample water supply in the town, with fire hydrants in the streets. Any kind of material can be had at LOS ANGELES. The only information available on water supply to the south is that there is water in the SAN DIEGUITO River five miles from the mouth, and that DELMAR is supplied through a long pipe line from the river. Headquarters of the Engineer Regiment is stationed at OCEANSIDE. With headquarters there are small detachments from the companies engaged on correcting the road maps. Six automobiles have been secured for their use. A detachment of 10 mounted men is with the cavalry for the same purpose. The 2d Battalion, less Company E, is at CARLSBAD. The Engineer train is 3 miles north of OCEANSIDE. The water tank train is in OCEANSIDE.

Required

(*a*) A brief preliminary statement of the manner in which Colonel A is assumed to have organized his headquarters to perform its various duties; and of the standing instructions designed to insure the transmission of orders and information within the regiment.

(*b*) The assumed results of any conferences with the appropriate officers necessary to the proper co-operation of the Engineer troops with other arms and services.

(*c*) The orders and messages issued by Colonel A and by his lieutenant colonel to carry out the mission of the regiment the next day, giving the distribution of each and method of transmission.

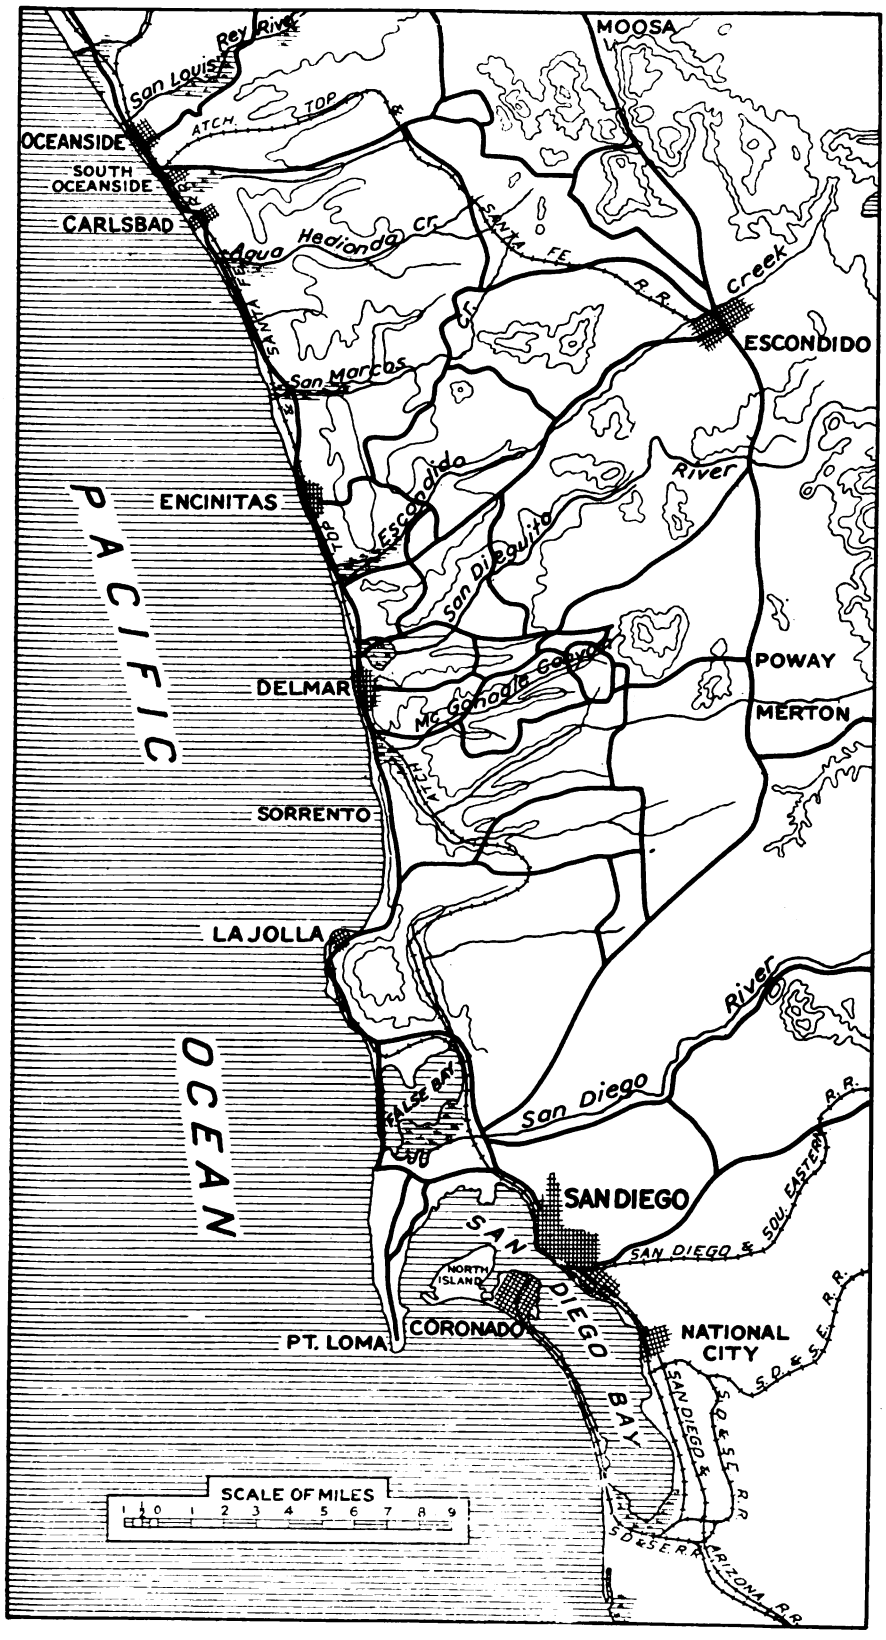
(*d*) A brief general outline of any action, not covered by the orders and messages issued, that Colonel A proposes to take the following day, if there is no change in the situation.

NOTE: The regiment has been mobilized but a short time, many of the officers have had no combat experience, and all instructions must be explicit as to what is to be done. The officers of the regiment may be expected to know how to do their tasks, after the various missions have been very clearly stated.

The requirements given are sufficient to clearly indicate the contestant's estimate of the situation. The committee will, however, give due consideration to any memoranda accompanying the solution which a contestant desires to submit in explanation of reasons for the action taken.

Portable Car Unloader

A remarkable machine for unloading bulk materials from railroad cars into vessels or storage bins has recently made its appearance. It is the result of a development extending over many years. In these times, when the rapid loading and unloading of cars is so vital a problem, such a machine fills "a long felt want."



The material is elevated by a bucket belt conveyor on a steel frame covered with sheet metal, all suspended from an overhead track or from a swinging boom of a derrick, or attached to a building. The length of the elevator is about 40 feet and its cross section 2 feet 6 inches by 3 feet 6 inches. It is driven by a 10-horsepower electric motor operating through a gear reduction, resulting in a speed of 2½ r. p. m. at the head sprocket of the conveyor.

Each bucket of the conveyor as it inverts in passing over the head sprocket discharges into a chute or spout, which in turn discharges into the vessel to be loaded.

This machine has a capacity of 125 tons per hour. Smaller sizes have capacities ranging from 50 to 75 tons per hour.

The operation is very simple, requiring only one attendant. The machines may be employed in "batteries."—*Ry. Age.*

Moisture in Concrete Vaults

[NOTE.—We print herewith two interesting letters on the subject of moisture from condensation in concrete vaults. Mr. Dingman's letter was referred for comment to Colonel Winslow, an authority of wide experience on this important subject.

To cure a disease it is first necessary to accurately diagnose it, and this Colonel Winslow does in most clear and convincing manner, after which he proposes the only practicable remedy.—ED.]

Sir: The letter in the *Engineering News-Record*, September 9, p. 521, in reference to the sweating of a concrete vault, is very interesting to us for the reason that we have had somewhat similar experiences in the past.

We do not know all of the conditions surrounding the construction of the vault, but we are inclined to believe that a large part of the trouble is due to the fact that it has never been dried out, and we feel that the sweating would be materially reduced if the vault had once been dried out by the application of heat.

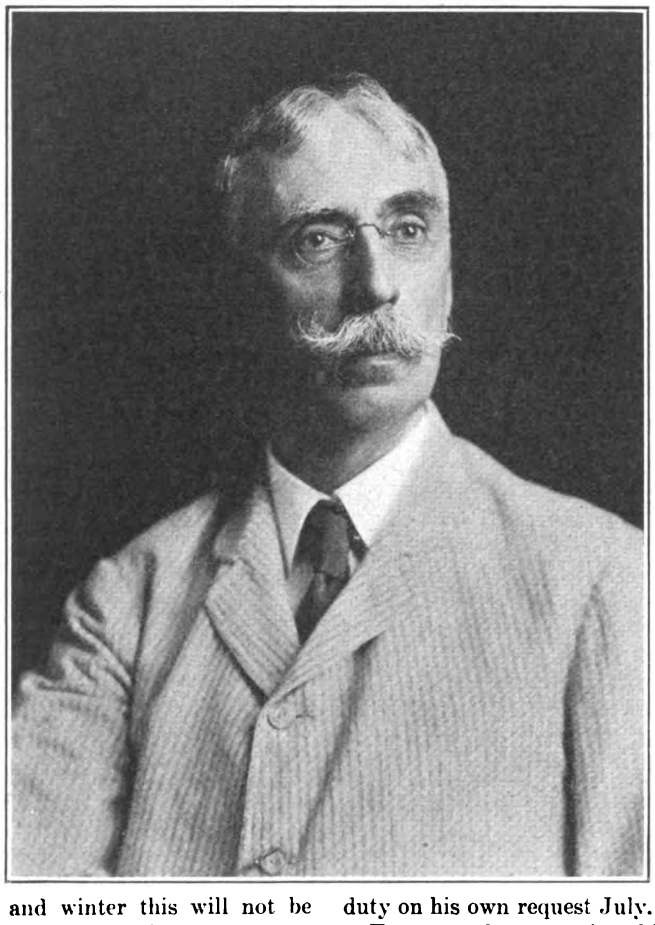
We have also conferred with an architect who has had a very extensive experience in the construction of banks and he advises us that he has never succeeded in constructing a vault below grade which did not sweat. This architect states that he has constructed a great many vaults which were waterproofed, but on account of the difference in temperature between the walls and the interiors of the buildings the vaults continued to sweat. His practice, where a dry vault is needed, is to install a small electrical heater and an expeller fan; then every few days the heater is turned on to raise the temperature and the fan is started and the vault dried out. As soon as any noticeable amount of moisture collects again the process is repeated.

CHARLES F. DINGMAN,
Engineer, Flynt Building Construction Co.
Palmer, Mass.

Comment by Col. Winslow

The letter from Mr. Dingman and the article appearing on page 521 of the *Engineering News-Record* of September 9th, 1920, and referring to the sweating of a concrete vault, are exceedingly interesting to the fortification engineer, as an illustration of a difficulty which occurs frequently and makes it hard to keep dry the rooms and magazines of concrete fortifications.

The cause of the dampness in the vault is evidently not leakage or seepage or the reappearance of the water used in making the concrete, but simply the condensation of moisture carried into the vault as watery vapor in the atmosphere.



The locality is in Wisconsin where the ground becomes exceedingly cold in winter and warms up in summer slowly, lagging in this respect behind the temperature changes of the atmosphere; consequently, in the middle of the summer the atmospheric temperature is normally above the temperature of the ground. Due to their contact with the earth the temperature of the concrete walls of the vault has a tendency to approximate the temperature of the ground, and this is ordinarily below, not only the actual temperature of the air, but even the dew point of the air. The inevitable result is that when this air comes in contact with the cooler walls of the vault, condensation begins to take

Digitized by Google

place and continues until there has occurred the condensation of all of the moisture in the air, which the air at its new and lower temperature is unable to hold in suspension.

That this is true is shown by the fact that the floor, which has naturally the coldest surface, is reported as always damp, while the comparatively thin ceiling, whose upper surface is in contact with the atmosphere, is reported as comparatively dry; and further, since on rainy days when the atmosphere is nearly or quite saturated, or in other words when the temperature of the dew point of the atmosphere approximates to that of the air itself, the condensation is reported to have been greater.

The rule for reducing the amount of condensation is very simple, and is based upon the idea that anything that serves to warm up the surface of the walls, or to prevent the surface of the walls from cooling off, will serve to reduce condensation. The surfaces of the walls are cooled off by the heat conducted from the walls to the ground. Consequently, if the walls had been made so that they were poor heat conductors, the loss of heat by conduction would have been less and the amount of condensation would have been reduced. This might have been done either by making the interior surface of porous tiles or by leaving air spaces within the walls themselves.

The vault being already constructed, with solid walls in actual contact with the ground, the only alternative is to heat up the walls artificially. This can be done by the application of artificial heat at intervals during the spring and summer. During the autumn and winter this will not be necessary, for as soon as the atmospheric temperature falls below that of the ground it will be found that the condensation will cease, because if the atmospheric temperature be below that of the vault walls the dew point of the atmosphere will be even more so. Consequently any air coming in contact with the walls of the vault will, by this contact, be heated rather than cooled, and will be made a better holder of watery vapor.

Incidentally it will probably be found that the troubles due to dampness will be reduced if, instead of providing only a few small ventilating openings, the arrangements for ventilation be much improved so that a large quantity of air can pass into and then out of the vault. The reasons for this are, that as each little volume of air comes in contact with the walls and is reduced to the approximate temperature of the walls, it gives off to the walls not only some temperature heat, but also as the watery vapor condenses the much greater quantity of the latent heat of vaporization of this watery vapor. This tends to raise the temperature of the walls, and if the ventilation be sufficiently good so that a sufficient quantity of air passes along the surfaces of the walls, they will be warmed by the heat from the air more rapidly than they are cooled off by the conduction of heat to the ground. If this process continues long enough the temperature of the wall surfaces will soon be raised up to the dew point of the air and condensation will cease. If then the supply of air still continues the wall temperature will be raised, but more slowly, by the transfer to the walls of the temperature heat of the air until the temperature of the wall surface is well above the dew point.

Apparently in the vault with its present system of ventilation, the conditions are such as to be most favorable for condensation. That is, the amount of air that gets in is such as to transmit to the walls its temperature and latent heat just about as rapidly as this heat is conducted away by the earth. Under these conditions condensation may continue almost indefinitely.

E. E. WINSLOW,
Colonel, Corps of Engineers.

Death of Col. Thomas W. Symons

With the death at Washington, D. C., on November 24, 1920, of Col. Thos. W. Symons, Corps of Engineers, U. S. A., was ended a noteworthy career in the annals of inland waterway development in this country.

Colonel Symons was born in New York State in 1850, and graduated from West Point at the head of his class in 1874. His entire army service was in the Corps of Engineers, in which he reached the grade of Colonel in May, 1908. He was retired from active duty on his own request July, 1908, after 37 years of service.

For several years after his graduation Colonel Symons was engaged on the government surveys in the west, under Captain Wheeler. His first experience with inland waterways was on the Mississippi River in 1882. Subsequently, as assistant to Major Lydecker, he took part in the construction of the Washington aqueduct, following which he served several years as assistant to the Engineer Commissioner of the District of Columbia. For six years he was in charge of harbor improvements in the Portland (Ore.) District, including the mouth of the Columbia River.

From 1895 to 1903 Col. Symons was in charge of the Buffalo District. Here he made a close study of the inland waterway problems of that region; reported on a project for a ship canal from the Great Lakes to the sea, and as a member of the New York state commission he took part in the planning of the Barge Canal. So great was his influence on this project that he was called the "father of the New York State Barge Canal."

On his relief from Buffalo, Colonel Symons served a year as Superintendent of Public Buildings and Grounds

Digitized by Google

in the District of Columbia, and as military aide to President Roosevelt.

When work on the Barge Canal was started New York State requested the services of Symons as Chairman of the Advisory Board of Engineers to supervise the construction. To take up this work he was granted leave of absence by special Act of Congress, and served on the Board from 1904 until the virtual completion of the waterway.

Since his retirement Colonel Symons' principal activity has been the investigation and preparation of plans for a canal from Pittsburg to Lake Erie, near Conneaut, Ohio, for the movement of coal and ore.

Colonel Symons is survived by a widow, two sons and a daughter.

New Organization of the Engineer Service for Military Operations

Under Act of June 4, 1920

By

F. B. Wilby

Major, Corps of Engineers

In accordance with authority granted in the Act of June 4th, 1920, a general project for the organization of the Army of the United States has been approved by the Secretary of War, and it is believed that an abstract from that project—showing the Engineer units proposed, with a brief discussion of the duties and functions of those units—will be of interest to many Engineer officers, both active and reserve.

Engineer Troops Proposed (War Strength).

For each Infantry Division—	Officers	Warrant officers	Men
1 Combat Engineer Regiment	38	1	806
For each *Cavalry Division*—			
1 Combat Engineer Battalion, Mtd	15	--	330
For each *Army Corps*—			
1 Corps Engineer Service, of			
1 Corps Engineer Hdqrs	4	--	11
1 Corps Engineer Regiment	38	1	1150
3 Auxiliary Engineer Battalions (each 15 officers, 1008 men)	45	--	3024
Total Corps Engineer Service	87	1	4185
For each *Army*—			
1 Army Engineer Service, of			
1 Army Engineer Hdqrs	28	--	105
3 Army Engineer Regiments (each 38 officers, 1 W O, 1150 men)	114	3	3450
1 Topographical Engineer Battalion	18	--	560
1 Camouflage Engineer Company	4	--	160
5 Heavy Bridge Trains (each 4 officers, 160 men)	20	--	800
2 Light Bridge Trains (each 4 officers, 160 men)	8	--	320
1 Water Tank Train	15	--	475
6 Auxiliary Engineer Battalions (each 15 officers, 1008 men)	90	--	6048
Total Army Engineer Service	297	3	11,918
For *G. H. Q. Reserve (for 1 Army)*			
1 G. H. Q. Engineer Hdqrs	32	--	130
1 Topographical Engineer Battalion	18	--	560
1 Camouflage Engineer Battalion	18	--	560
*2 Heavy Bridge Trains (each 4 officers, 160 men)	8	--	320
†1 Water Tank Train	15	--	475
†1 Road Engineer Regiment	38	1	1150
*4 Railway Engineer Battalions (each 18 officers, 560 men)	72	--	2240
1 Construction Engineer Regiment	38	1	1150
‡8 Auxiliary Engineer Battalions (each 15 officers, 1008 men)	120	--	8064
Total G. H. Q. Reserve (1 Army)	359	2	14,649

† Add one more for each additional Army.
* Add two more for each additional Army.
‡ Add four more for each additional Army.

For the *Communications Zone* (15 per cent of all troops assigned to Armies).

Allotment of Communications Zone Engineer Troops.

"Engineer Corps"	20. per cent of Cn.Z.—For one Army	9066
50 per cent of "Army Service"	9.87 per cent of Cn.Z.—For one Army	4474
** 40 per cent of "Transp. Corps"	4.8 per cent of Cn.Z.—For one Army	2176
Total Engineers	34.67 per cent of Cn.Z.—For one Army	15,716

(** Railway Operating troops to be organized by Corps of Engineers.)

Normal Assignment of Communications Zone Engineer Allotment.

	Officers	Warrant officers	Men
1 Cn. Z. Engineer Hdqrs. (about)	100	--	250
1 Section Engineer Hdqrs. (for each Base, Intermediate or Advance Section)	10	--	27
For each Army—			
1 Depot Engineer Battalion	18	--	560
1 Lumbering Engineer Battalion	18	--	560
2 Construction Engineer Regiments (each 38 officers, 1 W. O., 1150 men)	76	2	2300
4 Railway Engineer Battalions (each 18 officers, 560 men)	72	--	2240
9 Auxiliary Engineer Battalions (each 15 officers, 1008 men)	135	--	9072
Total Cn. Z. Engineers (for one Army)	429	2	15,009

The above allotment will provide, for an expedition of one army (total strength 382,532), an Engineer contingent of 63,819 men or 16.7 per cent; and for an expedition of six armies (total strength 2,310,695), an Engineer contingent of 342,167 men, or 14.8 per cent. In each case a little more than 50 per cent of the Engineer troops are provided in auxiliary Engineer battalions.

The troops proposed for the Engineer Service in time of war may be divided into two classes—General Engineer troops, and Special Engineer troops; the first class being ready to perform all kinds of engineering work, and the latter being recruited and trained for special work only.

General Engineer troops include:

Combat Engineers with Infantry and Cavalry Divisions,
Corps and Army Engineer Regiments,
Auxiliary Engineer Battalions.

Special Engineer troops include:

Topographical troops,
Road troops,
Railway troops,
Depot troops,
Water Tank Trains.
Camouflage troops,
Construction troops,
Lumbering troops,
Bridge trains,

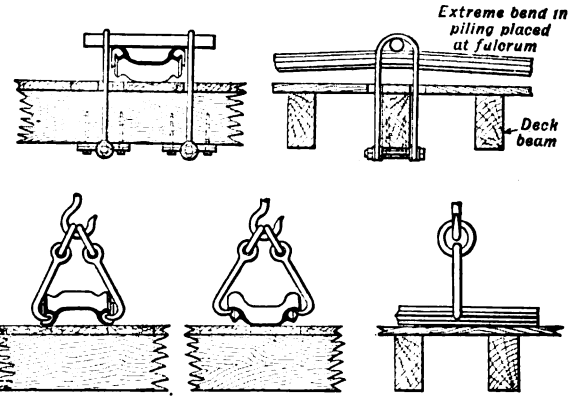
An Economical Method of Straightening Old Sections of

Lackawanna Steel Sheet Piling

DOUBLE-LOCK LACKAWANNA INTERLOCK



A balanced section with similar interlocks on each edge, permitting accurate and economical straightening for reuse.

Due to its uniform section a bar of used and bent Lackawanna Steel Sheet Piling can be straightened without fear of any twisting effect.

A simple method of straightening that was very successfully applied to bent steel sheet piling from the cofferdam for raising the U. S. S. Maine at Havana Harbor in 1911, and one which experience has proven preferable, is illustrated. A level floor, such as the deck of a scow, or the ties of a railroad track, is selected, and at a point about under the center of movement of a derrick boom, two links are securely fastened. Through these a pipe is inserted to act as a fulcrum against which the sheet piling section is set with point of extreme bend under the fulcrum, against which the sheet piling section is set. The weight of a few men will in extreme cases bend the section so that it will go under. The piling section is then raised by taking hold of one end and the upward lift and pull continued until the piling section is bent slightly past straight to allow for springing back. A badly bent piling section can be straightened in a very short time by repeating this operation, each time putting the point of extreme bend under the fulcrum.

Decidedly short kinks, especially near the end of the sheet piling section, are more economically removed by heating or cutting off.

Handling Hook will work equally well when engaged with thumbs and fingers of pile section.

We Also Offer for Better Construction

Elcannes

Concrete Reinforcing Bars

The Elcannes Bar combines maximum bonding surface, minimum weight, and uniform strength. The bonding surface is 15 per cent greater than that of a plain square bar of equal nominal size. The cross-sectional area is practically the same at all points and the regular surface facilitates fabrication and handling.

Lackawanna Steel Company

General Sales Office and Works: Lackawanna, N. Y.

BOSTON	CLEVELAND	ST. LOUIS
BUFFALO	DETROIT	SAN FRANCISCO
CHICAGO	NEW YORK	
CINCINNATI	PHILADELPHIA	

Licensees for the manufacture of Lackawanna Steel Sheet Piling:

For Great Britain and British Colonies in the Eastern Hemisphere, Cargo-Fleet-Iron Co., Ltd., Middlesbrough, England. For France, Italy, Spain, French Colonies and Protectorates, Italian Colonies and Spanish Colonies in the Eastern Hemisphere. Cie Des Forges & Aciéres de la Marine et d'Homécourt, Paris, France

Sole Exporter for Other Countries: Consolidated Steel Corporation, 165 Broadway, New York. 461

Digitized by Google

The following Special Engineer troops, organized during the War, have been omitted as unnecessary, and their duties assigned to other Engineer troops:

Water Supply troops,
Electrical and Mechanical troops,
Shop troops,
Light Railway and various kinds of railway troops,
Mining troops, Quarry troops.

The following special troops, which were Engineer troops in the A. E. F., have been omitted, as their duties have been assigned to other arms or services:

Searchlight troops to the Coast Artillery Corps,
Sound Ranging troops to the Coast Artillery Corps,
Flash Ranging troops to the Field Artillery,
Gas troops to the Chemical Warfare Service.

As far as possible only General Engineer troops have been assigned to tactical units in forward areas, and the minimum number of Engineer troops required under all circumstances has been assigned to each army and to the Communications Zone, with a small pool of Engineer troops in the G. H. Q. Reserve available for assignment in emergency where most needed, either to a particular army preparing for offensive operations, or to the Communications Zone during the earlier stages of its development.

As far as possible, a standard company, battalion and regimental organization has been used throughout the Engineer Service.

A brief description of each kind of Engineer troops—together with a few remarks as to equipment contemplated and duties proposed for each—will give a general idea of the operation of the Engineer Service under the approved project:

Combat Engineer Regiment, 800 Enlisted

This is a two battalion regiment of six 106-man companies, and one 170-man Headquarters and Service company, for assignment to Infantry divisions only. The old Engineer Train is included in the Headquarters and Service Company. The Engineers form only 4.35 per cent of the division, instead of 6.5 per cent, as used in the A. E. F. The combat Engineer regiment will be equipped with automatic rifles, a small amount of pack transportation, and a small mounted platoon in the headquarters and service company, in addition to the usual Engineer equipment. It should be trained to execute all military engineering required by the Infantry division, as well as to fight as Infantry, when called upon in an emergency.

Combat Engineer Battalion, mounted

This is a three company battalion with a small Headquarters and Service platoon. The Engineer train, Cavalry division, has been eliminated—4 wagons carrying intrenching tools for the Cavalry regiments being retained with the headquarters and service platoon of the mounted battalion, and the light bridge train being assigned to the army. The training of this battalion should be in general similar to that required for the combat regiment with the Infantry division, as described above.

Corps and Army Engineer Regiments

These regiments will be equipped the same as combat Engineer regiments with Infantry divisions, with the omission of automatic rifles, pack train, mounted platoon, and extra wagons of Infantry intrenching tools, and the addition of complete steam operated pile driving outfit. They will have to be prepared to carry on the following work for the corps and army:

General construction,
Construction and maintenance of roads and bridges,
Construction of railroads, both narrow and standard gauge,
Water supply installation and operation,
Electrical and mechanical installation and operation,
Defensive works, Engineer supply,
Military mining.

Auxiliary Engineer Battalions

These will be four company battalions (250-man companies), organized the same as the Engineer service battalion used during the recent war, and will provide additional man-power in the army areas for the work performed by the corps and army regiments, as outlined above, and in the Communications Zone for work with Construction, Road, Depot or Lumbering troops. The allotment of three Auxiliary Engineer Battalions to each Army Corps has been made with a view to the assignment of such troops as needed to the divisions in the Corps, in order to supplement the smaller engineer regiment now assigned to the Division.

Topographical Troops

One battalion to each army, and one battalion at G. H. Q., for handling the production and reproduction of maps. Present plans for equipment for these troops contemplate a base printing plant at G. H. Q., and a mobile power driven printing plant for the army. Corps and divisions will be furnished only hand presses for map reproduction work, to be operated by General Engineer troops.

Camouflage Troops

One battalion at G. H. Q., for operating camouflage factory and general supply of camouflage material, as well as furnishing details for camouflage instruction at training centers. One camouflage company per army for supply of camouflage material and supervision of such special camouflage work as may be directed. Ordinarily, the work required for the camouflage of troops or materiel will be performed by the troops concerned, whether Infantry, Artillery or other arm. Each corps and division, however, will have on the staff of the Commanding General, an Engineer Officer, to be known as the Corps or Division Camouflage Officer, with duties of inspection and supervision, similar to the duties of the Corps or Division Gas Officer.

Road Troops

One regiment per army, to be assigned to G. H. Q. Reserve, for use where most needed, on general supervision, quarry operation, or specially important and difficult road work. The principal dependence for road work in the communications zone, as well as in the forward areas, will fall upon Auxiliary Engineer Battalions, supervised by a small technical personnel, furnished from corps and army regiments, construction regiments, or road regiments. The road regiment will be equipped with tractors, dump wagons, dump trucks, graders, and small portable crushers. Other special road machinery and equipment, such as large crushing plants, air compressors, or road rollers, will be held in depot, and issued where required.

Construction Troops

These are for duty primarily in the communications zone, although one regiment is allotted to G. H. Q. Reserve for assignment where necessary. Construction regiments will be recruited and trained, so as to perform all kinds of general construction work, including among others, the following:

The Officer's Library

Here is the answer to your questions—How can I keep in touch with the Service? How can I get ready for examination for promotion?

Get your military library started—Devote your spare time to studying and reading Military Books. Here is a list that we recommend to you.

COMPANY ADMINISTRATION. Based on War Department Regulations No. 57. All blank forms used in the Administration of a Company Troop and Battery made out. Text explains all details ---------- $2.50

PLATOON TRAINING. Waldron. Published in two handy volumes. A complete Training Manual for the instruction of all foot troops. All subjects fully illustrated. The one book that should be included in the library of every Reserve Officer ---------- 2.50

THIRTY-MINUTE-TALKS. Stewart-Waldron. A collection of twenty essays on Military subjects. Invaluable to an officer who may be called upon to address an audience on a Military Subject. Will keep you brushed up on the Military Game ---------- 2.50

TACTICAL WALKS. Waldron. The details of the up-to-date method of training in Minor Tactics. The system that will be employed in Training Camps and in determining qualifications for promotion ---------- 1.50

ARMY PHYSICAL TRAINING. Waldron. The System of Physical Training in the Army systematized. Exercises all arranged in logical sequence and each fully illustrated ---------- 1.50

SCOUTING AND PATROLLING. Waldron. A little book that tells all about how the individual scout goes about his work and how the operation of a patrol are conducted ---------- .75

INFANTRY DRILL REGULATIONS. (Provisional), 1919. The Infantry Association Edition. Illustrated and Annotated. Original text preserved intact. Cloth bound ---------- .75

INFANTRY SCORE BOOK. U. S. Infantry Association. If you are going to take advantage of the opportunity for target practice this summer this is the book you will need. Detailed instruction for the individual marksman. Score sheets for all classes of Fire ---------- .35

MILITARY SKETCHING AND MAP READING. Grieves. The best and most complete book on the subject that has been produced. All that you need to know about it ---------- 1.50

TECHNIQUE OF MODERN TACTICS. Bond-McDonough. The standard American work on modern tactics and troop leading methods. Used by students at all service schools and by all officers preparing for examination ---------- 2.65

USE THE ORDER BLANK BELOW.

THE MILITARY ENGINEER, 423-425 G Street, N. W.

Inclosed please find ---------- for $----------. Please forward the books checked to the address below: Company Administration. Platoon Training. Thirty Minute Talks. Tactical Walks. Army Physical Training. Scouting and Patrolling. Infantry Drill Regulations. Infantry Score Book. Military Sketching and Map Reading. Technique of Modern Tactics.

ADDRESS----------

Write address plainly. ----------

CRANE LIMITED — MONTREAL, TORONTO, VANCOUVER, WINNIPEG, LONDON, ENG., SYDNEY, N. S. W., QUEBEC, HALIFAX, OTTAWA, REGINA, CALGARY.

We are manufacturers of about 20,000 articles, including valves, pipe fittings and steam specialties, made of brass, iron, ferrosteel, cast steel and forged steel, in all sizes, for all pressures and all purposes, and are distributors of pipe, heating and plumbing materials.

Digitized by Google

All kinds of building construction,
Water supply installation and operation,
Electrical and mechanical installation and operation,
Railway construction, Dock construction,
Bridge construction, Highway construction,

or, in other words, the construction regiments are to be the "General Engineer Troops" for the communications zone.

Railway Troops

All railway construction is done by general Engineer troops in the forward area, or by construction troops in the communications zone. Railway troops will, therefore, be provided only for operation and maintenance of railroads, either broad or narrow gauge, and will be organized into standard railway operating battalions—each battalion to include the personnel necessary for operation, maintenance of way, and maintenance of equipment for one railway operating division. The railway operating battalions will be assigned to the communications zone and G. H. Q. Reserve, the latter being available for pushing forward into the Army areas taking over the operation of new lines, ultimately to be absorbed in the communications zone.

Lumbering Troops

It is believed that the need for Engineer troops for the production of lumber in future operations will be much less than was required in the A. E. F. For any operations in the United States production will be mainly from commercial sources, although production in the theatre of operations should be developed to a maximum in order to relieve congestion on transportation lines from the Zone of the Interior. Such lumbering battalions, as are necessary in any given operation, will be organized and assigned to the communications zone.

Depot Troops

Depot battalions will be organized and assigned only to the communications zone—one company out of each battalion being recruited as a shop company. Engineer supply work in the combat zone will be handled by general Engineer troops, as explained above.

Bridge Trains

Bridge trains, heavy and light, have been provided to care for and transport ponton bridge equipment. The heavy train, when furnished with the new equipment now being developed, will have three divisions (178 feet of bridge per division), and one supply division, or a total for the train of 534 linear feet of bridge, capable of carrying all corps and army loads. The personnel for these bridge trains will care for and issue fixed bridge material provided in depots, including timber trestle material, as well as such portable steel bridges as may be developed. The bridge train, formerly assigned to the corps, has been withdrawn to the army, making five heavy bridge trains with the army, and none with the corps; the idea being to assign bridge trains to corps and divisions from the army pool, in accordance with the prospective needs of the military operations in each case. No light bridge trains are assigned to Cavalry divisions, but two are allotted to the Army for assignment in Cavalry operations, to meet local requirements. The light bridge train will be the same as that previously known as the advanced guard ponton train, consisting of three divisions of canvas ponton boats (185 feet of bridge per division).

Water Tank Trains

Each train will consist of five truck companies of 27 tank trucks each, and one truck company of 20 purification trucks; one train to be assigned to each Army, and one held in G. H. Q. Reserve, to be used for distributing and purifying water to troops in the forward areas.

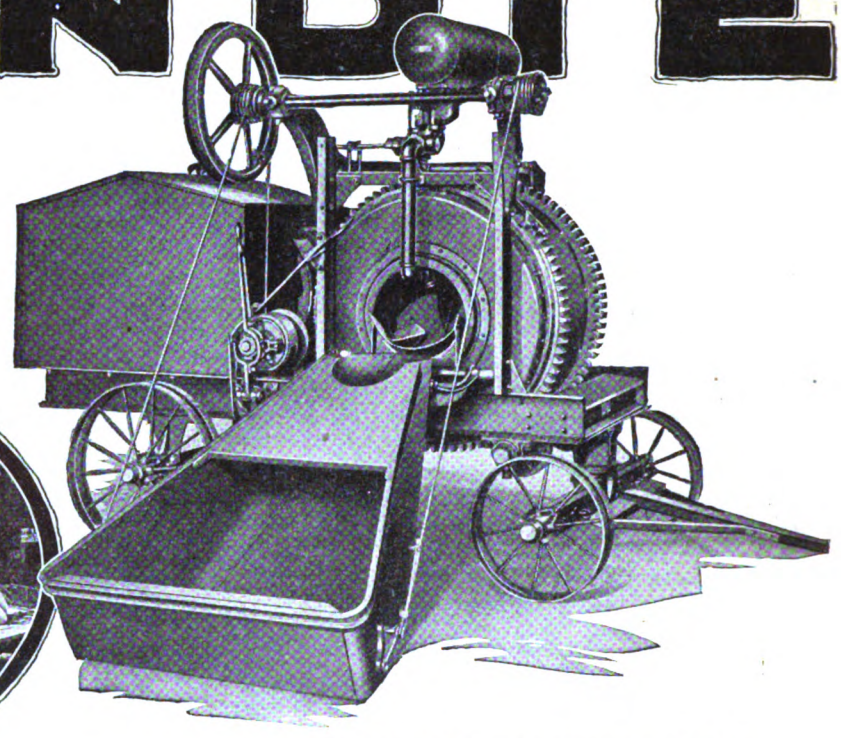
The *general policy* in regard to the *maintenance and operation of communications* is for the troops working on communications in the communications zone to push forward and take over the operation and maintenance of communications as rapidly and as far to the front as possible. For this reason, all special Engineer troops required for work on communications such as road and railway troops, have been omitted from the army Engineer service. In case these troops, under certain circumstances, are urgently needed in the army areas, they will be temporarily assigned to the army from the G. H. Q. Reserve, with a view to their transfer to the communications zone as soon as the newly acquired lines of communication can be absorbed in the existing system of communications, and their operation and maintenance taken over by the communications zone.

Detailed Tables of Organization and Equipment for all Engineer units included in the approved project are now being prepared in the Office of the Chief of Engineers. The tables for the Combat Engineer Regiment at war strength—as approved by the Chief of Engineers, and submitted for approval of War Department—shown herewith.

The strength of this regiment was fixed by the War Department at about 800 enlisted, after the Special Committee —convened for drawing up the general organization project —had recommended as the Engineer component of the Infantry division, only one three-company battalion, with a total enlisted strength of 650. The following extract from the Committee's report is of interest:

> That the engineer unit which forms part of the division should be reduced to the minimum number always required; the additional engineer and labor troops required for special situations should be furnished divisions from corps troops. The strength of the engineer component in the A. E. F. division frequently resulted in its employment as infantry, where the emergency did not justify such use of special troops. The smaller Engineer component recommended in Appendix 2 aids mobility of the division and should tend to regulate the proper employment of Engineers as Infantry.

The Chief of Engineers, as well as a number of officers of other arms, advocated strongly a regimental organization for the Engineer component of the Infantry division, no matter what size was finally adopted, as well as a minimum strength for that component of 6½ per cent of the total strength of the division (the A. E. F. percentage). The 1150-man regiment, accepted for all other Engineer regiments, was definitely proposed and recommended for the Infantry division, but—in view of the very pronounced recommendations of the Special Committee for a drastic cut in the Engineer component of the division—the War Department modified the committee project in this respect only so as to increase the strength from 650 to 800, and to authorize the change from battalion to regimental organization.



It is believed that the general organization of the Engineer Service, as outlined above, and as approved by the War Department, will provide a practicable plan for mobilizing our Engineer resources, so as to function efficiently in any future war, especially in a war on this continent. It is not modeled exactly on the organization developed during the recent war; many Engineer officers may believe that too many specialist troops have been retained, and others that important specialists have been eliminated, or that other details of organization do not represent the best practice as shown by our experience in the recent war. However, it is believed that the basic principles on which the organization was worked up are sound, that the essential lessons of the war have been incorporated, and that changes in details can well be left for future experience to dictate.

DANDIE

The Big Value
KOEHRING-BUILT
Light Mixer

Sizes 4 and 7 cubic feet mixed concrete. May be equipped with low charging platform, charging skip or batch hopper, automatic water measuring tank and light duty hoist.

The Lowest Price You Can Afford to Pay

THERE are lighter mixers than the Dandie. There are cheaper mixers than the Dandie.

But the Dandie is as light as a ***good*** mixer should be built. And its price is the lowest for which such a mixer can be sold.

The Dandie is made by the largest makers of heavy duty mixers in America. Every economy of automatic machinery, standardized processes, and quantity production is reflected in its price.

In it is incorporated many of the features of the Koehring heavy duty mixers. It has the famous Koehring re-mixing action—the double gear drum drive—drum rollers keyed to shafts turning in big bearings.

Its cost is the ***lowest price you can afford to pay!*** It is not the cheapest mixer, but the reliable, money-making, long-service light mixer, at the extremely reasonable price which makes it the ***big value*** buy in the ***light mixer*** field.

KOEHRING MACHINE COMPANY

The Harbor of Montreal

The Great Lakes-St. Lawrence Route to the Sea

By

Jno. C. H. Lee

Major, Corps of Engineers

A NAVIGABLE WATERWAY connecting the Great Lakes with the sea has been in the minds of progressive and farseeing Americans for many generations. The early explorers dreamed of it. The founders of our nation discussed it. The Erie Canal, built early in the last century from Buffalo to the upper Hudson, was an expression of it, and the prosperity thus brought to New York State and the Lake region was justification of the idea. Nor has Canada failed to act on it. By means of ship canals and improved river channels she has had 14-foot navigation from Lake Ontario to Montreal for many years. Like the Hudson below the Erie Canal, the St. Lawrence below Montreal has always been navigable for the vessels that could reach it from above.

Both countries have worked at the barriers between the several lakes, and the four upper ones are now interconnected for approximately 20-foot navigation. The rapid increase of commerce, however, has overtaken and passed beyond the capacities of the water routes below Lake Erie. Within the last decade the enlarged Erie Canal now known as the New York Barge Canal, affording 12-foot navigation, has been opened. This unfortunately offers even less navigable depth than the existing Canadian routes which parallel the St. Lawrence and which moreover the Canadians have apparently considered inadequate for some time past.

The bulk of lake-borne freight is now discharged from vessels in Lake Erie ports and transferred to the railroads. For export goods, a second transfer from railroad to ocean-going ships is, of course, necessary at the seaboard.

The strain which the war put upon all transportation in America has given further stimulus toward considering an adequate water route to connect the open sea with the great navigable lakes which border on some of the most productive sections of the United States and Canada.

The strongest expression of opinion today in favor of such a route is The Great Lakes-St. Lawrence Tidewater Association, which recently held its convention in Detroit. Their organizations in 14 states and representatives in many more are vigorously pushing the plan.

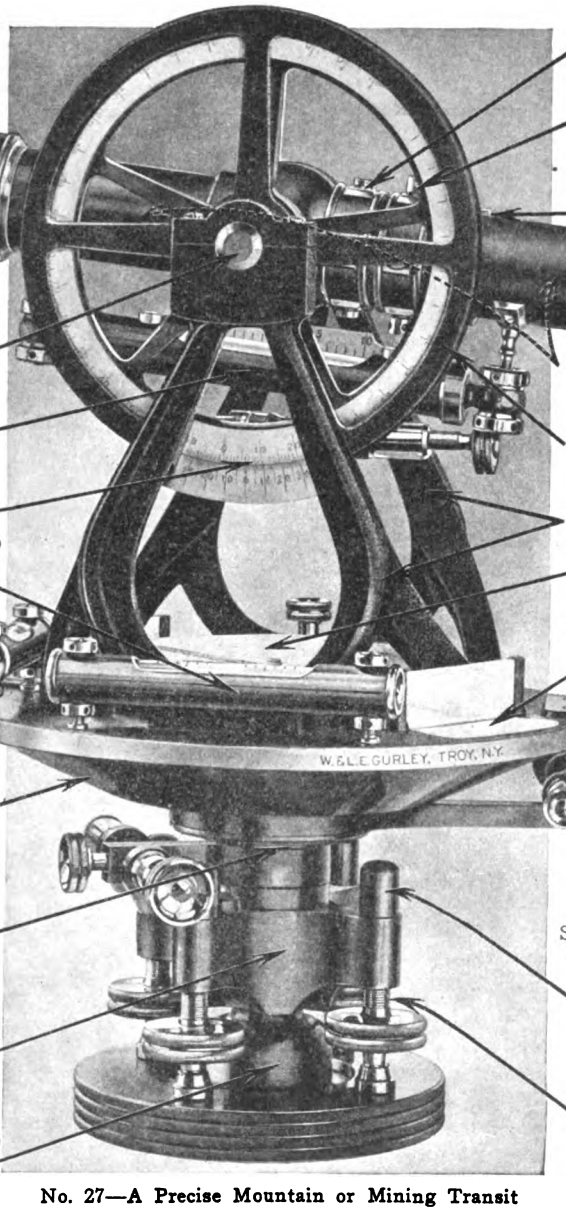
On the other hand some strong opposition has developed within this country and in Canada. The opposition is not as well organized apparently and may, therefore, not seem as strong as it may develop to be later.

Mr. Horace C. Gardiner, President of the Tidewater Association, recently said in a paper advocating the project that the territory included in black lines of Fig. 2 is economically nearer to Lake and St. Lawrence ports than any seaport east, south or west, either in actual miles or in considering mountain ranges to be crossed; that the territory is rightly called "The heart of the Country," because it comprises more than one-third of the continental area, more than one-third of the population, more than one-third of the wealth, and probably more than one-half of the productive capacity of the United States.

The latest available figures, according to Mr. Gardiner, show that within this area are produced the following percentages of the nation's total output:

	Per cent		*Per cent*
Corn	65	Cheese	57
Wheat	74	Apples	21
Flax, practically	100	Beet sugar	58
Cattle, over	50	Coal mined	36
Hogs	57	Coal reserves	72
Horses	60	Copper	39
Butter	54	Lead	46
Eggs	54	Zinc	74
		Iron ore	85

Production Centers



The encircled figure (Fig. 2) shows centers of population, production and value. They are based on data of 1910-1914, but, as Mr. Gardiner points out, such centers do not shift rapidly.

1. Center of population;
2. Farm acreage;
3. Farm values;
4. Wheat;
5. Corn;
6. Oats;
7. Potatoes;
8. Wool;
9. Tobacco;
11. Beet sugar;
12. Horses;
13. Sheep;
14. Milch cows;
15. Other cattle;
16. Butter;
17. Swine;
18. Iron ore;
19. Pig-iron production;
20. Bituminous coal reserves;
21. Bituminous coal production;
23. Manufacture—primary horsepower used;
24. Persons engaged in manufacture;
25. Manufacture — value added by—
26. Cheese;
28. Shoes;
29. Eggs;
30. Men's clothing;
31. Slaughtering and meat packing;
32. Automobiles;
33. Rubber goods.

Advocates of the plan point out that local charges on freight in the eastern seaboard ports are often in excess

of the freight charges to those ports and often many times over. Moreover, they say that the congested condition does not improve, that the neck of the transportaton bottle is near New York, causing delay to freight and freighters, increasing costs and damage to export and import trade.

Illustrating the cost of handling freight locally in New York, Mr. William H. Adams, of the Detroit Board of Commerce, refers to the statement of the New York Society for Improving the Condition of the Poor that:

"Out of every dollar paid by dwellers on Manhattan Island for foodstuffs sixty cents goes for transportation *inside the industrial limits of the city.*"

Opponents to the St. Lawrence Route contend that equal or even greater difficulty and delay would be caused by the fog and ice of the river. The advocates come back with the answer that the new route will take the peakload of traffic—the late spring, summer and fall seasons—then releasing the lake-to-sea carriers for coastwise trade farther South. Moreover, freight cars on the shorter haul to Lake ports could be returned more expeditiously over their own lines, at least doubling their freight capacity.

The opposition claims that the lake carriers cannot navigate the more hazardous open sea and that the sea freighters will not find sufficient depth in the lake channels, locks and ports. To this contention the boosters reply that no one intends that the long lake freighters should ply the open sea, they have all they can do and more in the lakes; that strictly lake traffic will not lessen; and, as regards the ocean freighters, the majority of ocean freight today is carried in bottoms that can navigate the 21 to 25-foot depths of the lakes. In other words, the great ocean freighters would remain characteristic of salt-water navigation even as the long whale-back and freighter will remain of the lakes, but the bulk of the lake-sea traffic will be carried, as is always the case, by the average type well under 10,000 tons burden.

The geographical advantages of this route are pointed out by Mr. Gardiner. Fig. 4 shows a projection of the North American Atlantic and European-Atlantic ports, with meridians as straight lines and parallels as concentric circles. The following comparisons, however, measured in actual great circle distances, are quoted as of interest:

Rochester is nearer Liverpool than is New York; Buffalo is a few miles farther; Toledo is nearer Glasgow than is New York; also nearer Belfast and all Scandinavian and Baltic ports; Detroit is but a few miles farther.

From Erie and Ontario ports it is 250 miles farther via New York to northern French ports and all North Sea ports than via the St. Lawrence.

To Glasgow, Belfast, Scandinavian and Baltic ports the differential is 500 miles. To Mediterranean ports New York's advantage is small.

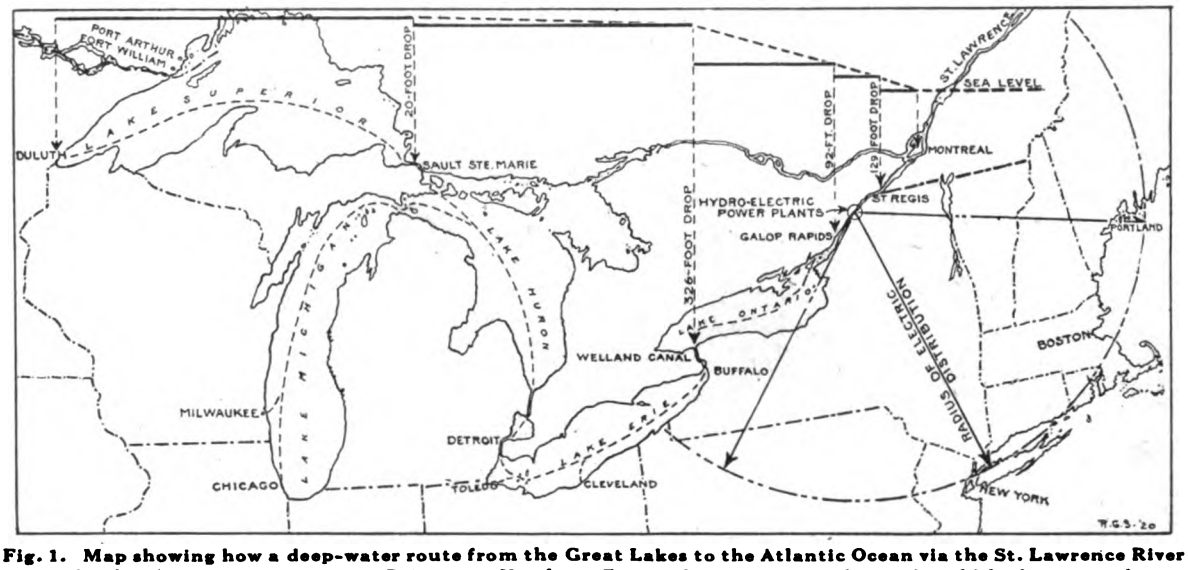

Fig. 1. Map showing how a deep-water route from the Great Lakes to the Atlantic Ocean via the St. Lawrence River would shorten a voyage to Great Britain or Northern Europe by quite 500 miles and yield hydro-power for distribution over a wide radius from the dams*

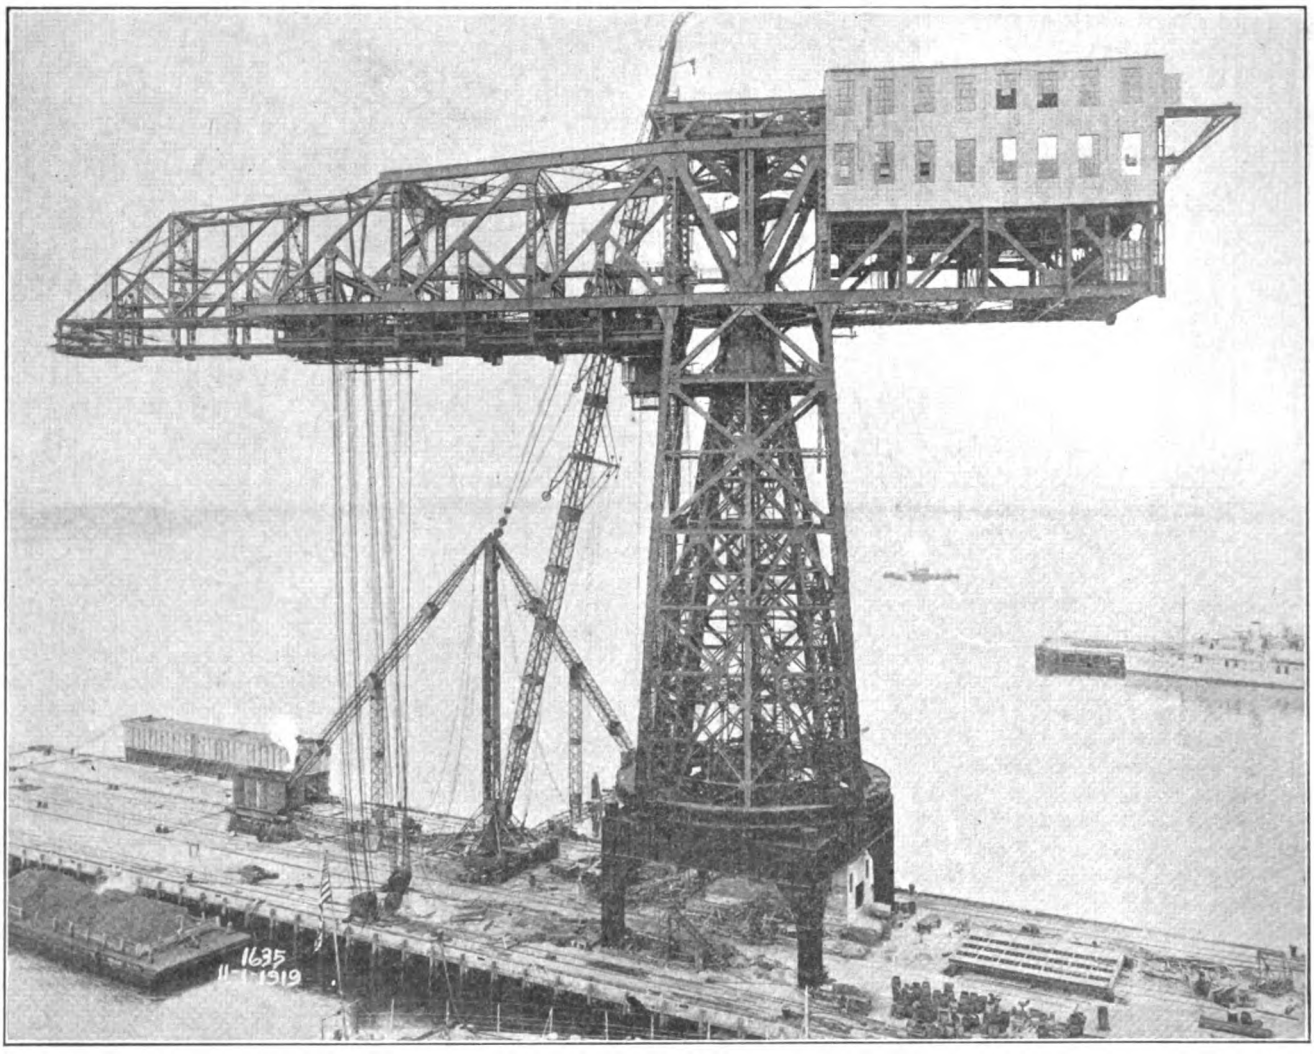
The advocates also express a belief that immigration from northern Europe to our Northwest will be stimulated and that the present lack of manpower in farming America and Canada will be relieved by these agricultural people being able to sail almost directly to the farming centers where many of their kinsmen are now developing the soil.

It is claimed also that something in the neighborhood of four million hydroelectric horse-power can be developed simultaneously with the river navigation improvements which must overcome the St. Lawrence rapids, that this power will be a boon to manufacture, will help solve the national fuel problem, and best of all, will actually pay for the cost of the entire project. The opponents deny this and say that the power is not needed. The pros and cons were generally summarized before the National Rivers and Harbors Congress during December, 1919, as follows:

For—

Bringing the Atlantic to the heart of the continent; making the Great Lakes an American Mediterranean; solving the national transportation problem; development of some 4,000,000 hydroelectric horse-power, thus remedying the national fuel crisis; enhancing the industrial powers of the seaboard; a national undertaking for national and international commerce; great saving in grain shipping costs; putting the profits into the pockets of the farmer; a lasting bond between the United States and Canada.

Against—



It would prove an economic failure and a waste of money; prohibitive cost; fogs and ice would make St. Lawrence Route too hazardous; ocean vessels cannot use restricted channels or afford lockage delays; no return

THE McMYLER INTERSTATE CO.
CLEVELAND OHIO

THE LARGEST CRANE AND THE LARGEST STIFF-LEG DERRICK

The crane shown, which lifted 505 tons at one time, is in operation in the Philadelphia Navy Yard, where it was erected by the aid of the largest stiff-leg derrick ever constructed.

The height of the crane is 235 feet, while the derrick is equipped with a boom 252 feet long.

Both the crane and the derrick were designed and built by THE McMYLER INTERSTATE CO.

By those who are uninformed, this crane installation may be accepted as an index to our possibilities.

loads, one-way traffic cannot be developed; underlying purpose is Canadian control of grain exportation; designed to destroy competition of the New York Barge Canal; the power is not needed; exposure to British naval attack.

Dismissing for the time being these questions of opinion it should be of interest to look into the real facts regarding the present condition of the Great Lakes-St. Lawrence water route. From our U. S. Lake Survey Charts, and they are thoroughly reliable, one can readily see that the Great Lakes generally are navigable for vessels of 21-foot draft.

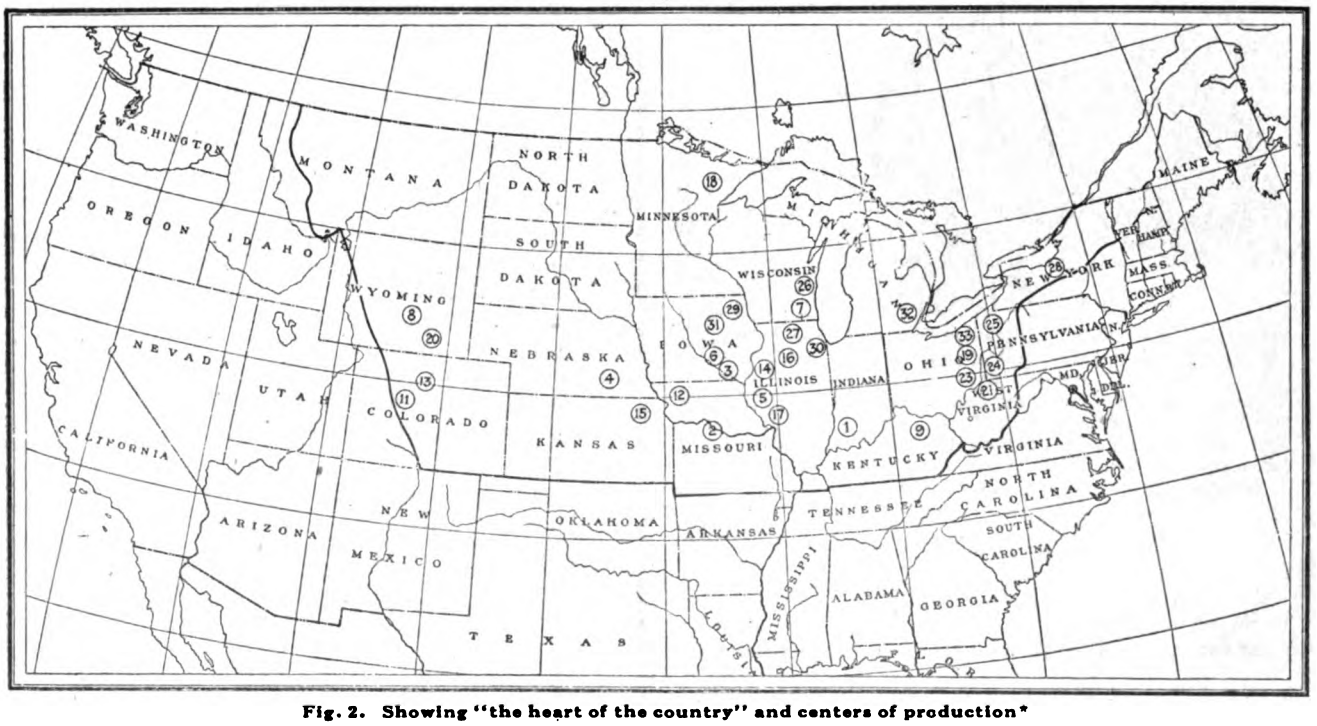

Fig. 2. Showing "the heart of the country" and centers of production*

The principal harbors have been dredged to this depth. Between the various Lakes of different level there exist certain natural barriers.

Between Lakes Superior and Huron the Rapids of the St. Marys River are now overcome by two large American locks, affording full depth, and by one Canadian and two American locks of lesser depth.

Between Lakes Michigan and Huron there is no important difference of level. The straits of Mackinac afford ample passage.

Between Lakes Huron and Erie the St. Clair River, Lake St. Clair and the Detroit River have been improved by the United States so as to afford 21-foot navigation.

Between Lakes Erie and Ontario stands the greatest barrier, Niagara Falls and Rapids. Our National Government has never undertaken the task of constructing a waterway around this barrier, although the matter has often been considered. The Erie and later New York State canals have been the only American developments. Canada, however, has had 14-foot navigation by means of her Welland Canal since the eighties. In 1913 she commenced a project to improve this canal to 25 feet, the twenty-five old locks to be replaced by seven lifts affording 30 feet over the mitre sills. Pressed by the demands of the war, Canada tried to push the work, but had to drop it in 1916 with the task about one-third completed. Work, however, was resumed last year and afforded employment to many discharged soldiers. Progress is being made in all sections and there is no doubt that its 25-foot navigation will be opened well before any channel of similar capacity can be completed along the St. Lawrence route below.

This new Welland Canal is an essential and therefore interesting link in the chain. Its line follows the old location from Port Colborne on Lake Erie as far as Thorold. Here, cut through almost solid rock, twin locks of three flights are being built. From that point the channel is practically straight, using four single locks, to the new Port Weller on Lake Ontario. Each lock has a lift of 46½ feet. The channels will be 200 feet wide on the bottom, 310 on the surface. The canal is 25 miles long and the time required for passage is expected to be about 8 hours. The original estimated cost was 50 million dollars; probably it will total between 80 and 100 million.

The barriers below Lake Ontario consist of the rapids of the St. Lawrence River between Ogdensburg, N. Y., and Montreal. Parts of this stretch are navigable. The Canadian Government has for years been operating a series of ship canals giving 14-foot navigation around the different rapids. Some of the rapids are navigated by down-bound vessels, but up-bound vessels must use the canals.

It is in this section that the real problem lies, the problem of opening deep water navigation from the Lakes to the Sea. Below Montreal the Canadians have already provided a 30-foot open river channel to the Atlantic.

The United States Rivers and Harbors act approved the 3d of March, 1919, carried a provision requesting the existing International Joint Commission (created by treaty, 1909, between Great Britain and the United States for boundary matters) "to investigate what further improvement of the St. Lawrence River between Montreal and Lake Ontario is necessary to make the same navigable for ocean-going vessels; together with the estimated cost thereof; and report to 'both governments' recommendations for co-operation by the United States with the Dominion of Canada in the improvement of said river."

Accordingly, both our government and that of Canada

BAYER Valves

BAYER Valves are made in heavy-pattern regrinding globe, angle and check types, screw and flanged ends—all good for working pressures up to 225 lbs. Each one is guaranteed to meet the metal composition requirements of U. S. Navy Department specifications 46-B-8, June 20th, 1913, covering valve bronzes or composition "M."

Body walls are of liberal thickness, with a uniform distribution of metal. Valve seats are radial, and can be ground continually, thus prolonging the life of the valve indefinitely. Discs are made of a hard bronze composition; stems are unusually heavy with a greater number of accurately cut threads than usually found in valves of this type.

Naturally, continued satisfaction is the only logical result that can follow adherence to the BAYER standard. Send for our book "The BAYER Valve."

asked the Joint Commission definite questions, the most important of which are: "What further improvement is necessary—for deep-draught vessels of either the lake or ocean-going type; what draught of water is recommended; and what is the estimated cost?"

In answering these questions the Commission is requested to consider:

(*a*) Navigation interests alone, whether by the construction of locks and dams in the river; by side canals with the necessary locks; or by a combination of the two.

(*b*) The combination of navigation and power interests to obtain the greatest beneficial use of the waters of the river.

In order to facilitate and expedite the preparation of the report, each Government appointed an engineer, the two men having full authority to confer mutually and to co-operate in acquiring data and in preparing plans and estimates. These plans and estimates must be submitted to the Commission within one year after the engineers were named. For the United States, Col. W. P. Wooten, Corps of Engineers, was appointed in January, 1920. Colonel Wooten is the officer in charge of the United States Lake Survey. For Canada Mr. W. A. Bowden, Chief Engineer of the Canadian Department of Railways and Canals, was appointed in March, 1920. All concerned are now busily engaged in the collection of information and in the preparation of plans and estimates. The Joint Commission has been holding public hearings for several months.

Between Lake Ontario and the International Boundary the United States Lake Survey had already covered the St. Lawrence with accuracy greater than was possible to repeat within the allotted time. Similarly, the Canadian Government had charts of the river below the boundary. It has, therefore, become necessary only to supplement this information by more detailed surveys and borings at critical points. At such places investigations are being pushed with energy and thoroughness.

The writer has corresponded and consulted with the two engineers, and through their courtesy is able to outline briefly the essential physical data now known. Of course, neither engineer can properly express an official opinion at this time, and neither could with propriety be quoted personally. There are many problems to be considered; navigation depths, discharge, compensation of water levels, flowage areas and damages, power development costs and possible market value, construction difficulties, foundations, ice obstructions and many others. The report of the Engineers to the Joint Commission will be a statement of such facts and estimates as they can, in general, present in so limited a time. There is no reason to believe, however, that sufficient data will not be available to enable the Commission to arrive at a sound recommendation.

It is of interest to look at those characteristics of the St. Lawrence already of record—the better to understand the problem that confronts our engineers. The river's tributaries above Lake St. Louis, where it is joined by the Ottawa River, are relatively insignificant. Its waters, therefore, having been subjected to long periods of sedimentation in the various lakes, are clear and carry practically no matter in suspension. Its flow is governed by the elevation of water in Lake Ontario. As that lake has an extreme fluctuation of about five feet and an ordinary annual fluctuation of very much less, the St. Lawrence naturally has a remarkably steady flow. No other river of its size compares with it in this respect. Its flow varies ordinarily from 200,000 to 280,000 cubic feet per second, although during the period 1888-1919 it has at times dropped as low as 186,000 due to a certain amount of ice choking. During extreme high water it has once or twice reached 300,000. Its lack of material in suspension, its constancy of flow, the stiff and stable quality of the material through which it flows, combine to render its banks and bed remarkably constant. Natural changes within the memory of man are practically unknown.

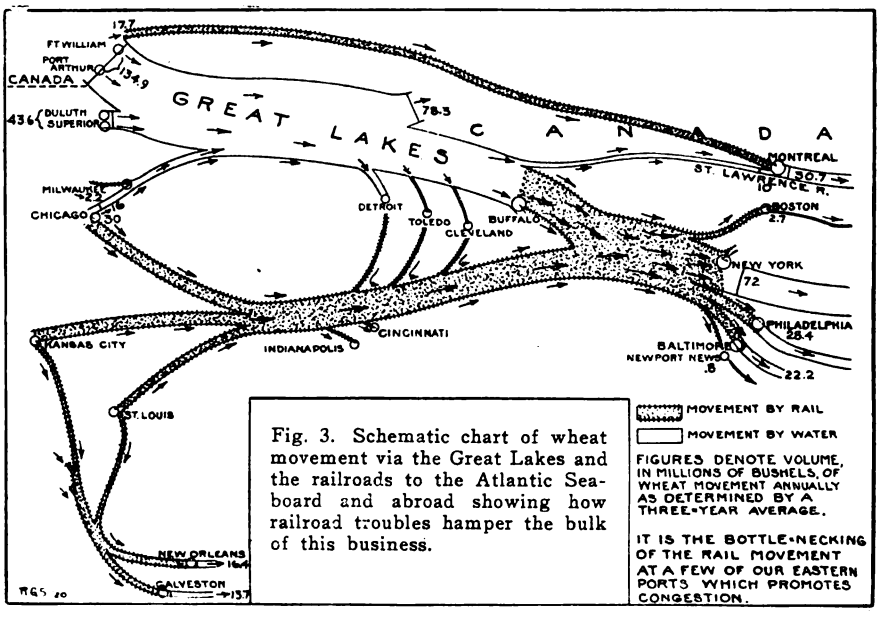

Fig. 3. Schematic chart of wheat movement via the Great Lakes and the railroads to the Atlantic Seaboard and abroad showing how railroad troubles hamper the bulk of this business.

Just above Montreal, in Lake St. Louis, the Ottawa River offers an additional problem. This stream has a very wide fluctuation, reaching a discharge in high water approximately equal to that of the main river. However, this condition affects only the lower end of the stretch requiring improvement. It is practically a local problem.

The river distance from Lake Ontario to Montreal (see Fig. 8), is about 182 miles and the total fall is between 220 and 225 feet. Considering that there are several long broad reaches, approximating lakes, it is evident from even a cursory examination that this length of the river naturally divided itself into six distinct sections of quite different local characteristics, each requiring special study and consideration and possibly its own special method of improvement.

The first section extends from Lake Ontario to just below Ogdensburg, N. Y. The total fall in this 62 miles is less than 1 foot. As one would expect, the river is broad and deep, and the velocity is low. The channel gives depths of 40 to 120 feet. Except in two places the width is better than 500 feet. Where the river passes the Thousand Islands and again at the Brockville Islands, the present ship channel is only a little wider than 400 feet and would probably require some work. For security of deep draught vessels this entire stretch should be "swept" in order to locate isolated pinnacles which may have escaped the soundings of previous surveys.

The second section extends from below Ogdensburg to

the head of Lake St. Francis, or where the St. Regis River comes in at the International Boundary. From this point on, the St. Lawrence flows entirely in Canadian territory. The length of this second section is about 54 miles and its fall is about 90 feet. Three rapids account for the greater part of this drop; the Galops Rapids, the Rapids Plat and the Long Saulte. The Canadian Government operates side canals, affording 14-foot navigation around these various rapids. The Galops Canal takes care of the rapids of the same name. The Morrisburg Canal overcomes the Rapids Plat. The Farrin Point Canal provides passage around a small drop of 4 feet. The Cornwall Canal takes care of the Long Saulte. Otherwise, vessels use the open river. Descending vessels habitually shoot all rapids except the Long Saulte. This rapid is navigated only by passenger boats featuring the excitement of the trip.

This second stretch offers quite a problem for improvement. One can hardly expect that dams and slack-water will be recommended for the entire section because sufficient water to flood out the upper (Galops) rapids would raise the level of the upper river and Lake Ontario about 15 feet. It would seem after brief study that dredging would be practicable in the upper Galops provided the lower part is drowned out by slack-water backed up by a dam further down stream. If dredging here were resorted to, care must, of course, be taken to provide a sufficiently large cross section to keep down the velocities in the ship channel.

It would seem that a dam in the general vicinity of Cornwall, and possibly another somewhere above, would provide sufficient depth for navigation while developing well over a million horsepower.

It is understood that a commercial project was at one time planned for a power dam near the head of Croil Island. Our engineers have made borings above Cornwall, as well, and have found rock at what might seem to be desirable elevations. The solution of the problem must, of course, be based on a balance of costs against the facilities developed. If the rock for the foundations of the upper dam is found at about the same elevation as at the lower site, then a single dam project would probably have an advantage in cost of dam construction, cost of power installation and better provision for navigation. The flowage damage or cost of dykes would be greatly increased between the two sites.

Realizing that the power developed at this section of the river could be delivered to the greater part of New England and New York (see Fig 1), there should be no difficulty in disposing of it at a figure sufficient not only to pay interest on the investment, but also on other work of the same project, if not indeed to give ultimately a return on the original investment. Considering the steady flow of the river and the high machine efficiency now possible, it would seem sound to count on about 75 per cent of the total theoretical horsepower or at least 1,750,000. If this were sold at $20.00 per horsepower per year it would return 7 per cent on $500,000,000.

The third section may be taken as Lake St. Francis, where for some 28 miles the river widens to four or five miles. In some places the channel will require widening and deepening. There is no apparent reason why open lake navigation cannot be provided for ocean-going craft at a low cost.

The fourth section is a stretch of 14 miles connecting Lake St. Francis with Lake St. Louis. In this length is a series of rapids; the Coteau, the Cedars, the Split Rock and the Cascade—a total fall of about 80 feet. At present a few down-stream boats "shoot" the rapids. The Soulonge Canal provides 14-foot navigation on the northern side. The old Beauharnais Canal lies on the southern side.

This section offers a problem similar to the second, but probably with not as many factors. There are apparently good general locations for a dam in one or two sections at the head of Lake St. Louis, just above the mouth of the Ottawa River. Judging from their practice in the past, however, we can expect the Canadians to consider seriously, if not indeed to favor, a ship canal around the rapids. A cursory examination would indicate that such a plan is practicable on the southern side. If no great obstacles are encountered, say in the valley of the St. Louis River, such a project should be considerably cheaper than a fixed dam and slackwater. Moreover, it is possible that if a fixed dam developing the full power head were installed and the power offered at the same time as that of section two, there would be little chance of complete utilization for several years. If this be true, if the power could not be immediately marketed, it might prove economical to provide the cheaper ship canal for the first decade or so, and later, if conditions seem to justify, make provisions for further development of the power.

The fifth section is Lake St. Louis, 15 miles long and rather shallow through the greater part of its 5 to 6 mile width. There exists, however, a fairly good channel which will require deepening and broadening, at least in parts. Due to the influence of the Ottawa River, whose variation in flow

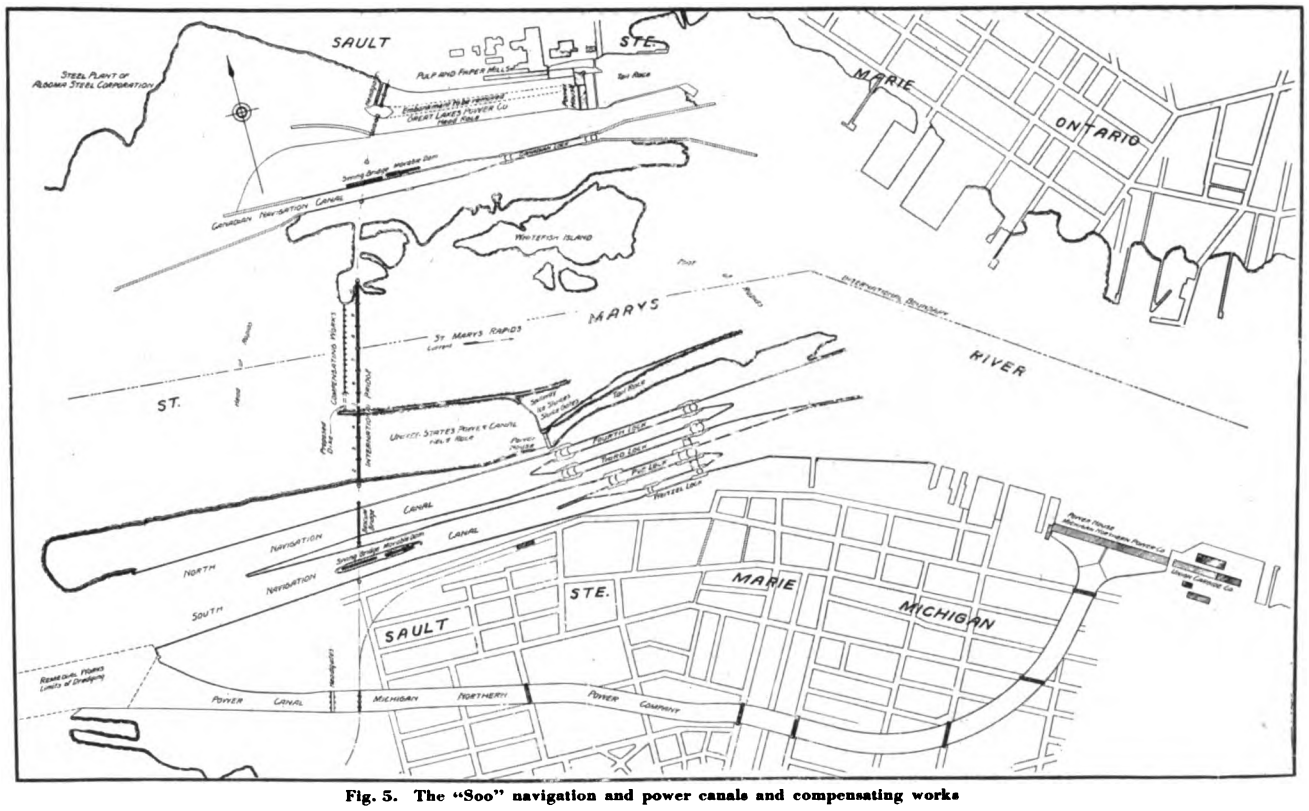

Fig. 5. The "Soo" navigation and power canals and compensating works

is quite large, the characteristics of the St. Lawrence below this point are less constant than above.

The sixth section is 9 miles of river between Lake St. Louis and Montreal. The river pitches down the Lachine Rapids, thence through the Prairie Basin, a broad and shallow lake with low banks. The total fall is about 50 feet, most of it confined to the Lachine Rapids which are navigated only by a few down-bound passenger boats. The Lachine Canal passes around them on the northern side, affording the regular 14-foot navigation. The improvement of this stretch is a problem in which the Canadian engineers can be expected to have most serious interest. Safeguarding the city of Montreal against the combined waters of the St. Lawrence and the Ottawa will play an important part. A power dam opposite or below Montreal, near the mouth of the present Lachine Canal, would require long dykes or levees to protect the city. Moreover, due to the low lying banks, a great flowage or very extensive dyke construction would be required on the southern side. This expense, coupled with the unreliability of the Ottawa River's discharge, would probably raise considerable opposition in the vicinity of Montreal. Moreover, it is understood that practically the only open opposition to the project in Canada is centered around Montreal, the present head of deep water navigation.

It is not improbable, therefore, to expect that some project such as the improving of the existing Lachine Canal will be seriously considered. If power is to be developed further, the site will probably have to be located above Prairie Basin at the foot of the main rapids. If navigation were locked past such a dam, there would remain the shallow Prairie Basin to be considered. The Basin has sufficient slope to make dredging through it perhaps a double task. As in the Galops Rapids of section two, if a single 600-foot channel 30 feet deep were cut through, hydraulic conditions would be so improved as to develop velocities probably beyond those desirable for navigation. Either additional cross section could be dredged, or the adjacent water kept out by a dyke, thrown up from the spoiled material which would be mainly rock.

This brings us to the head of existing 30-foot navigation to the sea. The Canadian Government has now provided at considerable expense, a good sailing channel through which some four million tons per season come up and go on through the cramped upper canals, to the lakes. The river and canals are usually open to navigation from the middle of April to the first part of December. During the winter and early spring ice closes the route.

Thus we see confronting the engineers and the Commission, six sections of river, three of which offer little or no difficulty; the upper river and the two "lake" reaches. There remain three stretches of rapids requiring individual study and investigation. Possibly they will require separate and different treatment.

The engineers are confronted with several interesting side problems. One of the first is the regulation of water flow in the river by the control of water level in Lake Ontario. A steady flow of large volume is desired in the river, yet a maximum and minimum level must not be passed in the lake. Naturally, the property owners on Lake Ontario care neither to be flooded out nor yet left high and dry. The power and navigation interests along the river cannot be given a perfectly steady flow, but it should be possible to guarantee them a minimum of about 200,000 c. f. s. without detriment to Lake Ontario interests. This takes into consideration 10,000 c. f. s. for the Chicago drainage district.

Another problem is that of ice. The Canadian engineers, and our own to a more limited extent, have been working on the problem for years. There is surface ice, "snow" ice, "frazil" ice and "anchor" ice. Rapidly moving water exposed to the bitterly cold air becomes chilled below 32 degrees, and then will frequently perform unusual things. For example, zero temperatures lower even the

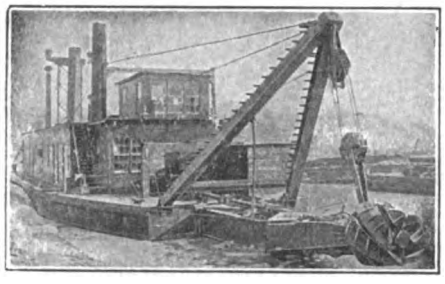
The "Soo." The most important link in the world's greatest waterway. First lockage in the new fourth lock, September 18, 1919

deeper water almost to freezing. When further exposed to the air at the swift and shallow rapids the water temperature falls to and below 32 degrees. Churned up among the rocks of the rapids it freezes much as do water ices or sherbets in an ice cream freezer. This is called "frazil" ice. Moreover, snow falling on such water does not melt but remains in suspension, floating along with the frazil ice. When quiet water is reached with its hard surface ice, the frazil and snow ice flows under at reduced velocity. The soft ice floats to the top and becomes congealed to the bottom of the surface ice, rapidly deepening it and causing unusual conditions. Anchor ice is solid and grows gradually from the bottom up. Ice packs and gorges often cause grave concern, with their attendant high water, but the river has a way of working under the ice and freezing itself. The engineers admit that the problem is extremely interesting, but there is no indication that they think it insurmountable.



The construction of dams in the main river bed should prove an engaging task to the men who may have to do the field work. Naturally the choice of dam sites will have to be governed to no small extent by this consideration. There is no way of shutting off the water during the working season. The flow is then distressingly steady. There is no "low water" as on the Ohio or the Mississippi. The task, if undertaken, must clearly be considered in its entirety, otherwise great difficulty, if not disaster, may result to construction work due to damming below or dredging above.

The economic feasibility of developing at first the full available hydro-electric power opens a serious question. Between Lake Ontario and Montreal the total theoretical horsepower is readily computed as over 6,000,000, 75 per cent of which totals some 4,500,000 horsepower. Whether or not this amount should be made available from the start or be provided for at an increasing rate, is a problem of industrial economics *vs.* costs and interests on costs of installation. To date only about 200,000 horsepower is actually being developed. Most of this is at two plants, one at Massena, N. Y., and the other at the Cedar Rapids between Lake St. Francis and Lake St. Louis. Plans for damming the river at the Long Saulte Rapids were prepared by a company some ten years ago. Failing to get legislative authority the project was finally abandoned. It is of interest to note, however, that financial interests were anxious to back the project for its power development and income. Although such a company would have to put in locks for the passage of navigation, the interests backing the scheme would derive little direct benefit therefrom. They merely recognized that the power would pay well on their investment.

Such being the general project, there naturally arises in one's mind the question: Is it practicable? Within a year the Joint Commission advised by the United States and Canadian engineers will make its report and recommendations. We can rely on them to recommend soundly. In the meantime we can do little more than consider the opinions of eminent public men on the question.

The writer has been told that a proposition has been suggested by a group of railroad engineers to lay a new

four-tracked-trunk-freight-line from a suitable point in the middle west, direct to a suitable eastern seaport, avoiding all existing railroad centers with their attendant congestion. The writer has been unable to get the details of this plan, or the names of the gentlemen responsible for it. It is said that they claim great saving would result and the first cost plus operation would be cheaper than any water route.

Mr. Herbert Hoover, in his study of the food and transportation situation, stated: "One of the first things which an engineer in surveying this problem would advise, would be the creation of a water-way all the way from the Great Lakes to the Sea by way of the St. Lawrence River. An engineer knows that this could be done at less expense than would be involved in increasing our railroad facilities to care adequately for our marketing."

Certain Eastern opponents of the plan claim that it is not practicable. *The Engineering News-Record* of New York, on the other hand, has said: "The opposers are those New Yorkers who fear for the prestige of the country's principal port and foresee the abandonment of the costly barge canal." Then it goes on to say, "New York, a year-round port, fed by the great railroad systems of the Nation, blessed by a magnificent basin of deep and still water at its very warehouse doors, has nothing to fear from the St. Lawrence Waterway; there also need be no fear for the abandonment of the Barge Canal following the canalization of the St. Lawrence."

The Merchants Association of Greater New York in April, 1920, condemned this project as chimerical and resolved that the delegates recommend to their respective chambers and commercial organizations that they use all reasonable means in opposition to a recommendation on the part of the International Joint Commission in favor of the United States joining with Canada in the construction of the proposed Ship Canal.

The New York State Legislature went on record last spring as emphatically disapproving the St. Lawrence project and sent copies of the resolution to the New York Senators and Members of the House of Representatives.

In this regard it is interesting to note that Dr. Roy S. MacElwee, Director of our Bureau of Foreign and Domestic Commerce, in advocating the St. Lawrence project, says: "It does not mean that all the traffic which will go out through the opened St. Lawrence will be traffic taken away from New York. On the contrary, it will be largely traffic that New York never can get because the merchandise at present can not bear the cost. It will be new business. The St. Lawrence will furnish abundant cheap power. The revival of lake shipping and cheap power are the two things needed to give the new barge canal the success it deserves. The New York state barge canal will be the greatest beneficiary of the St. Lawrence project."

Former Secretary Lane says: "It will make the Great Lakes the American Mediterranean for at least eight months of the year, making the lake cities practically sea ports, relieving the burden of the railroads, giving the Middle West more rapid dispatch to foreign markets at a saving of at least 5 cents per bushel." He adds that primarily he favors the project because of the tremendous electrical development and its subsequent saving to the country.

Governor Wm. L. Harding, of Iowa, has said: "Iowa knows that it is impossible to move its farms to the ocean but believes that through the St. Lawrence and the Great Lakes the ocean can be brought to them, and so Iowa is heartily in sympathy with the plan of developing the great water course to the extent that it will carry ocean-going vessels."

Dr. MacElwee, in his recent address before the Waterway Congress, asked: What ships will come into the Great Lakes from the ocean? Then he presented the figures of the United States Shipping Board, which show that the great majority of ocean going freighters today can navigate channels of 21 to 26 feet. Ships drawing 25 feet will be able to reach upper Lake Erie, while the 21-foot vessels will go beyond. Vessels can load to 21 feet in Superior, Michigan, or Huron, and complete their loading in Erie or below, to 26 feet, taking on the remainder to 30 feet at Montreal. Then, Dr. MacElwee asks, since they *can, will* they? His answer is based on the extensive use of the Manchester Ship Canal, where some 5,000,000 tons pass Liverpool annually and go through 36½ miles of restricted channel in order to reach a single city. The Kiel Canal, 61 miles long, is used in preference to the open sea in order to save a few hundred miles. And he shows further that many European ports, particularly in the Mediterranean and Black Sea, offer little or no greater depth than our lake harbors. Dr. MacElwee strongly favors the project.

Mr. Alex T. Vogelsang, 1st Assistant to Secretary of the Interior, stated, while acting as Secretary of the Interior: "Enlightened selfishness, the truest and highest interest of our country, our duty to all mankind, alike dictate that our back door as well as our front door be opened to ocean borne commerce." Moreover, he says, and his opinion de-

mands respect, that the power development can pay for the job.

Senator Chas. E. Townsend, of Michigan, said in a recent address: "We spent something over $400,000,000 to build the Panama Canal, but as far as serving the business interests of the country and of the world are concerned, the benefits are not comparable to those that would come through the development of the St. Lawrence Waterway to the Sea." Opponents of the plan might reply that the Panama Canal was not built entirely for business reasons.

Welland Ship Canal. Thorold locks, flight 4, 5 and 6

Mr. Julius H. Barnes, recent head of the United States Grain Corporation, says it may safely be estimated that from 5 to 6 cents per bushel on the exportation of grain could be saved via the St. Lawrence route over present facilities. If we continue to export 300 millions of bushels of grain, a saving of 15 to 18 million dollars would result in that trade alone. He points out that while to-day the railroad method of shipping grain to our eastern seaports keeps a heavy majority of our freight cars in the east for a majority of the months, if lake ports could be used for exporting grain the freight cars could make several short hauls to the Lakes during one season, and move largely under their owners' control. Union Pacific and Rock Island cars would not habitually winter in eastern yards.

Mr. Charles Whiting Baker, Consulting Editor of the *Engineering News-Record,* who has severely criticized what he terms our "lavish" national expenditures for inland water navigation, contends that generally speaking rail transportation is cheaper in the interior than canals and improved rivers, but nevertheless favors the development of a deep waterway connecting the Lakes with the sea. He contends that the final governing economic factor between railroad and water routes, lies in the cost of terminal charges, and therefore that the New York Barge Canal, necessitating a shift at Buffalo and again at New York, will prove prohibitive in cost for export commerce. He points out what has already been accomplished by the Shipping Board in a steamer sailing from Chicago direct to Liverpool. He believes that very capacious and seaworthy vessels can be built for the draft of 21 feet, and while habitually plying between sea ports during the greater part of the year, would then be released for coastwise trade during the closed lake season. Mr. Baker indicates a belief that the St. Lawrence project is a worthy one, but cautions that adequate terminal facilities must be provided if commerce is to be properly developed.

A statement of Mr. Baker on one point is of interest: "Lowering the cost of transportation between the Atlantic Coast and the interior cities on the lakes will benefit the Atlantic seaport cities ten times as much in domestic traffic as any loss of foreign business could injure them."

Open opposition to the plan seems to center in New York State. Before the National Rivers and Harbors Congress in December, 1919, Mr. Edward S. Walsh, Superintendent of Public Works, State of New York, spoke against it, as did also Mr. Geo. Clinton, of Buffalo. In addition to the contention before mentioned, these gentlemen declare that the St. Lawrence improvement would help a few states to the great injury of Southern, Southwestern, Middle and Atlantic states; that it would let Great Britain become a serious competitor in Great Lakes traffic; that our expenditure would greatly benefit Great Britain and Canada; that the improvement, lying largely in Canada, would menace our lake states in case of trouble with Great Britain; and that there would be no saving of coal by production of electric power, because almost all of the power would go to Canada.

Canadian River	2,000,000 hp.

Senator Lenroot, of Wisconsin, before the same Rivers and Harbors Congress, replied to the above objections. Whether or not they were answered is a matter of opinion. These papers can be readily obtained.

Proponents of the scheme claim that a very large amount of power would be used in New York, developing industries along the barge canal where raw materials could be brought in and the finished product sent out by the water route. They say that not only will the newly developed power replace that now made from coal, but will save the coal used in transporting the power coal, as transportation lines will become electrified. All in all an annual saving of many millions of tons of coal is predicted, as well as the labor of thousands of men.

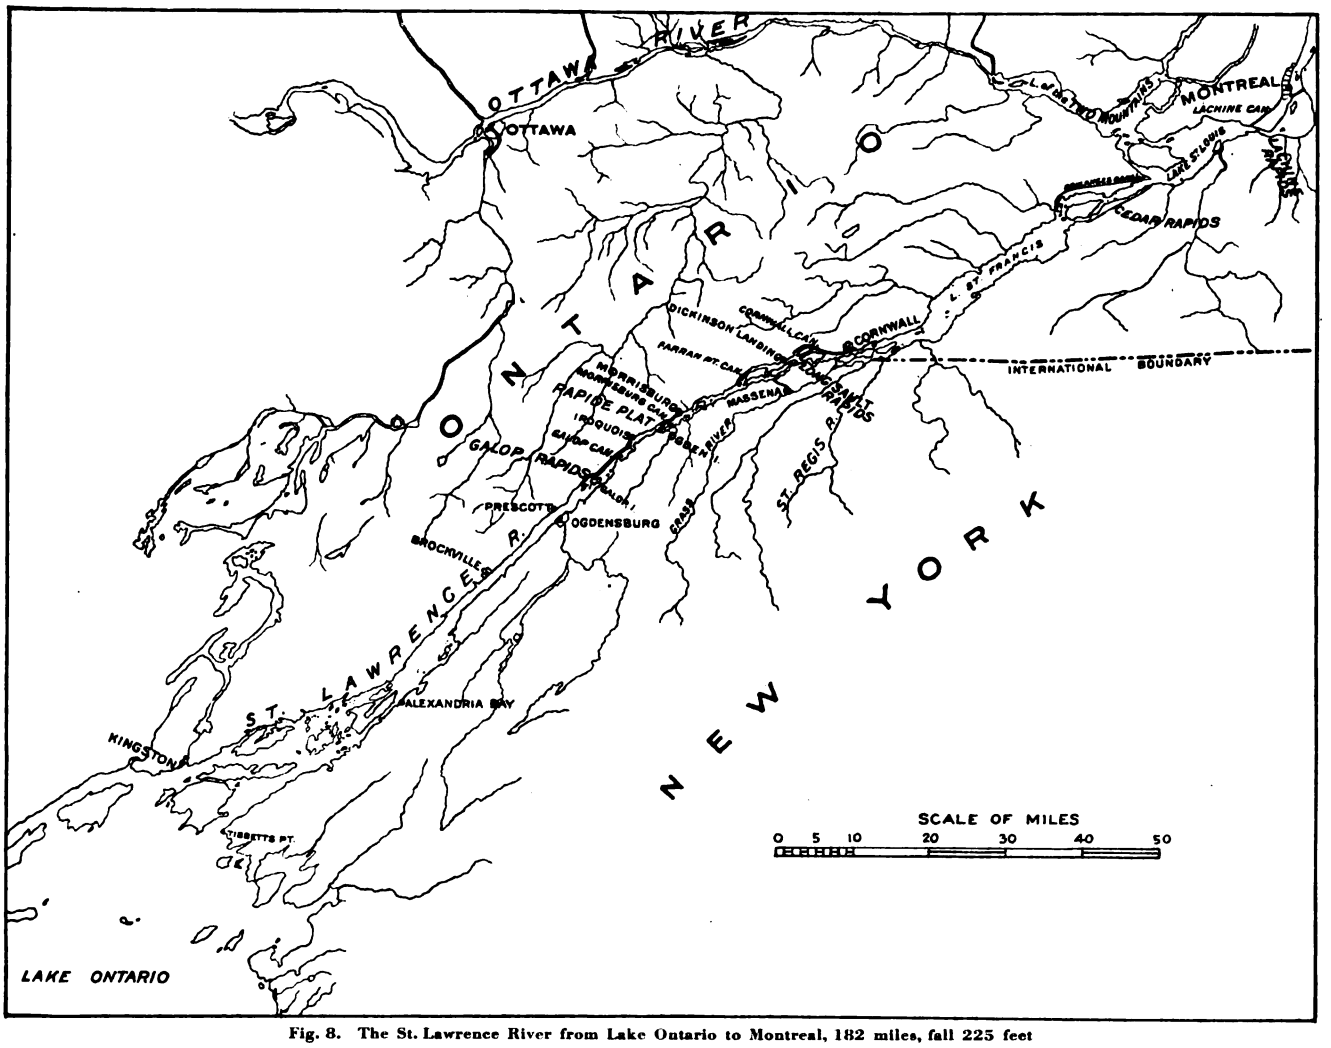

Fig. 8. The St. Lawrence River from Lake Ontario to Montreal, 182 miles, fall 225 feet

March, 1920, the Hon. D. P. Nelson, of Wisconsin, quoted the following public men as strongly in favor of the project:

Franklin K. Lane, then Secretary of the Interior; Leonard Wood, of the Army; John Barton Payne, Chairman of the U. S. Shipping Board; Herbert Hoover, United States Food Administration, and others.

Mr. Nelson presents the argument in favor of the project in a very comprehensive manner.

Apparently against the project stands the recommendation made by Colonel Warren, United States District Engineer Officer, Buffalo, concurred in by the Board for Rivers and Harbors and approved by the Chief of Engineers in 1918; that the improvement of the St. Lawrence River from Lake Ontario to the Canadian border with a view to providing navigation facilities for ocean going ships was not deemed advisable at that time. The official reports, however, carefully stated that this decision depended upon the facts that Canada, due to the war, had stopped work on the Welland Canal, and that apparently no steps were being taken to provide deeper navigation in the St. Lawrence from the Canadian border to the sea. Obviously, it was not worth while for the United States, during the war, to start a 21-foot project shut in by 14-foot water at both ends.

There can be little doubt but that one of the most vital factors in the development of our huge and economical lake borne commerce has been, is now, and will always be,

the provision of adequate and economical terminal facilities. In this the Great Lake ports have led the world. Herein, to no small extent, can be found the secret of their low ton-mile rate. Vessels are delayed a minimum time at port, and cargoes are rapidly handled at a minimum cost. If the Lakes do become the American Mediterranean, ports such as Chicago can well take to heart the advice of Mr. Charles Evan Fowler in his address before the Great Lakes Tidewater Congress during this last July. After pointing out the need of keeping port facilities ahead of actual requirements, Mr. Fowler explains the need of centralized authority and administration of port control; the need of permanent construction in not only piers and docks, but adequate and wisely located storage space. He closes with the remark that: "The final word may be to point out the great need for more labor-saving cargo-handling machinery and then to recommend still more cargo-handling machinery. What shall it profit a port in the future if it has fine natural advantages and yet is not built of the best plan and construction and lacks besides labor-saving equipment in sufficient amount to handle large cargoes quickly and cheaply? Let the Great Lakes cities profit by the mistakes made by their elders, the great salt water ports."

Elevator in Montreal Harbor

While awaiting the report of the Joint Commission it would not be amiss for the leading lake ports, such as Chicago, to examine into their own terminal facilities, the layout, their supervision and control, their future development. Great commerce will not come to crooked, bridge-cramped rivers, nor to poorly equipped and undersized wharves.

In a few months this question will be up for public discussion and possibly Congressional consideration. Laymen will turn to their engineer friends for sound opinions based on facts. It is only hoped that this necessarily brief resume of the matter may be of some small assistance to members of this Society in sifting out the truth and in arriving at a sound opinion.

The Capture and Defense of Hill 269 by the 1st Engineers

By

T. F. Farrell

Captain, Corps of Engineers, formerly Major 1st Engineers, A. E. F.

[NOTE—On many occasions during the late war the engineer troops with our combat divisions were called upon to take their places as infantry in the line of battle, both in attack and in defense. In a recent issue we related some of the battle experiences of the 2d Engineers in the second battle of the Marne. In the article which follows Major Farrell describes in most entertaining fashion an important offensive and defensive operation carried out by the engineers of the 1st Division in the Meuse-Argonne.

The habitual use of the engineers in combat, especially in attack, naturally interferes greatly with the performance of their proper duties, and is to be discouraged. We say the *habitual* use. Our engineers were frequently so employed and may always be so employed at the will of their division commander. And it must be said that the opportunity to occasionally engage in battle and prove that they are good fighting men, as well as good engineers, raises the morale of the engineers, and increases their efficiency in all their work.

To find their places in line, after a long march in inky darkness, mud and rain, seems to be the usual thing for the engineers. To acquit themselves with credit under such trying conditions seems to be invariable.

The confusion incident to battle, the tremendous difficulties to be overcome, and the tenacity of the American soldier, are well brought out in Major Farrell's story.—ED.]

DURING the second phase of the Meuse-Argonne operations, the First Division attacked in a northerly direction east of the River Aire, starting their attack about two kilometers south of the village of Exermont.

From October 4 until October 7, 1918, the division advanced about 4 kilometers against very stubborn resistance and at a very heavy cost. The reserves had become so depleted that it was decided to use the engineers in the attack.

Just outside of the limits of the division sector on the right was a hill, the possession of which was absolutely essential in order to continue the advance. It was an elevation with three knobs, the knob on the right being the highest; this one was designated Hill 269. The front line of the division on our right was about 500 yards in rear of our line and Hill 269 was slightly in advance. On October 7, some of the elements of our division and of the division on our right (the 32d) succeeded in gaining a foothold on the lower knob of the elevation, and as the country was quite heavily wooded, it was erroneously assumed and reported that they were on Hill 269. Two infantry companies of the adjoining division and a small patrol from our division were maintained on the rear slopes of this western knob of the elevation. At our division headquarters it was thought that the high knob of Hill 269 was in possession of the American troops, and a flanking operation to the right was planned, using Hill 269 as a pivot for the operation. This attack was scheduled for the morning of October 9th, and the plan was for the division to swing to the right while standing fast on Hill 269, and thus outflank the enemy on our right. The First Battalion, First Engineers, was detailed to relieve the elements of the adjoining division at Hill 269 and later to be the pivot troops for the attack. The first orders were to proceed during the night of October 7-8 to Tronsol Farm, about 600 yards in rear of Hill 269, during the day of the 8th to reconnoiter a route to Hill 269, and during the night of the 8th-9th to relieve the troops on Hill 269 and be prepared to participate in the general attack.

The engineers had been steadily engaged night and day since the 4th on road work and on the construction of a position of resistance a short distance behind the front line; the battalion had sustained about 100 casualties. About 5 p. m., on October 7th, orders were received by the battalion commander to assemble the battalion, to move it after dark to Tronsol Farm, a distance of about two miles, and to report in person to the commanding general of the 2d Infantry Brigade for orders. That sounds like a comparatively simple order to execute, but it was fraught with countless difficulties. It was pouring rain, the night was pitch black, and we knew neither the location of the brigade commander nor of Tronsol Farm; our men were scattered over the division area and the enemy shelling was particularly heavy. By earnest effort the battalion was assembled shortly after 6:00 p. m., the command was turned over to the battalion adjutant to march to Tronsol Farm, and the battalion commander set out through the rain and darkness to search for the brigade commander, concerning whose location he had a very indefinite idea. The battalion was marched to its destination with the aid of an engineer marching compass, and fortune smiled upon it since it arrived about 9:00 p. m. Each man had an engineer shovel and provided himself with cover as soon as possible; the previous fatigue was forgotten, and a long line of fox-holes soon made an appearance.

The brigade commander had been driven out of his post by a direct hit with a gas shell, and had taken up new quarters some distance away. It took a considerable search to find him; but that done, we thought we were to remain fairly comfortable for the night. No such good fortune, for about 10 p. m. telephone orders were received for the battalion of engineers to relieve the two companies of infantry at Hill 269 before daylight. The battalion was two miles away in unknown territory and neither the rain, darkness nor shelling had abated in the least. In fact, quite the contrary.

The men had their fox-holes just about completed, and were preparing for a night's rest after a strenuous day, when the battalion commander arrived with the orders to go forward. They shouldered their packs, rifles and shovels and started out over the slippery ground for a destination, the location of which was absolutely unknown. The ground here was strewn with dead, both ours and German; the enemy artillery was putting down a heavy bombardment of high explosive and gas. The problem of getting the battalion to Hill 269 in a heavy rainstorm and in the dark night with no one who knew the way, was not easy. There were no runners nor guides who could lead us there, but at brigade headquarters we got a runner who led us as far

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

OUR RESPONSIBILITY

The axiom "One Responsibility" adopted by the Allis-Chalmers Manufacturing Company will be fully appreciated by everyone who desires to purchase a complete power plant and place the order with one firm which designs and builds the complete equipment in its own works. This saves the customer a mutiplicity of negotiations with different manufacturers to collect various apparatus for a complete plant, the functions of which are not designed and built with reference to each other.

The purchaser can avoid annoying and some times expensive complications by placing his contract for complete units with a responsible manufacturing company with the full knowledge that same will be designed and built by one engineering staff, one shop organization centering its entire effort upon one goal—a complete unit with each part designed and built to suit the characteristics of the driven and driving medium to obtain maxium efficiency and satisfactory operation.

as regimental headquarters of the 26th Infantry; there we got a runner to guide us to the battalion P. C. of the right battalion, and there we were furnished a runner to the right company. This company furnished us with our final guide. Several times the guide went astray and we doubled back more than once; we forded a stream waist deep and climbed a bank so steep and slippery that it was necessary for two men to work together in order to reach the top. The shelling was so heavy that the men were marched single file with a couple of yards distance between men to prevent heavy casualties. Once we lost a whole company and spent an hour looking for it. We were so close to the enemy positions that it would have been a simple matter to have strayed into German territory. As we were making the final stage of the journey the enemy put down a particularly heavy bombardment on the tail of our column and dispersed the last company. It took until daylight to collect it again. As the crow flies the distance to be covered was about two miles, but we plodded wearily through mud and rain the whole night long and just as daylight began to break we reached our destination, about 100 yards from the enemy position and got our men under cover of the woods and brush.

Here we found two infantry companies of the adjoining division who were worn and depleted, but pleased beyond words to relinquish their hold on that particular piece of territory. From them we learned the true state of affairs: *i. e.*, that the Germans held the crest of Hill 269 as well as the entire northern slope of all three knobs of the hill and the eastern and southern slopes of the high part of the hill. They were firmly established on top of the hill with machine guns, and were sweeping all the slopes with machine gun fire. In other words the key-point of the next day's attack was held by the enemy, and if he continued to hold it, he could seriously embarrass any operation planned by our troops, because the hill overlooked all the surrounding territory and his machine guns could sweep the country in all directions.

The commanding officer of the Engineer battalion took over command at 5:30 a. m., October 8th, and made the following disposition of his troops: One company was placed on the western knob, another on the center knob, and the third company was placed in reserve on the southern slope. The elevation ran almost due east and west and the enemy held the eastern and highest knob. A flank guard was placed on our right facing the southern slope of the knob. The nearest friendly troops on our right was about 500 yards to the rear. Eight outposts were established on the western and northern slopes of the hill, and a patrol was sent to connect across a gap with the troops on our left. Liaison was also established by our flank guard with the troops on our right rear.

The situation was reported to the brigade commander, and in the meantime reconnaissances were made to determine if the hill could be readily captured. A patrol was sent along the southern slope and another along the northern slope with orders to occupy the top of the hill if the enemy were not there in force. Both met with heavy machine gun fire from the top of the hill, and after sustaining some casualties retired, having learned something of the nature of the enemy's position and his strength. The hill was covered with trees and underbrush so that it was possible to do considerable moving around without coming under observation.

The brigade commander said he would send some trench mortars and 37-millimeter guns to assist in the capture of the hill, but about 4:30 p. m. it was decided not to wait longer, but to capture the hill before the enemy had an opportunity to reinforce the garrison. As engineers the only weapons we had were rifles and bayonets—not a rifle grenade, a hand grenade nor a "37," any of which would have been of great assistance in the capture of the machine guns. Our officers and men were not highly trained in infantry tactics, but they were possessed of a courage and determination that boded well for success. Furthermore, they had absolute confidence in their ability to carry out any operation planned for them. They had never failed on a task, and the fact that this one was considerably different from any other, did not in any way effect their viewpoint.

Along the top of the hill was a narrow ascending ridge which broadened out into a sort of an elongated plateau on reaching the crest. The slopes of the hill on the northern, eastern and southern sides were steep and wooded. It was from the west along the ridge that our attack was launched. Three parties were formed; one proceeded along the northern slope, one along the southern slope, and one advanced straight along the ridge toward the top of the hill, thus meeting the enemy in front and on both flanks. The advance was timed that all three parties would reach the enemy simultaneously. The men had only rifles, bayonets and belts loaded with ammunition. Several of the men normally armed with the pistol, borrowed rifles for the attack. They advanced about half the distance before being detected by the enemy, who immediately opened fire with machine guns and rifles. Our men then advanced by rushes, taking such cover as was available and finally went forward in a bayonet attack. The attack was carried out with such precision and energy that the top of the hill was taken. A great number of the enemy were killed and wounded; forty-three were taken prisoner, and the booty included five machine guns, two anti-tank rifles and a number of rifles.

The Germans still held the slopes of the hill and were defending them with machine guns cunningly hidden in the woods, and up in the trees, so that our men were fighting until dark trying to clean up the slopes. There were many acts of individual skill and heroism. One sergeant, leading a few men to the capture of a machine gun, which was firing directly at his party, three times wounded the gun operator with fire from his rifle, but the German continued firing. Advancing in a final rush straight toward the gun, the sergeant, dropping his rifle, seized the wounded gunner in his arms and carried him back a prisoner, only to have him die a short time after he administered first-aid treatment. Another man, a bugler, had his mind set on capturing a prisoner and chased a German all over the top of the hill with a bayonet until he finally caught up with him. He would not shoot him because he wanted positive proof that he had gotten his man.

After dark we established three outposts about 500 yards north of the hill and formed a visiting patrol of an officer and two squads to keep in touch with these outposts. Once during the night this patrol encountered a large party of the enemy and avoided an engagement by detouring. The enemy were still holding part of the eastern and southern slopes of the hill. During the night four machine guns sent by the brigade commander reported and were posted in position to help defend our precarious position. Virtually our position on top of Hill 269 was surrounded by the enemy on three sides—front, right flank and rear, and could not in any way be called secure.

The division attack for October 9th was scheduled to take place at 8:30 a. m., and our part in the attack was to hold fast to Hill 269 while the whole division pivoted to

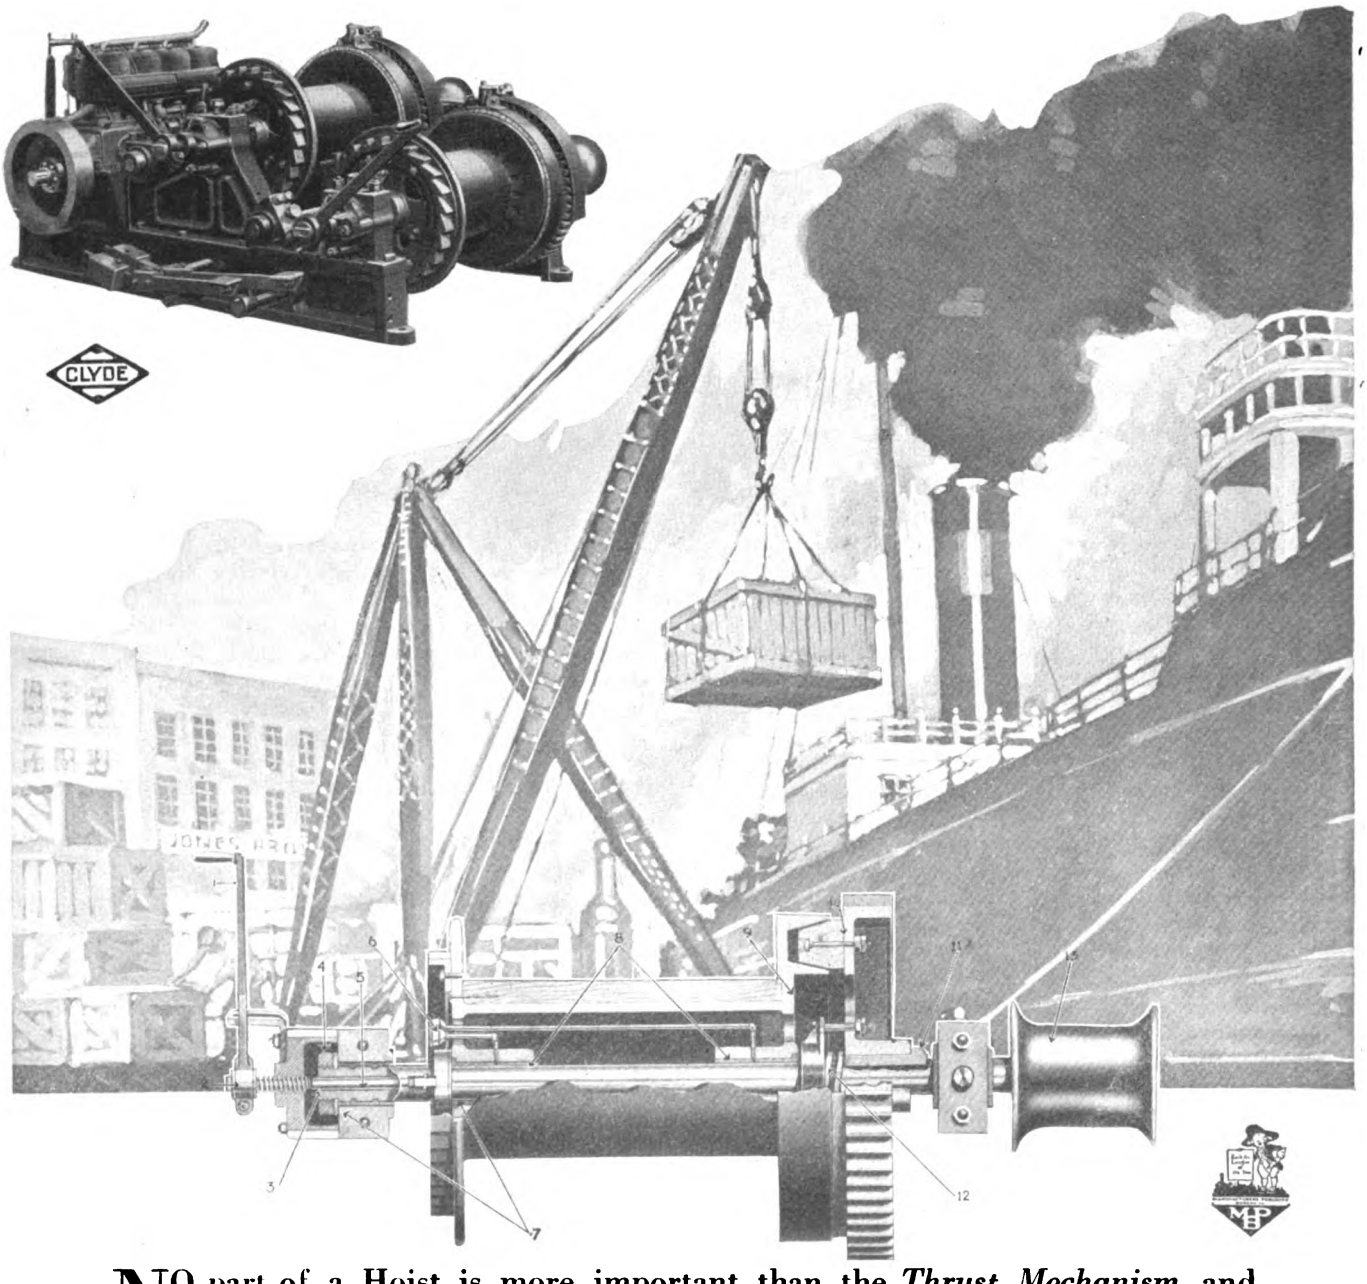
the right; furthermore we were given about 500 yards of line on which we were to attack. The battalion was being formed for the attack in two lines extended to the left from Hill 269, when at 7:30 a. m. the Germans launched an attack on the hill accompanied by a violent bombardment. The attack was a complete surprise and could not possibly have come at a worse time, because our own attack had to be carried out and this would use up practically all of our troops. And it was absolutely essential to hold the hill, or the entire operation of the division would be jeopardized. The attack came mostly from the south and east, which was really the rear and right flank of our garrison on the hill. Very heavy machine gun cross-fire from two neighboring hills swept the top of our hill, and shells of all calibers pounded away on this narrow strip of ground. Far down on the eastern slope we had an outpost—all of these men met their fate in the first rush of the enemy. Farther up the slope were two machine guns and they held out but a short time before they were captured.

For a while the situation was critical, with the grey masses coming from three sides up the hill. Lieutenant Bourland, the company commander of the right company, at the start of the attack, rushed down to his outpost in a vain effort to save them. He was killed before reaching the post. Lieutenant Trowbridge, who succeeded him in command, met the same fate. Most of our outposts had been withdrawn about 7:00 a. m. in order that they might escape our own barrage. This accounts for the fact that the enemy was well up on the slopes of the hill before we had any knowledge of the attack. Our men fought admirably, and contested every foot of the ground. The line was slowly forced up the hill to the crest where a determined stand was made and all the assaults were repulsed. Seven squads were drawn from the troops on the left scheduled to attack, and were sent to the top of the hill. Later on six squads more were sent, thus using up the last available reserves. The fighting for the possession of the hill continued through the whole morning, and it was 1:00 p. m. before the enemy definitely ceased his efforts to take the hill. It was truly a bitter contest and the small garrison put up a wonderful defense. The order was given "Hold the hill to the last man!" and it was carried out to the letter.

There were acts of heroism too numerous to mention. Immediately after Lieutenant Bourland was killed, the line was forced back slightly and the enemy captured his body and began to strip it. A young corporal refused to retire but advanced to protect the remains of his commanding officer. Three hours later, when the line was pushed forward again, the dead body of the corporal lay across his rifle near that of his commanding officer and there were six dead Germans in a narrow circle facing him. He had taken heavy toll before he "went West." A private remained fifty yards in front of the line and alone stopped a formidable attack on his slope of the hill. He killed twelve of the enemy with his rifle. Another man captured a German machine gun, turned it and used it on the enemy until he was shot through the shoulder. Then, taking up a pick handle, he smashed the gun and retired. A sergeant, who was later killed, captured a machine gun, using a German hand-grenade as a weapon. The brigade commander, hearing we were attacked, sent us message after message that we should hold the hill at all costs. We held the hill, and the cost was heavy.

At 8:30 a. m. the remainder of the battalion attacked as a part of the division operation, with two successive objectives. Both of these objectives were reached on schedule time. The two left companies, less the men who had been already sent to the defense of the hill, participated in the attack. The companies were in line, each company being formed in two lines of skirmishers 50 yards apart with the remainder of the company in squad columns about 500 yards in the rear. The left of the battalion swung to the northeast and drove the enemy toward the right of the battalion; the company on the right captured 80 prisoners during the attack.

On reaching the final objective the battalion dug in. The right company was in touch with the troops on top of Hill 269 who were still fighting to hold their ground. There was an open meadow at the left of the battalion which was under good observation as well as fire of the enemy and no liaison was established here until dark. Patrols were sent out in front of the objective and the position was organized for defense. We had no reserves, so a call was made on the brigade commander for reinforcements, as our position was rather precarious in case of a strong counter-attack. These reinforcements did not arrive until dark, and it was an afternoon of uncertainty and anxiety because a counter-attack on our line was momentarily expected, and we had barely held our own in the defense of Hill 269. Furthermore, the enemy's artillery action on our line and on the hill was extremely violent. They literally tried to blast us off the hill.



About 1:00 p. m. a company from the division on our right came up toward our position from the rear. Their orders were rather indefinite, so the battalion commander used them to clear up the southern slope of Hill 269 which was still occupied by enemy machine guns hidden in the bushes and in the trees. Placing their left flank on top of the hill they extended in a southwesterly direction and then swept around until the company was lined up east and west, cleaning up the machine gun nests as they went. Thus, for the first time since our arrival was our right flank protected.

During the night of October 9-10 we held our position at the "alert," and in the morning took part in the next day's attack by sending a party due north through the woods for a distance of one kilometer. The enemy had retired as a result of the division maneuver, and this advance was not difficult. For the next two days the battalion maintained its position as a security garrison for the protection of Hill 269. We were heavily bombarded on both days, and lost many men from artillery fire. At one time we had about fifty prisoners on the rear slope of the hill awaiting evacuation. The enemy started a violent bombardment. Such cover as was afforded by shell holes was already taken by our men and a large number of the prisoners were killed or wounded. Some of them started to run, but they were stopped by a few rifle shots.

During the attack and defense of the hill the battalion suffered heavy casualties in officers and men, but they captured 150 prisoners, 16 machine guns, 2 anti-tank rifles and a large amount of small arms and equipment. There were more than one hundred German dead on the slopes of Hill 269, giving proof of their earnest desire to get possession. After the first night our men were hungry, and it was a difficult matter to get food, but our pack mules came to the rescue. The valley behind was being filled constantly with gas and high explosive shells. One night the pack train started up for our position loaded with rations, but they were shelled and gassed. One of the mules was killed, an officer was wounded and all the food was spoiled by gas. Not daunted by this reverse, they tried it again the following night, and this time were successful. They brought the food up and unloaded it within a hundred

What The Clyde Thrust Mechanism Means To You

NO part of a Hoist is more important than the *Thrust Mechanism,* and upon its unfailing operation depends the service rendered on your jobs.

Note points listed below:

1. Forged thrust lever
2. Large head to avoid slippage
3. Renewable special bronze point
4. Oil collar thrust nut
5. Tool steel pin and cross key
6. Accessible grease cups for both ends of drum
7. Bronze liners on larger sizes
8. Long bronze bushings
9. Lagging pocket
10. Smooth turned hard maple friction blocks, grain circumferential
11. Gear pressed against gib head tapered key to prevent lateral motion
12. Bridled spring to release drum from friction
13. Large turned winch head

yards of the enemy. As the little animals came plodding up the slope they were greeted with a cheer from the hungry men, and we felt repaid for all the care we had taken of our hitherto burdensome pack train.

We were relieved at dark on the night of October 11th by an order from the brigade commander, and it was a weary but lighthearted battalion that turned over to the incoming division. For the five days every man had carried a heavy engineer shovel, and so well had they proven their worth that not a man left his shovel behind when we started out—a significant if silent tribute to the value of the oft-despised tool. As our men filed out in a long line, they passed the relieving troops, who were equipped only with the infantry intrenching shovels. The newcomers repeatedly asked for our tools, but for once the despised shovel of the engineers became a thing beyond price. We did not know how soon we might be called upon to take and hold another hill. In this operation the engineer battalion did credit to themselves, to their division and to the Corps of Engineers whose high standards they tried hard to maintain. The following Corps order from General Summerall, who commanded the First Division in this operation, tells in official language how well they performed their task:

HEADQUARTERS FIFTH ARMY CORPS
AMERICAN EXPEDITIONARY FORCES

France, *February* 16, 1919.

GENERAL ORDERS
No. 2.

The following citation is announced:

The First Battalion, First U. S. Engineers, for distinguished service in the taking of Hill 269, Bois de Moncy, France, at 4:00 p. m., October 8th, 1918, during the Meuse-Argonne operation.

This Battalion of Engineers with great courage and determination captured Hill 269, Bois de Moncy, together with many prisoners and machine guns, and successfully held it against strong enemy counter-attacks. On October 9th, 1918, and afterward, this Battalion of Engineers participated in the general attack of the First Division, attaining all their objectives, and capturing prisoners.

The action of this battalion in the capturing of Hill 269 without the assistance of the special infantry weapons other than the rifle and the bayonet, is especially to be commended, in that they carried out a difficult mission outside of the line of their normal engineer duties, with great skill, initiative and courage.

C. P. SUMMERALL,
Major General, Commanding.

OFFICIAL:
HARRY C. KAEFRING,
Adjutant General.

Activities of Our Local Posts

Chicago Post

On the evening of June 15th, Col. Wm. V. Judson, Corps of Engineers, U. S. Army, called a meeting in the rooms of the Western Society of Engineers, for the purpose of organizing Chicago Section of the Society of American Military Engineers. About thirty-five persons were in attendance, and interest in the new society was manifested by signing an application for a charter, as well as by submitting a number of additional applications for membership in the National Society.

Colonel Judson called this meeting to order, explained the purpose of the meeting and the aims and objects of the National Society, after which the following temporary officers were elected, and proceeded with the organization:

President, John de N. Macomb; Secretary and Treasurer, G. B. McClary.

At this meeting the following committee was appointed to draft a Constitution and By-laws, and to nominate permanent officers for the Local Section: Mr. C. M. MacChesney, Mr. Walter A. Hill, Maj. John C. H. Lee.

In order to give the Committee an opportunity to prepare the draft of the Constitution and By-laws, the meeting adjourned to meet at the same place on the 28th of June.

At the adjourned meeting on June 28th, 1920, about thirty-six persons were in attendance. The draft of the Constitution was presented by Mr. MacChesney, Chairman of the Committee, and after discussion was adopted. The draft of By-laws prepared by the Committee was referred to the Board of Directors. The report of Committee on Nominations was presented, and the following permanent officers elected:

President, Christopher Van Deventer; 1st Vice-President, William Godfrey Arn; 2d Vice-President, William Ward; Secretary, John Tull Montgomery; Treasurer, Col. William V. Judson.

Board of Directors: Henry A. Allen, Edward J. Blair, Gen. W. H. Bixby, Horace S. Baker, W. A. Hill, John de N. Macomb.

The meeting closed with a discussion of the objects of the Society by Maj. John C. H. Lee.

The directors met at luncheon at the Union League Club on September 1st. This was an important meeting. The By-laws were adopted and a program for future policy discussed. It was a pleasure to have Maj. Arthur S. Dwight, of the New York Post, present at part of the meeting. It was recognized that Chicago should be an army headquarters; that provision should be made to mobilize and house all the technical services required by an army. It was also recognized that cities had problems with boys which should be considered, and if possible these future citizens should have such direction and assistance as would make them good citizens. Many boys up to fifteen are interested in the Boy Scout movement. At about that age they lose interest. They want to be men. It was thought that to make the military service attractive to these young men—good citizens would be the result. The outcome of this meeting was to recommend at the meeting of the Society September 15th certain resolutions. The first that the parent Society so modify their By-laws as to permit Junior memberships, thus opening the doors to the boys. The second was to pledge support to an Engineer Armory, which would house equipment, and provide for division, corps, and army troops. The necessity for troops is very great. This is evidenced by the conditions during the floods of the Ohio a few years ago. The water was contaminated throughout the river's course. The State Military Department was able to secure two men only from the State University to use in the emergency. With proper listing of personnel and with necessary equipment available such emergencies can be met with efficiency and success. It is the aim to prepare for similar occasions. The armory project was endorsed by the Western Society of Engineers, The American Association of Engineers, and Castle Post of American Legion. Many of our members hold important and prominent positions in these organizations, and their assistance has been of great benefit. Castle Post declared their intention to follow a plan of

Vol. XIII JANUARY-FEBRUARY, 1921 No. 67

The Society Emblem

IN the issue of this Journal for July-August, 1920, we published an illustration and description of an emblem which had been tentatively adopted by the temporary Board of Directors at a meeting held in Washington in June. On the front cover of this number is a new design, or more accurately speaking, a revision of the former tentative device. This new design is now the official insignia of the Society by unanimous vote of the Board of Directors, acting under powers vested in that board by the constitution and by-laws.

The changes in the emblem merit some explanation. The committee appointed to devise an emblem attempted to ascertain the opinion of the membership of the Society, and to produce a device in harmony with the wishes of the Society as a whole. The original insignia was accordingly designed and adopted only after an extended discussion as to what should be the predominant character—the motif of such a device. Although the castle was embodied in the very first study it was omitted from the design as eventually published. This omission was in accord with the consensus of opinion expressed up to that time. It will be remembered that after the Armistice there was a rather violent reaction and officers and soldiers alike seemed to feel that one war was quite enough and that they "were off the military" for all time. Many of the most emotional, or the most articulate, had grievances, either real or fancied, and they took it out on the Regular Army and all its works, not overlooking the Corps of Engineers. Their criticism even extended to the castle as one symbol of the military authority which they fancied to have been unnecessarily oppressive. The occultation of the castle in the proposed emblem was therefore but a manifestation of the war fatigue.

Judging opinion as best it might, the committee felt that the castle, being identified with the Corps of Engineers, might convey a false impression concerning the Society, to-wit: That it was an organization primarily for officers of the regular service, or for their especial benefit. It was conceived also that the castle might not adequately represent the professional attainments of our members who derive from all branches of the engineering profession —civil, mechanical, electrical, mining and all their various ramifications.

The Society, even in its earliest days, was not an association of the Corps of Engineers of the United States Army. It has never been dominated, nor is it desirable that it should be dominated, by the Corps. At the present time the membership in civil life vastly exceeds in numbers that in the Regular service, and its form of government was carefully devised to insure an equitable representation therein of all classes of membership. Furthermore, there are thousands of engineers and technicists—physicists, chemists, metallurgists, geologists and other specialists—who did their part in the war in other branches of the service. Many of them, indeed, elected to serve as officers of Infantry or Artillery, or identified themselves with the Signal Corps, the Tank Service, the Chemical Warfare Service or the Air Service; others cast their lot with the Quartermaster Corps or with the Railway or the Motor Transport Branches. Not a few served in The Adjutant General's Department and in other branches not named herein. The fact that they donned the uniform indicates their firm belief in the purposes for which the Society was founded and they are eligible to membership notwithstanding that their personal inclination or their opportunity for service did not admit of their wearing the engineer castle on their uniform.

For these various reasons, the castle was deliberately omitted from the original emblem of the Society and an attempt was made to represent the major engineering activities by more specific emblems—the thunderbolt of Jove for the electrical arts, the cogged wheel for the mechanical and the bastioned fort for structural or civil engineering applied to military operations.

However, with the publication of the tentative design in The Military Engineer, new voices were heard in criticism. Many felt that it was too elaborate and that it attempted to convey too many ideas in small compass, especially in view of the necessity for reducing it to lapel button size; but, more important still, the war reaction against the Regular Army, if, indeed, it had ever really existed, had spent itself and the pendulum had entered upon its return movement. It became evident that the omission of the castle from the Society's emblem was unfortunate. One of the critics voiced the views of the great majority when he said: "The castle was the emblem of engineer service in the War. It was universally known as such by ourselves and our Allies. We wore the castle on our collars, we fought under it and we are proud of it. It should be the emblem of our Society—a source of in-

Digitized by Google

spiration to every engineer who has served or will serve his country."

It is quite true that the castle is the emblem of the Corps of Engineers. Since 1840, and possibly from an even earlier date, it, in its present form, has graced the uniform of the Engineers. In some shape or other it has been identified with the engineer service since the dawn of our history as an independent nation. The circumstances under which it was introduced in our army are not known, but it undoubtedly traces back to the gallant and talented French engineers who served with the Continental Forces. It did not, however, originate with these early members of the Corps of Engineers. In some form the castle, and not infrequently that with three turrets, has been used in heraldry from its earliest days to signify fortification, or the art of the military engineer. To this day it is borne in the coats-of-arms of many cities of Europe, having been granted them in recognition of services rendered in defense of their sovereign and his state. By reason then of its heraldic meaning the castle was adopted by the progenitors of the Corps of Engineers to indicate their function as military engineers. With the evolution of warfare it has come to mean engineering in war. It is worn by the engineers of the National Guard and of the Reserve Corps as well as by those who have chosen engineering in the Regular Army as their life's profession. In view of the fact that the military art turns to its uses all branches of science, and in view of the great number and great diversity of activities devolving upon the Engineers during the World War, it can now justly be said that the castle is the ægis of all branches of engineering and allied sciences in their special application to military purposes. Its signification is no longer restricted to those only who deal with the art of fortification in its narrow sense.

In the light of after events it appears that, in their effort to avoid conveying a false impression, the designers of the first emblem "leaned over backward." To-day the majority opinion appears to be that the castle is so identified with the military interests of the great body of our membership as to warrant its adoption to the exclusion of devices having a more special signification. Better than any other symbol it appears to represent the practical patriotism of the engineering profession as a whole, irrespective of the arms or branches of the war establishment in which its various members served the nation during the World War. It appears that it should be the outstanding feature of the emblem of our Society.

The committee charged with the design of a suitable device have taken cognizance of the views so expressed and in the new emblem have attempted to symbolize the dominating purposes of this Society. The American eagle, grasping the traditional olive branch and sheaf of arrows, has thus been retained as emblematic of American independence, to be maintained by peaceful methods if possible but to be maintained by force if recourse to force should be necessary. The national shield has been retained as the symbol of defense, in recognition of the world as it is and the consequent necessity for a wise preparedness. The laurel has also been preserved in the device in honor of those who have achieved in the past, as a tribute to their spirit of intelligent unselfish devotion and as a token of our aspirations and determination for the future.

The new design has been prepared by Mr. C. A. Houston, of the Bureau of Engraving and Printing, who executed the original device. It is believed that he has succeeded in retaining many of the artistic features of the original emblem which were most favorably commented on, and that he has incorporated in an attractive setting the castle as the emblem of engineering in war. It is believed that the device in its present form symbolizes the aims and purposes of the Society and its members, all of whom recognize that the privileges of citizenship in a republic such as ours carry with them the obligation to serve their country to the limit of their powers in any hour of need.

The Significance of the New Army Organization

WE are very glad to be able to present to our readers in this issue an article on "The Organization of the Engineer Service for Military Operations," showing the approved project for the reorganization of the Army under the Act of June 4, 1920, in so far as it relates to the Engineer Service. In the article will be found not only a concise statement showing the engineer components for the various tactical units—including the normal assignment of Engineer troops to G. H. Q., Reserve and the Communications Zone for expeditions of various sizes—but also a brief statement of the duties and functions of the various Engineer units proposed, together with the salient features of their equipment. Detailed tables of organization are shown for the Combat Engineer Regiment (war strength) as proposed for assignment to the Infantry division—the unit in which all Engineer officers are most interested.

The new army organization, as finally approved, represents the mature judgment of many of the best minds in the service, fresh from experience in the greatest war in history. One can be assured that the lessons of that war were carefully considered, and that an honest effort has been made to incorporate in the new organization those changes which actual experience in war have demonstrated as necessary, without regard to the special interests of any one arm, but with the single object in view of providing the most effective war machine for future military operations, whatever their nature, or wherever they may occur.

In general, the organization adopted has followed that used in the A. E. F., with radical reductions in the size of all tactical units, and with only such auxiliaries permanently assigned to the division, corps, and army, as are certain to be needed at all times.

The reduction in size of units has been accomplished, by limiting the infantry companies to 200 men instead of 250; by omitting one rifle company in each infantry battalion, and replacing it by one machine gun company, thus eliminating all machine gun battalions; by withdrawing heavier types of artillery and special troops to the next higher unit, or to a G. H. Q. pool; and by reducing the number of divisions in a corps, and the number of corps in an army. The net result of these changes has reduced the division to an aggregate strength of 19,385; the corps to 79,966; and the army to 302,220—creating a more flexible and mobile organization than that used in the A. E. F., and therefore one which would be especially suitable for operations on this continent.

With reference to the Engineer components of the new army, it will be noted that many kinds of special troops have been eliminated, and that very few special Engineer troops have been permanently assigned to the Combat Zone. The elimination of numerous specialized Engineer units reflects a careful consideration of our own experience during the World War, as well as a consideration of our probable future needs. When we went into the World War we naturally looked to the organization of those who had been in for nearly three years, and found therein a bewildering variety of special units. This was due in part to the pe-

Digitized by Google

culiar type of warfare which required all sorts of special services, and in part also to the fact that the average European craftsman is more narrowly specialized than the American and lacks the ready versatility of the latter. When the war of movement was resumed, the need for many of these narrowly specialized units disappeared and simultaneously the need was augmented for all-round handy men capable of meeting new situations and solving the new problems characteristic of that style of war. In this war of movement the American engineer soldier was in his element, and, although we had units bearing various specialist labels, they at once turned their hand to the work of the combat engineer and got away with the job to their everlasting credit.

Maps, highways and railways are, of course, always needed, irrespective of whether the war is fought out by maneuver or in trenches, and it is therefore eminently proper to incorporate the nuclei of these services in our peacetime establishment.

The engineer strength of each tactical unit throughout the new organization has been kept at this minimum, additional men needed for occasional operations being drawn from the next higher unit, which, in the case of the army, is from a central pool called the G. H. Q. Reserve.

The Combat Engineer Regiment assigned to the Infantry division while small in size, is well organized and equipped to carry out its mission. Noticeable improvements which may be mentioned, are the provision of an adequate Headquarters and Service Company, including the old Engineer train as well as the band, and a mounted platoon with pack transportation (formerly with the companies); the provision of automatic rifles at the rate of two per platoon; and the substitution of 1½-ton trucks for the heavier type, including one for the use of each company.

In spite of the fact that the percentage of engineers with the Infantry division has been reduced from 6.5 to 4.35 per cent—a fact which all Engineer officers, as well as many officers of other arms will keenly regret—it is believed that the organization of the Engineer Service, as finally adopted for our new Army, is sound in principle. While not perfect in all their details, the new tables indicate, in the main, a correct comprehension of the lessons of the recent war. They will be welcomed by all officers of the Corps of Engineers as a measure for placing the engineers in future wars on a sound working basis at the start.

Our National Society and the National Military Policy

THE Treaty of Versailles does not mean the end of all war, any more than the olive branch which the dove brought to Noah, aground on Mt. Ararat, meant that man need no longer fear the devastating power of floods. The Deluge did not revoke the laws of nature or destroy the causative forces of floods, and no more did the event at Versailles remodel human nature or remove the causes of war. The recurrence of war is as natural and inevitable as is the recurrence of floods.

Just before the World War certain purblind idealists told us that war was impossible. And now after the war they persist in telling us that there can never be another.

The best argument adduced in support of the belief that there can never be another great war, is that any nation contemplating war would shrink from the enormous expense involved. Let us see just how much this argument is worth. True, any nation must shrink from the expense of such a war as that through which we have just passed. But the World War was no more expensive in proportion to the wealth of the nations engaged than some wars of the past have been. Many previous wars have impoverished the nations who took part in them. All of the combatants of the late war will eventually recover. The wealth of the world was quite sufficient to support even so great a conflict. The casualties of the war were an insignificant percentage of the total population of the world.

Many a man has lost his life in personal combat. This fact may deter, but certainly does not prevent other men from engaging in mortal combat when vital interests are at stake. There are few of us indeed who will not risk our fortunes and even our lives in a just cause of sufficient importance. Too often we risk them in a cause we know to be unjust.

What is true of individuals is true of nations. Mere expense alone will prevent few nations from defending their sacred rights. Such nations would not have sufficient virility to continue to exist. If there be any nation that is afraid to go to war because of the expense, there are other nations prepared to take full advantage of that fact. The individual or nation that is afraid to defend its rights will soon find that it has none which others are bound to respect. There are things which all men and all nations value above wealth. And in defense of these things they will continue to risk their wealth and their lives. Patrick Henry's impassioned words: "Give me liberty or give me death!" were not mere words. They expressed a sentiment, an ideal, which in all ages has shaped the destiny of nations, controlled the course of history, and—incidentally—caused many wars.

And, finally, there is usually the expectation, and always the hope of victory. Successful war generally improves the condition of the nation. Several of the victorious combatants of the late war are better off as the result of it—including ourselves, provided we have the sense to "dig in and hold our gains."

We believe that considerations of mere financial cost, while undoubtedly they exercise a powerful regulating influence, cannot be relied upon to prevent all wars. There has never been any nation that was too poor or too proud to fight. It is rather wealth than poverty that has made nations disinclined to war.

It has been said also that since war is so expensive in these days, only the wealthy nations can enjoy the excitement of combat in future. But now comes so great an authority as George Bernard Shaw, saying that, in future, small nations can wage war just as effectively and be just as dangerous as the large ones.

The World War, far from quieting the mutual distrusts and fears, and dispelling the mutual animosities of nations, has roused them to a higher pitch. Nations which were united in war now regard each other with jealous distrust. Never since the disintegration of the Roman Empire and the ensuing flux of mediæval states were governments and international relations in a more unstable state than at present. Never was the world such a seething caldron of unrest and discontent.

As to our own United States, we may keep out of "entangling European alliances," perhaps, but we are apt to do so at the sacrifice of European friendships. We cannot keep away from contact with the world, out of the public eye. We cannot prevent the eyes of less fortunate nations being turned enviously towards us. We are already entering the competition for World Trade, the "cradle of war," as it has been called. Any trade agreement is an "entangling alliance" of most potent strength. We do not know to-day who our friends may be. Some pessimists even say we have none. We do not know what sudden untoward event (such as refusal to cancel a debt) may

Digitized by Google

change a friend to an enemy. But we do know that the only sure basis of international friendship is mutual advantage or profit. And which of the great nations of Europe will profit by our control of the trade of the world? Every one of them is a competitor in some line, and every competitor is a potential enemy.

Never before in our history have we been so much in the thoughts and calculations of others. Never have we been such an object of envy, not to say fear (for our strength has not heretofore been realized). And never, therefore, have we needed "preparedness" as much as we need it now.

And we must beware of a one-sided preparedness which would provide a huge navy and make no provisions at all for an adequate land force. The honor and independence of the nation we must be ready to defend on land or sea. Of the many elements of preparedness the most important is the recognition of the principle of universal obligation for service, and universal training to render that service.

As we cannot surely foresee the participants of the next great war, so we cannot foresee the course it will take nor the place in which it will be fought. We do not know what storm may in future threaten our Ship of State. We only know that every timber of the ship must be stout enough to weather any storm—and *that*, in plain language, means preparedness on land and sea, under the sea, and in the air.

Our Society of American Military Engineers is dedicated to such a policy of adequate defense. In general we aim to secure the adoption of such a policy by our country, and in particular we shall make certain that the American engineering profession is prepared to do more than its share—great as that will be. We have the noblest of missions to perform, and the highest of ideals for our guidance. To the accomplishment of this mission we pledge our sacred honor. We must stand together, work together, fight together to achieve it. We must gather strength and determination as we grow in numbers.

Our Society with its high aims is worthy of all success—it must be preserved and strengthened. Let this be the New Year's resolution of the Society and its every member!

The Training of Engineer Officers

THE "Proceedings of the American Society of Civil Engineers," for October, 1920, published in full a Progress Report rendered by the Military Affairs Committee of Engineering Council. The Committee was composed as follows:

Col. William Barclay Parsons, Chairman; Messrs. Paul G. Brown, Harold W. Buck, George Gibbs and Spencer Miller, D. Leonard Waldo, Col. R. D. Black, Col. F. J. Miller, Col. F. A. Snyder, Col. Lincoln Bush, Col. W. A. Starrett, Col. H. S. Crocker, Col. G. R. Solomon, Capt. A. B. Fry (Navy), Col. F. A. Molitor, Col. B. W. Dunn, Col. J. J. Carty (resigned), Lt. Col. F. E. Humphreys, Maj. A. S. Dwight, and Lt. Col. George D. Snyder, Secretary.

This report has been abstracted and published in various engineering periodicals, and it is believed that its essential features are now known to those members of the engineering profession who are at all interested in the usefulness of the civilian engineer in a national emergency, and in his proper relations to the regular military establishment in peace and in war.

The Committee deals with a subject of greatest importance to members of civil and military engineering circles throughout the United States in respect to the training of Engineer Officers for our country's future military needs. The difficulties inherent to the publication of a bi-monthly journal have unfortunately prevented THE MILITARY ENGINEER from making earlier mention of this highly valuable contribution to the cause of national preparedness.

The distinguished personnel composing the committee justifies the belief that its report embodies the best thought available on this subject from the point of view of the civilian engineer who has seen military service.

In brief, the Committee recommends taking advantage of every opportunity; first, for widening the experience of the Regular Engineer officer by making it possible for him to take an active and responsible part in engineering operations outside of the army, and, second, for increasing the Reserve Engineer officer's chance for an up-to-date acquaintance with the demands of the service by having him called to active duty with the Corps of Engineers at stated intervals.

For a number of years those officers of the Corps of Engineers in positions of high responsibility have recognized the great desirability, or it might even be called the urgency, of providing wider experience for the membership of the Corps by affording the officers opportunities for taking part in construction operations outside of the military service, and of establishing a sound policy concerning the additional supply of Engineer officers that must always be drawn from civilian ranks whenever the Army is expanded to meet an emergency.

Under pressure from both civil and military sources, Congress in the Act of June 4, 1920, authorized the Secretary of War, "in his discretion, to detail not to exceed 2 per centum of the commissioned officers of the Regular Army in any fiscal year as students at such technical, professional, and other educational institutions, or as students, observers, or investigators at such industrial plants, hospitals, and other places, as shall be best suited to enable such officers to acquire a knowledge of or experience in the specialties in which it is deemed necessary that such officers shall perfect themselves. The number of officers so detailed shall, as far as practicable, be distributed proportionately among the various branches; *provided*, that no expense shall be incurred by the United States in addition to the pay and allowances of the officers so detailed, except for the cost of tuition at such institutions."

The distribution among the various branches above prescribed has not yet been made, but it is understood that this question will be decided before the end of the present fiscal year, June 30, 1921, in the best interests of the service as a whole. If the distribution be made strictly on the basis of the authorized commissioned strength of the various branches, the Engineers (who furnish about 3⅔ per cent of the officers of the entire commissioned strength of 18,000 in the Regular Army) will be able to detail only twelve officers annually for the duty contemplated under this law. This is a very small number, and such restriction would seriously interfere with existing plans for the technological education of the younger officers of the Corps. On account of shortage of officers and lack of funds the Army as a whole has not been able to take full advantage of the Act, but the Corps of Engineers, with funds provided for the purpose in the appropriation for the Engineer School, has 41 officers taking courses this year at educational institutions as follows: Cornell, 1; Columbia, 1; Massachusetts Institute of Technology, 39.

No officer has as yet been detached for duty at an industrial plant, but in view of the great benefit to be expected from such practice, it is hoped that it will soon be inaugurated. There is no denying the necessity for thor-

Digitized by Google

ough technical preparation, but assuming a fair share of such preparation, it is safe to endorse Shakespeare's verdict, That our eyes are wiser than our ears—a literary way of reiterating the well-established truth that practical experience is by far the best of teachers.

Turning to the other half of this matter, that is, the calling into active service of the Reserve Officers, we find that the situation is not so encouraging. The Act of June 4th provides that Reserve Officers may, *to the extent provided for by appropriations for this specific purpose,* be called into active duty, with the reservation that in time of peace no Reserve officers shall be employed on active duty for more than 15 days in any calendar year without his own consent.

The crux of the entire question of calling Reserve Officers into active service lies in the appropriation by Congress of funds for the purpose. The office of the Chief of Engineers has been advised that for the present fiscal year no money is available to cover the pay, mileage and allowances for Reserve officers on active duty status except for a limited number assigned to General Staff duty and to fill vacancies temporarily in the Medical Corps. Furthermore, speaking unofficially, there appears little prospect of funds being appropriated for this purpose for the coming fiscal year. It is true that the War Department estimates for next year include an item of $3,000,000 for this feature (sufficient to make it possible to call to active duty about 900 Reserve officers in the average grade of captain and for a 1-year period) but, under the urgent necessity for reducing outgo, it appears only too probable that Congress will not see its way clear to granting the needed appropriations, and the Army will be unable to avail itself of the benefits of one of the wisest provisions of the recently passed law. It is to be hoped that the writer will prove a poor prophet in this instance, but in the face of the present situation it would be ill advised, to say the least, to encourage any member of the Regular Army or of the Reserves in the hope that the latter may expect soon to be called into active duty.

The officers of the Corps of Engineers have, as a group, always prided themselves upon being "liberal minded." The river and harbor improvements work entrusted to them has always been most highly regarded both because such operations furnish experience on constructive work for which all real engineers yearn, and because the officers obtained while on such duty all the benefits accruing from free association with municipal bodies and business men generally.

We believe that few, if any, members of the Corps will attempt to belittle the benefits to be derived by the Regular engineer officer from association with civilian engineers and from observation of their methods. War is no longer the exclusive affair of a professional soldiery and the Army personnel should *not* be a class apart. It is evident that the War Department is now acting on the conviction that every agency should be employed that holds a promise of broadening the general knowledge on the part of the civilian and the Army officer of the ideas entertained and the methods used by another.

The World War gave to some 200,000 men an opportunity to see army life from the viewpoint of an officer. For the most part these men are again in civil life, but they are thinking hard about their army experiences and many are making suggestions looking to improvement in army methods. Some former officers of Engineers go so far as to maintain that very little time should be devoted to military training for the Regular Army Engineer officer and enlisted man, and that during the greater portion of their period of service they should be employed on public works in all positions from laborers to superintendents, regardless of the protests that such a policy might well bring from members of the civil engineering profession as well as labor unions generally. As a broad generalization this appears to be sound, but it is subject to the important reservation that the Engineer officers must have a thorough appreciation of strategical and tactical requirements governing the application of engineering to military operations. Enough military training must be given the enlisted man to teach him to shoot, to march and to take care of himself in the field, to put into his head the fundamentals of military discipline and to acquaint him with the principles of the science of handling men under the stress of military conditions. The time required for this training will vary with the man's application and his intelligence; and the minimum may well be greater than will be accepted as necessary by those whose experience in the Army is confined to service in France. Such former officers apparently overlook the fact that our Army's experience in the World War was unique, that never before and perhaps never again shall we be called upon to wage war under such conditions or in such numbers.

There are also those who contend that since the engineer soldiers perform in war tasks similar to those which they are accustomed to in time of peace, the ranks of our engineer regiments can be filled very effectively at the outbreak of war with men recruited from the industrial trades, regardless of the fact that they have had little or no military training. This reasoning is based on the fact that the great bulk of engineer troops during the World War were peacefully employed on construction projects miles behind the fighting lines, where the rifle gave way to the hammer and the saw and the workers never heard as much as "a single shot fired in anger." However true this description may be and however plausible may be the theories as to training evolved from such experience, it must ever be borne in mind that the fact that these thousands of workers were without military training did not constitute an advantage either for the men themselves or for the country which they served; rather did it constitute a grave handicap which would have made itself felt immediately had the Germans broken through on the West Front, forcing these untrained men to be called upon to play the part of seasoned soldiers in a strenuous campaign.

Moderation may be observed in military training as in all other activities. It can, in fact, be stated that moderation is the preventive of militarism, but it can also be said that it is not for nothing that all the nations of the earth have found it necessary in our present stage of development to maintain armies and to prescribe for their soldiers thorough and systematic military training.

To return to the question of the training to be provided for the regular officer of engineers, we firmly believe that it will be found most excellent if every such officer could have the experience of being placed in charge of a hired labor project with no agencies to assist him in controlling his employees other than the pay roll and his own personality.

It is safe to say that the members of the Corps of Engineers are a unit in endorsing the plan of detaching regular officers for duty that will bring them into closer contact with civilians throughout the United States. This is necessary if preparation is to be made to meet effectively the military crises that may confront our country in the future. The Act of June 4th wisely provides for a constant interchange between the activities of the Regular

Digitized by Google

officers, who are primarily military men, and the Reserve officers who assist in carrying on the industrial business of this nation.

In order to derive from the law the benefit which it is designed to give our Army and our country, it remains with Congress to provide the funds needed to put the law into effect. While we recognize the need for true economy in governmental affairs, we hope that considerations of a false economy will not defeat the purpose of this wise legislation nor prevent the country from reaping the results the time, money and effort spent in organizing the Reserve Corps.

The Boy Scouts

AS the twig is bent so the tree is inclined. Bend and shape the boy into proper lines of right thinking and clean living and the ultimate result is a hardy upstanding tree in the form of an American citizen, whose roots have taken such firm hold in the soil of loyalty and devotion to country that he withstands and defies the blasting storms loosed by radical agitators, and whose straight trunk reaches ever higher and higher toward the heaven of the ideals that inspired the founders and the defenders of our country.

Preparedness involves not merely willingness to serve but also training that will enable the spirit of service to manifest itself in an effective form in time of emergency. The Boy Scout movement has demonstrated beyond all doubt that boys are not only keenly interested in and absorb readily much of the technique that is a necessary part of the training of a soldier, but, what is of much greater importance, that they acquire under proper direction an appreciation of the necessity and value of discipline and teamwork that is much harder to inculcate in grown men. Training therefore should start with the boy; not because such training will make him a soldier when he grows up, but because it will make him a citizen, in the fullest sense of the word, a citizen who loves peace and who follows peaceful pursuits, but who feels within himself the potentialities of the soldier.

The chief problem in connection with the Boy Scout movement is direction. Driving power, in the form of boyish enthusiasm and energy, is available in abundance, but skilled sympathetic personnel to direct this superabundant energy along proper lines is difficult to obtain. The work of the scoutmaster is not easy, but the rewards are great, for the results are immediate and tangible. Much of the training of the scout falls within the province of the Engineers. The Reserve Engineer officer has the opportunity of rendering valuable service by interesting himself in the work of the Boy Scouts. When active participation is not possible, mere interest on his part will serve to enhance the importance of the work in the eyes of the boys themselves. Contact with the work is inspiring and will well repay anyone who will devote himself seriously to it.

Local sections might well give serious consideration to the question of co-operation with this movement, in order that the transition from Boy Scout to Reserve Officer may be an easy and a natural one.

Activities of Our Local Posts

Continued from Page 57.

preparedness submitted in November, 1919, and is working in close harmony with our Society.

The directors held a meeting at the Union League Club on November 22, 1920, at which time they had the pleasure of entertaining Major General Leonard Wood and Colonel Nathan William MacChesney. At the meeting held later in the rooms of the Western Society of Engineers, these distinguished officers addressed the members. The enthusiasm resulting from the information, advice and council of these gentlemen was of real benefit to the members and of great value to the Society. This being the annual meeting, reports were read, after which the following officers were elected: President, C. Van Deventer, former Lieutenant Colonel with Office of Chief of Engineers, A. E. F.; 1st Vice-President, Wm. G. Arn, former Lieutenant Colonel, 13th Engineers; 2d Vice-President, Col. John Millis, Corps of Engineers; Secretary, J. T. Montgomery, former Captain Personnel Adjutant, 55th Engineers; Treasurer, Maj. John C. H. Lee, Corps of Engineers. Directors: Col. W. V. Judson, Corps of Engineers; Edward J. Blair, former Lieutenant Colonel, 311th Engineers; Horace S. Baker, former Colonel, 111th Engineers; Henry A. Allen, former Colonel, 108th Engineers; Walter A. Hill, former Major, commanding 46th Engineers; John deN. Macomb, Major, formerly commanding 548th Engineers (Serv. Bn.)

The officers and members of the Chicago Section recognize that there is much to be done, that only a start has been made. They are committed to a big project. They are, however, animated with both determination and enthusiasm, and intend to combine both slogans of the Engineers—"Essayons," and "Go ahead and do it."

New York Post

The New York Post has now had two very successful meetings; the Board of Directors has had five meetings; a Membership Committee has increased our membership 60 per cent in 60 days; and our Program Committee has a continuous program built on our last two meetings to take us through the year, so we think we may safely say we have established a healthy successful post.

The first step toward organizing a New York Post, S. A. M. E., was a meeting held June 15, 1920, at the Army Building, New York, in response to a call sent from Washington to erstwhile emergency officers in New York vicinage. One hundred attended and enthusiastically and unanimously voted to form such a post.

Temporary officers and a committee on organization were appointed, which at the next meeting in the Army Building, June 29th, presented a constitution and a slate for officers. The constitution was adopted after a slight amendment which made the By-laws amendable by vote at a general meeting, thus yielding to the figment that has led half the world astray—making things safe for democracy. The following are the officers of the Post:

Col. F. A. Molitor, President; Col. Geo. D. Snyder, Vice-President; Maj. Percy E. Barbour, Secretary; Sgt. Alan D. Fitzgerald*, Assistant Secretary; Maj. Phillip D. Fleming, U. S. A., Treasurer.

Directors: Col. Roger D. Black, Maj. E. F. Robinson, Lt. Col. Arthur S. Dwight, Col. B. W. Dunn.

The matter of dues was put off until the annual meeting in January, it being deemed sufficient to assess an entrance fee of $1.00, which would take care of expenses until that time. There are so many calls on the purse these days that it is felt that this movement at its inception must not be an expensive one. It is a patriotic effort and must generate its own momentum, for the country has already forgotten the lesson it was about to be taught when the too early signing of the Armistice convinced it that we can become prepared any old time on short notice and are invincible.

*Since promoted to Lieutenant 22d N. Y. Engineers.

Digitized by Google

The Program Committee laid out a very ambitious program, and the intense interest aroused by the meetings thus far justifies its effort. It reported in part:

1. It is believed that to achieve the greatest usefulness to and through its members the Post should evolve a definite Purpose and a Policy to further its Purpose. To this end it seems desirable at the outset to enunciate a tentative Purpose and Policy as a basis on which to work.

2. *General Purpose—*

To foster that active co-operation between the technical personnel of the regular army and the personnel of the civilian engineering profession which will result in the greatest efficiency on the part of all concerned when mobilized for war, either as part of the armed forces or in war industry.

3. *Specific Aims Corollary to the General Purpose—*

(a) To maintain and build up mutual respect and confidence, and prevent jealousy, misunderstanding, suspicion and conflicting activity.

(b) To cultivate acquaintance and co-operate activity between the regular army, the national guard, the reserve corps and civilians.

(c) To assist in the development of a sound military policy and the formulation of legislation and regulations thereunder tending most effectively to carry out the "General Purpose."

(d) To promote military education.

(e) To build up the reserve forces, particularly in the technical services.

(f) To prepare for the most effective use of the reserve forces and civilian personnel on mobilization.

4. *Premise for Policy—*

(a) The Post believes that both mutual confidence and efficiency are based primarily on real ability to perform a present or contemplated service. Such ability is based on character, experience and theoretical training. The first two are related only incidentally to the possible activities of the Post.

(b) It also believes that military training involves; *first,* a definite knowledge of function, that is of what is required of the individual, and *second,* the necessary technique to perform the function, that is, the ability to do what is required.

(c) Knowledge of technique is of little avail in organized work, such as that of a large army, without the corresponding knowledge of function.

(d) The technique of military engineering in its various branches is relatively simple, and the greater part of it can be based on the technique of corresponding civilian activity. The balance, that is the strictly military technique, can be best learned in training camps or left to the agencies of actual mobilization and service.

(e) To know his function, every individual in the military service must know the functions of all with whom he deals. This requires, for officers of the technical services, a broad and uniform general knowledge of the principles of military organization.

(f) A study of military organization involves a study of military policy, which in turn will result in informed and useful convictions on all of the "Specific Aims" cited above.

5. *The Policy—*

Therefore it will be the present policy of this Post to develop to its utmost the knowledge of the proper functions of its members, whether in the military service or in war industry, and in preparation for both.

The Policy will be Pursued—

(1) By a study of—

(a) Military Policy.

(b) Principles of military organization.

(c) Principles of organization of munition supply.

(d) The application of all these to the local situation as it affects our members and their activities; and

(2) By such line of action as will seem best as a result of this study.

After full consideration of the subject your committee recommends that the Local Post of the Society of American Military Engineers follow the lead of the various alumni associations and have four regular meetings, one smoker and one annual dinner each year, together with one or more outside trips to nearby points of interest or military importance. With respect to the scope of subjects to be treated at regular meetings, it is recommended that broad military questions bearing on the purpose and policy be discussed rather than technical details.

The following schedule is being followed:

Fixed date October 26th—Army Reorganization Bill and Opportunities for Reserve Officers and Organizations.

Tentative date December 14th—Relations between Staff and Services.

Tentative date January 26th—Annual Dinner.

Tentative date February 10th—Functional Organizations of Engineers.

Tentative date April 13th—Military and Engineering Defense of New York—War Game.

Tentative date May—Trip to West Point, N. Y.

The April meeting will be held jointly with the New York Section meeting of the American Society of Civil Engineers.

At the first meeting, besides the set speakers, a letter from General Haan was presented containing a scheme for "Training Courses for the Organized Reserves" with the request that it be considered and an expression of opinion given.

Col. Wm. Barclay Parsons prepared a reply, which he read. The fact of the presentation of such a plan for opinion was of no small importance. It indicates how the post may be of assistance not only to the parent society but to the Government, and fills us with courage and hope.

The progress report of the Military Affairs Committee of Engineering Council was considered in abstract and briefly discussed.

At both meetings we have had the privilege of addresses from distinguished members of the general staff in Washington, officers from Governors Island, and various reminiscences from officers who returned from France rich in trouble and experience.

Philadelphia Post

At a meeting of the Philadelphia Post, Society of American Military Engineers, held at the Engineers' Club, Philadelphia, Monday, October 25th, 1920, the constitution and by-laws of the local post were adopted and the following officers elected to hold office until January, 1922:

Col. W. B. Ladue, Commander; Maj. Marshall R. Pugh, Vice-Commander; Maj. H. W. Goddard, Adjutant; Capt. J. C. Hinton, Finance Officer; and the following staff officers were elected for two years: Lt. Col. Henry S. Spackman, Maj. Thomas W. Battin, Captain Clarence Roberts; and for a period of one year, the following: Capt. R. W. Robinson, Lieut. Robert L. Harding.

It was also decided to hold regular meetings the fourth Thursday of each month during the winter.

At a meeting of the Philadelphia Post, Society of Ameri-

Digitized by Google

can Military Engineers at the Engineers Club, November 30th, 1920, Lt. Col. Henry S. Spackman gave a very interesting talk on relationship of military to general engineering, which was followed by a general discussion by members and invited guests.

Washington, D. C., Section

On Friday, December 17, about 75 members of the Society of American Military Engineers gathered at luncheon at Washington.

Dr. Alfred Brooks of the U. S. Geological Survey presided. Dr. Brooks was formerly a Lieutenant Colonel of Engineers and was Chief Geologist of the A. E. F.

Brigadier General Henry Jervey of the General Staff, was the first speaker. He abandoned the material realm of engineering and spoke eloquently of the research spirit as a source of inspiration in the everyday affairs of life. Dr. Augustus Trowbridge, of Cornell, now serving on the National Research Council, gave a brief but interesting sketch of the activities of the Council, which is continuing the investigations along scientific lines that were started by this body during the war. Dr. Trowbridge was a Lieutenant Colonel of Engineers in the A. E. F., and was charged with the development and practice of sound and flash ranging for the determination of location of enemy guns. The last speaker, Mr. O. C. Merrill, Executive Secretary of the Federal Power Commission, outlined the vast problem that confronts the Commission in its task of working out a feasible policy for the development of the water power resources of the country.

This is the second of a series of luncheons to be held in Washington. A committee has been appointed to draw up plans for the formal organization of a Washington Post of the Society.

The Chesapeake and Delaware Canal

By

J. P. Jervey

Brig. Gen., U. S. A., Retired

[*Note.*—Somebody once propounded the theory that it required less power to move a ton of freight a given distance by water than by rail. This is true. It has been frequently seized upon as a proof that water transportation is inherently cheaper than transportation by rail, and has been responsible for the waste of many millions of dollars. The facts are that this consumption of power is only one of a vast number of items that enter into the cost of transportation, and sometimes it is a very insignificant item.

The best system of transportation to employ, and whether or not it will pay to employ it, must be determined by investigation of each case on its own merits. Transportation by rail is certainly cheaper than transportation on the backs of coolies or mules. Yet there are many situations in which the latter form of transportation continues to be used. If we wish to move the household furniture from one room to another, we do not put in a railroad, nor even employ a motor truck to do it.

General Jervey, in the entertaining article which follows, points out the fundamental economic conditions on this canal and indicates what it has already accomplished, and what it may accomplish in the future. Had more of our water-way projects been examined and studied in like intelligent manner before money was spent on them, many millions of dollars would have been saved the tax payers of the United States.

A deep intra-coastal waterway between Chesapeake and Delaware Bays, thence to New York Harbor and Long Island Sound, would have a tremendous value to the national defense. In providing a number of available outlets it would render it impossible for the combined navies of any probable opponents to blockade our fleet. The intra-coastal waterway, accordingly, finds its chief justification as an element of the National Defense.—ED.]

Historical. Fully two hundred years ago the question of constructing a canal through the upper part of the Maryland and Delaware peninsula was under consideration. Toward the end of the eighteenth century this agitation resulted in definite action and a charter was issued in 1799. Vigorous efforts were made to secure funds, the general government and the states of Pennsylvania, Delaware and Maryland all contributing. After twenty-five years of effort the necessary money was raised and in 1824 the construction of the present Chesapeake and Delaware Canal was begun. The water was let into the canal on July 4, 1829, and in the same year the canal was opened for traffic. The total cost was $2,250,000, of which the United States furnished $450,000; the state of Pennsylvania, $100,000; the state of Maryland, $50,000; the state of Delaware, $25,000, and the citizens of the several states the remainder.

This waterway, ordinarily known as the Chesapeake & Delaware Canal, but officially as the Inland Waterway from Delaware River to Chesapeake Bay, comprises at present a short tidal stretch at its Delaware River end (which is 40 miles below Philadelphia); a slack water section 4.3 miles long from Delaware City to St. Georges with a level 7 feet above mean low water in Delaware River; a slack water section 9.3 miles long from St. Georges to Chesapeake City, Md., with a level 17 feet above mean low water in Delaware River and a tidal section 4.2 miles long from Chesapeake City to the junction of Back Creek and Elk River, in which certain cutoffs must be made, sharp curves and detached shoals eliminated. The total length of the slack water section is 13.6 miles and of the tidal sections about 4.3 miles. All locks have horizontal dimensions of 24 by 220 feet.

An interesting feature of the canal was its use during the Civil War, in 1861, for moving troops to the defense of Washington. On the night of Friday, the 19th of April, all bridges on the Philadelphia, Baltimore and Washington Railroad from Baltimore to the Susquehanna River were totally destroyed by Confederate sympathizers and the Federal Government had then absolutely no means of transporting troops along the seaboard by rail to Washington. On April 20, however, the United States commandeered all the propeller steamers in Philadelphia that could traverse the Chesapeake and Delaware Canal, and these were passed through the canal, arriving before daylight on the morning of the 21st at Perryville, on the Susquehanna River. Early that morning the troop trains from the North arrived at Perryville and the troops were transferred to the steamers which then steamed down the river and bay to Annapolis, whence all troops were moved by rail to Washington, arriving just as the Confederate outposts appeared at the Virginia end of the Long Bridge in Washington. It is probable that this prompt and efficient use of the canal saved the city of Washington from capture by the Confederate forces. Subsequently, throughout the war this canal played an important part in supplying the Army of the Potomac with munitions and other stores.

Economical. In the economical transportation of freight

The Strength of the Pyramids

For centuries the Pyramids have stood with an endurance founded on solid, rugged strength. As these inanimate structures have endured through strength, so must an organization of men endure; and of the elements of strength, Service is the greatest, the most rugged, the most imperishable.

The strength of the American Association of Engineers lies largely in the service it renders to engineers. The 154 chapters of the Association supply non-technical educational courses, means for properly directed citizenship duties, opportunity for one to acquire experience in organization direction, business offices with interests of engineers as their principal endeavor, compensation and employment service, and the stimulating fellowship of other engineers.

Among such national activities as the publishing to the profession of a Code of Ethics, written for A. A. E. by the late Isham Randolph, the maintenance of a Practice Committee to enforce the Code, a great compensation service conducted in accordance with professional ethics, the Service Department stands in the forefront.

The positions filled during July saved members $35,000 which commercial agencies would have charged to place them in the same positions. This is more than two times the total monthly dues of the 21,000 members of the Association. Furthermore, the department did not fill all the positions on its list. It has 200 vacancies a month for mechanical engineers.

You should know more about the service rendered by this young, virile society. Send the coupon for a copy of our handsome new booklet entitled "An Ideal Which Has Become an Institution."

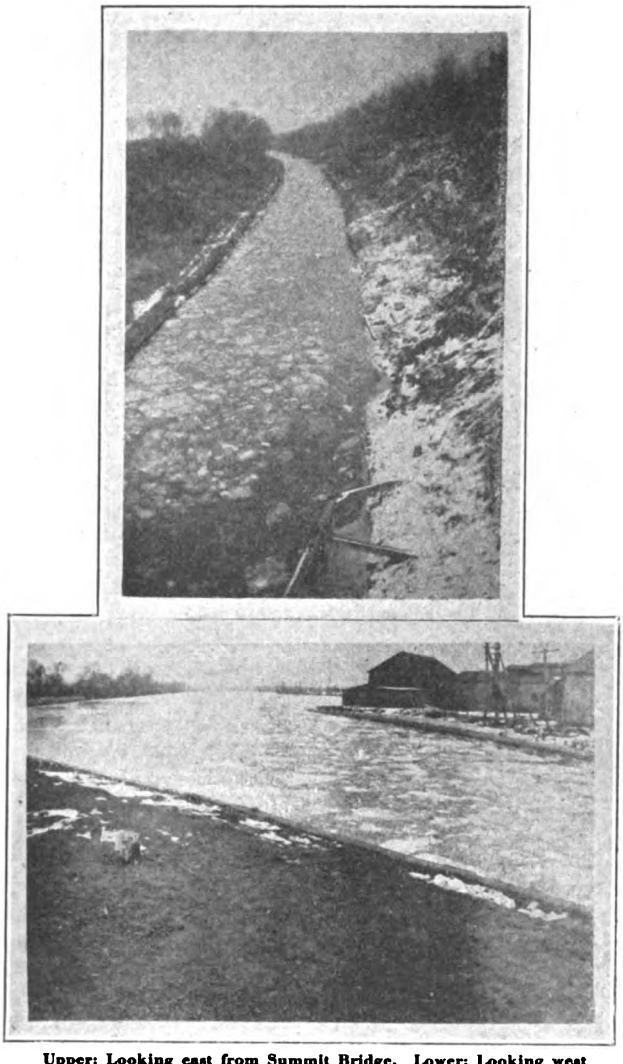
by water the question of the saving of time is a vital consideration. Any improvement or modification of our waterways which will result in the shortening of distances and the saving of time therefore deserves careful consideration. The conversion of the Chesapeake and Delaware Canal into a ship canal will shorten the distance between Philadelphia and Baltimore by 323 miles and the distance from Baltimore to the mouth of the Delaware by 184 miles. This will mean a saving of time in the first case of from 30 to 36 hours and in the second case of from 16 to 18 hours. When it is considered that the operating expenses alone of a freight-carrying steamer under present conditions runs from $300 to $500 per day and that if depreciation, loss of freight, etc., are considered, the total cost of avoidable delay will be from 50c. to 70c. per ton per day, it is seen that a very large saving will result due to the shortening of time between Baltimore and Philadelphia and Baltimore and the mouth of the Delaware River. Again the loss of vessels and lives which now takes place annually between Cape Charles and Cape Henlopen, between which points there is no harbor of refuge, except the inadequate one at Chincoteague, will be greatly reduced. The cost of marine insurance and of new construction will also be lessened. For outside runs insurance rates range from 8 per cent to 12 per cent annually as against the average of 4 per cent for an inside run. If the cost per ton capacity of a barge suitable for inside work to be considered as unity, that for a lake vessel will be 3.6 and that for an ocean-going vessel 6.3. If the entire waterway were completed from Norfolk to Boston for seagoing vessels delays to shipping on account of storms would be largely reduced. At times, barges and sailing vessels have been compelled to wait at Hampton Roads two to three weeks for favorable weather and as many as 75 to 100 vessels have at times been seen thus waiting in the Roads. Delays of this character would be almost entirely eliminated by the use of the Intracoastal Waterway.



Delaware & Chesapeake Canal

Upper: Looking east from Delaware City breakwater. Lower: Looking west from Delaware City lock

Commercial and industrial. The Chesapeake and Delaware Canal is a waterway connecting very directly two of the most important ports of the United States, namely, Philadelphia and Baltimore, and even with its present restricted dimensions carries an important commerce between the two points mentioned. In addition, the Delaware River from Wilmington, Del., north is probably the greatest manufacturing district in the United States; south along the shores of the Chesapeake Bay is one of the richest agricultural regions in the United States, and still further south at Norfolk three great coal-carrying roads bring to seaboard the products of the mines of Virginia and West Virginia; while from sounds of North Carolina come great supplies of lumber both for building and paper manufacturing purposes. Delaware and Chesapeake Bays have a combined shore line of 2,500 miles with 500 tributary streams, and more than 10,000 registered vessels ply on these waters. The registered tonnage operating on each bay is about 25,000,000 tons, to which may be added an unregistered tonnage of an equal amount, making a total tonnage on both bays in the neighborhood of 100,000,000 tons. The population of the states and portions of states bordering on the two bays and its tributaries is probably now in excess of 15,000,000. The canal may be therefore considered a great link connecting sources of raw material and agricultural products with the manufacturing centers, where these materials and products are consumed. In addition to its local value, the Chesapeake and Delaware Canal is the central link in the chain of waterways proposed between Boston and Beaufort, and it is essential to the construction of any intracoastal waterways connecting New York and Philadelphia with the South. It is difficult to estimate the amount of coastwise traffic which would use the canal, as, unfortunately, coastwise vessels are not required to furnish manifests of their cargoes to customs collectors. It has been estimated, however, some years ago, from very incomplete data, that the total inland traffic north and south via the canal, after it was made into a free canal, would be at least 2,500,000 tons valued at over $14,000,000 per annum, and that the annual saving, not considering the saving in insurance, on known existing coastwise commerce which would use the free canal would not be less than $2,230,000. The actual saving would probably be in excess of this. An investigation made in 1910 shows that the annual traffic between Baltimore and domestic ports which would be benefited by the free canal affording 25-foot navigation would be in the neighborhood of 4,500,000 tons, and without predicting any increase in navigation it was then estimated that the total saving including foreign commerce, due to a free canal affording 25-foot navigation would be $1,414,000. Since the date of this report the commerce of both Philadelphia and Baltimore has greatly increased, costs in nearly all cases have advanced more than 100 per cent, and it is probable that the benefits accruing from deepening the canal to 25 feet would show a corresponding increase, making the probable saving about $3,000,000 or more. With reference to Baltimore, the *Manufacturers' Record* of June 3, 1920, states:

> Baltimore's advantages include lower railroad freight rates than those of points to the north. The city's longitudinal location enables it to obtain freight differentials under New York, Philadelphia, and

Digitized by Google

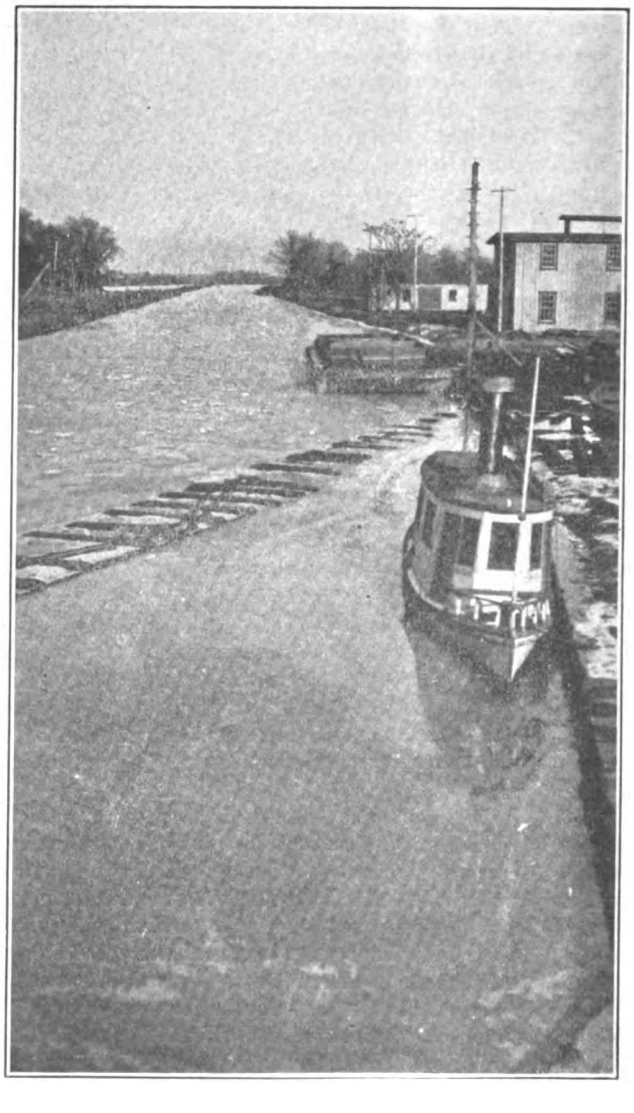
Upper: Looking east from Summit Bridge. Lower: Looking west from St. Georges Lock

New England points on shipments to and from Buffalo, Pittsburgh and the Middle West.

To the prospective industry Baltimore presents the advantages of saving in labor cost, lower freight rates, lower taxes and cheaper rates for power than prevail in most other cities.

Steamships are operated between Baltimore and practically every important port of the world.

In a report of the Export and Import Board of Trade of Baltimore dated August 5, 1920, it is also stated:



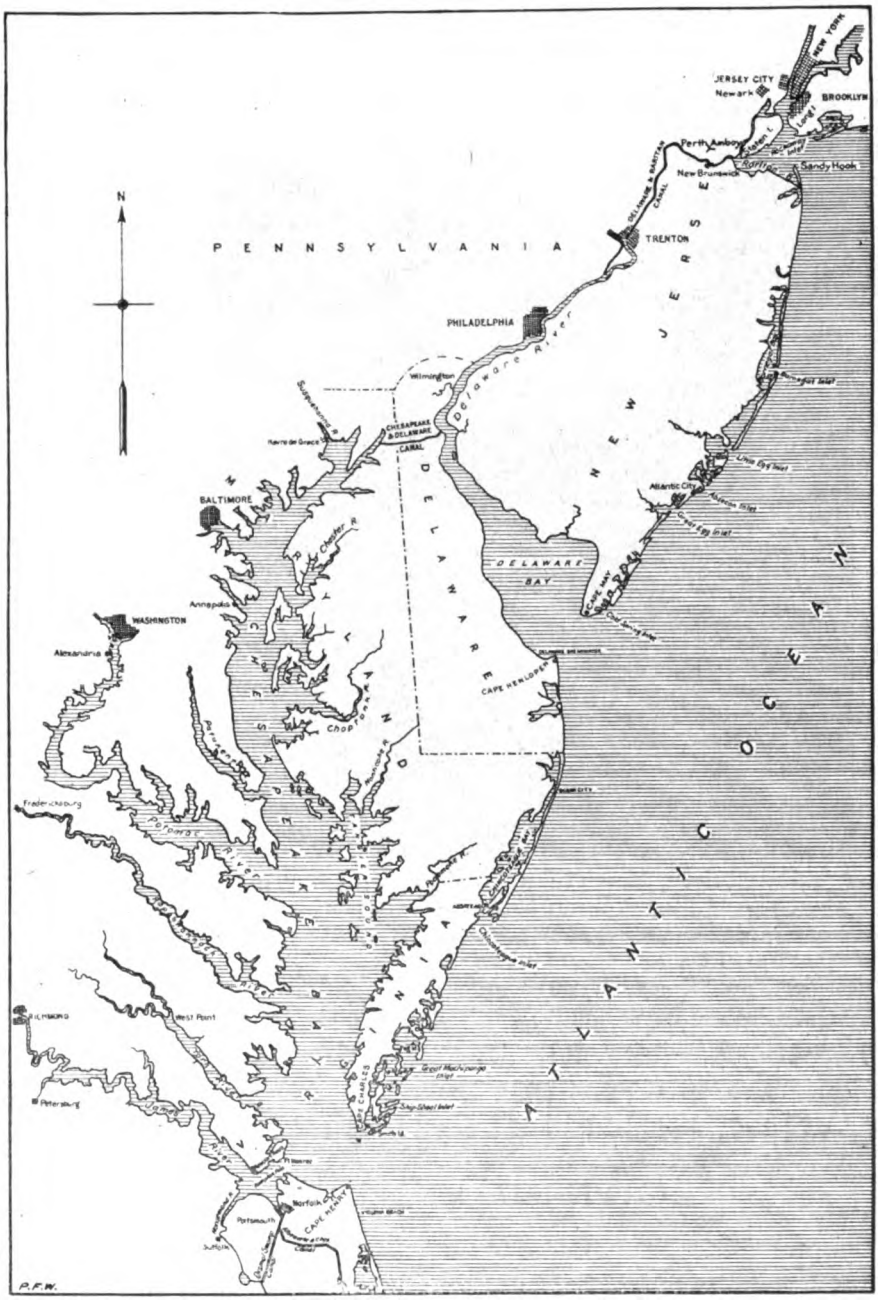
Baltimore's foreign trade has more than tripled in value since before the war, and the present outlook for 1920 indicates new records in every branch of shipping, including export and import business.

There are now 42 steamship lines operating more than 150 vessels on 59 services to over 80 foreign ports from Baltimore.

Exports and imports pass through this port without congestion or delay. The "turn around" of steamers costs less in this port than in New York, recent comparisons showing an average saving of more than $4,000 per vessel each time on similar ships and cargoes in favor of Baltimore.

The report of the Chief of Engineers for 1920 shows that the total tonnage and value of commerce of the port of Baltimore for the calendar year 1919 was 14,055,906 short tons valued at $873,891,200, and of the port of Philadelphia for 1918, 21,000,000 short tons valued at $2,600,000,000. It does not, therefore, seem extravagant to predict that the Chesapeake and Delaware Canal considered alone has promising prospects of being a successful investment for the Government. With the deepening of the canal to even 12 feet and its widening and conversion into a sea-level canal, the time between Philadelphia and Baltimore will be so reduced that the steamers will be able to make the distance easily under 12 hours and will need a crew consisting of but one watch. In addition, passenger steamers of practically the same type as now operate so successfully between Baltimore and Norfolk could also be operated between Philadelphia and Baltimore. The country along the upper Chesapeake, particularly along the Elk River, Back Creek and the line of the canal is a beautiful rolling section, which is being rapidly bought up and improved by residents of Philadelphia and Baltimore. The Delaware River is most interesting on account of its great industrial and commercial development. The passage by water between Philadelphia and Baltimore should therefore be most attractive and instructive.

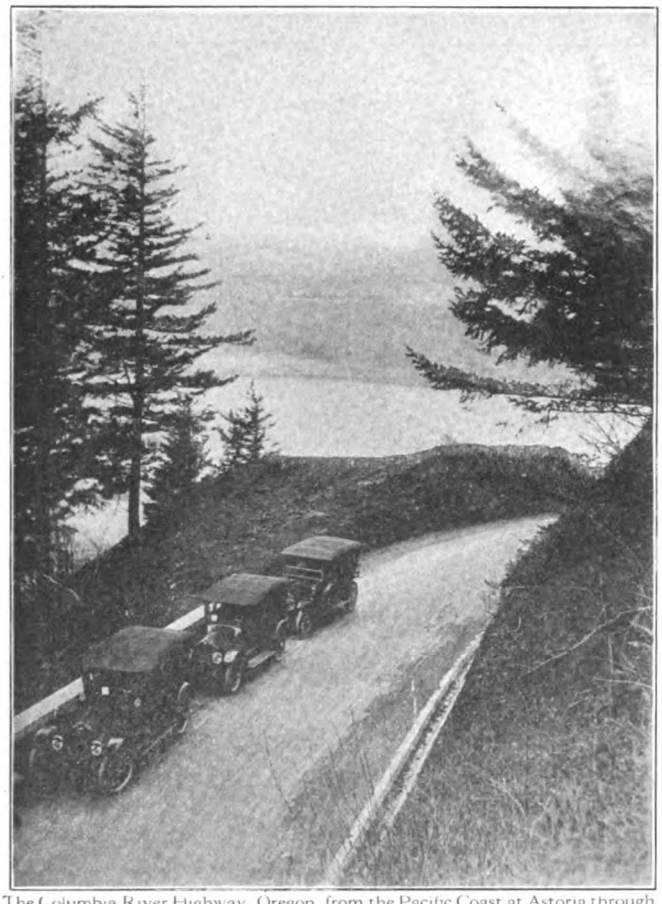
Canals vs. Railroads. Due to the decline of all waterborne commerce in recent years, it has been claimed that large outlays for the improvement and construction of intracoastal waterways are uneconomical when compared with the cost of freight carriage along the coast by ocean-going lines, and internally by the railroads. So far as the comparison with ocean-going vessels is concerned, it has already been pointed out that the cost per ton of capacity for the construction of a barge for an inland waterway is less than one-sixth of that of an ocean-going vessel. In addition the cost of insurance on vessels using the inland



Digitized by Google

waterway is only one-half to one-third that for vessels operating on the high seas. The greater safety for human life of the inland route is most important.

In the early days of the development of commerce in the United States there was a heavy traffic first on our natural waterways and then on the many artificial canals which were constructed by State, Federal or private funds. As the railways were constructed the water-borne commerce declined, and in many cases disappeared, as the population was not sufficiently dense to provide traffic for both methods of transportation, and the railways, due to the fact that they were able to place cars either for shipment or delivery at the exact spots desired by their patrons, presented great advantages as compared with shipment by water. As the population increases, however, it is reasonable to suppose that there will be a revival of water-borne commerce.



In the past, railway development in the United States has in many cases been unjustified and in advance of the actual necessities of commerce. In their consequent fight for existence the railways have been permitted to make discriminating rates to points where water competition was possible. As a result, lower rates were granted to such points and these rates had to be compensated by imposing higher rates on interior points not so fortunately situated. In other words, the interior population has had to pay, in part at least, for the freight service to the population on the waterways.

Moreover, in the past, it has been the policy of railway companies to obtain possession of all available wharfage space in terminal cities, partly with a view to preventing water competition. The requirements, however, of the last River and Harbor Bill as to public terminals should eventually counteract this evil. In many cases, also, the railways have refused to grant through bills-of-lading or pro-rate freight charges in connection with water carriers, thus making the all-rail carriage more advantageous. Since railways are public-service institutions, owing the possibility of their existence to certain rights granted in their charters, a policy of this kind which is manifestly contrary to the public interests must eventually be changed. From a report published in 1910 as to conditions in Germany, it would seem that as the population becomes more dense there should be sufficient traffic both for railways and waterways. This traffic will be divided so that each carrier will transport the character of freight most suitable to its particular form of carriage. In the report referred to above it is shown that in 1875 the traffic over 26,500 kilometers of railway amounted to 10,900,000,000 kilometer tons, and that over 10,000 kilometers of waterways amounted to 2,900,000,000 kilometer tons. In 1905 the traffic over 54,400 kilometers of railways was 44,600,000,000 kilometer tons and that over 10,000 kilometers of waterways was 15,000,000,000 kilometer tons. The increase of railway mileage was 105 per cent. There had been no increase in waterway mileage. The increase of railway tonnage was 400 per cent and of water tonnage, 500 per cent. There seems, therefore, no grounds for the fear that under favorable conditions it will not be entirely possible for both waterways and railways to operate successfully.

Military and naval uses. The Chesapeake and Delaware Canal would form a convenient and useful interior line by which troops or small vessels could be readily moved from Delaware Bay to Chesapeake Bay or vice versa. In order, however, to have any particular value from a naval standpoint the depth should be at least 16 feet, which is the minimum that would permit the passage of destroyers, submarine chasers, or submarines. If the canal is eventually deepened to 25 feet it would permit the passage of prac-

The Obligation of Supremacy

A reputation of "par excellence" in any trade is both an asset and a liability. It attracts business but at the same time obligates its holder to a most intense degree of concern to maintain his supremacy. This obligation operates as a guarantee as effectively as any written bond.

In laying pavements, WARREN BROTHERS COMPANY are compelled to give in their supervision and attention to detail that no engineer, regardless of his individual ability, can afford to give. The greater his skill and experience, the more the engineer realizes this and welcomes the technical supervision of detail by the specialist. Proven under every condition and climate.

Warrenite-Bitulithic

plus our expert supervision and inspection, has demonstrated its supremacy throughout the United States and Canada.

tically all coastwise vessels of the United States Mercantile Marine and would then become a convenient means of moving troops in large bodies from north to south or vice versa. For the moving of troops sheltered water transportation affords many advantages over transportation by rail. Among these advantages may be named:

a. The possibility of keeping the larger administrative units united in a single carrier.

b. The diminished chances of delay to an entire expeditionary force by the loss or delay of one of the transporting units.

c. The smaller number of transporting units required.

d. The greater freedom from ordinary delays in transit due to ordinary commercial traffic.

In the future, if a still further deepening of the canal is undertaken, it might be possible to pass commercial ships and battleships of the largest class conveniently and safely between the great commercial and naval establishments at Philadelphia and Norfolk.

Methods of construction and dimensions. The approved project for the greater canal provides, for the present, for a depth of 12 feet and a bottom width of 90 feet. It is proposed to carry on the work of improvement so that traffic will not be interrupted. This will require the work of reconstruction to commence on the summit level and be followed by the removal of the locks as the canal is gradually deepened. The question will naturally be asked why the 25-foot depth is not provided at once. The answer to this is that in order to economically dispose of the spoil from the excavation it will be necessary to provide at the outset a channel on which barges loaded with excavated material may be readily moved to the disposal areas at the eastern end of the canal without interfering with commercial traffic. A sea-level canal 12 feet deep and with a bottom width of 90 feet will be sufficient for this work. Again, a depth of 12 feet and a width of 90 feet is sufficient for all barge traffic, and it is believed that a very large percentage of the traffic between Chesapeake Bay and Delaware Bay will be carried in fleets of barges towed by tugs. The question of coastwise ships and ships bound to foreign ports moving out of Baltimore is principally a local one in which Baltimore is largely concerned, and it is thought that a large measure of co-operation by that locality would be proper before a 25-foot or greater depth was secured. After the 12-foot depth and 90-foot width have been obtained a further deepening will be comparatively a simple matter. It may be noted that in reconstructing the bridges, pier and abutment foundations will be carried deep enough to provide for a future depth of at least 25 feet and possibly more. The revised estimate of the cost of construction of a canal 12 feet deep with a bottom width of 90 feet, is $12,000,000. In order that the construction may be economically carried on, whether done by contract or by hired labor, this money should be appropriated so that the canal may be completed in four to five years. This will involve annual appropriations of $2,500,000 to $3,000,000.

Reports and surveys. A wealth of information in great detail as to the various surveys, examinations and reports on the Chesapeake and Delaware Canal is found in official documents. The most important of these are the Angus Commission Report submitted to Congress by the Secretary of War on Jan. 7, 1907, and published in Senate Doc. No. 215, 59th Congress, 2nd Session; the Intracoastal Waterway Report submitted to Congress on Jan. 4, 1912, and published in House Doc. No. 391, 62nd Congress, 2nd Session; the final report on sections of the Intracoastal Waterway from New York Bay to Delaware River and from Delaware River to Chesapeake Bay submitted to Congress Aug. 12, 1913, and published in House Doc. No. 196, 63rd Congress, 1st Session, in which is contained the basis of the present approved project; summaries of reports of Government Commissions, Officers and Engineers made upon a canal to connect Chesapeake Bay and Delaware River submitted to Congress March 11, 1915, and published in Senate Doc. No. 14, 64th Congress, 1st Session; and finally a letter from the Secretary of War dated December 14, 1918, recommending the purchase of the Chesapeake and Delaware Canal and published in House Doc. No. 1600, 65th Congress, 3rd Session. As a result of this last named communication the existing project was adopted by the River and Harbor Act of March 2, 1919, under which $3,000,000 was appropriated and which provided for the purchase of the Chesapeake and Delaware Canal at a cost to the United States not exceeding $2,514,289.70 and its enlargement to a sea-level barge canal, extending from the 12-foot curve in Delaware River to the 12-foot curve at the intersection of Back Creek and Elk River, a distance of about 19 miles.

Another Use for the Cement Gun

The cement gun, in experienced hands, lends itself to the solution of many of the more difficult problems of engineering, as is amply proven by the results already attained.

One of its latest achievements is the renewal of a battery of 42 cylindrical steel tanks whose plates had been rusted through by the acids contained. These tanks were 16 feet in diameter and 8 feet deep.

The tanks occupied a restricted space in a building, and to have replaced the damaged plates would have required a suspension of operations by the plant to which the tanks belonged, which at the time was working night and day to fill delayed orders. This would have caused a great loss. An alternative but preferable solution was to replace the tanks one by one. This also would have been very expensive.

In this dilemma the cement gun was brought to the rescue. The tanks were repaired two at a time. The tanks to be repaired were drained and thoroughly cleaned of rust and scale, this producing many holes through the damaged plates. Steel reinforcing rods, ¼ and ⅜ inch in diameter were then placed vertically against the shell, both inside and out, being hooked over the rim. The inside and outside rods were wired together through the holes in the tanks. Wire mesh was then attached on both sides and a 1-inch layer of "gunite," consisting of 1 part cement to 3 of sand, was shot on. The outside layer was left with the rough finish, the inside was troweled smooth. The tanks were thus converted into stone jugs of 2 inches of gunite, with a steel plate in the center, and rod and mesh reinforcement on each side of the plate.

The tanks proved to be perfectly tight, the acid having no effect on the gunite. After two years' service they promise to endure at least as long as any other portion of the plant. —*Concrete.*

The Civil Activities of the Corps of Engineers*

Their Value as Military Training, and their Relation to the National Defense

By

Gilbert A. Youngberg

Lieutenant Colonel, Corps of Engineers

[INTRODUCTORY NOTE. For more than a hundred years the Corps of Engineers of the Army has faithfully and efficiently prosecuted the public works pertaining to navigation, and many other such works of a miscellaneous nature. And that record of a hundred years of honest and efficient service, attested by works that cover the country from the Atlantic to the oriental shores of the Pacific, and from Alaska to Panama, cannot be overlooked nor set aside by the American people.

But aside from the efficient prosecution of the works themselves, the training thus gained by the Corps of Engineers has, as Colonel Youngberg points out in this excellent article, a most vital relation to the national defense.

The Corps of Engineers knows that the success which its officers have achieved in war, both in the field of engineering and that of high command, is in large measure due to the training gained in the prosecution of the public works.

And in our desire to attain the utmost in economy and efficiency in our public works, we also must not overlook the value of the military training which they afford to our army engineers. Not on a doubtful chance of saving a few dollars a year on public works can we afford to entrust the engineering operations incident to a great war, to a body of men who are not both thoroughly trained soldiers and thoroughly trained engineers. For a single mistake in their judgment in the critical time of armed conflict might easily wipe out the saving of years of peace, and might even spell national disaster. Let us fully realize what it might have meant to our country and to civilization had the important construction work in France, on which the operations of the A. E. F. so greatly depended, fallen into the hands of incompetents, instead of trained soldiers and trained engineers.

And it is not a mere knowledge of construction methods which is alone or even chiefly of importance to our military engineers. The highest virtue of the soldier, whether as commander or as engineer, is not the physical courage which enables him to face fire, but the higher (and rarer) moral courage, self-reliance and resourcefulness, which enable him to face and shoulder grave responsibilities involving the lives of men and the fate of a nation.

And so the most important feature of the training gained on the public works, is the ability and courage to assume responsibility. These require training in *responsible charge* of work. If our military engineers merely occupy subordinate positions in a great Department of Public Works they will fail to obtain this vitally necessary training for *carrying responsibility*. And in the next great war the lack of such training would jeopardize our chances of victory.—ED.]

THE Corps of Engineers is charged by law with the executive direction of so-called civil or public works having to do with the navigable waters of the United States. This civilian activity of a technical staff service of the War Department, this civil (and hence apparently anomalous) employment of an inherently military force is a matter which is little understood by the people in general and there exists also throughout the army a prejudice against the Corps of Engineers being charged with this responsibility. There is a feeling that in some peculiar and not clearly defined way it constitutes a class distinction in that it affords the officers of engineers preferment in the matter of station and duty and that it must necessarily militate against their efficiency as military men.

This prejudice grows out of misunderstanding of the nature of this duty and a misconception of the relation which it bears to the work of the Corps of Engineers in war. It is fostered by the infrequent opportunity given officers of the line to observe this work and the lack of any occasion on their part to give it analytical study.

The civilian public at large, so far as it is acquainted with the matter, has no such prejudice and is satisfied that the Corps of Engineers has, in accordance with the enactments of Congress, administered this important national activity with entire credit to itself. There is, to be sure, at this moment a well organized and active body of propagandists whose purpose it is to take this activity out of the hands of the Corps of Engineers and the War Department altogether.

Statements made by accredited representatives of this body, as reported in the press, display a woeful ignorance of the duties of the so-called military engineer who, after all, is none other than the engineer of civil life with such an additional knowledge of military matters as will enable him most efficiently to apply his art in support of military operations. In view of the magnitude and variety of engineering operations executed by engineers in the military service in France, any one claiming that the work of the engineer in war is concerned only with fortifications or other work subject to enemy fire is guilty either of crass ignorance or of criminal misrepresentation.†

The Corps of Engineers has confidence that it has given a good account of its stewardship and is prepared to defend before any proper tribunal its efficiency in the conduct of the work entrusted to it. In this connection it is also well to bear in mind that the Corps of Engineers is not an independent governmental body possessed of unlimited powers in respect to public works. It is subject to the will of Congress and, to quote General Bixby, "it has been the established policy of the Engineer Department to avoid as far as possible any action that might be misconstrued into an attempt on our part to decide for Congress what it should do in river and harbor matters. The Corps of Engineers is the servant of the people and not their master, and while the recommendations of the army engineers, when asked for, have always been made according to their own best judgment, their actual work has always been restricted to what has been ordered by the United States Congress."

Historical

The connection of the Corps of Engineers with this work harks back to the early days of the nation. In the simple agricultural life of the colonists there was practically no work of a technical engineering nature, though in the progress of the Revolutionary War, the need for military and topographical engineers became urgent. This need was supplied by officers from foreign armies, principally French, though the colonists themselves produced a few practical military engineers of no mean ability. In 1800 James McHenry, Secretary of War, urging the re-establishment by law of a military academy and a corps of engineers, said, in his argument, that "fortifications is but a single branch of their profession" and "their utility extends to almost every department of war and every description of general offices, besides embracing whatever respects public build-

Digitized by Google

ings, roads, bridges, canals, and all such work of civil nature." In 1802 the Military Academy was established at West Point for the sole purpose of educating engineers for such service. For many years past, however, its graduates have been assigned to all combatant branches.

Up to 1824 West Point was the only school which taught civil engineering, and all engineering work was necessarily started under the guidance of West Point graduates. In 1824 a specific Act of Congress gave to the army engineers the definite charge of all government roads and canals.

The Rensselaer Polytechnic School did not start until about 1824, and the Sheffield Scientific School at Yale, and the Lawrence Scientific School at Harvard not until about 1847. When, after the Civil War, civil engineering and other technological schools began to develop all over the United States, the Military Academy graduates still held their own good standing in the civil engineering profession because of their added knowledge of governmental methods and their special military training as to careful observation, obedience, and rigid responsibility in all matters of engineering work, property and funds.

The road and canal work of this country, started officially under the charge of the army engineers in 1834, was soon extended to embrace occasional rivers and harbors, and so continued until naturally stopped by the Civil War. About 1867 such work came to the front again, mainly in the matter of river and harbor improvements, and was naturally reassigned to the army engineers, and there it has remained ever since.

The river and harbor work of this country has come, therefore, to the Army Engineer Corps by original endowment and by natural processes of national development and remains with it as a natural inheritance and duty in which its service has special value to the country at large by reason of its century of special training and of careful, efficient, honest stewardship.

Organization and Administration

The civil works under the supervision of the Chief of Engineers embrace the improvement of the rivers and harbors of the United States and other public works whose execution has been entrusted to the War Department, including the survey and preparation of navigation charts of the Great Lakes, the public buildings and grounds in the District of Columbia, the Washington aqueduct and filtration plant, and road construction in Alaska.

For purpose of administration and control, the country is divided into engineer districts, each in charge of a district engineer, usually an officer of the Corps of Engineers. The district areas are determined by the character and amount of construction work embraced in them. As the responsibility of the district engineer includes the enforcement of the laws for the protection and preservation of navigable waters as well as the supervision of construction work, the boundaries of the districts are usually based upon drainage systems and so drawn as not to cross any river system, except such large systems as the Mississippi and Ohio rivers, the work on which is divided into several districts. The districts are grouped into divisions, each of which is in charge of a division engineer, who has general supervision over the operations of the subsidiary engineer districts. The division engineers report directly to the Chief of Engineers.

Every precaution within its power is taken by the Corps of Engineers to protect the best interests of the United States. All specifications and contracts are examined and checked up by officers more experienced than those having immediate charge of the work. All projects for new work —and these are initiated in the first instance by Congress— are reviewed by the division engineer, by a board of engineers and the Chief of Engineer before any appropriation is made for the work itself by Congress. There are, of course, differences of opinion as to when improvement work is worthy to be undertaken by the United States, and in the system of reports, such differences are laid before Congress. Needless to say, when Congress makes an appropriation for improvement work, this action becomes the law of the land and the officers have no discretion in the matter of obedience to law, irrespective of their own personal opinions as to the merits of the case.

This river and harbor work is decentralized to the greatest degree permissible under existing law and these officers in the various districts and divisions operate under appropriations separate and distinct from the appropriations for the support of the army, under the general supervision of a "River and Harbor" section in the office of the Chief of Engineers. Not infrequently, however, these same officers, stationed on the seaboard, have charge of defensive works and their maintenance and so have duties under the heading of "Military Construction," which is administered through a construction section in the office of the Chief of Engineers. While this admixture of duties may appear illogical and inconsistent with good organization, it is done as a matter of economy for the same reason that in small military commands a single officer may, and often does, represent several staff corps, departments or operating services. This dual assignment to officers of the Corps of Engineers has other benefits in that it keeps them in intimate touch with distinctly military matters.

River and Harbor Works Afford a Reserve for Military Engineers

If it were indeed true that this civil work interferes with the military efficiency of the officers engaged in its administration, the objection to placing it in the Corps of Engineers would be legitimate and would logically lead to its separation from such work. The objection, however, is not well taken. The one purpose of the Army of the United States, the one reason for its existence is as a means of preparation for war. In war a large number of competent engineers thoroughly versed in military affairs and in military administration are essential. Experience has shown that for our service about seven per cent of the fighting forces at the front are engineer troops and that, including the troops needed in the services of supply behind the fighting lines, the percentage will mount up as the total strength increases until the troops required for engineering activities of various kinds may approximate twenty per cent of the whole.

During the World War we commissioned in the engineers alone over 13,000 officers, and on Armistice Day the enlisted strength was in the neighborhood of 285,000 men. It is obvious that however urgent may be the demand for their services in an emergency we cannot maintain in peace a sufficient number of military engineers to meet our needs in war. At the present time the War Department is bending its utmost energies to the establishment of a reserve corps to be composed of persons in civil life who shall be given opportunity to fit them for service as officers in war. It follows that there must be in the permanent service a suitable number to withstand the first shock of hostile attack and to serve as a nucleus to generate that vastly greater number to be drawn from civil life and to guide and direct them until such time as they shall have become thoroughly

Digitized by Google

conversant with military conditions, until they shall have become in fact military engineers in the true sense.

Under existing conditions, an officer is trained for his work in the Corps of Engineers by an intensive course of study at West Point, including a thorough grounding in mathematical, mechanical, electrical and civil engineering subjects. This is followed by one or two years' service in the field with engineer troops and supplemented by two years' post-graduate work in civil, electrical and mechanical engineering lines and in military subjects at the Army Engineer School. Upon the completion of this course, it is the policy to assign the officers as apprentice assistants to the district engineers, and after a period of instruction in actual field and office engineering they are placed in responsible charge of separate construction works.*

The procedure is very similar for those officers entering the Corps as graduates of approved technical schools. The number of officers has, however, never been sufficient to provide for all such supervision and in each district there are also civilian assistant engineers, who in an emergency may and do replace the military personnel. As a consequence of this organization the officers of the regular establishment are not definitely tied to this civil work, but can be relieved for military duty whenever the necessity arises. It is to be noted also that in a war the amount of civil work is reduced to a minimum and the nation's funds and resources are turned to the prosecution of the war.

The employment of engineer officers of the regular army on civil works furnishes a reserve of military engineers instantly available for military duty. When not needed for strictly military duty they are economically employed on public works which are for the benefit of the people as a whole and the country thus obtains in time of peace an immediate return on its investment in its military establishment. In homely phrase, these officers, though not on military duty, still "earn their keep."

As a consequence of this reserve of engineer officers, the Chief of Engineers during the past war was able to successfully expand the organization of the Corps of Engineers much more readily and efficiently than other services which had no such reserve. Just before the entry into war, there were something over 100 officers of the Corps of Engineers engaged in construction work of whom 43 were on non-military duty exclusively. Just prior to the armistice this number had been reduced to five. If the Corps of Engineers did not administer these public works there would be no such reserve; the expansion to a war basis would be more difficult, and at the same time the country would be obliged to pay much higher salaries to civilians charged with equal responsibilities.

Educational Value of River and Harbor Work

A further most important consideration lies in the practice that this work of civil construction affords to officers of the Corps of Engineers. In common with all other forces, the military engineers must be schooled for their duties in war. The infantry, the artillery, the cavalry can all be trained in peace to a very appreciable degree to fit them for their military work. By means of target practice they are taught to shoot. In the absence of the actualties of war, it is possible to assume certain conditions and through the study of maps and the solution of map problems based on those conditions, officers and men receive instruction for their guidance in war. Through maneuvers, terrain and battle exercises on a suitable topographic field it is possible to gain a measure of training in the movements of war without the heart-breaking costs of tuition exacted by the sterner master—war itself. The circumstances of daily life with its incidence of disease and its recurrence of accidents, affords the military medical man most helpful experience.

For the military engineer the case is quite otherwise. It must be conceded that the mere study of text-books and the reading of engineer literature will not make an engineer. The solution of strain diagrams and mathematical computations involved in design, though valuable, are not sufficient to fit him to execute construction work of the variety and magnitude required in modern war. For such work actual practice is an absolute necessity. Without it an engineer may become a learned man but he will be no more competent to perform his duties than would a surgeon who has studied but has never performed an operation, or a prosecuting attorney graduated from a law school who has never appeared in court.

The practice of engineering involves the use of large quantities of material and the employment of great numbers of laborers. This nation, rich as it is, can not afford to expend public money for material or labor for the mere purpose of training its military engineers. Their work must at all times serve some direct utilitarian purpose. Special measures are therefore necessary for this training, though fortunately such measures need entail no great extra costs. The industrial life of the country provides the means, and all that is necessary is to recognize their existence and to so organize the military engineering service as to take advantage of them. This training can be obtained in time of peace through the employment of the Corps of Engineers on public works, that is on river and harbor improvements, construction of public buildings, the construction of various kinds required for the army itself and on other governmental construction affording practice similar to that required in war.

In considering the need for civil practice, a further desideratum may be referred to. During and since the war there has been much discussion of the defects of the so-called military frame of mind, and the failure of the average regular army officer to understand the psychology of the citizen soldier. The civil works upon which engineer officers are engaged bring them in contact with the professional engineers and contractors in civil life upon whom great dependence must be placed in time of war. It enables the engineer officer to grasp the civilian viewpoint and to deal on terms of mutual understanding and sympathy with those, who by reason of their own experience and habits of thought, must look at things from this view-point. In his intercourse with civilians, in or out of the employment of the United States, the engineer officer must so comport himself as to inspire respect for his judgment, his sense of justice, and his integrity of character.

It is believed that the training which many of our officers had received on civil work prior to our entry into the war was an asset of great value and gave them a broader outlook and a greater grasp of the problems presented, and enabled them to solve those problems with a great measure of success.

Engineer Work as Training for Military Command

Up to this point this discussion has been concerned with the employment and training of the officer of the Corps of Engineers in his capacity as an engineer or constructor. In some army circles, while it is conceded that the military engineer requires training for this specialty, it is nevertheless maintained that this class of work interferes with his development as a military commander or that it inculcates in

*During the current year 41 young officers of engineers are pursuing courses in engineering subjects at three of the leading technical institutions of the country—this in lieu of instruction in similar subjects at the Engineer School at Camp Humphreys, Va.—G. A. Y.

Digitized by Google

fact a habit of mind which prevents such development.

Now let us consider the mental qualities required in a successful commander. These are:

First: The power of analysis so that the mind may reason to a logical conclusion; that is to say, the ability to weigh facts and figures, to detect and discard the false, the improbable and non-essential, to harmonize apparently divergent elements and to appraise each at its proper value; in brief to perform quickly and accurately those mental processes necessary in arriving at what in military parlance we call "the estimate of the situation."

Second: The power of synthetical decision, the ability to decide rapidly and unerringly upon measures, which, though not necessarily the best, shall nevertheless be adequate to meet the situation as it has been determined to exist, with a ready resourcefulness in devising ways and means to that end; the power to resist the temptation to temporize and delay while searching for the ideally perfect course.

Third: Steadfastness of purpose, confidence in one's own judgment, and the determination to abide by decisions previously made; the ability to pursue a course which once adopted, though not ideal, is yet sufficient to the purpose in view; the tenacity, the self-reliance, and the will "to fight it out along these lines if it takes all summer."

Fourth: Leadership involving initiative and readiness to accept responsibility; the faculty of judging men, their capacity and limitations; the ability to select assistants, the power to utilize all available resources and to operate them with the highest possible degree of efficiency.

These qualities are in constant daily exercise by the engineer officer engaged on civil work *where the full responsibility for such work is placed upon his shoulders,* and this to a degree seldom possible to an officer of the line in the ordinary discharge of garrison duties. In the conduct of his work the individual engineer must study cause and effect; must devise plans to meet the end required; must organize his force, alloting to each man his quota of responsibility; must see that this force is effective, and to this end must enforce discipline and an observance of sanitary measure; and this with men drawn from all ranks of society and without a military organization and without the aids of military law. He must purchase proper materials and in the most economical manner and must see to their economical use. He must learn to discriminate between the cheapness of first cost and economy in the results. Finally, he must be prepared to meet any emergency which may arise due to storm, flood, fire or accident, promptly, effectively and economically. The changing conditions cause a struggle frequently suggestive of a human enemy and afford "the special advantage given to the mind by the habit of coming to decisions in the presence of a real adversary and especially by resisting such emotion as naturally follows a blow." (Marshal Foch.)

An engineer officer of the rank of captain must at times organize from nothing a force of one thousand men of all grades of skilled and unskilled labor, install them in semi-permanent camps distant from commercial centers, supply them, care for their health, keep them disciplined and effectively at work. He must devise, supply and operate an extensive plant, comprising all classes of shop and field engineering, machinery installed on shore or on boats, with the complement of tugs, houseboats and other equipment.

On the other hand a captain in the ordinary military routine is afforded relatively small scope for the exercise and development of his powers of command. He has above him a battalion commander, who is over-topped in turn by a colonel and so on up through the grades of military command to the division commander or even higher.

Lacking the means of training afforded by active campaign, an attempt is made in peace time to simulate the school of war experience by map problems, terrain exercises, and maneuvers; but these, excellent as they are, lack one vital element as an educational force. The student never knows beyond a reasonable doubt that he has a correct answer to his problem. His mistakes are not materialized and they do not "come home" as in active campaign.

The engineer officer engaged on civil work, on the other hand, speedily receives a demonstration of his errors. If his "estimate of the situation" is faulty, if his plans and decisions are not logical, if he lacks tenacity of purpose, if his leadership is not efficient, if his organization is not sound—he soon rears a visible monument to his shortcomings. If in building a lock and dam he fails to meet an emergency due to storm or flood, much of his work may be swept away; if the dam should slip due to his failure to correctly appraise foundation conditions, he has at once a memorial to his discredit in the way of loss and avoidable high costs. If a dredge fails to achieve its proper output he has again in his accounts an ocular demonstration of his errors. The engineer officer on civil work deals at all times with hard cold facts which will not be denied and his actions must square with these facts day in and day out. As in actual war, the umpire is inexorable and his verdict can not be waived aside and glossed over by a glib explanation that the circumstances were not sufficiently set forth in the statement of the problem.

There is nothing in the practice of engineering as such which militates against the development of the engineer as the commander of a tactical unit, be it a battalion or an army. On the contrary most if not all of the mental qualities which make a good military engineer are necessary also to his success as a military leader.

I do not contend that all military engineers will necessarily prove to be good commanders of large military forces; there have been some notable failures and these failures have betrayed some army writers—reasoning from a few exceptional cases only—into the deduction that failure was due to their engineering training and experience. It might be said with equal propriety that they failed in spite of such training, or we should be equally justified in assuming that the failures on the part of those infantry or cavalry officers who have attained general rank were due to their infantry and cavalry experience.

In the absence of comparative statistics I venture the statement that the percentage of failures as commanders by former engineer officers is lower than that of either the infantry or cavalry. It may not be amiss to mention the fact that Robert E. Lee and George Gordon Meade who faced each other at Gettysburg had both been officers of engineers and had distinguished themselves in that capacity. Did one fail because of that fact? If so, why did the other win? Lord Kitchener, of England, and Marshal Joffre, of France, are more recent examples of engineers endowed with qualities of command to a superlative degree. Other examples might be cited, but to what purpose? The truth is that military failure or military success is dependent upon a large number of complex factors and their particular combination at any given moment, and that while we may train ourselves and develop certain qualities which are indispensable to success there will still be circumstances, combinations and causes beyond our power to foresee and much less to control, and for this reason the most skillful

Digitized by Google

commander has never been beyond the danger of defeat. How else could wars be won?

One Element Lacking

Excellent as this river and harbor work is, it unfortunately does not cover the whole field of training necessary to the education of the military man. There is at least one phase, in addition to the four above discussed, which is indispensable to the development of the military commander and in which his work as a river and harbor engineer affords no experience. I now speak of the knowledge of strategy and tactics, of the handling of troops, their care, training and management as such, and experience in the routine duties of an officer. In other words, this river and harbor work fails utterly to teach the technique of the art of war. The fact, however, that river and harbor work does not afford instruction in this one class of military duties, important as they are, is no conclusive argument for the discontinuance of river and harbor work as a function of the Corps of Engineers. For if this deficiency is to be accepted as final then the detail of line officers to the staff bureaus or to desk duty of various kinds away from troops would bar their being considered for high command. There is, to be sure, a well recognized objection to the detail of line officers to staff duty for indefinite periods. Legislation requires them to exercise actual command of troops for a reasonable percentage of their time, and though this requirement is principally to maintain touch between the staff departments and the line, it is essential also in the interests of the officers themselves to maintain a just balance in their training and experience. On the other hand duty in command of troops to the exclusion of all other duty is also recognized as being too restrictive in its effect.

It is my contention that the principle which is now applied to officers of the combatant arms should apply also to engineer officers, and that they should all serve with engineer troops and with other troops for such periods and at such intervals as will serve to keep them in touch with military matters and make them proficient in the tactical handling of troop organizations suitable to their rank and to a grade at least one step in advance of their actual rank. In view of the small number of engineer troops in our peace time service, there will be some difficulty in accommodating all the higher officers with suitable frequency, but under the principles advocated for the adoption of a single promotion list, many of these officers could get the necessary training by service with other troops. This plan would be desirable for officers of all arms, but would be particularly appropriate for engineers who constitute an auxiliary service not intended for independent action and whose purpose it is to assist other arms. These officers of engineers should attend the general service schools and should be at all times "up" on all the military phases of their profession.*

Notwithstanding this one deficiency, as a post-graduate course in how to think and how to act in emergencies, there is no comparison between the results obtained through reading and study, no matter how conscientiously carried on, and the real school of experience given our engineer officers by the regular performance of their duties as district engineers on river and harbor work. The civil construction devolving upon the officers of the Corps of Engineers constitutes in fact a most powerful agency for their training in preparation for the emergencies which must fall to them in war. It should be retained for that purpose as well as to provide the reserve of military engineers necessary to the nation's preparedness for defense.

To fit their graduates for the practice of engineering the necessity for well-balanced courses is recognized by the leading technical educational institutions. So, to enable them to cope with the varied emergencies of war, officers of the Corps of Engineers should not spend their entire lives in charge of a special class of public works. They should be given experience in a variety of construction work and should also serve at suitable intervals with troops in positions of actual command appropriate to their grades. In the last analysis, the Corps of Engineers can only justify its existence as a component part of the military establishment by an adherence to its primary function as a corps of military engineers, and the officers of the Corps must at all times be prepared to take up their duties as military men. Nevertheless, a too narrow schooling in either military or civil engineering lines should be avoided. In the interests of national defense a thorough understanding of the role of the engineer in war and the necessity for affording him both civil and military experience must be brought home to those within the army and those without, who now seek to restrict the activities of the Corps of Engineers solely to duty with the very small force of engineer troops which the country can afford to maintain in time of peace.

*The Army Reorganization Act of June 4, 1920, included the Corps of Engineers in the combatant arms or the line of the army. This act also directs that no officer shall be detailed to or remain a member of the General Staff unless he has served for two of the next preceding six years in actual command of troops. It further directs that every officer below the grade of Brigadier General shall perform duty with troops for at least one year in every period of five consecutive years. —ED.

More About Light Railways

By

J. P. Hallihan

Consulting Engineer; Major, Engineer Reserve Corps;
formerly Major, 70th Engineers, A. E. F.

[NOTE. Major Hallihan, the author of this article, has had an extensive experience in railroad location and construction. In 1899 he was assistant engineer in charge of the location and construction of the El Paso and Northeastern R. R. He left this road in 1901 to take charge of railways for the Cananea Consol. Copper Co. From 1907 to 1909 he was general manager of the company engaged in the construction of the Bolivia Ry., and subsequently he was interested in various projects in Peru and Spain. In 1913-14 he was in charge of the National Railway of Haiti, and in 1917 was Consulting Engineer and Assistant General Manager of the Brazil Railways (3,500 miles in southern Brazil). During the War Major Hallihan made an examination of and report on the damage to French railways.—ED.]

THE writer was much interested in reading in a recent issue of THE MILITARY ENGINEER the article on Light Railways by Colonel Kelly and in the discussion resulting therefrom. It may be that the subject will be better understood by reference to a few examples of extremes in both standard-gauge and light-railway construction taken from American and British practice.

The Alamogordo and Sacramento Mountain Railroad runs from Alamogordo, N. M. (elev. about 4300) to Cloudcroft (elev. 9200) and Russia, N. M. (elev. about 9000), a distance of 31 miles. It has a maximum grade of 4.5 per cent, maximum curvature, freely used, of 30 degrees, with all curves spiralled, and is laid with 60-pound rail, with tie-plates on all curves. The track is surfaced with earth from alongside. Spirals meet on the 60-foot tangent between 30-degree curves in reverse directions.

The road is operated with direct-connected Baldwin locomotives, 2-6-0, weighing about 100 tons, with a driving wheel base of 13 feet. The traffic is principally logs brought down from the mountains to a saw mill at Alamogordo, though considerable passenger traffic has developed to summer resorts.

The logging cars are about 24 feet long, and passenger cars exceeding 50 feet in length are not used. This road connects with logging roads of standard gauge having 40-degree maximum curves, grades up to 8 per cent, 40-pound rail, and operating 100-ton Shay geared locomotives at a speed of 10 miles per hour.

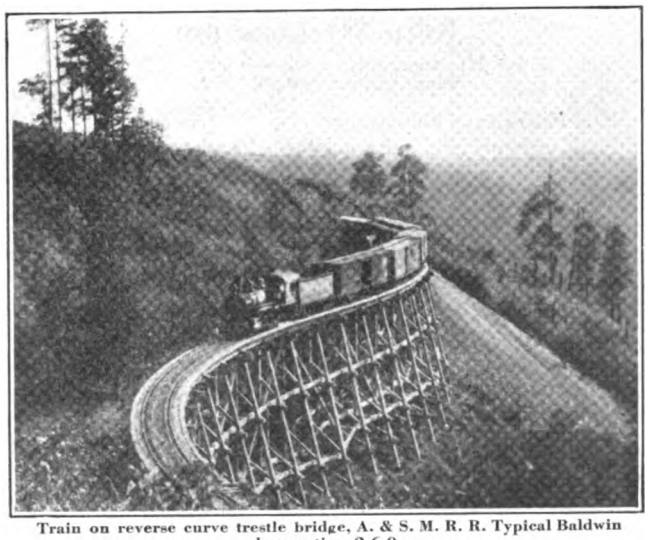
The primary reason for adoption of standard gauge was to secure the greatest possible stability for the logging equipment. The writer's observation of operation covers the first five years. There were occasional accidents on the logging roads, principally due to careless handling, in several of which was demonstrated the surprising ability of a geared engine to stay on the track and defy the law of acceleration of velocity in falling bodies. On the A. & S. M. proper, accidents were few and unimportant. For a time there were frequent derailments due to shifting of logs in transit. With greater expertness and care in loading and binding these became infrequent. Outer rail elevation was finally limited to 3 inches and gauge was widened 1 inch over 30-degree curves, which helped matters considerably.

The Antofagasta & Bolivia R. R. runs from Oruro, Bolivia, to Antofagasta, Chile, approximately 900 kilometers (550 miles). It is of 75-cm. gauge, with rail of about 20 pounds on wooden ties. A third rail, meter gauge, has been laid from Oruro to Uyuni, about 260 kilometers, permitting joint operation with Bolivia railways. So far as the writer knows, it is the longest mileage of 75-cm. gauge in the world.

The operation of this road, from both a physical and financial standpoint has been very successful. It offers a rather good example of sound judgment in the adaptation of the means to the end. Circumstances, increasing business and the overshadowing importance of its meter gauge connections will no doubt shortly cause its conversion to meter gauge, but by reason of its low capital cost, it is probably now able to write off its original investment.

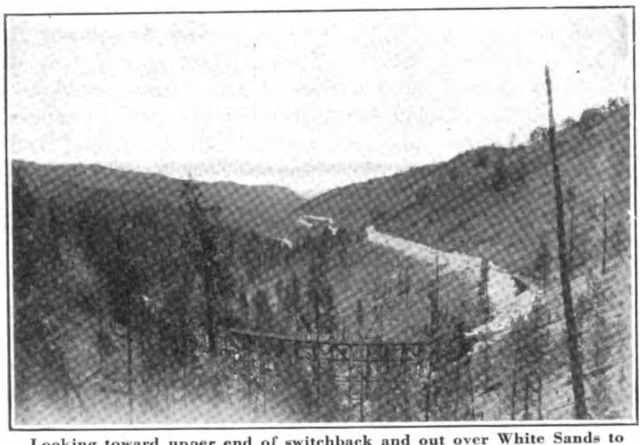
The 75-cm. gauge is commonly used in the mining regions of Mexico, one of the best examples being the road running from the City of Chihuahua to the Santa Eulalia mines, about 12 miles. The common practice is 20-pound rail laid on wood ties, following the characteristics of the 18-inch gauge mine tracks. Fabricated track of either gauge is unusual, and in fact, undesirable for mining purposes.

Fabricated tracks in 5 m. sections with rails of 8 to 10 kilograms, riveted to pressed steel ties, usually called from its inventor, Decauville track, has found its highest development in France and Belgium for industrial uses, and to a considerable extent for the 75-cm. gauge on the secondary railways. In this country, for industrial use and for contractors' use, both on domestic and foreign work, the 60-cm. gauge has found most favor. Its use has greatly increased during the past two years by reason of the increased activity in highway construction throughout the United States.



The suggestion of Colonel Kelly to abandon the use of light railway of 60 cm. or 75 cm. gauge for military purposes in favor of a light railway, standard gauge, does not appear entirely feasible, even if we could ourselves select the terrain.

It is, nevertheless, a fact that it is common practice on railroad construction to run material trains at the front over several miles of open track, not only unsurfaced but frequently half-spiked. Naturally these trains proceed at a low speed—about 6 miles per hour. Also, until within a very few years, a diligent search would have revealed a good many miles of 45-pound rail on the main line of one of our foremost western railroads. The writer has operated, with safety, heavy consolidation engines on 40-pound rail, both here and abroad.



We have to consider, however, not only physical possibilities, but time, weight and cost of material employed, power and space, or equipment used in transporting it to the place of use, and rapidity of getting the railway in operation. All of these factors are against the employment of a standard gauge road using even 40-pound rail and 60,000-pound capacity cars, beyond the point of safety from enemies fire.

Considerations of location also have a bearing on the subject. The standard gauge line picks its own location with reference to further advance and conditions of operation. The location of the light railway is determined by

Looking toward upper end of switchback and out over White Sands to San Andreas Mountains

the strategic position of the artillery it serves, which is its real *raison d'etre*.

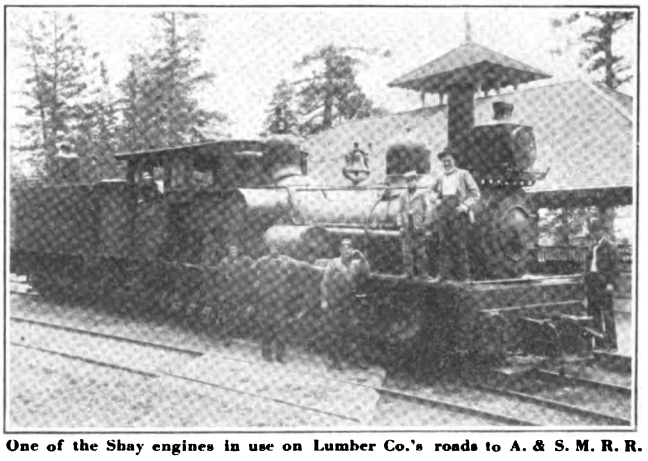
When it comes to retiring equipment in face of an enemy drive, it would seem that a light third rail laid on the standard gauge for 10 or 15 miles back (a very short job if prepared for) would offer sufficiently effective insurance.

Rehandling is to us in this country a good deal of a bugbear. We acquired a further distaste for it while waiting for cranes to arrive in France, or rather to assemble themselves from the various ports to which parts were consigned. Yet our export business would be greatly benefited if we were to make a serious study of rehandling. As a military duty we should be able, under the worst circumstances, to handle material easily, quickly and systematically and keep track of it from start to destination.

Considering that in war it is essential to dispense with every pound of weight beyond that necessary to serve the purpose, a 60-pound rail would seem to be a reasonable weight for standard gauge lines. For light railways, 60 cm. track in 5 m. sections of 20-pound rail with 10 ties per section might be considered a minimum requirement with 25-pound rail as a maximum.

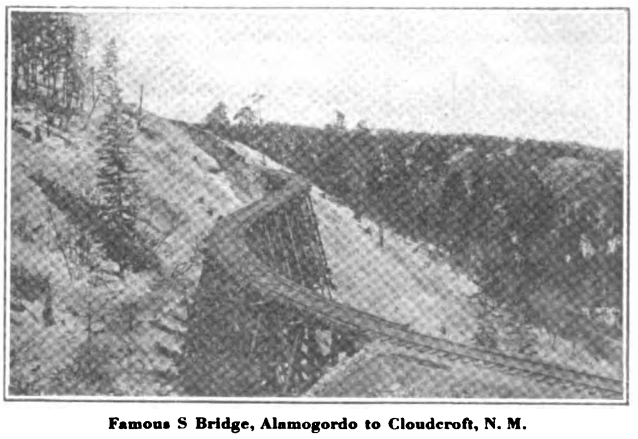
The adoption of 75-cm. gauge as a standard in face of its diminishing use on civilian work would be a tactical error, and it is doubtful whether the margin of increased stability offered would balance in value the increase in space required in both marine and land transportation.

Hazen L. Hoyt, Jr.,



Formerly Captain, 21st Engineers (Light Railway), A. E. F.

I have read with great interest the article by Colonel Kelly entitled "Is the Use of Narrow Gauge Railways Profitable in War?" that appeared in the September-October issue of THE MILITARY ENGINEER and as a sequel to this would it not be well to discuss the question of Road Transportation?



Summing up the discussions on Colonel Kelly's article the writers seem to be of the opinion that the narrow gauge railways served their purpose in France just so long as the line remained stationary, but utterly failed as soon as the line started to advance.

My own observations while serving with the 21st Regiment of Engineers, Light Railway, during the St. Mihiel and Meuse-Argonne Drives, bore out these conclusions, and I am convinced that no change in the design of motive power and cars or the concentration of men and material before hand, can make it possible for the railroads to keep up with even a moderately rapid advance. The narrow gauge railroads may have their place in future wars but so will road transportation, especially gasoline driven vehicles.

An army in the field will probably never be able to dispense with horse-drawn transportation, but gasoline-driven vehicles will take its place more and more as time goes on. At the same time I believe that every one who has had any experience with motor vehicle operations at the front will agree with me when I say that the motor equipment of the A. E. F. left much to be desired. It is only fair to say

One of the Shay engines in use on Lumber Co.'s roads to A. & S. M. R. R.

Famous S Bridge, Alamogordo to Cloudcroft, N. M.

Digitized by Google

that the fault did not lie with the Motor Transportation Corps, but was due to the fact that for the first time in the history of the world, motor equipment was used on a scale hitherto undreamed of and under conditions for which the vehicles had never been designed. It speaks well for the automotive engineer that the performance of this equipment was as good as it was.

My experience as M. T. O. of the 21st Regiment of Engineers, Light Railway, during the St. Mihiel and Argonne drives led me to the belief that the motor equipment of a field army should properly be divided into three general classes.

1. Two-wheel drive trucks operating from the broad gauge railheads to the advance dumps. These dumps to be situated as far forward as good road conditions will permit.

2. Four-wheel drive trucks operating from the advance dumps to as far as the road conditions allow, and

3. Caterpillar treaded trucks operating in the extreme forward areas delivering ammunition, etc., to dumps situated off the roads or other places where the condition of the ground will not permit of the operation of wheeled vehicles, and for following up the advance ahead of the road troops.

This division of motor equipment is, in my opinion, advisable as it would require a special type of vehicle of both the four-wheel drive and caterpillar design, for which there is a very limited demand in civilian work and would have to be specially designed and built for the use of the army. It would, of course, be possible to use these types exclusively in the forward areas, but the number required for even a moderate-sized army would be so large that it would be nearly impossible to secure the necessary appropriation for their construction. If, however, these types were used for only the final hauls while standard commercial makes were used for the long hauls in the rear areas the number of special trucks required would be reduced to a minimum.

The question of roads alone is rather a large subject and one which has received considerable thought, but in this connection I might suggest a broadening of the road to include a shoulder from 3 to 4 feet wide outside a line of white-washed posts set at intervals along the entire road to guide the drivers at night, and also as a warning to a driver who gets off the road, as posts of this sort, if not too firmly set in the ground, will not damage the truck in colliding with them, while the 3 to 4-foot shoulder outside these posts will allow the driver to stop his truck before it becomes hopelessly ditched. If thought advisable this shoulder could be widened to include a narrow gauge track, or even roadway for foot troops, while the center of the road would be left free for vehicle traffic.

John Wickersham

Formerly Lieutenant Colonel, Engineers; Deputy Engineer Supply Officer, G. H. Q., A. E. F.

The writer is of the opinion that the function of the light railway in war is to relieve the highway as much as possible (in many cases to replace the highway), and that the narrow gauge railway is at no point in competition with the broad gauge railway. He does not believe this point has been made sufficiently clear in Colonel Kelly's paper or in the discussion.

The writer, during the fall of 1917, visited the Second Army, B. E. F., to study engineer supply and equipment for combat troops. Much of the area occupied by this Army was low ground and in consequence, road construction and maintenance was difficult and expensive. The writer's observation was that 60 per cent of the traffic on the roads consisted of engineer material used on road construction (*i. e.*, the roads were very largely worn out by the traffic necessary for their making). This matter was discussed in the Second Army, B. E. F., with the Division Engineer of a British Division, the Corps Engineer of a British Corps, the Chief Engineer of the British Second Army, and the Chief Engineer B. E. F. These officers agreed that the ideal arrangement for the Second Army area would be a single highway in each divisional area for tactical purposes, and a loop of narrow gauge railway for the normal traffic of men and supplies. The highway was to be used only for emergencies.

The writer's experience, civil and military, has not been such as to make him competent to discuss the design or layout of narrow gauge tracks and equipment, and he gladly leaves this discussion to officers more capable of handling this phase of the question. He is of the opinion, however, that the use of narrow gauge railway should not be abandoned in future war plans of the United States Army; and that in these plans the narrow gauge railway should be considered as an alternative to highway construction. If the single narrow gauge track is considered the equivalent of the one-way road, and the double track the equivalent of a two-way road, the military engineer will frequently find he can build and maintain a narrow gauge railway line with greater speed and less expenditure of labor and material than the equivalent highway construction. When this is the case, the narrow gauge railway should be used. The handling of supplies and railhead facilities will be equal for light railway or motor traffic. More salvage is possible from a light railway line than from an abandoned highway.

The enemy used narrow gauge railways to better advantage than we or any of our allies. I would suggest a study of their use by the enemy in his offensive operations in the spring and early summer of 1918. It will prove most instructive.

World's Rainfall—The total annual rainfall of the world amounts to 29,347 cubic miles, quite a shower. Of this only 6,524 cubic miles finds its way through rivers to the sea, carrying with it, however, 2,735,000,000 tons of solid matter in suspension.—*Journal Frank Inst.*

PERSONALS

The retirement of Col. R. R. RAYMOND, Corps of Engineers, took effect December 21, 1920.

Col. WILLIAM B. LADUE, Corps of Engineers, has been relieved from his duties in Philadelphia, Pa., and assigned to command the 1st Engineers, Camp Dix, N. J.

Col. C. W. OTWELL, Chemical Warfare Service, has been relieved from his duties at Wheeling, W. Va., and assigned to duty at Lakehurst Proving Ground, N. J.

Lt. Col. A. E. WALDRON, Corps of Engineers, has been relieved from duty with the 8th Engineers, Fort Bliss, Tex., and assigned to duty with the 5th Engineers, Camp Funston, Tex.

Lt. Col. ELLIOTT J. DENT, Corps of Engineers, has been relieved from his duties at New Orleans, La., and assigned to duty in the Philippine Islands.

Lt. Cols. F. W. ALBERT, A. F. ALLEN, GLENN S. SMITH, and JAS. E. CASSIDY, Engineers, have been honorably discharged from the service of the Government, their services being no longer required.

Maj. THOMAS M. ROBINS, Corps of Engineers, has been relieved from his duties at Providence, R. I., and assigned to duty in the office of the Chief of Engineers.

Maj. ERNEST GRAVES, Corps of Engineers, has been granted a leave of absence for four months.

Maj. WILLIAM A. JOHNSON, Corps of Engineers, has been relieved from his duties at Montgomery, Ala., and ordered to Honolulu, Hawaii.

Maj. JAMES J. LOVING, Corps of Engineers, has been relieved from his duties at Camp Dix, N. J., and assigned to duty at Montgomery, Ala.

Maj. JAS. G. STEESE, Corps of Engineers, has been ordered to report to the Army Retiring Board, San Francisco, Cal., upon his arrival from Alaska, and then to report to Washington, D. C.

Maj. VIRGIL L. PETERSON, Corps of Engineers, has been relieved from his duties at Boston, Mass., and taken station at Providence, R. I.

Maj. FRANCES C. HARRINGTON, Corps of Engineers, has been relieved from his duties at Camp Humphreys, Va., and ordered to Baltimore, Md., for duty.

Maj. CHAS. J. TAYLOR, Corps of Engineers, has been relieved from duties at Fort Monroe, Va., and assigned to duty at Norfolk, Va.

Maj. CRESWELL GARLINGTON, Corps of Engineers, has been assigned to temporary duty in the office of the Chief of Engineers.

Maj. RICHARD U. NICHOLAS, Corps of Engineers, has been relieved from duty at Wheeling, W. Va., and reported to Fort Benjamin Harrison, Ind., for duty in the Fifth Corps Area.

Maj. ARTHUR P. VON DEESTON, Corps of Engineers, has been relieved from duty in Portland, Ore., and ordered to Galveston, Tex.

Maj. WALTER F. BEYER, Chemical Warfare Service, has been relieved from duty in the U. S. Engineer Office, Wilmington, Del., and ordered to duty at Fort Dupont, Del.

Maj. MALCOLM ELLIOTT, Corps of Engineers, has been relieved from his duties at Florence, Ala., and assigned to duty at Wheeling, W. Va.

Maj. WALLACE W. KIRBY, Corps of Engineers, has assumed charge of the Engineer Reproduction Plant, Washington Barracks, D. C.

Maj. WILLIAM C. LEMON, Corps of Engineers, has been relieved from his duties in New York City, and assigned to duty at Jacksonville, Fla.

Maj. LEON E. LYON, Corps of Engineers, has been relieved from his duties at Norfolk, Va., and assigned to duty at Philadelphia, Pa.

Maj. PAUL REISINGER, Corps of Engineers, has been relieved from his duties with the 2d Engineers, Camp Travis, Tex., and assigned to duty with the 8th Engineers, mounted, Fort Bliss, Tex.

Maj. ELIHU H. ROPES, Corps of Engineers, has been assigned to duty with the 2d Engineers at Camp Travis, Tex.

Majs. CHAS. L. DASHER, WILLIAM J. SHEA, Engineers, and FOSTER VEITENHEIMER, Signal Corps, have been honorably discharged from the service of the Government.

Capt. ALEXANDER B. ACKERMAN, Lieut. GORDON C. DAY, and Lieut. C. W. BALL, Corps of Engineers, have been assigned to the 11th Engineers, Panama.

Capt. LEROY W. CUMMINGS, Corps of Engineers, has been assigned to the 12th Engineers, Camp Grant, Ill.

Capt. EDWARD H. DIGNOWITY, Corps of Engineers, has been assigned to the 2d Engineers, Camp Travis, Tex.

Capt. GEORGE W. GILLETTE, Corps of Engineers, has been relieved from his duties at Wilmington, N. C., and assigned to duty with the 7th Engineers, Camp Jackson, S. C.

Capt. HAROLD S. GILLETTE, Corps of Engineers, has been relieved from his duties at Fort Sill, Okla., and assigned to duty with the 2d Engineers, Camp Travis, Tex.

Capt. EDWARD D. HILL, Engineer, has been honorably discharged from the service of the United States, his services being no longer required.

Capt. KENNETH S. JONES, Corps of Engineers, has been relieved from his duties at Norfolk, Va., and assigned to duty at Florence, Ala.

Capt. WILLIAM V. HILL, Corps of Engineers, has been assigned to duty with the 5th Engineers, Camp Humphreys, Va.

Capt. JOHN E. LANGLEY, Corps of Engineers, has been assigned to duty with the 2d Engineers, Camp Travis, Tex.

Capt. THOMAS H. MESSER, Corps of Engineers, has been relieved from his duties in the office of the Chief of Engineers and assigned to duty with troops in the Hawaiian Department.

Capt. EVERETT D. MURRAY, Corps of Engineers, has been ordered to duty with the 2d Engineers, Camp Travis, Tex.

Capt. HENRY B. POST, Corps of Engineers, has been relieved from his duties at San Francisco, Cal., and ordered to duty with the 2d Engineers, Camp Travis, Tex.

Capts. ROBERT A. RADFORD and HARRY O. TUNIS, Corps of Engineers, have been relieved from their duties in Washington, D. C., and assigned to duty with troops in Germany.

Capt. HARRIS D. W. RILEY, Corps of Engineers, has been assigned to duty with troops at Canal Zone.

Capt. RICHARD L. SMITH, Corps of Engineers, has been ordered to duty with the 2d Engineers, Camp Travis, Tex.

Capt. CHAS. H. SWICK, Corps of Engineers, has been relieved from his duties at Camp Upton, N. Y., and assigned to duty at Florence, Ala.

Capt. ELLIOTT VANDEVANTER, Corps of Engineers, has been assigned to duty at the Eighth Corps Area, Fort Sam Houston, Tex.

Capt. HERBERT C. WHITEHURST, Corps of Engineers, has been relieved from his duties at Camp Lee, Va., and assigned to the Engineer Depot, Army Supply Base, Norfolk, Va.

Capts. WILLIAM F. BARCK, EVERETT S. BEALL, Jr., GUY B. BYAM, ROBERT COE, CHAS. EVANS, ROBERT M. FOX, JOHN H. JONES, EARL R. LEWIS, and ARTHUR G. SPENCER have been honorably discharged from the service of the United States, their services being no longer required.

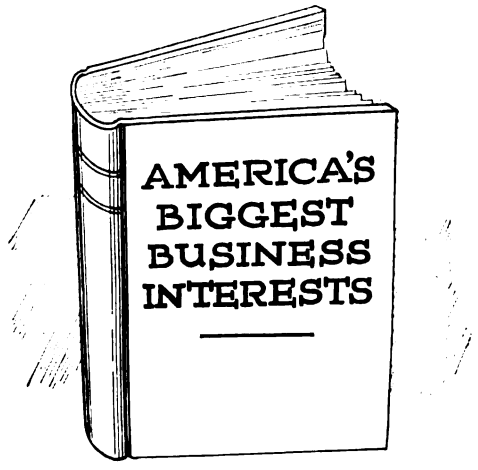
1st Lt. ROBERT F. GILL, Corps of Engineers, has been assigned to duty at Camp Humphreys, Va.

Lieut. JOHN N. HARMAN, Lieut. FREDERICK W. DECK, and Lieut. CHESTER C. HOUGH, Corps of Engineers, have been assigned to duty with the American Forces in Germany.

1st Lts. FREDERICK A. PLATTE and GEORGE S. WITTERS, Corps of Engineers, have resigned their commissions as officers of the Army.

1st Lt. WALTER D. LUPLOW, Corps of Engineers, has been relieved from his duties in Washington, D. C., and assigned to duty with the American Forces in Germany, Coblenz, Germany.

Lt. EDWARD S. PEGRAM, Corps of Engineers, has been relieved from his duties at Camp Jackson, S. C., and assigned to duty at Coblenz, Germany.



Lieut. EDWARD H. RAYMOND, Corps of Engineers, has been assigned to duty in the Panama Canal Department.

1st Lts. FRENCH W. LAKE, EUGENE NICHOLS, RENO F. RUNCK, and KENNETH R. WOODFORD, 2d Lts. HENRY A. HAENSELER, HUGO A. KEMMAN, and WILLIAM H. MCGRATH, Engineers, have been honorably discharged from the service of the United States.

Lieut. WILSON Y. STAMPER, Jr., Corps of Engineers, has been relieved from duty at Camp Lewis, Wash., and assigned to duty with the 2d Engineers, Camp Travis, Tex.

The List of Purchasers from War Department Sales Reads Like a Blue Book
America's Biggest Business Interests

NEARLY one hundred thousand individual orders representing sales amounting to nine hundred million dollars is the staggering total of property disposed of through War Department sales to date.

The buying power of America has responded to these sales in a big way, many manufacturers, jobbers, wholesalers, and dealers looking to them as a regular source of supply.

Manufacturers have bought, dealers have bought; the smaller interests have purchased in small lots, the larger business and industrial firms have bought heavily.

Thousands of machines purchased through this channel are in operation. Thousands of motors, generators and other electrical equipment are supplying heat, light and power in every industry. Huge quantities of chemicals have found their way to use through these sales. Thousands of tons of iron and steel from this source have been wrought into every conceivable tool and commodity. Millions of dollars worth of high grade wanted materials, supplies, etc., and equipment of every description has reached the consumer's market through regular re-sale channels.

As long as War Department stocks last, opportunities are many! As a unit of the buying power of America it is to your advantage to follow every War Department offering. Others have benefited. Why not you?

Proposals

U. S. ENGINEER OFFICE, WHEELING, W. VA.—Sealed proposals will be received here until 11 a. m. (Eastern time), January 22, 1921, and then opened, for furnishing and delivering forged steel and cast iron wheels for gates and structural steel for gate tracks for Dam No. 11, Ohio River. Information on application.

UNITED STATES ENGINEER OFFICE, BOX 72, LOUISVILLE, KY.—Sealed proposals will be received here until 2 p. m., December 15, 1920, and then opened, for furnishing and delivering gate and valve operating machinery, etc., for Lock No. 48, Ohio River. Further information on application.

PROPOSALS FOR DREDGING.—U. S. Engineer Office, 329 Customhouse Bldg., New Orleans, La.—Sealed proposals for dredging in the Intracoastal Waterway between Mermentau and Calcasieu Rivers, La., will be received here until 11 a. m., January 10, 1921. Further information on application.

PROPOSALS FOR STERN-WHEEL STEEL STEAMBOAT "LUTHER L. GRIFFITH."—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Sealed proposals will be received here until 11 a. m., January 18, 1921, and then opened, for furnishing the stern-wheel steel steamboat "Luther L. Griffith." Further information on application.

PROPOSALS FOR DREDGING.—U. S. Engineer Office, Philadelphia, Pa.—Sealed proposals will be received here until 12 noon, December 20, 1920, and then opened, for dredging in Delaware River, Phila., Harbor. Further information on application.

PROPOSALS FOR BOILERS.—Office of the Secretary, Mississippi River Commission, 1311 International Life Bldg., St. Louis, Mo.—Sealed proposals will be received here until 12 noon, January 17, 1921, for furnishing six return-flue boilers for steamboat. Further information on application.

PROPOSALS FOR LEVEE WORK.—Office of the Secretary, Mississippi River Commission, 1311 International Life Building, St. Louis, Mo.—Sealed proposals will be received here until 11 a. m., December 22, 1920, for constructing about 1,100,000 cubic yards of earthwork by the hydraulic method in the Sny Island Levee Drainage District, Ill. Further information on application.

U. S. ENGINEER OFFICE, WHEELING, W. VA.—STRUCTURAL STEEL, FORGINGS, STEEL CASTINGS, ETC.—Sealed proposals will be received here until 11 a. m. (Eastern time), January 27, 1921, and then opened, for furnishing and delivering structural steel, forgings, steel castings, etc., for trestles, aprons and horses for Dams on Kanawha River. Information on application.

U. S. ENGINEER OFFICE, P. O. BOX 72, LOUISVILLE, KY.—Sealed proposals for furnishing and delivering two steel dump scows will be received at this office until 2 p. m. (Central time), December 20, 1920, and then opened. Information on application.

PROPOSALS FOR REMOVAL OF WRECK.—U. S. Engineer Office, 329 Customhouse, New Orleans, La.—Sealed proposals will be received here until 11 a. m., November 16, 1920, and then opened, for removing wreck of sunken barge "Detroit" from South Pass, Mississippi River.

PROPOSALS FOR FURNISHING SOUTHERN YELLOW PINE LUMBER, DOORS, WINDOWS, HARDWARE, ETC.—Office, Mississippi River Commission, 1st and 2d Districts, Customhouse, Memphis, Tenn.—Sealed proposals will be received here until 11 a. m., December 22, 1920, and then opened, for furnishing and delivering Southern Yellow Pine Lumber, Doors, Windows, Hardware, etc. Further information on application.

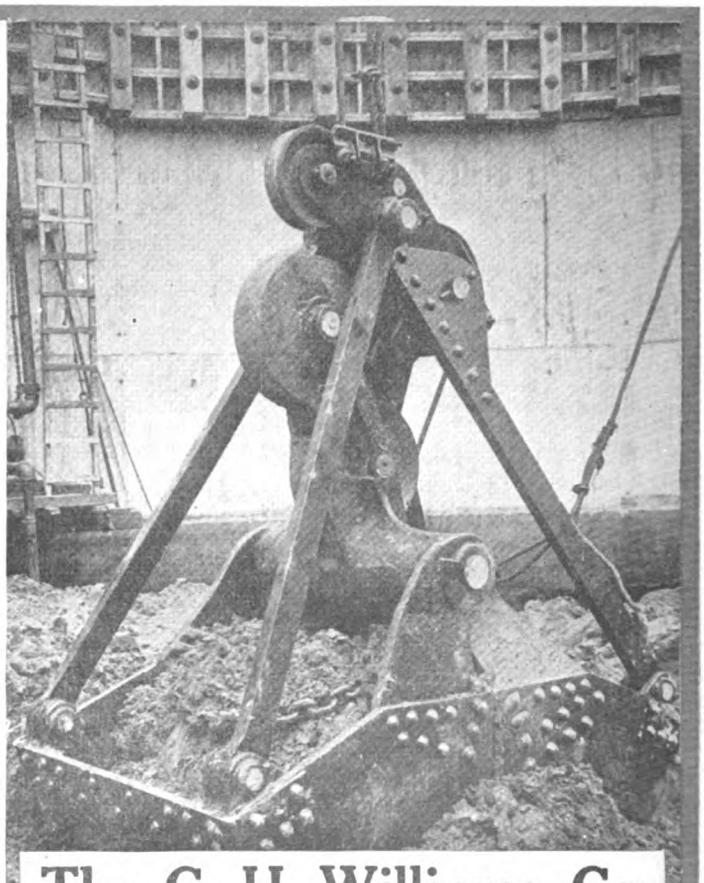
PROPOSALS FOR STEEL DUMP SCOWS.—United States Engineer Office, Philadelphia, Pa. Sealed proposals will be received here until 12 o'clock noon, December 31, 1920, and then opened, for furnishing and delivering five steel dump scows. Further information on application.

Williams Buckets

Simple, Speedy, Efficient and Easy to Operate

WILLIAMS BUCKETS are built to meet any condition. That is one reason why you will find them in use by all large steel plants and contractors in the world, by the United States and French Governments.

Note its sturdy, all-steel triangular construction—that insures rigidity and perfect alignment of all parts. Large bearings and fewest parts are other features. These with perfect lubrication reduce friction to a negligible quantity.



And remember we build them to dig—in addition to economy of operation, long life and *low cost of upkeep*.

Let us send you *full* details, including catalog.

Real Congestion of Traffic

Those who believe that rail traffic in America is unduly congested should read the following report by S. M. Vauclain, President of the Baldwin Locomotive Works, of travel conditions in Rumania:

We hear all sorts of criticisms of the services rendered by the railroads in this country. God forbid that we ever have to undergo transportation difficulties such as I underwent on my way to Bucharest. The bumpers of the cars were crowded; in some inconceivable way men locked themselves to the long buffers with their legs so intertwined that it was impossible to drop on the track. Two men would sit that way, sometimes holding their wives on their laps. The cars were fitted with ladders, and there were resting places for people, and the roof actually afforded seating capacity. After leaving Czernowitz, there were twenty-five people, men, women and children, on the roof of my car, leaving in the dead of night. They had their belongings with them. I counted seven pigs and many chickens, all carried under the owners arms, while waiting for the train to move.

The most interesting feature of it all, says Mr. Vauclain, was that the people seemed to thoroughly enjoy the transportation which they had. There was no grumbling or swearing. In fact, the competition for places was too keen to leave any time for this.

The fact of the matter is that we are far from having reached the ultimate in congestion of traffic. The following story, vouched for as a fact, shows that there is nothing new in these conditions:

During the days of '49 there were two methods of reaching the Eldorado (in the absence of railways.) One was by the "prairie schooner" across the plains, and the other by sailing vessels around "The Horn." Freight ships, which had never been intended for passenger traffic, were packed like sardine boxes, and the rated capacity of passenger vessels was usually multiplied by ten. A small sailing vessel, having an authorized capacity of fifty passengers, started out of an Atlantic port with several hundred aboard. The first week of the passage was exceedingly stormy. The skipper had his troubles, but his passengers were not amongst them. They were in no mood or condition to make any trouble. At the end of a week the weather moderated considerably. One day an inoffensive little man boldly appeared in the Captain's private cabin. "Captain," he said, "I have paid for my transportation on this ship, and you really must find me a place to sleep." "Well," replied the Captain, "Where have you been sleeping for the last week?" "Why," replied the little man, "It's this way; I have been sleeping on top of a big sick man, but he is getting better now and he won't stand for it much longer."

Analysis of Samples of Ancient Armor

The analysis and microscopical examination of about one dozen samples of ancient armor from the Metropolitan Museum of Art, New York, have been practically completed. The analysis indicates that all the samples were made from very pure wrought iron converted into steel by the old cementation process, as would be expected. The carbon determination was made on the entire cross-section as the material of all the pieces was too thin and corroded to obtain samples from different layers.

The microstructure indicates that the process used in the production of the original iron was very similar to our wrought iron process. The metal was then carbonized, probably by a supplementary process, hammered into sheets, differing in hardness (*i. e.*, in the amount of carburization), and those sheets welded together. The whole was then hammered into shape and quenched, thus producing the final hardening effect.—*U. S. Bureau of Standards.*

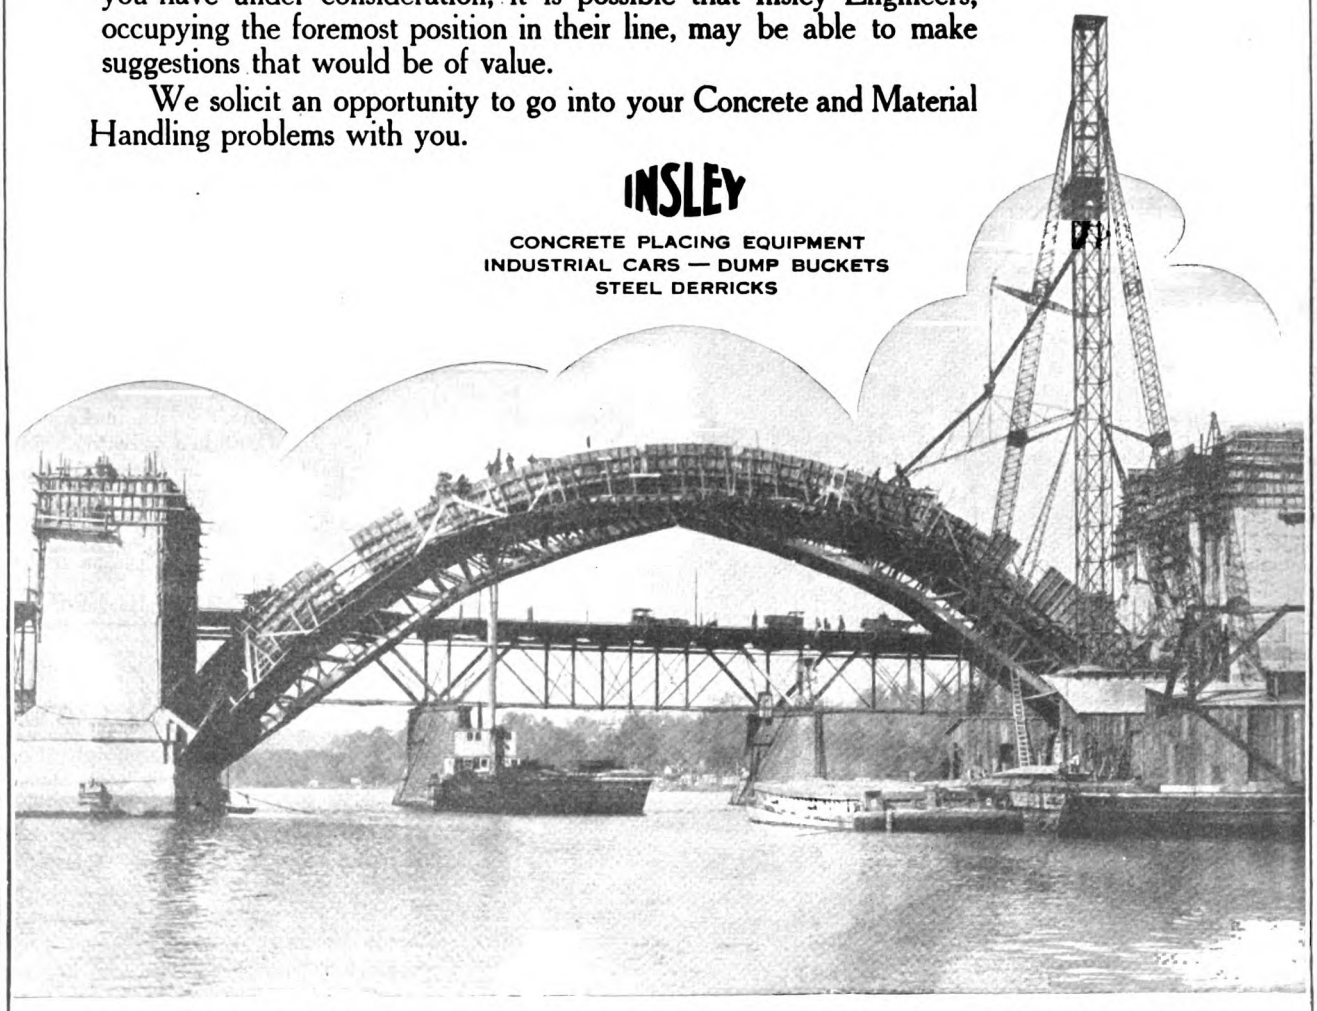
Accomplishment

WHEN the United States Engineer Officers planned the construction of a bridge across the Potomac River at Georgetown, D. C., they asked Insley Engineers for suggestions concerning concrete placing equipment that might advantageously be employed.



The photograph shows the self-supporting 140-foot Steel Tower, Quick Shift, Counterweight Chute Floating Plant design that was recommended and adopted. It is giving complete satisfaction in service and is making possible lower concrete placing costs than could be attained in any other way.

While you may not require special equipment on the work which you have under consideration, it is possible that Insley Engineers, occupying the foremost position in their line, may be able to make suggestions that would be of value.

We solicit an opportunity to go into your Concrete and Material Handling problems with you.

The Galveston Seawall Extension

By

J. W. Henderson
Assistant Engineer, U. S. Engineer Department

ON September 8, 1900, Galveston Island was visited by a severe hurricane which caused a loss of life of more than 6,000 and damaged property, etc., to the estimated value of seventeen million dollars, the water reaching a height exceeding by far any previous record at Galveston. After this it was decided to adopt protective measures to prevent a recurrence of the disaster, and on November 22, 1901, a board of engineers, consisting of Gen. H. M. Robert, Corps of Engineers, U. S. Army (retired); Alfred Noble, and H. C. Ripley, was appointed to consider and report upon the most efficient way of protecting Galveston against overflow from the sea.

Foundation of seawall, showing wood foundation and concrete sheet piles

The report of this board, dated January 25, 1902, recommended the building of a solid concrete wall, over 3 miles long, connecting with the south jetty near 8th Street; thence to 6th Street and Avenue "D;" thence across the island and down the beach as far as 39th Street; the top of this wall to be 17 feet above mean low water, or 1.3 feet higher than the highest point reached by the water in the storm of 1900, the sea face of the concrete sea wall "to be curved so that its upper portion will be vertical. This will give the wave an upward direction and prevent to a great extent its running up and over the embankment behind the wall. The wall will be founded on piles and protected from undermining by sheet piling and also riprap. It will be located back from the high water line where the ground is about 3 feet above mean low water. Its width at the bottom (1 foot above mean low water) will be 16 feet, and at the top (17 feet above mean low water) 5 feet."

The seawall, as proposed by this board of engineers, was constructed between October, 1902, and July, 1904, and as will be seen on the index map (Plate I), the eastern portion of the island, extending to the south jetty, averaging about 11,000 feet long, and containing about 1,600 acres, was left in an unprotected state, the eastern portion, containing about 600 acres, of this unprotected area being the original Fort San Jacinto Reservation.

The rivers and harbors act approved July 25, 1912, provided for a board of three engineer officers whose duty was to examine and report upon certain harbors and channels in Texas, at or near Galveston. This special board of officers consisting of Col. Edward Burr, Lieut. Col. Lansing H. Beach, and Lieut. Col. C. S. Riche, met at Houston, Tex., on January 6, 1913, and during the course of that week inspected the various portions of the harbor, holding meetings also at the United States Engineer Office at Galveston, Tex. The report of this board is given in House Document No. 1390, 62nd Congress, 3rd session.

The special board, in their report, invited attention to a matter of great concern to the safety of Galveston Harbor, which related to the easterly end of Galveston Island, and especially to the narrow neck just east of the then existing seawall of the city of Galveston and between that and Fort San Jacinto, and stated that—

> The most desirable method, one which would not only protect this narrow part of Galveston Island from being breached by a storm, but also provide suitable communications to and from Fort San Jacinto and protection for its garrison, would consist of an extension of the Galveston seawall from its angle at 6th Street and Broadway to and around the Fort San Jacinto batteries, thence following the south jetty and just inside thereof, to the intersection of said jetty with the present southern boundary of the reservation. Such a sea wall, with a suitable fill behind it, would not only afford all necessary facilities for a garrison at Fort San Jacinto and for its communications, but would render Galveston Harbor safe from obstruction by such a storm as that of 1900. It would also render impossible any flanking of the jetties by the cutting of a channel to the south of them and would permit the erection of wharves along the channel from the eastern end of the present wharves to the boundary line of Fort San Jacinto Reservation.
>
> The work described would be of benefit in part to the harbor and in part to its defenses, and its cost should be shared by the two organizations of the Government concerned. There would also be a benefit accruing to the city of Galveston and to the owners of land between Fort San Jacinto and the present protected portion of the city of Galveston, and the interests thus benefited should bear some equitable portion of the cost.
>
> So far as the protection of the harbor is concerned, it is believed that this can be effected by the extension of the Galveston seawall

Digitized by Google

from its angle at 6th Street and Broadway to a point abreast and in front of the nearest battery at Fort San Jacinto, a total distance of 10,300 feet, and its connection with that battery by a wall of heavy riprap which would so unite the end of the wall with the storm protection of the battery as to afford temporary security to the exposed end of the wall until such time as its further extension might be undertaken in the interest of affording protection to the fortifications and their garrison.

This proposed extension of the seawall for 10,300 feet is believed to be that portion of the whole seawall plan above suggested that peculiarly pertains to the protection of the harbor, to the extension of its facilities, and the prevention of its blockade by storm. The wall should be similar to that now in front of Galveston, and it should be backed by enough filling to give a width of 200 feet from the edge of the wall to the rear crest of the fill. Beyond that crest the material should be given such slope as it would naturally assume as a hydraulic deposit—probably 1 on 30. The front part of the fill next to the concrete should be protected by a sidewalk and brick paved roadway as has been done in the Government's similar extension of the seawall to and in front of Fort Crockett, and the top of the fill between this roadway and its rear crest should be protected from the blowing away of its material by suitable soil covering and vegetation.

One-cubic-yard concrete mixer with aggregate hopper on separate car, pouring superstructure forms

Rear of wall, showing concrete base

The board further stated that "any appropriation that the Government might make towards this extension of the seawall should be contingent on a satisfactory cession to the United States, free of cost, of all land east and north of a line originating at the intersection of the center line of the south jetty with the present southern boundary of the Fort San Jacinto Reservation and extending thence approximately south 16° east, to the Gulf of Mexico (this line being made parallel to the numbered streets of the city of Galveston)," the triangular area thus donated to the Government between this line and the extended seawall and the present southern boundary of Fort San Jacinto, being estimated to contain 600 acres. In addition that, 'the Government's appropriation for such extension of the seawall should be contingent upon the quieting of any claims that may be outstanding against the present Fort San Jacinto Reservation." Also that, "the Government's appropriation for such extension of the seawall should furthermore be contingent upon local interests providing for the building of that portion of the extension which lies between the angle of the present seawall at 6th Street and Broadway, and the above new boundary proposed for the Government Reservation. It is estimated that this will require the building of 3,300 feet of wall, with the fill immediately behind it, by the local interests, and 7,000 feet further by the United States."

The recommendation of the board for the seawall extension was as follows:

That, for the protection of the harbor from blockade by storms, and to permit an extension eastward of its wharf facilities, as well as for other reasons, the United States build 7,000 feet of seawall with suitable backing, at an estimated cost of $1,185,000, said work, however, not to be undertaken until the city of Galveston and other local interests first donate certain lands to the Government, quiet all claims to the present San Jacinto Reservation and provide for the construction of 3,300 feet of similar seawall extension.

The river and harbor act of July 27, 1916, contained a preliminary appropriation for this work as follows: "Galveston Channel, Texas: Continuing improvement by construction of seawall extension in accordance with the report submitted in House Document No. 1390, 62d Congress, 3rd session, subject to the conditions therein named, $200,000; Provided, That no part of the amount herein appropriated shall be expended and no contract shall be entered into under this appropriation until the county or city of Galveston and other local interests shall have donated the lands to the United States, as set forth in said Document No. 1390, and shall have quieted all claims to the present San Jacinto Reservation, nor until the said county or city of Galveston shall have obtained a right-of-way and made provision in a manner satisfactory to the Secretary of War for paying the cost of constructing at least 3,300 feet of similar seawall extension in addition to that herein appropriated for; Provided, further, That the entire work of construction shall be done under the direction of the Secretary of War, and the funds appropriated by Congress and those furnished by the county or city of Galveston shall be expended by him."

The estimate made in 1913 for the construction of the wall with fill, etc., and given in House Document No. 1390, due to increased costs of labor and materials, was inadequate for the work in 1918. The county of Galveston having stated that they could only furnish funds for the construction of their portion of the wall alone, without any fill, paving, etc., it was recommended to the Chief of Engineers under date of August 18, 1917, that, if it was considered that the county of Galveston and other local interests had complied with all the requirements of the act of July 27, 1916, appropriating the initial amount of $200,000 for construction, that the construction of the seawall with riprap protection be undertaken, leaving the sand fill behind the

Digitized by Google

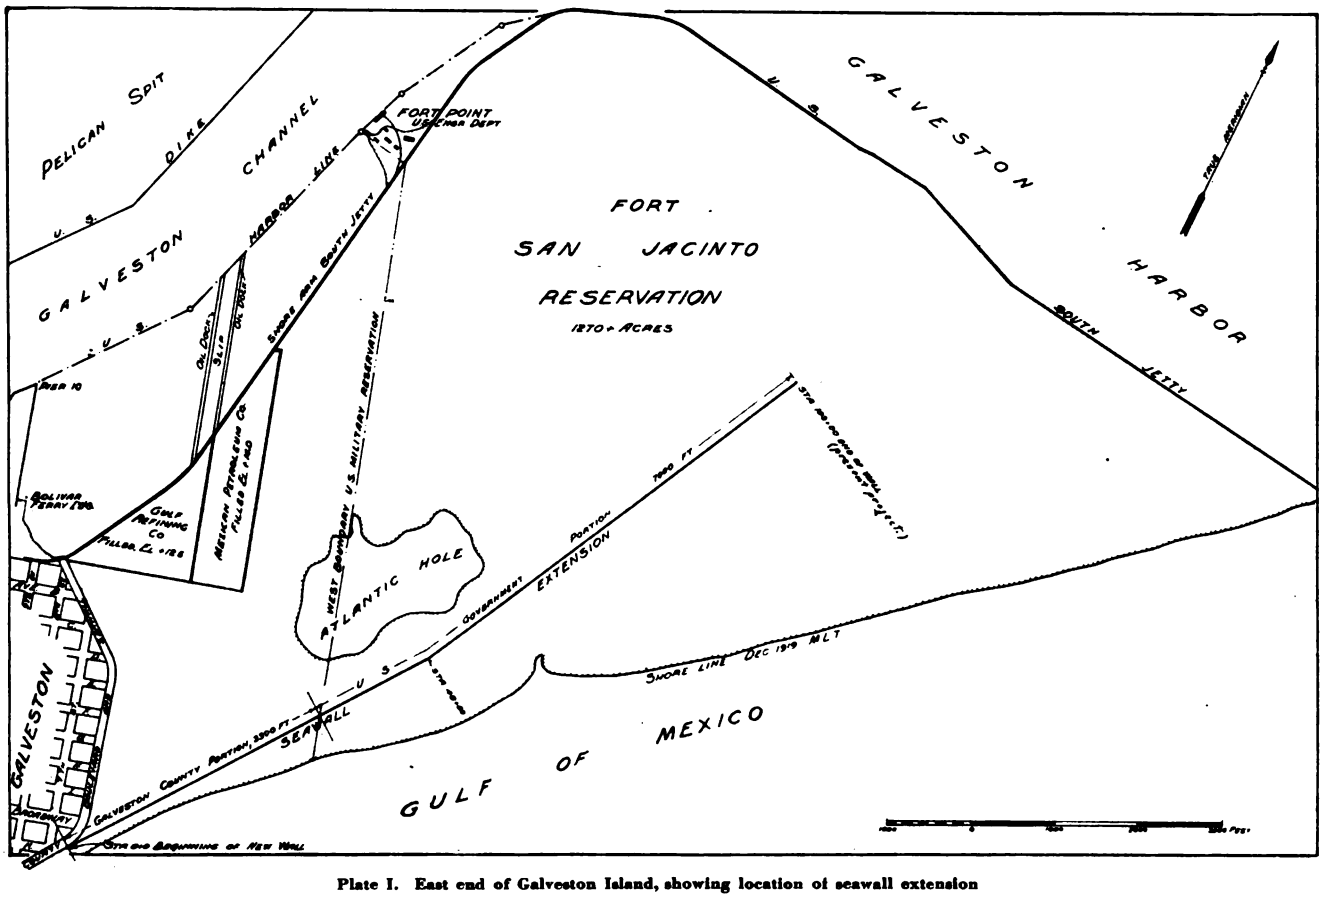

Plate I. East end of Galveston Island, showing location of seawall extension

wall, sidewalk, brick paving, etc., to be provided for at some later date. Authority was received to proceed with the actual construction of the wall, under date of October 20, 1917.

The preliminary work of procuring plant, materials, laying railroad track, etc., was immediately begun, and the first actual construction work of driving foundation piles was started on June 20, 1918.

Description of the Work

As shown on Plate II, the cross section of the seawall approved for the extension, is the same as was adopted by the original board of engineers in 1901, with the exception that the sheet piles are driven in front of all the foundation piles in the present wall, while in the old wall the sheet piles were placed behind the front row of foundation piles, and that the concrete foundation or base is built wider, with overhangs to carry the tracks for the steel traveler which handles the steel concrete forms. The wall proper has a vertical back, the top being 5 feet wide, and the base 16 feet wide, the face being a compound curve joining the top to a vertical portion extending 6 inches above the foundation. The elevation of the top is 17 feet above M. L. T., and that of the base being 1 foot above M. L. T. The wall is supported on four rows of foundation piles 4 feet apart, each round pile sustaining a dead load of 12½ tons, with a line of triple lap sheet piling under the front toe. The foundation and sheet piles are of green pine lumber, the foundation piles being 30 feet long with 9 inch diameter points, and the triple lap piles composed of three 3-inch by 12-inch planks, bolted together, 36 feet long. These triple lap, wooden piles were later changed at Station 56 and 40 to reinforced concrete sheet piles. Twisted reinforcing bars, 1½ inches square and 10 feet long, are imbedded in the concrete 6 inches from the face of the wall.

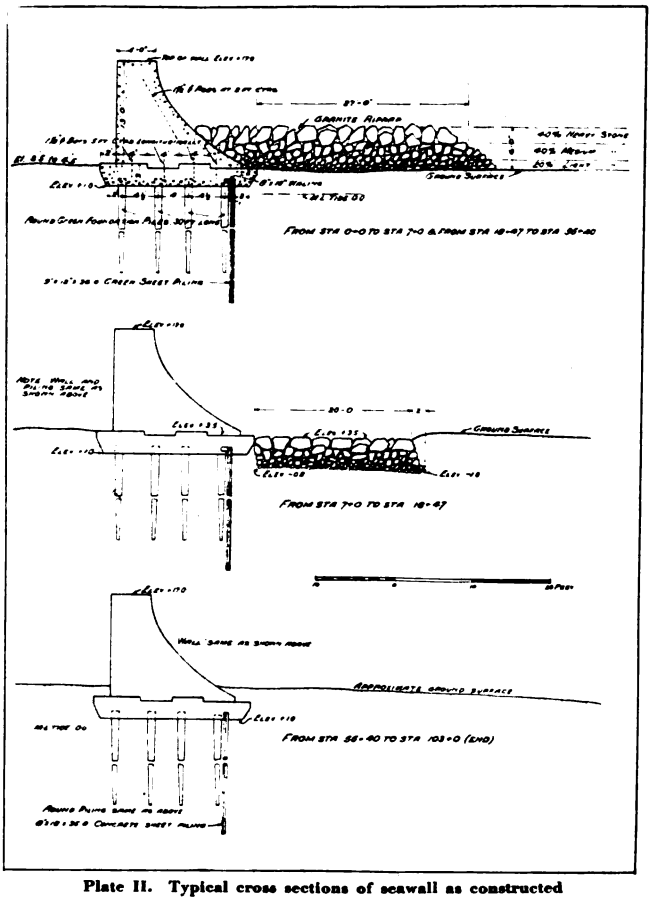

Plate II. Typical cross sections of seawall as constructed

Digitized by Google

The riprap protection in front, as originally approved, consisted of heavy riprap 6 feet thick and 27 feet wide, the stones being in the following proportions: 20 per cent of stones weighing from 15 pounds to 200 pounds placed on the bottom, then 40 per cent of stones weighing from 200 pounds to 1,000 pounds, and on top 40 per cent of stones weighing from 1,000 pounds to 5 tons, the rear protection consisting of light riprap placed against the wall in a triangular section 6 feet high and 12 feet wide.

Under date of April 19, 1919, approval was given to a change to be made in the placing of the front, heavy riprap protection, this being the placing of the stone in a trench, the bottom of which is 4 to 4½ feet below the top of the concrete foundation, and 20 to 22 feet wide, the top of the stone being horizontal and on a level with the top of the concrete foundation. It developed during the hurricane of September 13-14, 1919, that riprap protection on the natural beach was superior to that placed in a trench, and the laying of riprap on the natural surface was then authorized by the Chief of Engineers.

Approval was also given under date of May 15, 1919, to the change from wooden sheet piles at Stations 56 and 40, to reinforced concrete sheet piles, of a 1:2:4 mix, the remaining 4,660 feet to be of concrete sheet piles with the front riprap protection omitted, the omission of the riprap being considered justifiable on account of the wide foreshore reducing the violence of wave action on the wall.

Plant and construction methods

The foundation and sheet piles were driven by No. 2 Warrington steam hammers and turntable leads, but on account of difficulty in driving through the fine, packed sand, it was necessary to use 2½-inch jets at 75 pounds pressure to assist in driving them to grade. These turntable drivers work on sills on the previously driven piles. It was found necessary to increase the jets, formerly 2 inch, to 2½ inch in order to drive the large concrete sheet piles more expeditiously.

The concrete in the base and superstructure is of a 1:3:6 mix, or 1.1 barrels of Portland cement, 0.47 cubic yards of sand, and 0.94 cubic yards of broken stone. The sand used is a sharp, freshwater sand with fine gravel, up to 3/16-inch diameter. The broken stone is a limestone from Comal County, Texas, with a specific gravity of 2.68, in pieces ranging from ¼ inch to 2½ inches.

The main construction plant is mounted on standard railway cars. The concreting plant for the wall proper consists of a one-cubic-yard Lakewood mixer and engine, with chuting tower 30 feet high, all mounted on a flatcar and chuting directly into the steel form. A sand and stone hopper to serve this mixer is mounted on another flatcar, this hopper being filled by a locomotive crane from the cars of material. The concreting plant for the base is a ¾-cubic-yard portable Foote mixer mounted on one end of a flatcar, with sand and broken stone hopper on the other end, and chuting directly from the mixer into the base. The cars were rented from the Gulf, Colorado and Santa Fe Railroad.

The heavy riprap stone for front protection was handled direct from the cars by a 15-ton "A"-frame derrick, with 60-foot boom, the base being trussed, and mounted with one side on rollers on top of the completed wall and the other side on cribbing erected on a standard flatcar. This enables the cars to pass under it as they are unloaded. This derrick was used also in excavating the trench for the front riprap stone.

A steel guy derrick, 90-foot mast and 81-foot boom, was used in unloading broken stone and sand from cars to storage piles, when these materials were received faster than they could be used in the construction, and loading cars when there was a shortage of this material being received. It also handled the material for the casting of concrete sheet piling, and the cured piles to storage piles, and on cars.

The wall being of a uniform section throughout, it was considered more economical to use steel forms for the concreting, and a plan was made for the use of six steel forms with a traveler to move the sections, the forms and traveler being constructed by the Blaw-Knox Company, Pittsburgh, Pa. These forms were so designed as to stand alone without outside braces, and when the two sides are swung in the traveler for moving, a form in place can be passed without interference. The toe of the curved side of the form is anchored to the concrete to prevent uplift, by means of threaded bolts anchored in the base, and connected to the form by short ¾-inch rods with long nuts, these latter rods being afterwards withdrawn when the form is removed. When it is desired to move the forms, turnbuckles on the traveler raise the steel sides up and away from the concrete, when one end of all top-connecting channels have been unbolted. These turnbuckles are attached to the form by pins for ease of removal. The wall is built in alternate sections 30 feet long, the steel forms being of such length that the end bulkheads in an isolated form are recessed 6 or 8 inches, and therefore, with the bulkheads removed and angles bolted to the edges, the same sides can be used for the closing sections, plenty of overlap being thus provided. The forms are tied inside with ¾-inch rods, and in the case of the isolated sections have a diagonal wooden brace near the top, which assists as in stabilizing the form and does away with outside bracing. When the concrete reaches the bottom of the brace, the latter is removed.

The steel forms have worked very satisfactorily and have cut the cost of forming more than half, the only improvement necessary being the changing of the top liner angle on the vertical side of the form to an I-beam to stiffen the top of the form, the angle having a little too much flexibility.

The steel form and traveler are shown in Plate III.

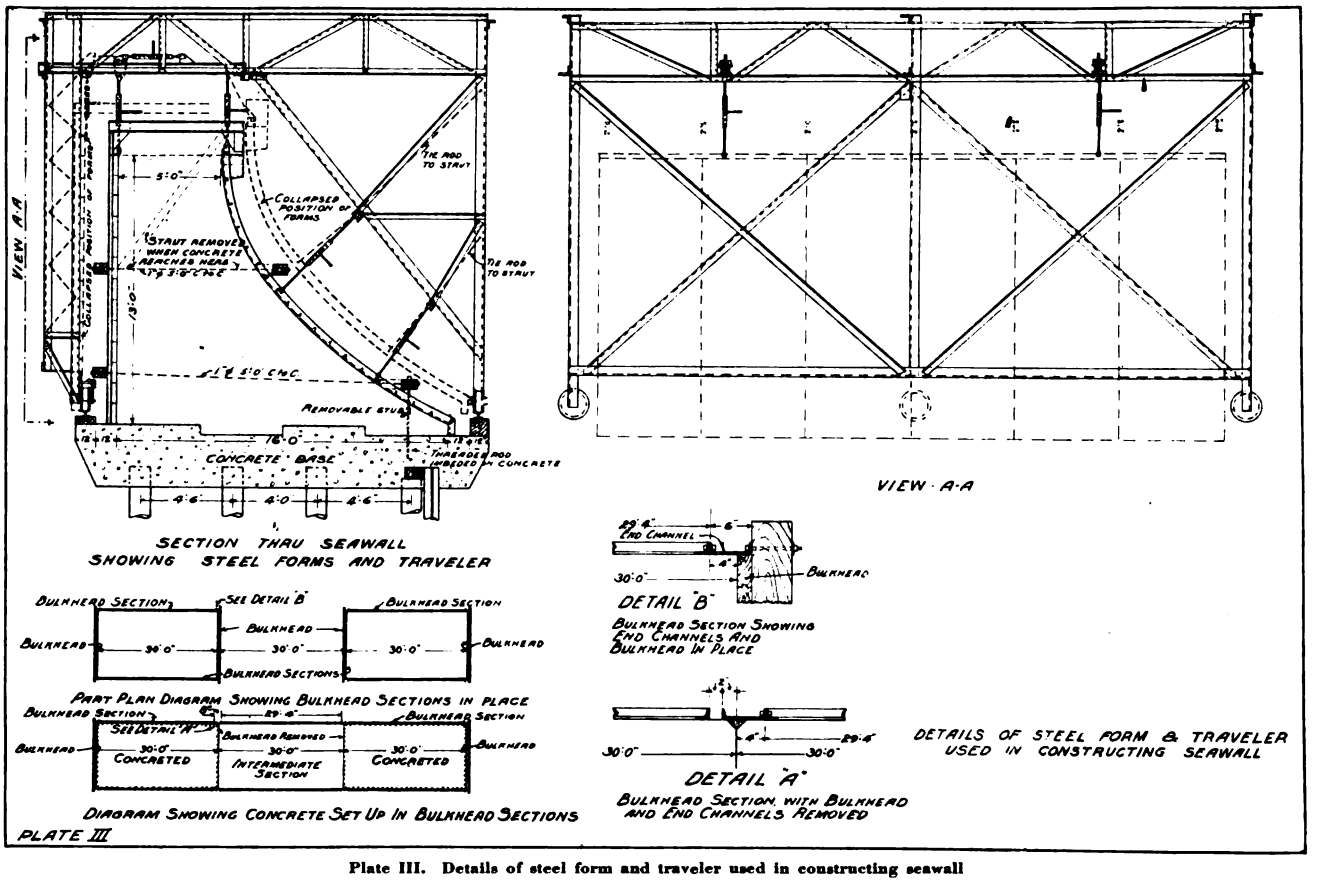
On account of the large amount of switching to be done on the work, and the excessive cost per car for having it done by the railroads, it was decided that it would be economical for the Government to procure a locomotive for this work, and a second-hand standard locomotive was purchased, which receives the loaded cars from the railroads, distributes them and does all switching in connection with the construction work.

The construction plant is such as to permit of each branch of the work being carried forward by the machinery assigned to that branch, without interference with the progression of any other part of the work. Excavation for the foundation is done by a locomotive crane operating an orange-peel bucket. Immediately behind that, a piledriver drives the round foundation piles, followed by another piledriver for the sheet piling. Then the ¾-cubic-yard mixer pours the concrete foundation, followed by the 1-cubic yard mixer pouring the superstructure of the wall. Following the wall mixer and completing the wall construction, is the "A"-frame derrick excavating the trench and placing riprap protection.

History of the construction work

The County of Galveston having complied with the requirements of the act of July 27, 1916, making the initial appropriation for this work, the actual construction work

Digitized by Google



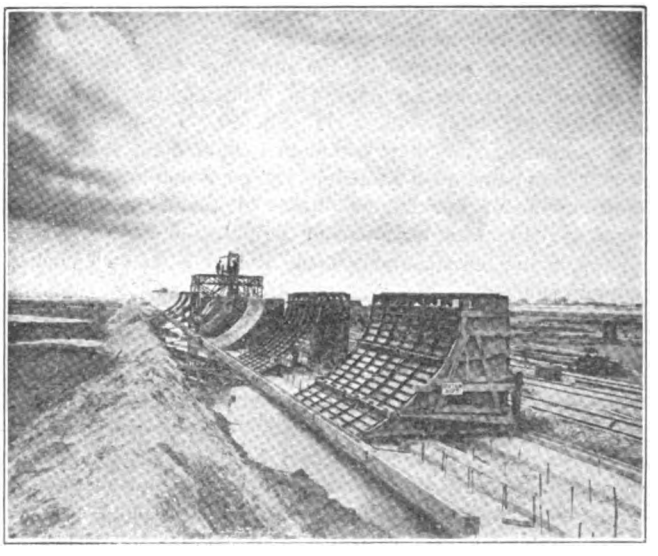


Plate III. Details of steel form and traveler used in constructing seawall

was started in June, 1918, with the county portion of the wall, this being the nearest to the point of connection with the old wall. The new wall being a prolongation of the tangent to the old one, it was decided, in order not to disturb the curve of the old wall, to effect the junction by the construction of a solid concrete ramp, starting with the toe opposite the point of curvature, with a width of 16 feet and extending 147 feet, at which point the line of the new wall was 16 feet from the curve of the old wall, and at this point the regular section of the wall was started. The work was continued from that time, being very much delayed by labor shortage and lack of materials due to the various embargos on cars, etc. When the wall was about 45 per cent completed, and the end of the concrete construction was about opposite the entrance of the Atlantic Hole (a large barrow pit in the flats from which about three million cubic yards of fill for the original Galveston grade raising had been procured), the hurricane of September 13-14, 1919, with a maximum tide of 8.8 feet above M. L. T. occurred, caused a considerable current around the end of the completed wall and scoured a hole about 2,000 feet wide, 924 feet of this hole being at the rear of the foundation and 1,043 feet being the new channel ahead of the wall with varying depths to 19 feet, and an average depth of about 8 feet, where previously the entrance to this hole had been less than 200 feet wide with an average depth of about 2½ feet. This narrow channel had been closed with steel and wood sheet piling and excavation for the wall made, and the work of constructing the wall across the entrance was in progress when the hurricane occurred. In order to continue the wall, approximately 250,000 cubic yards of fill had to be made in this scoured portion. About 19,000 cubic yards were placed with an 8-inch centrifugal pump in the scour at the rear of the completed foundation, and the balance of the fill was placed by the 20-inch hydraulic dredge *Sam Houston*. This latter fill, on account of there being no available material closer, had to be made through a pipe line between 7,000 and 8,000 feet long.

On account of the Atlantic Hole being on one side and the Gulf of Mexico on the other, this fill, the top of which was at elevation 4 feet above M. L. T. would not drain and remained in an unstable condition. It was therefore decided to construct a single-track railroad trestle 981 feet long over the worst part of this fill to take the heavier pieces of construction plant, the other lighter plant to travel over a track laid on a dry, sand embankment placed

Steel superstructure forms with form traveler

Digitized by Google

on the original fill. The making of this fill and the difficulty of procuring timber for the trestle, with other drawbacks caused by the hurricane, delayed the construction work for some months.

It may be stated that this hurricane did not do any damage to any part of the completed wall. While it was not as severe as the hurricanes of 1900 and 1915, it was accompanied by heavy seas and a tide of 8.8 feet, and was severe enough to test the new wall to an unusual degree. Despite the severity of the test, the completed portion of the new wall stood without any backing. One of the steel forms had been filled two days previously, and even this green concrete was not damaged, it being protected by the steel form which was still in place. Three isolated forms were in position empty and two of them were badly damaged. One of them had the front curved face smashed in, but stayed anchored to the foundation, though leaning over very materially. The other form was torn loose from its anchorage and carried away into deep water about 80 feet from its original position, being damaged beyond repair.

The riprap protection on the seaward side of the wall settled very generally where it had been placed, an average settlement of 2½ feet occurring in the whole distance over which stone had been placed.

The reinforced concrete sheet piles are of an unusual size, viz., 8 inches thick, 18 inches wide and 35 feet long, with circular tongue and groove, and considerable difficulty was experienced in getting them down to grade and keeping them in line. 2½-inch jets were used in addition to a No. 2 steam hammer. A maximum of 25 of these piles was about all that can be put in place by an 8-hour shift.

Completion of the project

As soon as funds shall have been appropriated for the Government portion of back fill of 7,000 feet, and the County of Galveston has arranged to furnish the money for their portion of back fill of 3,300 feet, it is proposed to complete the balance of the project adopted in the river and harbor act of July 27, 1916, viz., the making of the fill behind the wall, which is to have a crest 200 feet wide and rising on a 2 per cent slope from the wall, the rear slope from the 21-foot elevation to be about 1 on 30. The fill is to be soiled and sodded on all parts not covered by the brick paving, sidewalk, etc. The concrete sidewalk is to be 16 feet wide, and the brick-paved roadway 84 feet wide. At the edge of the brick paving, or 100 feet from the wall, a continuous line of reinforced concrete sheet piles is to be driven to form a cut-off wall, these piles to be 6 inches thick, 18 inches wide, and 14 feet long. The tops of these piles will be incased in a continuous reinforced concrete cap 2 feet wide and 1 foot thick, and anchored to a continuous reinforced concrete deadman. A concrete retaining wall tapering from 1 foot to 2 feet thick, and 6 feet deep, is to be placed at the rear crest of the fill and projecting 1 foot above the crest, or elevation 22 feet above M. L. T., to prevent any possible overpour.

Dredging Tests on Dredge "Raritan"

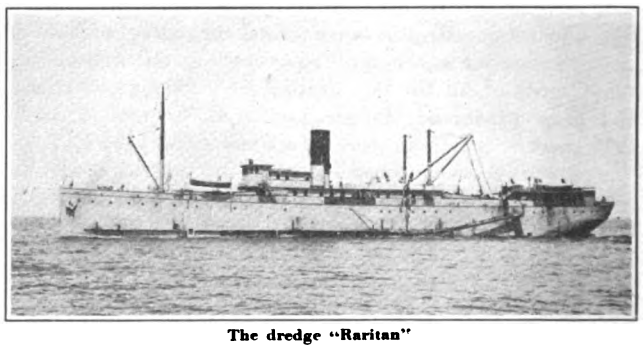
By

E. J. Dent

Major, Corps of Engineers

The dredge *Raritan* is a sea-going hopper dredge, completed in 1908 for Ambrose Channel, New York. She is equipped with two dredging pumps, direct connected to engines having about 450 indicated horsepower. There are two bins, having a total capacity of 2,884 cubic yards; one bin being forward and one aft of the engine room. As originally equipped, each pump had a 20-inch diameter suction pipe and discharged into a special "Y" from which one 20-inch pipe led to the forward bin and one to the after bin. In other words, the pump had one 20-inch suction and two 20-inch discharge pipes.

The general features of the old pumps on the dredge *Raritan* are shown on page 417, PROFESSIONAL MEMOIRS, July-August, 1916, Vol. VIII, No. 40. On page 407 of the same magazine there are shown the general features of a new pump installed in 1916. On page 430 will be found a discussion of working conditions on the *Raritan* and the reasons for making a change in the pump design.



The writer also advocated the use of a 24-inch suction pipe in place of a 20-inch pipe. One such suction pipe was purchased and was used during part of the tests referred to below.

The new pump was installed in February, 1916, and was immediately given an acceptance test while pumping water only. During this test the openings in the drag were reduced in order that the suction head might simulate, as nearly as practicable, the actual working conditions.

As soon as the acceptance test had been completed, an actual dredging test was started. When this test began the following presumptive evidence was available to justify the expectation that the new pump would out-dredge the old pump, under identical conditions, and that the new pump with the 24-inch suction would prove a still more effective unit.

(*a*) With the same expenditure of horsepower the new pump could deliver more mixture than the old pump when both were equipped with the same diameter suction pipes.

(*b*) At the point where the mixture of water and sand enters the drag the new unit, including the larger suction pipe, had a greater available suction than the old unit. Other conditions being equal, the new unit should, therefore,

The dredge "Raritan"

be able to suck in a higher percentage of solids than the old unit.

During March, 1916, seven loads were dredged by the *Raritan* using the new pump only, and seven loads were dredged under as nearly identical conditions as practicable, using the old pump only. The results are shown in the following table:

Tests on Dredge *Raritan*, March, 1916. Loads obtained

The Operation of Motor Trucks in War

Pooling versus Fixed Assignment

By

G. R. Young

Major, Corps of Engineers; formerly Lt. Col., G. S. [G-4], G. H. Q., A. E. F., in charge of motor transportation

With discussions by Maj. Gen. James G. Harbord, Col. M. L. Walker, Brig. Gen. Malin Craig, Col. H. C. Smither, Lt. Col. Geo. P. Tyner, Lt. Col. L. D. Gasser, Lt. Col. J. Edward Cassidy, Maj. Jno. F. Franklin, Maj. Marmion D. Mills

[*Note.*—There was probably no one question which aroused more discussion in the American Expeditionary Forces than that of the relative merits (and demerits) of "pooling" versus "permanent assignment" in the use of motor transport.

The obections to the pooling system were apparently all on a small scale. Nevertheless they were very real, and poignantly felt by those who suffered from them. For example, the division engineer who had to depend on a daily assignment of trucks to carry on his daily work, had real cause for the objections he voiced. He could not depend upon the arrival of trucks which were not under his control; the truck drivers, not being members of his organization, had no particular interest in its work, and were often insubordinate; and motor transport officers exercised, from the engineer's point of view, too great a control over engineering operations.

These very real obections to small-scale pooling are largely removed by the policy of fixed assignment to meet minimum needs, as recommended by Major Young. They are, moreover, relatively unimportant as compared with the great necessity of flexible pools under the control of the higher units.

Major Young, at General Headquarters, had an opportunity to see the problem and its solution, in their larger aspects, as affecting the operations of the army as a whole. There will be few to question the soundness of his opinions. Amongst his commentators there is, except in minor details, not a dissenting voice.

It is believed that this article, and the able discussion following, should settle for all time the proper policy as to the general distribution and control of the motor transport of an army.—ED.]

The two theories

EXCEPT for the supply columns of the Punitive Expedition into Mexico, our first large-scale use of motor trucks in the Army was in the late War. At the beginning of the war, our Tables of Organization were extensively motorized. The method apparently was to compute what horsed transportation would have been needed for the various units, to carry the required supplies, and then convert to motor trucks by the ratio of carrying capacities. Consideration was probably given to the increased radius of action of trucks, in that a division could function farther from its distributing points. Otherwise, it does not seem to have been considered that the old supply system, in or behind the combat zone, would need change.

This is the same as if one had armed Napoleonic infantry with modern rifles, and expected them to fight on Napoleonic tactics, except that they could shoot at a greater range. The substitution of breech-loading repeating rifles for muzzle-loading single-shot smooth-bores did more than increase the killing range of infantry; it utterly changed the theory of infantry tactics. The substitution for animal transport, of vehicles which move three times as fast; which need skilled mechanical repair and operation; which need good roads, and tend therefore always to block those roads, has largely changed the theory of logistics. Much of our Field Service Regulations still needs to be rewritten to conform to the change. But practice precedes the enunciation of theory, and in practice we learned a lot about gas-engine logistics in the war.

The system for handling trucks which was inherited from the days of animal transportation, may be called the theory of fixed or individual assignment. According to this theory there is assigned to every unit of an army, at all times, the number of trucks needed to enable it to function under maximum pressure, or at "peak-load." The opposed theory may be called the theory of pooled transportation. It holds that beyond a certain minimum, trucks should be operated not by tactical units, but by transportation units for the benefit of tactical units; that peak-loads should be met not by a fixed maximum assignment, but by loans for the emergency; that all down the line from high command to division, the commanders should hold out certain truck reserves; and that truck operation implies traffic control. Roughly speaking, the history of the late war showed a drift from the first theory *in the direction* of the second.

In general, this change in technique was forced by the failure of the old system, occurring haphazard and on the individual initiative of unit commanders. There were also two systematic efforts to introduce in a modified form the pooling system during the war.

The theory of the fixed assignment and its breakdown

Previous to the late war, the largest scale on which the American Army ever fought was in the Civil War. In that war an army of 100,000 effectives was a large army. It normally operated over a front of many miles. It fought a war of maneuver, with major engagements occurring perhaps once in a period of months. Its expenditure of artillery ammunition, even in the heaviest battle, was a small thing compared to the expenditure for a large-scale raid, in modern warfare. Outside of railroads, it had not means of moving large bodies of dismounted men on land, at a greater speed than infantry could march. Its transport was animal transport, which could move over almost any kind of road.

When the Tables of Organization of 1917 were framed for the A. E. F., the mental picture of motor transport logistics for the field army was apparently as follows:

a. When the combat trains of a unit were to be motorized, there would be motor trucks attached to that unit with the same carrying capacity as previously assigned animal transport.

b. Where, heretofore, animal transport had been used for food and supplies in a division, there would be a truck train. Its size was computed on the basis of the daily expenditure of food and supplies, and of the average length of haul from rail-head. This was the supply train.

c. Where, heretofore, horse transport had been supplied for ammunition in a division, there would be a truck train. Its size was computed on the basis of the average expenditure of ammunition by a division in action, and of the average length of haul from railhead. This was the ammunition train.

d. Similarly there would be an engineer train, and a motorized section of the sanitary train, consisting of cargo trucks for hauling the field hospitals, size computed in the same way.

e. Similarly there would be trains or artillery parks for hauling ammunition for non-divisional artillery units, and supply trains for the supply of non-divisional units, attached to the Corps and Army.

Digitized by Google

All this mass of transportation was to function as per Field Service Regulations. As a division went into action, the divisional trains passed from the jurisdiction of the commander of trains; the division quartermaster, division engineer, and artillery brigade commander sent their respective trains to railhead or refilling point and brought them back. The corps and army staffs handled their particular trains in the same manner. Every unit being motorized to full strength for active combat, every unit would be ready at all times for a major engagement, with the transportation available to supply itself during that engagement period. It was an attractive picture.

I have said that this system broke down. This is not strictly true, but it bent badly. The reasons were:

1. Shortage of vehicles,
2. Unsystematic shipments, resulting in inequitable assignment,
3. Fluctuation of demand,
4. The troop movement problem,
5. The road control problem.

All these factors are interwoven; it is hard to discuss them separately.

1. The A. E. F. was always short of its allowance of motor vehicles. The shortage increased both absolutely and proportionally, up to the Armistice. This shortage is too often passed over, in theoretical discussions, as incidental, one of our war failures due to "unpreparedness," which should not occur again. It deserves, however, more careful consideration. I do not believe it due, to any great extent, to either individual or departmental inefficiency. Our demands were simply greater than the country could meet. They could have been met for a while (assuming sufficient shipping) by shipping any kind of vehicle, regardless of standardization. This would have been satisfactory for a three months' war, while the vehicles were new, but the cumulative difficulty of repairing and maintaining such a diversity of types would rapidly have become an impossible problem. Figuring as it must on an indefinite period of war, the War Department wisely concentrated on a few makes of vehicles. It did its best, with good men and unlimited money. As a result, by the Armistice we were 50 to 60 per cent equipped. We had been fighting seriously for only four months, so that the vehicles were comparatively new; yet thousands were on their last legs, or wheels, needing immediate overhaul. A winter campaign, 1918-1919, would have seen a great increase in percentage shortage.

I believe that the same thing done again on the same scale would produce the same result; that we cannot equip, in a reasonable time, and with reasonably standard equipment, an army of three or four million men with trucks, on the basis of the 1917 tables. And the great demand under those tables was due very largely to the theory of fixed assignment, as will be shown later.

2. Unsystematic shipment of vehicles results from two causes: One was that for several critical months following the offensive opening March 21st, it was very hard to anticipate what troops were coming. The other was that after a certain tonnage for a given month had been allotted for motor transport, and a detailed list of needs sent back, with a tearful cable emphasizing the importance of the shipment being sent as requested, there was but one result which the A. E. F. could anticipate: that neither in quantity nor in kind would the resulting shipment resemble the demand. Reason unknown.

As a result of this shortage, and these uncertainties of supply and demand, equitable assignment was impossible. It was hand-to-mouth work, the only thing which could be considered being immediate shortages and existing stocks. Divisions arriving early when troops were few; and divisions arriving late when a good many trucks had been made available by stripping the S. O. S. were equipped fairly well. There was an intermediate period when they were equipped very scantily.

Fluctuation in demand might have been anticipated. Of course, if you equip a unit for "peak load,' then when the load is not on, some of the equipment is idle. That was anticipated. What seemingly was not anticipated was that "peak load" itself is indefinable. Trucks are to be furnished sufficient to haul the ammunition for a division in combat. To figure how many are needed, you must take, say, the average experience of a hundred divisions in combat. This I believe is how our Tables of Organization are made up—from Allied experience. But when you take the average of a hundred cases, and try to apply it to any one of the hundred cases, any engineer will see the result. No *actual* case is ever an *average* case. The actual need of a unit, for, say, ammunition carrying trucks at a given time, is dependent on many factors—supporting artillery, nature of fire, length of haul, kind of roads, expected development of the attack, etc.; in no two cases are they the same. This sounds elementary. Yet, although recognized in practise immediately, it was not until the very end recognized in theory.

4. Movement of large bodies of troops by truck was a new thing with this war. We had made no systematic preparation for it in our theories or tables of organization. Probably it was assumed that if such a move were made, it was simply a question of mobilizing the trucks, loading and moving as with supplies. But troop movement differs from supply movement in several respects. Troops to be moved are generally camped or billeted over a large area; within this they must be assembled at definite times, at prearranged spots, and not kept waiting a long time. If the move is of any length, special arrangements for feeding and camping are desirable, though not usually essential. If the move is to a point of combat the convoy must be kept together, so that the unit will arrive as a unit. It cannot be echeloned all down the road to arrive piecemeal, as supplies can. Considering the number of trucks needed to move, say, a division, this means the handling *en bloc* of an immense convoy. The consequences of taking a wrong road are more serious than with ordinary supply movements. For these reasons a large troop movement requires a careful time-tabling and dispatching, a centralized operating control, even more than does supply movement. It cannot be done by a dozen separate, hastily summoned trains breezing into camp and picking up men as they find them. As a result, then, of an unavoidable shortage, inequality of assignment, fluctuation in demand, and the peculiar difficulties of troop movement by truck there was throughout the war a *continued shifting of trucks from one command to another and a perpetual improvisation of elastic truck operating organizations.* And because we had no machinery for doing this systematically, it was done hodgepodge.

Early in 1918, there was a division on the Alsace front. Its sector was quiet—hushed. It had many more trucks than it needed. It also had some highly efficient staff officers, who kept a large part of these trucks permanently parked, rotating the companies in use, and thus ensuring continuous repair. For immediate use, it could have dispensed with, probably, half its trucks. Notoriously, neither we nor the enemy were going to start anything serious

Digitized by Google

in that sector—probably not at all, surely not on 24 hours' notice. That is, the extra trucks would have been just as useful to that division anywhere in a radius of 150 miles—a 24-hour emergency run.

At the same period, there were several divisions in training areas in the Advance Section, desperately in need of trucks. It was recommended that one or two companies from the Belfort division be loaned to the divisions in training. But this was disapproved. The former was at the front, and under existing theories must be equipped for peak load.

In latter May, 1918, the 3rd Division was rushed to Chateau-Thierry, in trucks, from its training area. Very short notice was given. The trucks were assembled from all over the Advance Section, trickling in individually and in small groups, and were somehow whipped into an improvised organization. They got there; but by "main strength and awkwardness," and through the energy of the Motor Transport Corps officer who engineered the movement, for no system existed to cover such contingencies.

Some time in June, I believe, five divisions, then in training behind the British front, were shifted to the Paris Group and the Alsace-Lorraine fronts. They came suddenly, and needed equipment at once. Again it was a case of raking over the S. O. S., depots, units in training and like miscellaneous sources, to find the needful minimum of trucks, organizing them somehow into provisional companies and hurrying them up. The divisions were equipped, more or less, but again, it was through no existing system, but in spite of its absence.

In later August, on two weeks' notice, the new First Army had to be equipped for the St. Mihiel fight. This time, as I recall, between 1,000 and 1,500 "truck-tons" were sent forward. They were taken from the S. O. S., which was almost stripped for a time, and they were assembled in much the same way. The Motor Transport Corps organization in the S. O. S., where pooling was being developed, helped; but I believe most of the organizations were improvised.

These are important examples from the writer's personal experience at G. H. Q. The same sort of thing was happening all down the line. I give one example which is at hand, from an indorsement by a former chief of staff of the 1st Corps:

"Truck tonnage of the 1st Corps were never completely withdrawn from division and corps troops and assembled in pools, but all truck tonnage, including ammunition, engineer and all other trucks, except special service trucks (meaning repair, equipment, tank, telephone, etc.) was considered subject to call and at the disposition of G-1 of the Corps for use when, where and for whatever purpose needed. * * *

"We consider all trucks as cargo trucks for use where and for any purpose needed, whether originally assigned to an ammunition train or to a supply train. Wherever practicable the Nash Quad (ammunition body) trucks were used to haul ammunition, but road conditions ofttimes limited their use between Army and Corps dumps. It was found necessary to use cargo trucks indiscriminately; sometimes all were used to haul rations and more often all were put on ammunition. * * *

"The trucks of one division were frequently called upon to assist another division. The 'pooling principle' was in force inasmuch as all available transportation was at the disposition of G-1 of the Corps, and if sufficient transportation was not available the most urgent task was given priority."

If space allowed, such examples could be multiplied indefinitely.

5. The last reason mentioned as a cause of the breakdown of the theory of fixed assignment and individual operation is the matter of road control and operation of dense traffic. Our existing theory of combat-zone logistics took little account of traffic congestion, except as an acute occasional condition at critical points like cross-roads, to be handled by a strong-armed M. P. But in modern semi-mobile fighting, with densely packed armies and a huge demand for ammunition, and with a type of transport which must stay on the few good roads, general congestion is the rule. It is impossible to let any one who wishes inject a truck train into or across a main artery. You might as well allow hand-cars to ramble up and down a New York subway—better, for the handcars would meet their deserved fate, while the uncontrolled truck-train lives on and blocks traffic. Conditions on these rocade or axial roads, at such times, approximate to those on a railroad. As on a railroad, there must be a despatching system. The conception of the divisional train, under the absolute command of one of the various officers prescribed in F. S. R., going to and from distributing point on its own breaks down. Control of such trains, at least a limited control of their operation while on main roads, and control of all traffic on such roads, must be centralized; up to division headquarters, up to corps headquarters, sometimes up to army headquarters.

Fortunately, our first experience of an all-American army in a large fight was late in the war, at St. Mihiel. By that time we had learned much regarding centralized truck operation. In the two days following the fight, we learned a lot more, and had experience in untangling some very pretty road blockades. In the Argonne, the 1st Army had developed a workable road control scheme. I am not qualified to describe it. I believe that, roughly, G-1 prescribed traffic control, and G-4 co-ordinated truck movements, with some assistance from borrowed French C. R. A's (see below). But all this was improvised. It was not in the books, and not contemplated by the theory of fixed assignment and independent unit operation.

The above is an outline of how, everywhere, this theory was proven inadequate, and modified in improvised ways. Naturally, the General Staff turned its attention to developing a proper theory and system. It moved, *in general*, toward the French system; which it is accordingly desirable to describe.

French system of truck operation

We recognize a broad division of trucks according to use, into two classes, which may be called "combat transportation" and "supply transportation." (Terms descriptive, not technical.) The former is that directly attached to units of a brigade or less. It has three characteristics: the groups of trucks are small; their loads (combat equipment, etc.) are fixed, and their length of haul is about the same as a march of their units; and they must be with their units to make those units mobile.

The latter class, "supply transportation," includes trains of divisions and larger units. It has the following characteristics: The groups of trucks are large; their loads are widely variable (e. g., an ammunition train in rest-camp, and in a major offensive); also their length of haul, depending as it does on distance to railhead. And while needed for active fighting at "peak load," they are *not* needed in toto to make their units mobile.

The French agree with us that "combat transportation"

Digitized by Google

—motorized field trains, technical trucks, etc.—must not be separated from its tactical units. But here the theories diverged. Ours, as stated above, was that the same applied to supply transportation; and we *assigned to divisions, etc., an irreducible amount roughly sufficient for peak-load,* to be operated wholly by such divisions. But the French are realists. They knew that they had not enough trucks to do this. They knew that if they could and did do it, the handing of the trucks under peak-load conditions by divided authority meant hopeless blocking of roads. And if these conditions could be met, the system would still not give the needed elasticity to enable them to handle large troop movements and ammunition for big attacks. So they assigned to divisions, etc., *an irreducible amount roughly sufficient for average load;* and organized the remainder into *operating truck units under G. H. Q., loaned where needed to handle p ak load.*

Such units were, however, loaned not as a man loans a typewriter, but as a railroad loans a freight car. The S. A.* said in effect to a field army: "Your divisions are going into battle. Your field trains and technical trucks are intact. But your divisional trains are adequate only for a quiet sector. You cannot move the necessary supplies and troops in this attack. Therefore we will move them for you. Notify our representative in your area of what you want moved, where it is, where it is to go and when. He has the trucks and will move it. But you must keep your hands off the trucks. Further, our representative is responsible for traffic control on certain critical roads in your sector. If you want to move *your* trucks on or across those roads, you must notify him, so that he can coordinate their movements with those of his trucks."

The "representative" mentioned was a C. R. A. ("Commission Regulatrice Automobile"). It had a headquarters, and a group of platoons or "cantons." When heavy fighting was due, a C. R. A. moved in behind the field army; was assigned a territorial area, and was given a group of the G. H. Q. reserve trucks. It had two functions. First, it received from the army or smaller units, calls for movement of men or supplies which the army with its permanent transportation could not handle, and ordered their movement, when and as requested, by its own trucks. Second, it handled road-control and despatching of *all* traffic, on critical roads (called "routes gardees") through its cantons, which were simply despatcher groups assigned to different parts of the C. R. A. area, with telephone communications. There were nine of these C. R. A. organizations, but they were shifted into different areas as necessary. The C. R. A's reported (through our intermediate channel) to the Director S. A. at G. H. Q. Traffic from one C. R. A. area to another was controlled from above, in a manner that need not be described.

This system as it stood was not applicable to American organization. But it is not true, as sometimes charged, that it failed the French; nor that they tested it only in "fixed" warfare. No defensive test could be severer than that of March, 1918, when the French had to cover and refuse their flank, rush troops from all parts of the line and close the gap behind the broken British Vth Army. On the offensive, the French in October and November had, I believe, about as heavy fighting as we in the Argonne; and being farther from the Allied pivot, they moved as fast, at times, as we ever did. Their truck system met both tests.

The Motor Transport Reserve

The project for an A. E. F. Motor Transport Reserve was an attempt to meet the demonstrated inadequacy of our theories of truck operation, by a system somewhat similar to the French. It was also intended to meet the demands of the Allied High Command, that the truck organization of each army be elastic enough so that trucks could be readily shifted between zones of operation, and so that truck groups of the various Allies could work together. The High Command here had especially in view the expected 1919 campaign, where major attacks in depth, over country without railroads, would make great demands on truck transportation.

Following a meeting of the Military Board of Allied Supply, the writer submitted a report recommending:

a. That divisional, corps and army amunition, supply and transport trains be reorganized into uniform operating units.

b. That they be divorced from rigid assignment to tactical units, and considered on paper as all part of a G. H. Q. Truck Reserve.

c. That a necessary minimum of such truck companies or trains be *attached* to divisions, etc., to handle average load, the remainder to be held behind the lines or loaned out when and as needed.

d. That a traffic-control system approximating the French be introduced.

Absolute control of Reserve trucks loaned for emergency, by C. R. A's or equivalent, was not contemplated.

These recommendations were approved in principle by the Commander-in-Chief. In September and October they were put into a working form, and covered in detail by a proposed order prepared by Lieut Col. L. D. Gasser. This differed from the basic proposal in that, for various reasons the ammunition trains were omitted from the reserve; which was drawn from divisional and other supply trains, but leaving part of the supply trains permanently with the divisions. It was to be organized, as an army reserve, in the 1st and 2d Armies. Traffic control was to be handled by Traffic-Control Officers in those armies, reporting to a similar officer at G. H. Q., along the French lines.

The order was approved, to go into effect November 15th. When the armistice occurred, the whole thing was dropped.

Truck pooling in the S. O. S.

The idea of centralized operation in the S. O. S. did not meet such opposition as in the case of the armies. It was sanctioned in May, 1918. The system developed was in principle that now existing in posts and camps in this country. "Supply transportation" was organized uniformly, and placed, by units, under M. T. C. officers throughout the S. O. S. These units received calls for transportation and handled them, just as a transfer company does for a customer. The M. T. officer had no say as to what was to be moved, where or when, but he had complete operating control of his trucks.

The system was organized simply and well. By insuring skilled mechanical supervision, it caused a great saving in operating and maintenance expense. In the last two months of fighting, when the armies made such demands, it enabled the S. O. S. to function on a surprisingly small allowance of trucks.

Conclusions

I think there is no question that truck pooling in camps and posts, as developed in the S. O. S. and now practiced in this country, is the most satisfactory system. The argument centers around the system in tactical units in war.

Any system of handling trucks in the combat zone must fulfil the following requirements:

(a) Divisions* must be mobile.

* "Service Automobile:" our M. T. C., with a dash of General Staff.

* Read "divisions, corps and army troops, etc."

Digitized by Google

(b) Divisions must be capable of feeding and supplying themselves under average conditions (camp, quiet front).

(c) Divisions must be supplied for intensive fighting.

(d) The high command must have facilities for moving large bodies of troops by truck, and meeting emergency calls.

(e) Roads must be kept open.

(a) is met by requiring that motorized combat and technical vehicles and field trains ("combat transportation") be assigned to and operated by their units. This includes the old divisional engineer train, really a regimental combat train, and much of the old sanitary train. (b) is met by assigning permanently a small divisional supply (and ammunition) train. 250 truck tons for the old division of 27,000 men is a fair allowance.

All available trucks beyond this should be organized into uniform units, and carried on paper as a reserve of the high command. This reserve could function in two ways. It could be operated as a reserve, or units could be *attached* to divisions, etc., to be operated by the division or higher commander, just as additional artillery is attached for an emergency. A portion at least should be operated as a reserve, for troop movements (d), and to handle emergency calls.

How to dispose of the remainder to meet requirement (c), depends wholly on the situation, especially on the road conditions (requirement e), and available supply of trucks. To take one extreme, suppose a small army operating in northern Mexico, principally by scattered small units. There would be plenty of trucks in the country to supply it; there would be plenty of room, plenty of roads, all equally bad, and no question of traffic interference. Also, due to the distances, it would take a long time for the high command to reinforce a hard-pressed unit with trucks. Here it would be well to attach to divisions, above their allowance, lots of trucks, all they wanted, say for a division of 27,000, an additional 750 truck tons. The arrangement would work, and the only man to get grey hair would be the M. T. C. in charge of maintenance.

The other extreme is conditions in France. There was a shortage of trucks and always would have been; there were continual emergency calls for troop movement, etc. Excellent roads and a compact zone of operations made possible rapid reinforcement of trucks. And the enormous traffic behind active fronts required good road-control.

The solution here would be to create two or three great reserve parks, say fifty miles behind the line, and to attach to divisions, from these, above their fixed allowance, what the condition required. A division goes into a dead sector; loan it two extra truck companies. A division goes into a doubtful sector; loan it four, and move four more to 20 miles behind it (2 hours' run). A group of divisions is to start an offensive. Loan thirty companies to the army commander, to distribute as he wishes; shift another thirty to behind his front; and tighten up on road control.

A group of divisions, say, in a supposedly quiet sector and with the minimum of trucks, are attacked by surprise and driven back. Much is made, by advocates of the old scheme, of this situation; they point to the British disaster of March, where masses of combat equipment (guns, etc.), demobilized by previous withdrawal of trucks, were lost. But such trucks are *combat* transportation, which must never be detached. A division can pick up its material and run, if it has time, with no supply transport whatever. Extra trucks are needed for a retreat as follows: (1) to supply the artillery when it has fallen back to new positions; (2) perhaps to save infantry; (3) especially, to rush up reinforcements. (1) does not develop at once, in a surprise attack; the first phase is confused infantry fighting and guns firing from their old positions and dumps till they are driven back. It would certainly take eight hours to withdraw a mass of artillery and reorganize it for fire; in which time trains could be sent up from a reserve park fifty miles back. Need (2) does not develop at once, nor at all unless there is a disastrous rout. In such a case, organized trains brought up from the rear, under single command, will do a much better job in picking up masses of beaten men, than a medley of trains under independent command, already caught in the confusion of the retreat. As for need (3), the most important, it simply demands an organized reserve. Indeed, the greatest need for extra trucks in a retreat is not with the attacked troops, but precisely somewhere else.

For traffic control, there should be a transport officer at army or corps headquarters, under the supply and transport general staff (G-4). Under quiet conditions he would have little to do; ordinary divisional regulation and M. P.'s at cross-roads could handle things. When traffic became dense, he would take over critical roads. On them, nothing would run without his permission, and he would despatch and regulate traffic through despatchers strung along the roads.

He would not "own" and farm out truck reserve units attached to the armies. This part of the French system is over-systematized for the American mind. Units loaned from the reserve to armies and divisions would be operated by them, subject to road control. But such units are *simply* loaned for existing conditions; subject to reinforcement or recall as conditions change; permanently a part of a great uniform organization, under G. H. Q., and whose commander is responsible for training, administration and repair.

Such an arrangement, with no loss that I can see, gives an efficient and elastic organization. Under it, one could handle the everlasting necessary shifting of trucks, to meet varying conditions, as one shifts a regiment of infantry; not as one shifts three thousand unorganized men, scrabbled together from all sources. And this I believe to be the great lesson of truck operation given us in the late war. If we did not learn it, we are due for another schooling next time.

Wind Maps for Aviators

In olden times, when the commerce of the world (such as there was of it), moved in sailing vessels, the wind was a very important factor. For ages mariners had no guide in the selection of their route of travel, except tradition and personal experience. To-day the winds of the sea are accurately known and charted, and the sailing master may select the most favorable route for travel. But the steamship proceeds direct to its destination, paying little attention to the wind.

With the advent of aerial navigation it became necessary to greatly extend our knowledge of air currents; to cover the land as well as the sea, and the upper strata as well as the surface of the earth. Wind charts, thus far of limited areas, are now being published for the use of aviators. As so great a choice of route is open to the aviator, he being able to detour either horizontally or vertically, these charts are of special value. They might indicate, for example, that it would be advantageous to the aeronaut to make his voyage out at one level, and his return trip at a different level.—*Geographical Review.*

The Ice Problem in Canada

Extract from an Address by John Murphy, Electrical Engineer, Department of Railways and Canals, Dominion of Canada

With Comments and Explanation
By

Col. Chas. Keller
Corps of Engineers

FOR some twenty years, Mr. Murphy, in co-operation with Prof. Barnes, of McGill University, has been engaged in investigating the causes of ice formation and the possibility of devising practicable remedies to enable us to avoid the difficulties that result therefrom.

The principal part of the matter that follows is from the report of an address by him. It possesses considerable interest for all engineers having to do with power plants, locks or other structures, such as Taintor and other sluice gates in our northerly latitudes. His suggestion that it may be possible to keep a large stream from freezing is at least an interesting one.

The remedy for ice difficulties proposed by Mr. Murphy should be compared with that found to be effective at Keokuk as described in a recent article in this journal by U. S. Civil Engineer M. Meigs. It will be recalled that the leakage of compressed air kept the upper lock gate free from ice, and that this purely accidental result pointed the way to an easy remedy for ice troubles at the Keokuk lock, dam and power plant.

The report of Mr. Murphy's address is reproduced almost without change. It is needless to say that the field it covers is important to canal and river engineers and that the possibilities of remedial measures are worthy of careful study and field observation.

For the sake of clearness, "anchor" and "frazil" ice are defined as follows:

"Anchor" ice forms on the bottom usually at night or in dark, quiet places. It is in long needles. "Frazil" is the same as "slush" ice. It forms in flowing water as small crystals which gradually interlock or combine. These are fairly exact definitions, in discussing which Mr. Murphy writes the following:

The *agitation* of water, at the critical (freezing) temperature, causes it to crystallize—and the introduction into it of an ice-forming nucleus (anything below the freezing point) also starts crystallization. Each newly formed crystal, no matter how minute, also acts as a nucleus, and so the cumulative action in ice formation merrily proceeds when it is once started.

Rocks, on the beds of streams, which have lost their heat by radiation and against or around which water at the critical temperature is tossed (disturbed or agitated) are soon covered with "anchor ice," which remains clinging to those rocks and growing larger and larger in mass in two ways—namely, by self-propagation and by the adhesion to that mass of all floating particles of "frazil" which come within the grasp of it.

Frazil forms most abundantly at the surface, but it will form in any part of a stream when water, at the point or part in question, is at the critical temperature and when it is *agitated*. The agitation of surface water by the wind (or in rapids), the cooling action of the air, the prevention of the formation of sheet ice by such disturbances of the surface (which would, if quiet, soon be covered by sheet ice), and the self propagating faculty of frazil all combine to make the *surface of streams* the place where most frazil is created.

These feathery crystalline spicules are formed as the result of agitation; they *may* all be called "frazil" (and, by the way, they look something like the frazzled end of a rope); and when they have been attached to the beds of streams it is proper to call them "anchor ice." When "anchor ice" rises, after being loosened by heat from the sun, and when it is seen at the surface, it is usually found to be quite dirty in appearance (frazil is beautifully clean), because it has permeated throughout its mass the slime, etc., from the rocks upon which it grew.

Frazil, when floating at the surface, resembles sodden snow and is often called "slush." Until it accumulates into masses it will, however, like a fluffy feather in the air, follow the slightest current up or down in any direction.

Having made the nature of these two kinds of ice fairly clear, we may now proceed understandingly to his principal statements regarding them, which follow:

The ice problems of Canada can be divided into two different classes. The first has reference to the operation of hydraulic apparatus and the necessity of keeping this free from ice. The second is the necessity of preventing the blockading of streams by ice which in this country causes an immense amount of damage by flooding the surrounding country every year.

For a great many years past it has been the objective to discover adequate methods of preventing the shutting down of hydraulic apparatus by frazil ice. We have succeeded in effecting this by the introduction of a small amount of heat so as to keep the machinery one thousandth part of a degree above the freezing point. When this temperature was maintained it was found that frazil ice in the stream would not cling to the machinery, but would pass right through.

We have now stepped into the bold undertaking of discovering a method of keeping great streams, such as the St. Lawrence River, open in the winter time and preventing them from getting choked with ice and causing floods.

Mr. Murphy presents many figures to prove his contention that it is a small matter after all to keep any stream open.

The average flow of the St. Lawrence past a given point is 250,000 cubic feet a second. The winter flow is 200,000 cubic feet a second. In about 50 ice-forming days during the past severe winter only 2 feet of ice had formed in a 3,000-foot stretch across the river. As there are 4,320,000 seconds in 50 days, in the time that 2 feet of ice has been forming over 864,000,000,000 cubic feet of water pass down the stream. Only 6,000 cubic feet of ice had formed, or in other words, only one one-hundred and forty-four millionth part of the water passing down the stream had been frozen. Up to the present time this question had been looked upon as a task of preventing *all the water* in the St. Lawrence River from freezing, whereas the real problem was to keep the small fraction mentioned above from freezing. When looked at in that light, it is found not such an impossible task after all.

It is well known that a stream freezes from the banks out towards the center, but the reasons for this have never been discussed up to the present. The solution of this is that the molecules of water near the edge of the stream are

Digitized by Google

continually being rolled about, and in that manner the heat is taken away from them and given up to the shore.

Mr. Murphy showed pictures of dams clogged with frazil ice and racks of power houses, which, because the spaces in them were generally too small, caught the frazil ice and thus became clogged, causing a shut-down, which might have been avoided if the ice had been able to pass through.

Some of the most interesting of the views were diagrams to show the method of introducing the required heat to prevent a power plant from freezing and shutting down. At one particular plant there were sometimes ten shut-downs a year through ice. During these times the load was taken over by an auxiliary steam plant, which used 150 tons of coal a day. The capacity of the plant was 3,000 h. p. The hydraulic engineer, when approached on the prevention of these shut-downs, treated it as a matter of warming all the water passing through, and gave figures to show that energy to the amount of 147,000 h. p. would be required to keep a 3,000 h. p. plant open. Mr. Murphy, however, told him that he was looking at it in the wrong light, as the *machinery* should be kept above the freezing point and *not the water* passing through. In the end he succeeded in getting the machinery heated by steam from a small boiler, using one ton of coal a day, which had the effect of doing the same work that required 150 tons when a shut-down occurred.

Another interesting illustration was a bottle of water just at the freezing point, which was taken into a warm room. Although the outside temperature was warm, it was found the water could be turned to ice quite easily by dropping a nut on the end of a piece of string into it and causing friction. The temperature of the room at the time was 70 degrees. By means of a microscope the small particles of ice were shown in process of formation, and it was clearly demonstrated that the ice formed in the first place on the string and nut, but that once ice had started to form, the action was accelerated by the little particles of ice themselves which rose to the top when detached from the string by friction and became the nucleus of other ice formation. Anchor ice was shown at the bottom of the bottle, where it was firmly lodged.

The final picture was that of a stream where an ice company had harvested its ice supply for years. One year no ice formed on that side of the river, although there was ice to a thickness of 2 feet on the other side. On investigation it was found that a cement mill, which had been built during the summer, poured condensing water into the stream at the rate of 8 cubic feet a second. It was found that this small quantity prevented the water from freezing for a mile and three-quarters down the stream. In litigation, which lasted over five years, the ice company secured heavy damages and an injunction restraining the cement company from ever again preventing the freezing of the stream.

Building the Earth Dams of the Bridgewater Project

The new Bridgewater reservoir for the Western Carolina Power Co. is formed by three dams, called the Catawba, Paddy Creek and Linville dams. Of these the Catawba has a gravity concrete section crossing the river, but the remainder of that dam and all of the other two are earth fills, built by hydraulic sluicing of earth brought in by trains from nearby borrow pits and deposited along the outer edges of the dam from timber trestles.

The three earth fills are of approximately the same design, with a 20-foot top, upstream slopes of 1 on 3, and downstream slopes of 1 on 2½, with a central bottom trench and a downstream low rock fill toe wall. Catawba is 120 feet high and contains about 1,820,000 cubic yards, Paddy Creek 165 feet maximum height with 1,450,000 cubic yards, and Linville 160 feet high with 1,250,000 cubic yards total fill. They were located within 2½ miles of each other, and the material used in building them was of essentially the same nature and composition.

Before the construction of any of the earth dams could be commenced it was necessary to unwater the dam sites, to strip the ground to be covered from all vegetable matter, to excavate a trench along the center line of each dam down to a surface of hard and impervious material and to construct a rock fill toe on the downstream side of the earth fills. While this work was going on suitable borrow pits were located, containing the material used in the construction of the fills, consisting in general of disintegrated gneiss and mica schist, sand and clay intermixed with small stones. The materials from the various borrow-pits were loaded by steam shovels into side-dump cars, made up into trains and transported by locomotives to the timber trestles, the first set of which was built along and inside the upstream and downstream toelines of each dam. From these trestles the materials were dumped, and after the two dykes thus created had reached the required size, the trench excavated along the center of the dam was filled with water.

Two scows equipped with pumping plants capable of delivering 1,000 gallons of water per minute at each 2-inch nozzle of the sluicing monitors, were then floated in the pool formed between the two dikes. After the second set of trestles was built, the inner portion of the fill materials side-dumped from these trestles, was mixed with water and washed down by use of the monitors, the result being that the finer materials settled in the center of the dam. As soon as beaches began to form the surface of the pool was raised by pumping in additional water.

Both dykes of a pair were advanced at the same rate by frequent throwing of the tracks toward the center of the dam; it was, however, not permitted to dump materials which would fall inside the limits of the middle-third zone before being treated with water. In general, trestles of 20-foot height were used, and with the exception of the stringers the trestle timbers were not removed. When the earth fill was above the spillway crest, the hydraulic sluicing was discontinued and the selected material dumped in the small pool between the two dikes. Above the highwater level of the reservoir the pool was discontinued and the dam finished to the specified height, allowing for shrinkage of the earth fill. The grading of the side slopes was done by teams and drag scrapers. Stone riprap was placed on the water slope of the dam, and the downstream slope was planted with grass.—*Eng. News-Record.*

Air Temperatures in the New York-New Jersey Vehicular Tunnels

By

Harry L. Van Zile
Major, Engineer Reserve Corps

THE vehicular tunnel now being constructed between New York City and Jersey City, New Jersey, presents many new problems, the solution of which will be carefully watched by engineers and all those interested in attempts to increase the traffic facilities for large centers of population.

New York and New Jersey will jointly bear the cost of building and equipping this tunnel, and therefore every effort has been made by the legislatures of these states to have experts on tunnel construction and traffic movement make intensive studies of all of the elements entering into this project.

The Chief Engineer of the New York State Bridge and Tunnel Commission has had available a board of eminent consulting engineers, and it is therefore proper to assume that the pioneer construction of a tunnel for vehicular traffic will not prove to be defective in any important feature.

The Chief Engineer has published a remarkably complete report of his analysis and findings dealing with all of the matters which enter into the location, size and construction of the tunnel. From this report it is learned that there are to be two tubes, each of 29 feet external and 25 feet 6 inches internal diameter, with roadways of a width of 20 feet. The traffic will be in two lines from New York to New Jersey in one tube and two lines in the opposite direction in the other tube.

The total length of this tunnel will be 8,500 feet, and the length between ventilating shafts 3,800 feet. The maximum traffic for one hour in one direction is figured to be 1,900 vehicles if they are all motor driven. On this maximum traffic limit and the average to be reached per day of 24 hours the income from tolls is figured to be sufficient in twenty years to pay the amortized cost of construction after deducting the cost of administration, maintenance and operation.

This result being important to the tax-payers of these two states, much scrutiny has been given to the published report, as anything which would interfere with the amount of traffic obtainable would delay the amortization of the construction cost.

The public will undoubtedly welcome any new traffic route between New York and New Jersey, and thousands of tons of goods will be sent through this tunnel in each direction. One fundamental requirement, however, must be fulfilled, and that is the journey must be safe and not notoriously uncomfortable to the drivers of the trucks.

There will be no question about the safety of the tunnel itself, but the condition of the air must be such that men breathing it, either for short or long periods, will not absorb excessive amounts of noxious or harmful gases or suffer from excessively high temperatures.

Many of the readers of THE MILITARY ENGINEER no doubt recall the discussion some years ago relating to the quality and temperature of the air in the then recently constructed New York City subways.

The public became so insistent in its demands for the remedying of conditions in the subways that the engineers were forced to make an exhaustive examination of the air at various points and even installed some power-driven exhaust fans, which proved to be ineffective. The published report of the subway engineers showed that the quality of the air in the subway was equal to that of the outside air, and that the real trouble was excessive temperature during the summer months.

The report states that during the summer of 1905 the temperature of the subway between 50th and 59th Streets was 5.6° F. above that of the outside air, but that in 1915, with the recently installed ventilating louvres closed, the excess temperature in the subway at the same points was 16.76° F. This increase, the report states, was due to the increase in the number of trains passing through this portion of the tunnel. This is explained by the following statement taken from the engineers' report:

> This energy is transmitted to the subway, is there utilized in moving and lighting the trains, lighting the stations and performing other useful work, the energy thus utilized being reconverted into the form of heat, which must be dissipated by convection of air currents or by conduction through the walls, roof and floor of the subway to the surrounding earth and neighboring subsurface structure. The amount of energy, and, consequently, the amount of heat units, varies directly as the number of trains and as the number of cars per train.

It would seem, therefore, that the examination of the probable condition of the air in the vehicular tunnel during the maximum hourly traffic in the summer months may lead to some interesting conclusions.

This vehicular tunnel will operate under very different conditions than the subway tunnels, as the continuous line of motor vehicles, burning gasoline or other combustible fuels, will be expelling gases that are either non-supporters of life or actually harmful to the health, and further than this, all of the heat from such combustion will be contained in the tunnel except such a comparatively small amount as will be radiated through the concrete sides to the surrounding water.

To determine the temperature condition of the air the following calculations are made:

Length of tunnel between ventilating shafts ft.	3,800
Net cross-section area between roadway and ceiling sq. ft.	318
Net air content between ventilating shafts cu. ft.	1,208,400
Weight of air content at 70° F. lbs.	90,571
Heat necessary to raise this amount of air 1° F. B. T. U.	21,511
Maximum motor vehicles per hour	1,900
Maximum vehicle miles per hour for 3,800 ft. (0.72 mi.)	1,368
Gasoline per hour at 6 miles per gallon lbs.	1,368
Heat units developed at 19,000 B. T. U. per pound	25,992,000

If the air in the tunnel is not changed for one hour, and

Digitized by Google

it requires 21,511 B. T. U. to raise its temperature 1° F., the development of 25,992,000 B. T. U. in the tunnel will raise the temperature 1,208° F.

The ventilating system proposed is of sufficient size to fill the tunnel with air thirty-two times per hour, or dividing 1,208 by 32 it is found that such an amount of air will be heated 37¾ degrees above its entering temperature. The changing of the air thirty-two times an hour is believed by the chief engineer to afford sufficient dilution to protect the occupants of the tunnel from any harm due to the carbon monoxide given off from the gasoline-burning vehicles.

It may be thought by some that the heat contained in a pound of gasoline, estimated at 19,000 B. T. U., should not be considered as completely liberated in the tunnel, but unless the gasoline is practically all burned there will be an excess amount of carbon monoxide which would have a disastrous effect on the people in the tube.

The allowance of 6 miles per gallon of gasoline for all makes and kinds of trucks and automobiles may be more or less than the actual distance covered, but it is thought that the assumption is near enough to warrant the conclusion that some further provision must be made for ventilating this tunnel.

Either the maximum traffic expected will not be reached in the warm months of the year or a provision for possibly four times the amount of air delivered will be needed. As this would require 64 times the amount of power provided for at present, such an increase becomes a serious matter.

If the traffic does not approximate the amount figured, the tunnel cannot be paid for in twenty years. If the ventilating system has to be enormously increased, further amounts must be spent for equipment and operating, which will also delay the amortization period. Manifestly the problem is a serious and important one.

Dredging Tests on Dredge "Raritan"

(Continued from Page 98)

by using one pump at a time, the pump in use discharging into both bins.

Locality and material.	Cubic yards per minute dredged.
New pump, 24-inch suction.	
Red Hook Channel; mud about 15 per cent sand	3.80
Bay Ridge Channel; fine hard sand about 10 per cent mud	5.82
Ambrose Channel; coarse sand	10.65
Buttermilk Channel; mud and debris	4.92
New pump, 20-inch suction.	
Red Hook Channel; mud about 15 per cent sand	3.06
Bay Ridge Channel; fine hard sand about 10 per cent mud	3.98
Ambrose Channel; coarse sand	9.30
Old pump, 24-inch suction.	
Red Hook Channel; mud about 15 per cent sand	3.58
Bay Ridge Channel; fine hard sand about 10 per cent mud	5.10
Ambrose Channel; coarse sand	9.12
Old pump, 20-inch suction.	
Red Hook Channel; mud about 15 per cent sand	4.14
Bay Ridge Channel; fine hard sand about 10 per cent mud	4.91
Ambrose Channel; coarse sand	9.23
Buttermilk Channel; mud and debris	4.37

During April, 1916, one of the discharge pipes on each pump was closed so that one pump would discharge into the forward bin while the other pump was discharging simultaneously into the after bin. Eleven loads were dredged with this arrangement, three of the loads being obtained while the 24-inch suction pipe was attached to the new pump and eight of the loads while using a 20-inch suction pipe on the new pump and the 24-inch suction pipe on the old pump.

Near the end of April, 1916, all tests were suspended and were not resumed until January, 1920. During the 1920 tests a 20-inch suction pipe was used with each pump. The new pump discharged into the forward bin and the old pump discharged into the after bin. The results of these tests are shown in the following table:

Tests on Dredge *Raritan*, April, 1916, and January, 1920. Loads obtained by discharging entire output of one pump into forward bin while entire output of other pump was simultaneously discharged into after bin.

		Cubic yards per minute dredged.	
April, 1916. (Day)	Locality and materials.	New pump 24-inch suction.	Old pump 20-inch suction.
10	Ambrose Channel; coarse sand	9.54	7.35
10	Bay Ridge Channel; fine hard sand	6.10	5.26
11	Opposite Robins Reef; mud	4.19	3.47
		New pump 20-inch suction.	Old pump 24-inch suction.
17	Ambrose Channel; coarse sand	5 84	7.18
18	----do	6.79	8.33
15	Bay Ridge Channel; fine hard sand	4.67	4.37
17	----do	4.63	4.80
25	----do	4.78	4.94
24	Opposite Robins Reef; mud	4 97	5 19
25	Gedney Channel; coarse sand	12.28	13.02
Jan., 1920. (Day)		New pump 20-inch suction.	Old pump 20-inch suction.
5	Battery to Canal Street—70 per cent ash and cinder, 30 per cent mud, sand, etc	6.05	5.32
12	----do	9.22	4.92
19	----do	8.55	5.40
21	----do	10.85	7.22
6	Edgewater Channel; soft clayey mud	5.47	4.68
15	----do	5.28	2.82
16	----do	6.85	3.82
21	Gedney Channel; coarse sand	14.07	7.75
22	----do	16.90	9.03

During the 1920 tests, the indicated horsepower of the engine driving the new pump was about 7 per cent greater than that of the engine driving the old pump.

The results given above show practically that the use of a higher efficiency pump on the dredges operated by the Engineer Department will ordinarily result in an increase in output. In the case in question, the new pump has been found to be more durable than the old pump, which is a further advantage.

The Introduction of Mechanical Warfare on Land

And its Possibilities in the Future

Abstract of a Lecture delivered

By

Col. J. F. C. Fuller, D. S. O.

(From The Royal Engineers Journal)

Opposition to the Coach.—In 1565 it is recorded that the first coach constructed in England was built for the Earl of Rutland, but on account of the execrable condition of the roads of this period and the dangers of the highways, it was not until 1669 that systematic journeys were attempted in England and then only between Oxford and London.

Coaching was a novelty and, like every rational and profitable novelty, before or since, its progress met with strong opposition. Early in the seventeenth century a Bill was brought before Parliament 'to prevent the effeminacy of men riding in coaches;" and in 1671, Sir Henry Herbert, M. P., stated that—"if a man were to propose to convey us regularly to Edinburgh in coaches in seven days, and bring us back in seven more, should we not vote him to Bedlam." Nevertheless the coach had come to stay, for its time, and on October 13, 1712, a weekly service was instituted between London and Edinburgh. The journey was made i thirteen days.

Opposition to the Locomotive.—In 1641, that is twenty-eight years before the first coaching service was instituted in England, the Marquis of Worcester, famous as the inventor of an early steam engine, went to see Solomon de Caus in a madhouse in Paris. Marion de Lorme wrote of this visit as follows:

"We were crossing the court, and I, more dead than alive with fright, kept close to my companion's side, when a frightful face appeared behind some immense bars, and a hoarse voice exclaimed: 'I am not mad! I am not mad! I have made a discovery that would enrich the country that adopted it.' 'What has he discovered?' asked our guide. 'Oh!' answered the keeper, shrugging his shoulders, 'something trifling enough; you would never guess it; it is the use of the steam of boiling water.'" Why was Solomon de Caus there? To keep his brain from mischief; he had actually suggested that carriages and ships could be propelled by steam!

In 1769, James Watt invented the first practical steam engine. He also was considered mad, but fortunately for posterity he was not locked up. In 1804 a locomotive guided by rails attained the speed of five miles an hour at Merthyr Tydvil, and ten years later George Stephenson, financed by Lord Ravensworth, to whom was originally applied the adage—"A fool and his money are soon parted," began work on the Killingworth Railway. He met with immediate obstruction, Lord Eldon saying, "I am sorry to find the intelligent people of the North country gone mad on the subject of railways."

Once the locomotive began to crawl, the sluice gates of abuse were opened, and its inventor met with obstruction at every turn. A meeting of Manchester ministers denounced the railway as being "contrary" to the law of God. Lord Derby drove the railway surveyors off his land, and Stephenson had to hire a prizefighter to carry his theodolite in order to prevent it being smashed to pieces. Pamphlets were written and newspapers hired to revile his work. I was declared that the railway would prevent cows grazing, hens laying, and would cause ladies to give premature birth to children at "sight of these things going forward at the rate of four and a half miles an hour."

Parliament supported the reactionaries; birds would be killed by the smoke, foxes would become extinct; horses would be useless and oats and hay unsaleable; country inns would be ruined; boilers would burst and blow passengers sky high, and finally, "the weight of the locomotive would prevent it moving."

The Committee of the House of Commons assembled on March 21, 1825, and the opposing counsel addressed these words to the great inventor:

"Suppose, now, one of these engines to be going along a railroad at the rate of nine or even ten miles an hour, and that a cow was to stray upon the line and get in the way of the engine; would not that, think you," asked the barrister, "be a very awkward circumstance?"

"Yes," replied George Stephenson, with his face in a humorous pucker, "very awkward indeed—*for the coo!*"

In 1914 was the tank conceived; in 1915 was it built; in 1916 was it first made use of; in 1917 did it fight for its existence, and in 1918, I go so far as to say, that without its existence we should not that year have won the war. In 1919, an experimental machine attained a speed of 20 miles an hour; and now, in 1920, is it still struggling against difficulties, for prejudice to things new dies hard and vested interest is a powerful adversary.

Whatever the tank has accomplished, it is still far from perfect, it is still in the Puffing Billy stage of 1822; Puffing Billy, which George Stephenson was wont to drive close by his brother's house and concerning which, when i stuck fast at a curve, he would shout out to his wife, "Hey! Jean, come oot, and gie us a shove around the turn!" Twenty years later we read, "On Saturday last the Leeds Express, formerly called the 'Sleepy Leeds,' which has been on the road upwards of a hundred years, ceased running it being no longer a profitable speculation."

The coach was dead, the railway had come into its own, a new and stupendous world was born, and through mechanicalizing civil movement, by replacing the horse by the steam engine, civilization has advanced more rapidly

Digitized by Google

during the last eighty years than she had advanced during the preceding eight thousand.

Here then is the gist of my lecture. What the locomotive has done for civilization will the internal combustion engine do for war. It opens up before us a new world of warfare stupendous in its possibilities. Let us inquire into it, an do not let us fall into a frenzy because possibly rifles and swords, bayonets and lances, horses and limbers may disappear, for even if they do, we may be perfectly sure that things more efficient will replace them.

Opposition to the Rifle.—I will now turn for a few minutes to what I will call the coaching period in the history of war, chiefly in order to obtain a background whereon to throw into relief the future tendencies of mechanical warfare.

In the 15th century gunpowder was considered useful for frightening horses, a century long argument then followed, concerning the bow and the musket, and many arguments were launched for the retention of the bow. The bow has, however, vanished, but not without a struggle, for as late as 1797 a certain Mr. Mason once again proposed to equip British infantry with it.

In 1742, Benjamin Robins in his "New Principles of Gunnery," made a remarkable prophecy as to the eventual adoption of the rifle, which, however, did not take place until a hundred years after his day; he says:

" . . . whatever State shall thoroughly comprehend the nature and advantage of rifled-barrel pieces, and having facilitated and completed their construction, shall introduce into their armies their general use, with a dexterity in the management of them, will by this means acquire a superiority which will almost equal anything that has been done at any time by the particular excellence of any one kind of arms, and will perhaps fall but little short of the wonderful effect which historians relate to have been formerly produced by the first invention of firearms."

1780, Major Patrick Ferguson invented a breech-loading rifle. He paid for its manufacture out of his own pocket and equipped his men with it so that they might meet, on equal terms, the American backwoodsmen. He then, unfortunately, went sick and Lord Cornwallis, the Commander in Chief, had the rifles withdrawn and destroyed.

In 1824 the British Government refused to accept Captain Norton's cylindro-conoidal bullet. It was reproduced by Captain Minie, of the French Army, in 1849. The Minie rifle became the weapon of the day, nevertheless, Sir William Napier strenuously opposed it, as in his opinion, it would destroy the infantry spirit by turning infantry into what he called "long-range assassins."

In 1858, Greener declared the "time and ingenuity spent in planning and constructing breech-loading cannon will always end in disappointment and failure," and again, that "striving to produce perfect breech-loading cannon is like striving to square the circle." Consequently the British Army did not permanently receive such a weapon until 1886. Even as late as 1895, when the *Victoria* went down with Admiral Tryon, some of her guns were still muzzle loaders.

In spite of opposition, the breech-loading rifle and field gun, which I will call the "military coach," for both depended on muscular movement, came into their own.

Phantom Wars.—In August, 1914, the finest muscularly organized body of troops ever raised by Great Britain left her shores. I was fortunate enough to see them all, and I can frankly say that in all my life I have never seen such a perfect force of men and horses as those which sailed for Zeebrugge and Ostend. The Duke of Teck himself told me that he had not a horse in his regiment under the value of 200 guineas. A fortnight later the 7th Division had almost ceased to exist. What had happened?

Many things, amongst which was one, to my mind the most important, which for long remained obscure. The war we had prepared for was a phantom, a will o' the wisp, which literally led us off the highway of progress into a "slough of despond."

What had we failed to realize? We had not realized this—that an Army to prosper must be based on the civil sciences, that an Army must keep pace with the progress of industry, and that an Army which does not do so is but a phantom force for war.

Irresistible Science.—Since 1842, when the "Sleepy Leeds" had run her last journey on the great north road, what had been happening in civil life? A mechanical evolution so rapid that no revolution in the whole world's history can compare to it. Every day brought to birth some new invention, every hour civilization gathered greater speed; epochs crumbled away, epochs sprang up in the night, science was sweeping brute force off the face of the earth, and was replacing muscle by mechanical energy.

In 1885, Gottlieb Daimler designed the first practical internal combustion motor. In 1896 the first motor car in England ran from London to Cambridge preceded by a man carrying a red flag. Parliamentary opposition was revived, humanity could not live with the road car, the roads would become unsafe, children would be run over, dogs and fowls exterminated, and carts overturned. The country gentleman got his back up, but the Rolls-Royce soon got it down.

In 1770 the first patent for a footed wheel was registered; in 1888 an agricultural tractor, almost the future tank, was designed; in 1907 a motor car on tracks attained the speed of 20 miles the hour on firm sand. In 1909, at the first flying machine meeting held at Rheims, General Grierson, an able soldier, watching an aeroplane, turned to General Stone and said: "I say, Stone, do you really think there is anything in it?" and General Stone's comment on this remark is worth recording: "That is only ten years ago, and it is a very striking fact that such a very short time ago as that some of the best brains in the Army thought that anybody who took up flying seriously was a little bit 'gone in the head.' I speak of what I know."

It is indeed easy to be wise after the event, but surely it is better to be thus wise than never to be wise at all. In 1914 the armies of Europe marched forth to fight Worth, Gravelotte, and Sedan over again; forty-four years of scientific progress had been neglected, and the bill—10,000,000 men killed and over £60,000,000,000 expended.

The Nature of the Great War.—Let us turn for a few minutes to the nature of the Great War. One of its most remarkable features was that it resembled the battle of Marathon (B. C. 490), for the greater portion of its duration the battle had no flanks. Why? Because the enormous size of armies enabled battle fronts of upwards of 500 miles to be held in strength, entrenched and wired. What had rendered this possible? The locomotive, the railway, and the steamship, the great mechanical movers of civil life. Soldiers had not considered them very deeply, then, when war was declared, they, like great funnels, poured forth men in cataracts. Immense tracts of country were inundated and for over three years, on the Western Front, armies lay opposite each other in stagnating puddles and slowly evaporated away.

We see a strange sight—millions of men facing each other, millions of men, the subsistence of which, prior to

Digitized by Google

battle, depended on every yard of rail and road behind them being utilized to the full. Lorries and locomotives worked day and night to supply this enormous muscular mass, to pile up the military coaches which, from time to time, were launched from their mechanical base into battle areas devoid of railways and all but devoid of roads. What do we then see? We see strings of pack mules and thousands of human carriers wallowing through the mud: in a single day the administrative needs of the Army have increased tenfold and the means of supplying these needs has retrogressed by several thousand years. This brings us to our first main problem in mechanical warfare, the problem of road capacity.

Road Capacity.—In August, 1915, a meter-gauge railway ran from Gezaincourt to Albert, and I suggested to an officer, quite an able man, that if a certain British Corps made use of it considerable economies could be effected. His answer was: "It can't be done, for if we use this railway we shall disorganize the whole of our lorry service!"

In the eighteenth century the squire who brought his wife to London sitting behind him on his cob, objected to the stage coach. In the nineteenth century he had accepted the stage coach and objected to the locomotive. In the twentieth he accepted the locomotive and fell foul of the motor car. And so, in 1915, we find an able officer objecting to the light railway. Why? Because of what I will call congenital prejudice, which can only see the means and not the end, and which, having made a hobby of the means, refuses to see the end.

In 1914 a few score of lorries formed the mechanical equipment of the British Army. In 1917 they had grown in number to about fifty thousand, hundreds of miles of new railways and thousands of miles of tramways covered the British fronts. For three years we had been fighting for road capacity, and behind our front line we had attained it, but in advance of it, it ceased to exist. Armies became like caged animals, they could move about in their own prisons at will and in perfect safety, but to escape from them was next to impossible.

I will take a few examples to illustrate this and will select them out of the events of the last year of the war, during which the bars of the cages had become somewhat more elastic.

(1) In March, 1918, the Germans advanced some 40 miles in 14 days and were then forced to halt. It was apparent that it was not the British Army which caused this halt, but the weakness of the German Army, due to the "Petering out" of its supply system. Road capacity in the Somme area was limited; want of road capacity, which might well have been foreseen, completely wrecked the last chance the Germans had of winning the war.

(2) In May, 1918, the Germans gained another overwhelming victory, this time over the French, the result of which was an advance of 30 miles in 4 days, and the formation of the Chateau Thierry Salient. As long as Soissons remained under gun fire and Rheims held out, road capacity, from the railway point of view, was to all intents and purposes non-existent. To remain in this salient without road capacity was to commit suicide. This is exactly what the Germans did.

(3) In August, 1918, we attacked eastwards of Amiens; behind us was an efficient railway system, in front of us good roads, which, during the battle, were never much damaged; nevertheless, our initial success, which was stupendous, rapidly "Petered out" after the first day's fighting. This was due to several reasons, one being the difficulty of maintaining the energy of the battle by supply, in other words, "road capacity" was insufficient to enable us to continue the advance, and would have been more difficult still had we attempted to force our way across the old Somme battlefield.

The lesson to be learnt from all this fighting, and probably the most important lesson to be learnt from the whole war, is "That the chances of victory or defeat are multiplied directly by any increase or decrease of road capacity in an area of operations, and that unless this road capacity be equal to the supply requirements of the attack, either the attackers must eventually die of starvation or the attack must be abandoned."

This problem may be viewed under two main headings:

(1) Means of cutting down the necessity of supply.
(2) Means of increasing the transportation of supply.

I do not intend to discuss the first beyond saying that the quicker an army can move, the less supplies, in the long run, will it require. As regards the second, it may be viewed under four subsidiary headings:

(*a*) Concentration of traffic.
(*b*) Additional road space.
(*c*) Additional roads.
(*d*) Dispensing with roads.

The first is gained by increasing the tonnage per road mile. The second by constructing vehicles which will move alongside a road over plough and grass land. The third by making use of badly metalled roads or by building new ones. The fourth by cross-country traction which will enable all normal country, plough and grass land, desert and scrub, to be crossed as easily as a lorry today will move along an average road.

Can such a machine be obtained? It can!

The Administrative Link.—What will the cross-country lorry accomplish? It will mechanically link up the strategical base of operation, which consists of a network of railways, with the battlefield itself. No longer will there occur that terrible hiatus between railheads and battle dumps. You won't dump, but you will move. As the battle starts, so will it be continued, there will no longer be an exchange of supply horses in midstream. Right through the Great War this problem remained all but unrealized, and only towards the end was any notice taken of it, and yet on its solution depended the dividend of every attack.

Often was the question asked: "What happens when a penetration has been effected?" The answer is: "Push up supplies"—supplies of men, weapons, munitions, and food; the side which can do this the most quickly is the side which is most likely to win.

The Tactical Link.—Given a mechanical strategical base and a mechanical supply system, logically, the next link to forge is a mechanical tactical striking force. In other words, to cease hauling up to the front innumerable military coaches by means of mechanical power, as the old four-decker sailing ships were towed into position opposite Sebastopol and towed away again after an engagement, but instead to replace the coach by a military motor car and so render the whole army from start to finish a mechanical one.

The necessity of this was realized early in the war by a few farseeing men, and the result was the tank—a cross-country battery which, protected by armour, was enabled to make use of protected mobility for offensive ends.

The idea of protected mobility caused much mirth; one noted officer requested Colonel Swinton to abandon his "flights of imagination and come down to solid facts;" another, when he was informed that his troops were to be led

Digitized by Google

by tanks through the Cambrai wire, exclaimed, "fantastic! fantastic!" The press correspondents filled the newspapers with "slimy monsters and Gargantuan toads," but what was worse, a passive and effective barrier of obstructions was raised against all efforts of the Tank Corps to expand.

A bad second to the obstructor was the amateur enthusiast, who, knowing nothing about tanks, expected them to perform miracles.

I am not going to plan for you a mechanical army, nor picture to you some imaginary Armageddon of 40 years hence. In place I am going to glance at our present military problem and point out to you how cross-country traction will help us to solve it.

If I can walk from Chatham to London, a distance of thirty-five miles, in twelve hours and you can motor t London in two hours, when reducing space to terms of time you will find that you have decreased the area to one-sixth of the size it appears to be to me. [The Colonel means one thirty-sixth.—Ed.]

A moment's thought will enable you to realize how cross-country traction can decrease the area of the combat zone.

As regards the machine required, it must be adapted to the nature of the country in which it may be used. The great, lumbering tank, suitable for flat country, must be supplemented by a lighter machine which will serve for the protection of supply columns in hill warfare and which will have the large radius of action necessary in desert warfare. A light, cross-country chassis which can be fitted with either a lorry body, an armoured car body, or a tank body and which, as a lorry, can carry either five tons of supplies or water, or a field gun and 200 rounds, is the type of machine I think we require for this purpose. Its cost complete would probably be well under £3,000.

Co-operation with the Navy.—Some years ago Sir Edward Grey made use of the following pregnant phrase: "The British Army should be a projectile to be fired by the British Navy." If we consider for a moment the meaning of these words we shall realize what an enormous economy could be effected in our small wars if it were literally possible to shoot armies on to coast lines when punitive expeditions become necessary.

There is only one real difficulty in a combined naval and military operation—namely, ships cannot swim out of the sea and walk on land. Because of this inability parties of soldiers have to be landed in lighters, rowing boats, pinnaces, barges, motor boats, and what nots, and in half an hour the beach is like Epsom Downs on a Derby morning.

It is the old difficulty of launching military coaches from a mechanical base, steamships in the present case replacing railways. If now, instead, from these ships floatable tanks and tractors be launched into the sea two miles from the coast line and are able to propel themselves ashore and crawl up the beach and move straight inland, confusion can be replaced by simplicity and surprise. It is so simple that people will not see it, and I have been voted to Bedlam on several occasions for suggesting it, but I am not there yet. In a couple of years from today, I see no reason why such a mechanical force should not operate 1,000 miles from its naval base even in desert land.

Co-operation with the Air Force.—Punitive expeditions may, however, be required at greater distances than 1,000 miles from a naval base, how are we then to proceed? As from our battleships we launched our tanks and tractors, so from these should we now launch our aeroplanes, which should have no difficulty in extending our military influence over another 1,000 miles, that is 2,000 miles in all from the sea coast. The tanks will protect the landing grounds of the aeroplanes and the aeroplanes will carry supplies for the tanks.

Though I do not want once again to be voted to Bedlam or to share the fate of Solomon de Caus, nevertheless, as ships can carry tanks and tractors, I see no insuperable difficulty in aeroplanes doing the same, for machines weighing not more than 6 tons. Recently I have read a prophetic account of the next war written by a Belgian. He suggests carrying half a million men through the air. But why carry men? For at best we shall be depositing but military saddle horses (not even coaches) in our enemy's country. The "Sleepy Leeds" ceased to run because it was "no longer a profitable speculation." Masses of men do not pay, a few efficient machines do. If your strategy is based on mechanical power so must your supply system be and so must your tactics. This brings us to yet one more consideration.

Conclusion.—The soldier of the present must cease thinking purely in terms of land operations, for he must think in terms of sea and air warfare as well. Today, warfare at sea and in the air is purely mechanical, on land it is still nine-tenths muscular. We cannot get unity of action until we have instituted unity of movement, in other words, until our present muscular army has become a mechanical one.

Feasibility of Air Mapping Tested at Washington

To prove further the reliability and the utility of maps made from the air, representatives of the Rand-McNally Co., in co-operation with the Army Air Service, are making detailed maps of the immediate vicinity of Washington. On the success of this venture will depend certain projected larger ventures in map making from the air.—*Eng. News-Record.*

Dredging Tests of the Dredge "Raritan"

Discussion

H. N. Babcock
U. S. Assistant Engineer

Continued from Page 107

The comparative tests of the *Raritan's* two pumps from April 17 to April 25, 1916, are clouded by a suspicion of some obstruction in the suction pipe. During that period, only, the new pump was doing less work with 20-inch suction pipe than the old one had done. Immediately thereafter work was suspended on account of strikes and of the near exhaustion of funds, and the dredge was laid up for general repairs. When dredging was resumed, the new pump was again doing the better work and the nature of the obstruction has not been ascertained.

The 24-inch suction pipe with corresponding drag and with 24 to 20 inch reducing elbow was discontinued after wearing out, because:

(*a*) It cost much more.

(*b*) Unless all of the 20-inch pumps were so equipped, a larger assortment of spare parts would be required.

(*c*) And especially because their weight taxed the capacity of the hoisting engines too far.

The runner of the new (D-W) pump had six vanes, and proved more liable than did the old pump, with five vanes, to choking at the entrance, the result of picking up pieces of piling, fenders, or other small timbers which are common in New York Harbor.

In further pumps of this type for New York Harbor use it is designed to reduce the number of vanes to five.

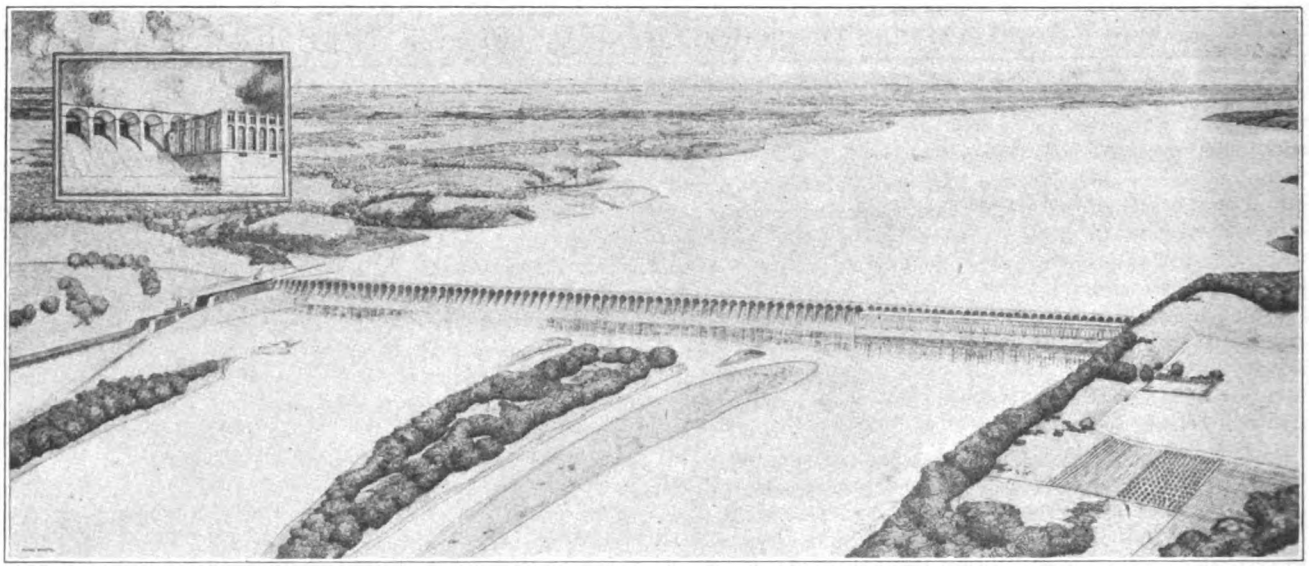

Fig. 1. Sketch showing Wilson Dam as it will appear when completed. Detail of power house and roadway in insert

Notes on the Construction of the Wilson Dam

By

Lt. Col. W. C. Weeks and Maj. S. C. Godfrey

Corps of Engineers

MUSCLE SHOALS. Since the first white settlers came down the Tennessee River, the Muscle Shoals have been recognized as the most formidable obstacle to the navigation of that river. Extending for about thirty-seven miles upstream from Florence, Ala., the resistant strata of flint limestone, which form the bed of the stream, have prevented the river from cutting into the softer strata below, and caused it to spread out into a wide and shallow river, racing swiftly over a series of rocky steps, with low-water depths of only a few inches in places. The total drop in this section is 134 feet; the slope is as great as 15 feet per mile, and velocities exceeding 10 miles per hour have been measured. The river is from one to two miles in width, and contains many islands, for the most part covered with timber. The discharge varies, roughly, between 7,200 and 500,000 cubic feet per second. The banks are generally high and steep, the rocky cliffs towering in many places a hundred feet sheer above the river.

Early Improvements to Navigation. The first effort to surmount this barrier to navigation was undertaken by the State of Alabama, and a canal which paralleled a part of the shoals was completed in 1834. This was unsatisfactory, however, and soon became obsolete. In 1871 a more ambitious project for the improvement of this section was authorized by Congress. This involved the construction of two lateral canals, at the Big Muscle and the Elk River Shoals, with a total of 11 locks, 57 by 275 to 284 feet in size, and a navigable depth of approximately 5 feet. The remaining shoals were to be improved by the contraction of the low-water channel and by rock excavation. This project was completed in 1890, and while it did not provide continuous navigation past the entire Muscle Shoals section, it did place this section in a navigable condition substantially as good as at the principal shoals above and below.

Water-power Projects. The combination of steep slope, high banks and great volume of water at this section of the river make it a favorable location for a large power dam or dams. This fact has long been recognized and numerous examinations and surveys have been made under Congressional authorization with a view to securing development of water power in connection with improvement of navigation through the joint action of private agencies and the Government. An exhaustive report, published in Committee Document No. 20, 63d Congress, 2d Session, contained a favorable recommendation for such an improvement at an estimated cost of $18,701,000, of which approximately $8,575,000 was considered as representing the value of the improvement to navigation, the remainder being chargeable to power development and to be reimbursed to the United States. A report published in H. Doc. No. 1262, 64th Congress, 1st Session, gave the results of a later survey made for the purpose of final selection of sites and the making of detailed estimates of cost. This report increased the estimate of cost to $19,000,000. This report was also favorable, but called attention to the provision contained in Section 124 of the Act to increase the efficiency of the military establishment of the United States, approved June 3, 1916, respecting the establishment of nitrate plants to supply Government needs in the manufacture of explosives for military uses, and in view of this legislation recommended that action on a proposed contract with the Muscle Shoals Hydro-Electric Power Company for undertaking the work be suspended until it had been determined whether the power would be utilized for such a nitrate plant.

The Nitrate Plants. During the war, Nitrate Plant No. 1,

Digitized by Google

and later, Nitrate Plant No. 2 were constructed in this vicinity. Plant No. 2, which utilizes the cyanamid process of manufacturing ammonium nitrate, was in successful operation at the time of the armistice. The construction of the Wilson Dam (Dam No. 2 of the complete project) was directed in a letter from the President on February 23, 1918, under authority of the National Defense Act above referred to. The money hitherto allotted for its construction—a total of some $17,385,000 to date—comprises the bulk of the original twenty millions appropriated for a nitrate plant and appurtenances. The Dam is to provide for the generation of electrical power for the production of nitrates or other products needed for munitions of war and useful in the manufacture of fertilizers and other products. It will also insure a minimum navigable depth

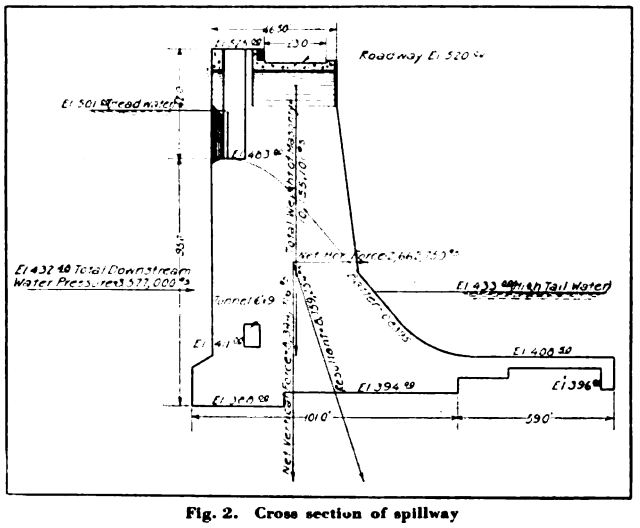

Fig. 2. Cross section of spillway

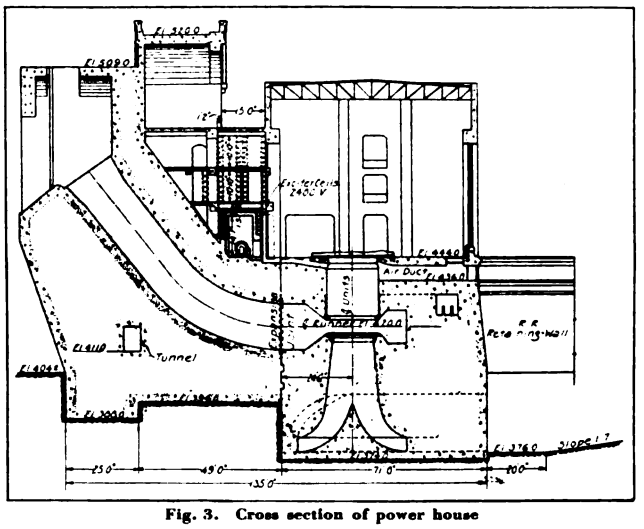

Fig. 3. Cross section of power house

of 9½ feet for a distance of 15 miles upstream—to the proposed site of Dam No. 3, another combined power and navigation dam about 50 feet high. The plans for Dam No. 1, for navigation only, contemplate a small structure across the channel two miles below the Wilson Dam.

The dam may be divided into three typical sections, the lock section on the north or right bank of the river, and the spillway and power-house sections, both founded on the river bed. All three sections support an ornamental mass concrete arch highway bridge having a 23-foot roadway, running without change in grade or alignment from bank to bank of the river at an elevation 19 feet above that of the upper pool.

Fig. 1 shows a general view. The length of the spillway section is 2,890 feet.

The entire structure—lock, spillway and powerhouse—is founded on solid rock, a hard, flinty limestone locally termed Lauderdale chert. The upper layers of the chert are separated by thin mud seams; below these, occasional thin, open seams are encountered, but they are of limited extent and easily closed by grouting. The great number of borings made at and near the dam site gives accurate information as to the character of the foundation two hundred feet below the bed of the river. Rock excavation during construction has disclosed nothing new. All foundations are carried down below any mud seam, and all open seams are grouted to refusal through two rows of closely spaced holes under a pressure 10 per cent less than the weight of the rock above the seal of the grout pipe before any concrete is placed. The rock is hard to drill, but breaks into fragments convenient for loading with steam shovels.

The lock section comprises a cutoff wall running into the north bank from the north lock wall, two locks, and a non-overflow dam, 156 feet long, extending from the south lock wall to the spillway section. The highway crosses the upper lock by means of a bascule bridge, the details of which are not yet complete. The locks are largely in solid rock excavation, and are of the usual design, with chambers 60 feet wide by 350 feet long, and a minimum depth over miter sills of 7½ feet. Both lifts are about 46 feet. The lock gates are the usual miter type, and a double installation is provided for each lift to care for emergencies; in addition, an emergency dam is provided above the upper pair of gates.

The spillway section is 2,890 feet long and is divided by the piers that support the highway bridge into sixty-three 38-foot openings, controlled by vertical sliding steel gates 18 feet high. These gates will pass without appreciable rise of upper pool level a flood 75 per cent greater than the highest ever known. The design of the spillway (Fig. 2) is very substantial, and under the most adverse assumptions, the resultant of pressure passes through the base of the dam at about its middle point. Calculations for stability do not include the apron section. The weight of the masonry is assumed to be 145 pounds per cubic foot. The ratio against the dam sliding on its base is as 1 to 2.29, and against overturning as 1 to 4.16.

The upper pool will be maintained at a constant elevation of 501, and the parabola of the spillway crest is designed to fully support a jet of water issuing beneath a gate under an 18-foot head. The downstream batter, 0.84, merges into the horizontal of the apron by a curve of 40-foot radius. The apron is from 4 to 9 feet thick, 59 feet wide and solidly anchored into the rock by up and down stream trenches. The heel trench is carried down below the base of the dam so as to give a minimum breast wall of 5 feet without any seams. It is 35 feet wide up to the level of the river bed, elevation 404, from which plane it slopes upward to the face of the spillway.

An inspection tunnel, 6 feet by 9 feet, runs straight through the spillway and powerhouse sections. The concrete is brought up to the elevation of the tunnel floor, 411 feet, and 6-inch drill holes at 23-foot centers are sunk through the tunnel floor before the tunnel is formed, to a level 35 feet below the bottom of the heel trench. (See Fig. 7.) These holes are intended to relieve any uplift pressure, and provision is made by a system of valves to

Digitized by Google

cut off or to discharge any leakage through pipes concreted in the dam section at tunnel floor level.

The 63 sliding gates on the crest of the spillway, each 18 feet by 38 feet, are counterweighted by steel tanks operating in steel displacement chambers, one counterweight to each end of each gate. The displacement chambers extend from the level of the upstream parapet wall of the bridge to the inspection tunnel floor level. Provision is made to connect the bottoms of the displacement chambers with head and tail water through the system of valves by which the gates will be operated.

The powerhouse section, 1,221 feet long, is shown in Fig. 3 in cross-section. The heel trench is reduced to a width of 25 feet, and the power house occupies the space corresponding to the apron on the spillway section. The present installation in the powerhouse will be 4 vertical, 30,000 H. P. turbines, running 100 r. p. m., direct connected to 25,000 K. V. A. 12-000-volt generators, and one 1,000 H. P. vertical turbine, direct connected exciter, all units spaced 55½ feet on centers, and served by the usual crane arrangement. Ultimately 14 additional units, probably with 36,000 H. P. turbines, will be installed. The head on the turbines varies from 68 to 93 feet.

The roadway over the powerhouse section is identical in line and grade with that over the spillway, but the arch span is increased to 47½ feet to conform to the unit spacing. Beneath the roadway and toward the powerhouse, the space is utilized for the installation of oil switches and other electrical devices; upstream from the roadway, the piers are extended to provide the necessary support for the gates controlling the admission of water to the penstocks. The three heavily reinforced, rectangular penstocks, each 12 feet 4 inches wide by 15 feet 10 inches high, serving each main unit, descend from the rack chamber at an angle of 45 degrees and, curving to the horizontal on a 50-foot radius, merge into the scroll case moulded in the concrete around the speed ring. From the runner the water descends through the draft tube, 14 feet 3 inches diameter, and expands by easy stages over a concrete cone into two horizontal exits, each about 20 feet square, the tops of which are 2½ feet below extreme low water. From the base of these exits the rock of the river bed is excavated horizontally for 20 feet, then on a rising slope of 1 on 7 to the original river bed.

Construction methods

Seven areas along the dam site are enclosed or are to be enclosed by cofferdams. These dams are rock-filled cribs, 14 to 16 feet square, sheeted next the sealing material with scrap lumber and sealed with clay and earth. For the dam, the upstream coffers consist of a single row of cribs with the sealing material dumped on the upstream side. The river arms and downstream cofferdams are built of two rows of 16-foot rock-filled cribs, 16 feet apart, with the sealing material dumped between. The powerhouse cofferdam consists throughout of two rows of 14-foot cribs with a 20-foot puddle wall between. (See Fig. 8.) This construction provides for a minimum of damage when the cofferdams are topped by floods. In most places the original dams have been greatly strengthened by waste rock excavation. The leakage into the enclosed areas, even that of the powerhouse, over 12 acres in extent, is almost negligible.

The salient features of the method of construction are undoubtedly the concrete and steel girder, 4-track, construction bridge and the full circle, 10-ton, traveling cranes. The concrete piers supporting the girders were founded on the bedrock of the river, without unwatering the forms, on the lower portion of the apron of the dam. Where the apron has been built, the rock has been excavated from 3 to 6 feet below the bottom of the concrete piers. The piers and rock footings are enclosed by forms, and when the construction bridge is no longer needed the pier and rock will be removed and the dovetail cavity filled with concrete.

The tracks supported by the construction bridge and elsewhere throughout the work are standard gauge.

The seven traveling cranes for the dam proper run on girders resting on the upstream end of the construction-bridge piers, and on concrete piers so located as to be entirely submerged in the concrete of the dam. (See Fig. 4.) The 75-foot booms of these cranes span all four construction tracks and the base of the dam, and barely reach the floor of the highway bridge. In the powerhouse section, three traveling, full-circle cranes, with 118-foot booms, are installed, two above the line of the spillway and one below the powerhouse. (See Fig. 8.)

Three mixing plants supply concrete. One on the north shore is equipped with two 2-yard Smith mixers; that on the south shore has two 2-yard Lakewood mixers, and that on Jackson Island has two 4-yard Smith mixers. All mixers operate under material bunkers, from which charging is done by gravity. The mixed concrete—approximately 1-2¼-5—is conveyed in 2 and 4 yard buckets on flat cars to the cranes. Large cement sheds at each mixing plant provide ample storage, from which the cement, after testing, is carried to the mixer bunkers by conveying belts.

A rock-crushing plant is located at the Jackson Island mixer, consisting of a 48-inch gyratory breaker and a battery of six 14-inch gyratory crushers, two of which take care of the oversize from the revolving screens. The elevator from the 48-inch crusher passes its product over a grizzley, the rejects from which drop to the 14-inch machines. The product of the small crushers and the grizzley is elevated to revolving screens above the bins by means of an elevator, so arranged that it will also elevate gravel from the storage pile. Sand is placed in the sand bins by means of steam-operated guy derricks.

Gravel and sand are obtained from a dredging plant located at Buck Island, 9 miles below the town of Florence. Two 15-foot hydraulic dredges elevate their output 28 feet to revolving screens mounted on a scow; from the screens the sand and gravel are spouted by gravity to scows moored alongside. These sand and gravel scows hold from 200 to 600 cubic yards, and are towed to the dock at Florence by stern-wheel river boats. The material is unloaded into bunkers by two electrically operated gantry cranes, each having a 4-yard grab bucket. The sand and gravel is drawn off through bottom gates into 20-yard air-dump cars and hauled to the mixing plants at the dam.

The general plan of stream control at Wilson Dam is to enclose an area of the spillway section by a cofferdam and bring the concrete to elevation 411, 7 feet above the river bed. (See Fig. 5.) From this elevation certain sections of the dam, including the arch bridge, are completed. In other sections, corresponding to the river channel, 12-foot piers for sections of the dam, including the arch bridge, are raised above elevation 411, leaving alternate 30 and 38 foot openings, through which the river discharges. When the remainder of the structure is finished, the forty-two openings will be raised by successive 6-foot lifts to the crest of the spillway.

Progress of the work

The first steps toward the actual construction of the Wilson Dam were taken in 1918. During the spring of

that year a small force was assembled and the preliminary work of constructing a camp and assembling plant commenced. In the fall of the year, however, all work was suspended on account of the pressure of other war activities, and from August 20, 1918, till the resumption of work on November 9, 1918, nothing was done.

During 1919 more substantial progress was made. A commodious construction camp was erected; the first cofferdam was completed and pumped out (September 1, 1919); the construction bridge was 50 per cent completed; the railroad lines, yards, shops and warehouses largely finished; and the greater part of the plant assembled. Coincident with the commencing of rock excavation in the unwatered cofferdam, preliminary earth excavation was undertaken on Jackson Island, midway along the axis of the Dam. This central section was subsequently inclosed on both flanks by cofferdams 3 and 4. No work was done on the south side of the Tennessee until the fall of 1919, when a separately organized construction division commenced operations on the powerhouse section of the dam.

During the spring of 1920 the work of excavating in the first two coffers and of constructing the powerhouse coffer was pushed vigorously. The construction bridge was put into service, and the ten big travelling tower derricks erected. Meanwhile the plant for the sand and gravel operations had been assembled at Buck Island, and the first dredged concrete materials were available in time for the first permanent concrete poured. On May 7 the first section of the apron of the dam was commenced, inside the Jackson Island cofferdam.

The procurement of cement in adequate quantity became a serious problem at this time. Little or none could be purchased from southern mills, and although cement was available at more distant points, the railroads would not undertake to move it. The problem was finally solved by the purchase of 75 rebuilt box cars, which were devoted exclusively to the cement service between the mills and the dam, and which furnished almost the sole dependence up to the fall of 1920, transporting over 100,000 barrels of cement.

During the summer and early fall the pouring of the apron was continued, while the rock excavation for the main section of the dam was being carried deeper into seamless rock. This concrete was mixed in the north-side mixing plant, with its two 2-yard mixers. Meanwhile the big Jackson Island plant was being completed. The destruction of the latter plant by fire on July 5, together with the adjacent cement shed and crushing plant, threatened to be a serious blow to the progress of the work; its complete rebuilding in three months was a conspicuous achievement, and no material delay was caused.

Modifications in the original design for the dam had necessitated additional rock excavation, postponing until September 29 the pouring of the main sections of the spillway. On that date the preparatory period may fairly be said to have ended. The average daily yardage of concrete poured jumped from about 100 to about 1,300 cubic yards. Operations have gone forward without sensible interruption since that time. Up to February 1, 1921, there had been no stages of the river high enough to interfere seriously with progress. To that date Construction Division No. 1 had placed 148,922 cubic yards of concrete, which is approximately 12 per cent of the total volume of masonry in the entire work.

One section of the powerhouse cofferdam was completed and pumped out in May, 1920, but the entire cofferdam was not unwatered until August. Since that time rapid progress has been made on the great amount of rock excavation necessary for the draft tubes and tail race, and over 100,000 cubic yards, about one-third the total, has been taken out. (See Fig. 8.) The first concrete in the powerhouse section was mixed at the south-side mixing plant and poured on February 1, 1921.

At the locks a large amount of preliminary earth excavation was handled by steam shovel before the side of the upper lock chamber was uncovered. Rock excavation for this chamber is now well advanced.

The Camp. The construction camp at the north end of the dam is a small city of 3,000 inhabitants. The buildings include 107 bunkhouses, 14 mess halls, 230 family residences (30 "permanent" and 200 "temporary"), 2 dormitories, 2 recreation halls, 2 hospitals, and moving-picture shows and poolrooms (run by concessions, together with a store). (See Fig. 6.) Excellent meals are furnished employees at a rate of 75 cents a day, or $20.00 a month. A sewage disposal plant and complete sewer system have been installed, and a refrigerating plant provides for cold storage.

The Wilson Dam Chapter of the American Red Cross was granted its charter on April 3, 1920. It is the officially recognized organization for relief and welfare work on the reservation. Among other activities, it has built and equipped a playground, and maintains a supervisor for it.

The total number of employees is about 4,200, a considerable part of whom live in other smaller camps and in the neighboring towns.

Depletion of timber resources in the United States

The outstanding facts of a recent report from the Forest Service of the Department of Agriculture are that three-fourths of the original timber of the United States is gone, and that we are using timber four times as fast as we are growing it. The forests remaining are so localized as greatly to reduce their national utility. The bulk of the population of manufacturing industries is dependent upon distant supplies of timber as a result of the depletion of the principal forest areas east of the Great Plains. The depletion of timber is not the sole cause of the recent high prices of forest products, but it is an important contributing cause whose effect will increase steadily as depletion continues.

The fundamental problem today, according to the bulletin, is to increase production of timber by stopping forest devastation. At one time the virgin forests of the United States covered 822,000,000 acres. They are now shrunk to one-sixth that area. All classes of forest land now aggregate 463,000,000 acres. Of the land remaining not utilized for farming, approximately 81,000,000 acres have been so severely cut and burned as to become an unproductive waste. New timber remaining in the United States is estimated roughly at 2,215 billion board feet, three-fourths of which is in virgin forest; the rest is second growth of relatively inferior quality. About one-half the timber left is in the three Pacific Coast states, and over 61 per cent is west of the Great Plains. A little over one-fifth of the timber left in this country, or 460 billion board feet, is hard wood. There is now consumed or destroyed annually 56 billion board feet of material of saw timber size. The total yearly consumption of all classes of timber is about 26 billion cubic feet, and the depleted forests are growing less than one-fourth of this amount.

Pipe Lines of U.S. Dredges "Multnomah" and "Wahkiakum"

Operating on the Columbia River below Portland, Oregon

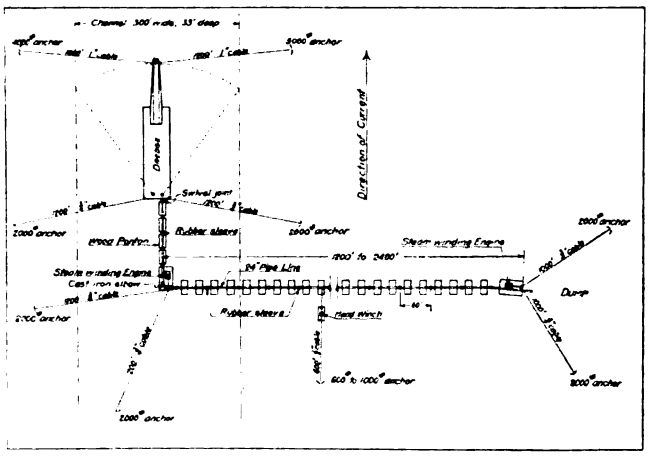
By

R. E. Hickson

U. S. Assistant Engineer

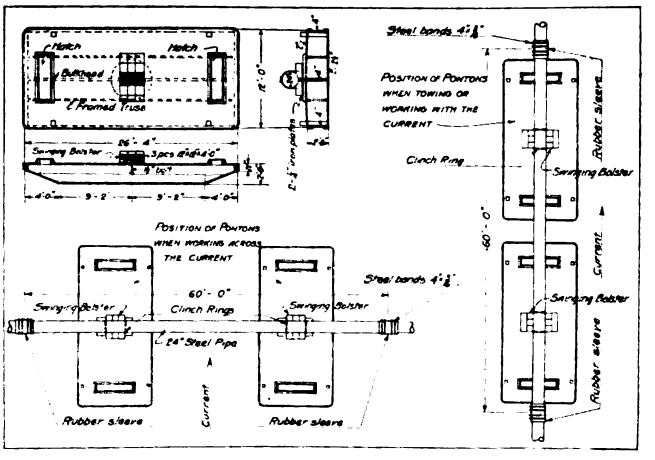
THE floating pipe lines of the dredges *Multnomah* and *Wahkiakum* average about 1,800 feet in length. They are made up of 60-foot lengths of 24-inch lap-welded steel pipe, supported on wooden pontons and connected with rubber sleeves in the usual manner.

It is the object of this article to discuss the methods of assembling and handling these pipe lines; the apparent advantages of the wooden pontons and rubber sleeves used; and the relative cost of this plant compared with steel equipment.



Sixty-foot lengths of pipe are used in order to reduce the number of sleeves, and for the reason that longer lengths supported on two pontons, one at each of the quarter points, make a steadier line without any vertical angles and give much better horizontal alignment, than shorter lengths each supported on a single ponton, as often used In general, the sections of pipe should be as long as practicable consistent with ease in handling and size and number of pontons necessary for their support.

No rivets are used in construction of the pipe, as these, even with countersunk heads, cause excessive wear at some points, and eventually will cause leaks and perhaps scrapping of the pipe before it has served the life possible if the wear were evenly distributed. The pipes are turned through about 120 degrees every four or five months of service in order to distribute the wear. The end bands on the pipe used to hold the sleeves are bored to the outside diameter of the pipe for a depth of one inch. They are slipped over the pipe and spot welded on the outside. The band is three inches wide and accordingly extends two inches beyond the end of the pipe, protecting the end of same until the outer two inches of the band has been worn away. The band is then cut off and a new one placed on the pipe. These ¼-inch pipes will last about six or seven seasons, or about 1,400 to 1,600 working days of 24 hours in the sand encountered in the Columbia River. The elbow used at the angle in the pipe line is made of cast iron with flanged ends, which are bolted to the adjacent sections of pipe, also fitted with flanges. Generally two 45° ells are bolted together to make a 90°, and these are generally taken from the interior of the dredge where they have served their safe life for hull piping. No new elbows are now bought for the ponton pipe line.



The pontons used to support the pipe are built of Douglas fir lumber. They are little deck barges, 12 by 26 by 2½ feet, as shown in the accompanying picture and drawings. They are submerged about 13 inches with the pipe empty and 17 inches with the pipe full. The gunwale strakes and bulkhead are 4 inches thick, deck 2 inches, and bottom 2½ inches. Hatches are provided at each end to allow air to circulate through the ponton during fine weather, and canvas covers are used over these in stormy weather. In the center of the ponton is a swinging center or bolster, consisting of three pieces of 12 by 12 inch timber, 4 feet long, bolted together, and cut out to a depth of 6 inches in a cylindrical recess to receive the 24-inch pipe. A 1½-inch king pin passes through the center of this bolster and down into the longitudinal bulkhead below deck. A ¼-inch steel plate is fastened on the bottom of the bolster and a similar plate on a raised bed on the deck of the ponton. These plates take the wear and reduce the friction between the swinging bolster and the bed on the deck. The pipe rests only on this bolster, and is fastened to it by means of two sets of curved straps ½ by 2 inches, one set at each end of the bolster, connected and tightened with bolts at the top of the pipe. The ponton itself is free to be swung under the pipe into any position that may be desired. A walk and handline are fastened to the top of the pipe to aid men in walking the line during rough weather.

In operation, these pipe lines are generally set up across the current and the pontons are set at right angles to the pipe line. If it is necessary to lay the pipe at any other angle with the current, the pontons are swung accordingly, and at times it may be necessary, in order to relieve the side pull on the dredge or anchor scow, to "cut" the pontons slightly into the current when they will act like the rudder boards on a shear boom, and thus place the greater strain on the anchor lines at the end of the pipe. When the pipe line is towed any distance, especially up stream, it is absolutely necessary that the pontons be lined up with the pipe as the surface velocities of the Columbia River vary from about 3 to 5 feet per second, and it will be understood how difficult it would be to tow 1,500 to 2,000 feet of pipe line against this current with all the pontons connected rigidly at right angles to the pipe, and if connected longitudinally, as is done with some dredges, it would be impracticable to hold the pipe line across the current when set up for operation. The bolster or swivel type of ponton overcomes these difficulties admirably. The pipe line is held in place when in operation by means of anchors, two of which weighing 2,000 pounds each are placed beyond the end of the pipe line and are connected to a winding engine on a 22 by 56-foot scow supporting the last length of pipe. Dead men on shore are often used instead of the anchors. At the elbow in the pipe line near the dredge two anchors are also connected. These two sets of anchors pulling in nearly opposite directions hold the pipe line in position. One or more smaller anchors are also used, when necessary, with hand winches to hold up the sag in the middle of the line. These winches are mounted on independent pontons, which can be shifted to any point in the line without disturbing the main pipe-line connections. Between the elbow in the pipe line and the dredge two lengths of pipe are generally used.

General layout of pipe-line and anchors, dredges "Multnomah" and "Wahkiakum"

Plan of ponton and pipe-line assembly, dredges "Multnomah" and "Wahkiakum"

By using the anchors at the elbow in the pipe, nearly all the pull of the floating line is taken off of the dredge and much more satisfactory operation on channel work is possible than when the long pipe line leads directly from the dredge. Steam for the winding engines connected with the anchors is furnished by an upright boiler of 35 horsepower on each of the scows. Slab or block wood is used as fuel for these boilers. The main anchor lines are ¾-inch cables, 1,000 to 1,200 feet in length. The lines to the smaller anchors and hand winches are ½-inch cables about 600 feet in length. As the work progresses the anchor lines are gradually paid out and a tug equipped with a steam winch and derrick is used to shift the anchors. This is generally done once each day. When deep-draft steamers pass, the dredge is swung out to the edge of the cut and the anchor lines crossing the channel are slacked off and drop to the bottom while the steamer is passing. When the vessel has safely passed over the cables, the "donkey man" on the anchor scow hauls in the slack of the cable, and again tightens the pipe line into its proper position. The anchor lines at the end of the pipe line are generally not disturbed during the passing of a steamer, as the end of the pipe may be in shallow water or up against a bank or dump, and cannot be moved any farther away from the channel. The drawing herewith will show the general lay out of the dredge, pipe line and anchors when set up for operation.

It has been observed that dredges are often operated with only small anchors holding the pipe in position, and that the pipe line is often quite slack. This results in excessive wear on rubber sleeves through the bumping or chafing of ends of the various sections of pipe and buckling of the sleeves. A large part of this trouble can be avoided by providing winding engines of sufficient power at the end of the pipe line to keep the slack out of the line. With lines over 1,000 feet in length operating where there is any wind or current, good winding engines and heavy anchors are almost indispensable. In addition to saving rubber sleeves, a tight, straight pipe line offers less resistance to pumping than a slack line with numerous angles and sleeves buckled up to restrict the flow.

Rubber sleeves are used every 60 feet throughout the pipe line. These sleeves are 36 inches long and 25½ inches inside diameter. They are now manufactured under standard specifications of the Engineer Department for Class "A" sleeves. It is believed that for work on the Columbia River ship channel, rubber dredging sleeves are more satisfactory and economical than steel, ball joints or so-called flexible joints. Between the dredge and the elbow in the pipe line, flexible steel joints might be used to advantage, as this part of the line is generally straight and not subject to kinking. Beyond the elbow however, where the pipe line leads across the current, kinking or buckling of the pipe line at some of the joints is at times unavoidable. Angles of 45 degrees or more sometimes occur when the anchor cable stretching the line has to be dropped for a steamer to pass, or if it should be cut, or if the anchor drags slightly when working in very swift water, or heavy wind. A rubber sleeve will allow such a deflection without failure, while 15 to 20 per cent is about the limit of deflection for steel joints. A greater deflection than that for which a steel joint is designed results in a breaking of the joint or crumpling of the pipe. In the matter of cost it is also believed that the rubber sleeves have the advantage, as will be shown. Since 1914, when the dredges *Multnomah* and *Wahkiakum* were placed in commission, the average life of dredging sleeves has been 245 working days of 24 hours. The maximum life has been 739, and minimum 88 days. Some sleeves, broken through wrecks or unusual causes, have been eliminated from the averages. It has been found from the sleeve records of the dredges that the average life of the sleeves has been greater during the last two or three years than in the earlier periods of operation; for while the average life of all sleeves for both dredges has been 245 working days, the sleeves renewed during the last fiscal year had an average life of 272 days on the *Multnomah* and 365 days on the *Wahkiakum*. Two sleeves not included in the above averages were replaced on the *Wahkiakum* during the month of August, after serving 467 and 470 days, respectively. Both sleeves broke during a storm on account of kinks in the pipe line. The added life in the later records may be due to better quality of sleeves, but it is believed should be attributed also to the use of rope "mats" or "jackets," which have in recent years been placed around each sleeve, while in service, to take the strain from excessive pressures and prevent to a great extent the bulging of the sleeves, which often causes a rupture of the inner tube near the points where the pipes end. The "jackets" were installed first on the *Wahkiakum*, which it is believed accounts for the greater average life of the sleeves on that dredge.

These "jackets" are made up of 1-inch manila rope, woven in the form of a mat or net with length of meshes about 12 inches, the meshes being fastened with a seizing of marlin (9 turns) instead of being knotted as in a net. The "jacket" is about 6 feet long, and when placed around the sleeve the two ends are laced together. When the rope stretches, this lacing can be tightened up at any time the

Digitized by Google

dredge is not pumping. About 100 feet of rope is required to make a "jacket" for a 24-inch sleeve. The estimated cost is about $8.00 or $9.00 for materials and about 4 hours' time for one man, for which no charge should be made, as it is all in the day's work. It is believed that this device adds 25 to 50 percent to the life of the sleeves, although this would be difficult to prove. Use of the "jackets" is also advantageous in reducing the loss of head in the pipe line caused by enlargement of the pipe section at the joints. The picture shows one of these "jackets" in position. The sleeves purchased recently under the standard specifications of the department have not yet been in service a sufficient length of time to determine their life, but it is expected this will be considerably greater than the average of those previously used on account of the high tensile strength of duck and rubber now called for under the standard specifications.

The proper length of sleeve to use with a given diameter of pipe is a question which has not been definitely settled, but must probably be determined by the conditions to be met and by actual trial. With these dredges working under the conditions on the Columbia River, a 36-inch sleeve has been found most satisfactory, after trial of 30 to 32-inch lengths. The trials were not very exhaustive, however, and the experience of others in this matter would be of interest and value to the writer. The price of 36-inch sleeves for 24-inch pipe has advanced from $50.00 to $55.00 in 1913 to about $115.00 in 1920. Part of this increase is no doubt due to the more rigid specifications.

Recent figures obtained from makers of flexible steel joints were $500.00 each if purchased in lots of 10 or more. To this cost would have to be added for some joints the cost of fitting and installing on the pipe. No figures are available as to the life of these joints in the sharp, clean sand of the Columbia River, but from experience gained with two modified ball joints installed for trial, it is estimated at about 800 to 1,000 working days. It accordingly appears that in addition to the advantage of greater flexibility in the rubber sleeve, so essential when operating on ship channel work before mentioned, they also have the advantage of smaller cost over any steel joints thus far developed.

Cost of the pipe lines of the dredges in 1914 and 1920. and maintenance cost over this period, are shown in the following tables:

First cost of 60 feet of pipe line.

	1914	1920
60 feet 24 by ¼ inch lap-welded pipe	$360.00	$590.00
2 wooden pontons 12 by 26 by 2½ feet	350.00	900.00
1 36-inch rubber sleeve, 25⅛ inches I. D.	55.00	115.00
1 rope jacket	5.00	9.00
60 feet walk handline, etc	9.00	16.00
Total for 60 feet	779.00	1,630.00
Total cost per foot	12.98	27.17

Cost of maintenance.

	Depreciation, per cent	Cost basis 1914	Cost basis 1920
60 feet pipe	100	$360.00	$590.00
2 pontons	75	262.50	675.00
1 rubber sleeve	600	330.00	690.00
Miscellaneous repairs, etc.		100.00	200.00
Total		1,052.50	2,155.00
Maintenance cost per foot for 6 years		17.54	35.91
Maintenance cost per foot per annum		2.92	5.98

With steel pontons of the catamaran type at $1,600.00 per unit, with two units for each 60 feet of pipe, the first cost of pipe line per foot in 1920 would become $65.50, and if steel, flexible joints were also used in place of rubber sleeves, the cost would be about $71.77 per foot of pipe line.

A comparison of the cost of wooden pontons as used

View of pipe line, showing swinging bolster and rope "jacket" in service Dredge "Wahkiakum

here, with those constructed of steel, considering the life of the two plants, shows a decided economic advantage in the wooden plant. Based on a life of 8 years for wooden plant and 40 years for steel, the following comparison of cost of a single ponton unit is drawn:

Estimated first cost of wooden ponton $450.00
Estimated first cost of steel ponton catamaran type 1,600.00

For a period of 8 years:

	Wood	Steel
Interest on first cost @ 5 per cent per annum	$180.00	$640.00
Depreciation for 8 years	450.00	320.00
Repairs, etc.	50.00	20.00
Total	680.00	980.00

Saving in a wooden ponton in 8 years $300.00

The cost of repairs to wooden pontons given above does not include minor repairs made from time to time by the crew while the plant is in operation, as these are made during spare time of the crew, who are necessary in any event for handling the plant, and no extra labor cost is involved. The value of materials used is small. The only real repairs made on these pontons has consisted in lifting them out on a dock with a derrick, setting up the caulking on the rakes and repitching the decks. The cost was less than $50.00 each.

In the above estimates the life of wooden pontons is given as 8 years. It is known, however, that this is practically a minimum, and that with careful selection of seasoned lumber, can be materially increased. Investigations are now being made as to the probable cost of construction, using creosoted lumber, indications being that the life of wooden plant will be thereby increased 50 per cent to 100 per cent, or more, depending on the treatment, at a comparatively small additional cost.

Vol. XIII MARCH-APRIL, 1921 No. 68

The Secretary of War

JOHN WINGATE WEEKS, newly appointed Secretary of War, whose portrait forms the frontispiece of this issue, was born in Lancaster, N. H., on April 11, 1860. He graduated from the U. S. Naval Academy in 1881, and served in the Navy until 1883, after which he served for ten years in the Massachusetts Naval Brigade. During the Spanish-American War he served in the Volunteer Navy.

In 1900 he was elected alderman, and in 1902 mayor of his home city, Newton, Massachusetts. He was a member of the 59th, 60th, 61st, 62d and 63d Congresses, and was elected to the Senate January 14, 1913, serving until March 3, 1919.

The Army Officer and the Engineer as Salesmen

THE day of the old frontier regular officer is past. His duty was at a one-company or one-troop post. His service was arduous. His mission was one of deeds, not words. He did much. He said nothing. He was a man of hard physique, strong will and unquestioned courage. There grew up in the service a resentment against the talker, and Army officers were proud of their reputation of not being good after-dinner speakers. They prided themselves on their powers of repression of speech. "Silence is golden," was their motto.

These observations have been almost equally true of the engineering profession at large. The engineer, like the soldier, was a man of works, and of silence. Other professions, notably the law, have taken a different attitude. They have cultivated their powers of speech. By reason of the attention attracted by their vocal utterances, lawyers and others have been frequently elected or appointed to public office and other important positions of trust and responsibility, for which, in many cases, engineers were by training better fitted.

Salesmanship, or efficiency in promotion or exploitation, is the slogan in business today. That the Army is a big business concern is now well recognized, both without and within. The Army man must compete with specialized organization of the highest type. It is he, and he alone, who can put his profession and his mission before the public. The Army is an instrument of the American people, and they are entitled to know about it. If they do not know about it, they cannot be expected to support it.

In most army activities of today the regular officer is in a position where his personality, his power to convince others, his personal magnetism and his ability to express ideas all come into prominent play. We have a few outstanding examples of talent in this respect, but for the greater part it seems that the old reputation of the Army, men of deeds, and not of words, is the rule, and the Army suffers accordingly.

Among engineers it has long been recognized that the officer who can win friends to the service is of great value. If he has the community behind him, he can accomplish great things. If he does not have the good will of the public, he is seriously handicapped.

Elsewhere in the Army this need is becoming more and more apparent. In our relationship with the National Guard, now firmly established as the "second line of defense," the personality of the Inspector-Instructor is of paramount importance. The old feeling that the Regular Service is antagonistic to the National Guard, or to the Militia as people used to call it, must be overcome if the regular officer is to succeed with the new National Guard. That the development of the National Guard requires more than the law and the efforts of experienced soldiers, is evident to all who are working with the problem. The only men who can successfully recruit National Guard organizations are National Guard officers. If they are to carry out the policies of the regular establishment, they must work in friendly spirit and full co-operation with the regular personnel. There must be absolutely no feeling of antagonism. There must be friendship. The regular officer must "sell" his service, "sell" the standards of the regular establishment to the National Guard officers, as to the public. His strength is great if it is properly applied. His weakness is fatal.

At the large centers of education where the government has established units of the R. O. T. C., the Regular Army has one or more officers representing the service in the direction of military instruction. Where these officers are capable, and their relations with the faculty and the student body happy, success is assured. Where there is misunderstanding and dissatisfaction, results cannot be expected. The success of the work of developing officer material at these institutions depends chiefly upon the personality of these regular officers, the Professors of Military Science and Tactics.

The newly announced policy of the War Department for the development of the Organized Reserve, shows that certain regular officers will be permanently assigned for duty with units of the Organized Reserve, with one officer to

Digitized by Google

each regimental unit, and five for each division headquarters. These officers will have headquarters in the locality assigned for the unit, and must do the great bulk of the work in bringing together former officers of experience, and through them the non-commissioned officers and specialists for the organization. An officer who cannot represent the Army favorably; who cannot convince former service men as to the excellence of his mission; who cannot win to the colors the man whom the Nation needs, such an officer must fail on this assignment. On the other hand, the man of experience and personality, the man with initiative and personal magnetism, can make a splendid record for himself and for the Army in such a position.

Examples might be adduced in great numbers regarding army relationships at home and abroad, in industry, in business, in society. In all national activities the Army officer will be rubbing elbows with the civilian. He will be judged, and the Army which he represents will be judged favorably or unfavorably by comparison. He must therefore be equipped and trained for these activities

It is accordingly apparent that the Army must recognize the need of training its officers in the art of appearing favorably in public, of convincing others, in fact, of salesmanship in its highest form. Far from cultivating habits of bombastic oratory, or indulging in high flown speeches not based on careful thought, the regular officer must be master of his subject, direct and forceful in its presentation, as well as tactful and pleasing. The officer's training as a soldier should guarantee directness and forcefulness—the eloquence of simple truth, simply but clearly expressed. The educational system of the Army must guarantee the other requirements.

Such abilities will be no detriment to the officer in time of war, and will not hamper him in his relationship with other officers of our own army or of allied armies. Most of our successful officers during the recent emergency were men who appeared well in the company of their brother officers, either American or Allied.

Golden silence is well enough in its place, but there are times and occasions when silvery speech is far more effective. The military and engineering professions alike now appear to recognize that in their devotion to "deeds not words" they have been pursuing a will-o'-the-wisp policy.

The new course at West Point recognizes that lucid language is necessary to comprehension, and provides for 217 hours of class-room instruction in English as compared to 94 in the previous course. This course in English has for its aim three objectives, viz, to form habits of clear, concise and correct written expression; to stimulate interest in good reading in the field of contemporary prose, and to give practice in oral expression. It is a hopeful sign of the times that in the leading technical educational institutions of the country, no little time is now devoted to this important subject, with a view to training the engineer in oral and written expression. Clearness and accuracy of expression are essential in the work of the professional man and facility in presentation is of the utmost importance. The Army officer and the practicing engineer are both under the necessity of selling their services not only in their own interest, but in that of the public as well, and it is gratifying to find that the institutions of learning, both military and technical, are now awake to this important truth.

The Congress and the Army

JUST before the close of the last fiscal year, after exhaustive hearings on all phases of national defense, Congress passed a bill which was approved June 4, 1920, amending the National Defense Act of June 3, 1916, These two acts embody in legislative form the military policy of the United States. With the so-called Draft Act, which gave us our armies for the World War, they constitute the most enlightened legislation ever enacted by Congress in the interests of national defense.

In view of these outstanding exhibitions of constructive military statesmanship, those who are most interested in the continuance of a sound military policy have been at a loss to explain the more recent actions in this field on the part of our national legislators.

The casual observer might well conclude that there is a concerted effort to undermine the policy which enabled us to enter the World War and to conduct our share therein to a successful issue. It might appear that a deliberate attempt is being made by the House Committee on Appropriations to hamstring this wise legislation so recently adopted. The action of the Committee, which on January 29th reported out the Army Appropriation Bill for the fiscal year 1922, is best stated in its own words, as follows:

> "The grand total of this bill, combining the sum of $328,861,123 for the support of the Army and the sum of $2,361,489.62 for the support of the Military Academy, is $331,222,612.62. The combined amount of the estimates (submitted by the War Department) for the fiscal year 1922 for the two purposes is $699,275,502.93, and the combined amount of the appropriations for the current fiscal year is $394,700,577.70. The grand total recommended in the bill, therefore, is $63,477,965.08 less than the grand total of the current appropriations and $368,052,890.31 less than the grand total of the estimates.
>
> "The figures of the War Department were based upon an army of the maximum size provided by the Army Reorganization Act of June 4, 1920, an enlisted force of approximately 280,000 men, and 17,000 officers.
>
> "The appropriations in the present bill are based upon an enlisted force of 150,000 men, exclusive of the Philippine Scouts, which number about 6,500 enlisted men, and the Flying Cadets authorized in the law of June 4, 1920, to the number of 2,500. Provision is made to care for 14,000 commissioned officers, which is approximately 1,000 more than are now in the Regular Service."

Since the House Committee made its report, the bill has been passed by the House and has been reviewed by the Senate Committee on Military Affairs, which conducted extensive hearings on its own account. The bill has also been passed by the Senate, which was more liberal than the House in its estimates of the needs of the Organized Reserves and certain training activities conducted by the Regular Army. More recently still, the bill has run the legislative gauntlet "in conference," followed by action in the two branches of Congress on the reports of their respective conferees. The net result has been to increase only slightly the amounts voted by the House for the more important items favored by the Senate. The figures desired by the latter were rarely met in full, even on items of minor consequences.

If it be granted that Congress is in fact a representative body, its action in the matter of appropriations for the army for the fiscal year 1922 leaves small room for doubt that the people of the United States are not disposed at this time to invest funds in the military establishment beyond the most conservative estimate of bare necessities. The pendulum of reaction has swung far indeed, and there appears little to do but to take counsel of patience and await a happier day.

The truth of the matter is that under the methods now in

Digitized by Google

force, which make the Committee on Appropriations responsible for the apportionment of all funds, this Committee must of necessity take on the functions of a budget commission; it must balance national outgo against national income. It must cut the garment according to the cloth, and it is obvious that, in the existing state of things, few of the departments of the government can be clothed in voluminous folds of broadcloth and fine linen. All departments will have to practice economy of the most rigorous sort. In time of famine it is well to bear in mind that "a half loaf is better than no bread."

Lack of funds is the determining factor, but this entrains manifestations of a public sensitiveness, a touchiness which finds expression in diatribes against standing armies, militarism, Prussianism and all the other pet bugaboos of an excitable public opinion.

The situation is well described in the following extract from a letter, which we publish with the permission of the writer, the Honorable Frank Lester Greene, of Vermont. Mr. Greene is a member of the Military Affairs Committee of the House, and has taken a leading part in all military legislation enacted by Congress in recent years. With an experience as a member for twelve years of the National Guard of his State, as an officer of volunteers in the war with Spain, as a newspaper reporter and editor and as a Congressman, active in the affairs of the House; possessed of an analytical mind, a profound student of military affairs in their bearing on the national security and welfare, a man of constructive ideas with a pleasing, forceful style of presentation, there are few men in public life today better qualified to express an opinion on the subject matter of his letter. It merits the consideration of every man who has at heart the best interests of the military service. Mr. Greene says:

> "I am by instinct, observation and study heartily in favor of a good-sized, well-balanced, regular or professional military establishment in this country.
>
> "I do not mean by that that I favor what is sometimes called a 'great standing army,' and for that matter I doubt if any sensible person does. But I have seen enough of the story of the world and humankind, since my years of discretion, to convince me that we must have a splendid permanent professional military force for the nucleus of any war army it may ever be necessary to raise in emergency.
>
> "I approach the matter of results of the possibilities in the Army Reorganization Act with a sympathetic interest and with a predisposition to favor any reasonable and practical means of accomplishing the purpose.
>
> "But when I say to you, as I have said to many, that it is a serious mistake for the War Department to hurry the creation of the force made possible by the Army Reorganization Act, or to employ the Army in all the activities possible under that Act, I am saying what I believe to be the most earnest truth in the most earnest interest of the Army itself, as well as the country, whether the Army or its friends believe it or not.
>
> "In my opinion, sincere friends of the Army who understand the situation, will urge the War Department not to begin to pile up enormous bills of costs to be charged up, in popular judgment, against the new Army Reorganization Act. The War Department, if it wants to keep that Act, and the possibilities in it, will do mighty well to make haste slowly. Already there are signs of a reaction against even as large a military establishment as is provided for in that Act; and if we irritate some sensitive opinion at this time by demonstrating that this Act simply means an enormous burden of expense in this tax-ridden, debt-ridden time, we can expect the usual explosion that follows exasperated human nature.
>
> "Moreover, I would counsel the heads of departments in the Army itself to stop whining about some of these things and get to work to do the best they can with the tools they have to work with. They have been given a law that is, in many respects, the greatest Military Act ever put upon our statute books. They have been given resources and opportunities such as never entered the imagination of the average Army officer as a possibility before. The Act is not perfect, but it is a marvelous improvement over former military statutes, and is remarkable in the fact that in so many things it upsets what might be regarded as traditional American policy and points the way to a liberalism that at one time, not long ago, would have been thought an impossibility.
>
> "We have to deal with human nature as it is and not as we may theorize about it. The Congress very readily adopted this law, but the public has not become used to it. The people of this land are struggling with a very intense and even threatening economic situation. Statesmen who are prudent will try to get along with the least possible budget of Government expense, consistent with such savings as do not sacrifice foundations themselves. If they do not, they can expect a storm of public protest and indignation; and any thoughtful man knows that these storms of reaction are often illogical and unreasonable, and do not simply correct the abuses complained of, but destroy institutions themselves sometimes, or so seriously impair them that they result in effects that are worse than the original abuses.
>
> "If our friends of the Army are well advised, they will keep quiet at a time like this. They will make the best they can of what they have at hand and wait for better times gradually to develop the possibilities of that Act to such extent as may be consistent with the demands for national preparedness.
>
> "There are many men who are not only sympathetic with the Army, but who are ambitious for its progress and development along the lines laid out through experience in the great World War. Those men are eager to help in legislation or administration that will serve this purpose, but many of those men are placed where they can see that if some good-intentioned but misdirected spirits in the Army keep up a complaining and irritating criticism of Congress or the Administration for not permitting the utmost freedom in expenditure under the Act at the very start, they stand in danger of being the very ones whose folly will so exasperate the people and the Congress that some of these results gained for the Army after so many years, may be swept away with one short Resolution. Prudent men in the Army now will be content in the ancient philosophy of 'letting well enough alone,' and biding a saner time."

The Military and Non-Military Mind Combined

THERE are so many branches of engineering which find application in the conduct of war that it is manifestly impossible that the military engineer should be an expert, or even that he should have a smattering of practical experience in more than a very few of them. West Point is a school for the inculcation of the

Digitized by Google

fundamental principles of the art of war, including its economics, and not for specialized instruction along any line.

The subsequent experience on works of rivers and harbors acquired by officers of the Corps of Engineers is of military value *not* because of the technical knowledge gained, but because of the broadening effects of a training which brings the military engineer in contact with civilians, requires him actually to carry out work involving the use of plant, labor and construction materials, and which, above all, compels him to exercise his practical resourcefulness, meet emergencies, and shoulder responsibilities. The exact nature of the work is not a matter of vital importance, except that it is well that it be in the field of general construction in civil engineering. It is quite probable that practical experience in railroading would be as good, perhaps even better, than the river and harbor work, provided the engineer officers could be placed in positions of *responsibility,* calculated to develop their initiative and resourcefulness. This would not be possible in any railroad corporation where all such positions are already filled by civilians. It is the pioneer stage in civil enterprises which most nearly approximates the service of the military engineer in time of war. Much of the pioneer work in this country was done by graduates of the U. S. Military Academy, because in those early days there were no engineering colleges and the West Pointer was the best technically trained man in the country. But the pioneer days in railroading and other lines are past. There is no enterprise under civilian control in which the military engineer could receive the most essential part of the training he gets on river and harbor work, because he would not be in responsible charge of his work. Such training would be useful, but could not replace the work of rivers and harbors as a military asset.

Railroad construction is so important a matter in war that it is well that there should be a few officers of the regular establishment sufficiently experienced in railroad work to meet the civilian railroad engineer in times of war, "talk his language" and co-operate with him in producing results. In this connection it may be of interest to state that arrangements have already been made and are now being carried out to train regular engineer officers along certain specialized lines of civilian engineering practice at civil educational institutions. This is to be followed by the detail of selected engineer officers for practical training with civil industrial institutions.

A fundamental knowledge of military requirements and military economics, a broad mind resulting from proper training and diversified experience, practical resourcefulness and courage in assuming responsibility—these should be the qualities of the military engineer, rather than highly specialized technical knowledge. It is at the development of such characteristics that the training of the military engineer should aim. If, in addition, a limited amount of specialization is practicable, so much the better. But the narrowing influences of over-specialization the military engineer must carefully avoid.

So important is a broad knowledge of military requirements and military methods, if results are to be attained under war conditions, that it would seem generally unwise to commit an important military construction project to the *sole charge* of a civilian engineer *having no military training.* However skilled he may be in civil construction, more than this is needed to assure success in war.

On the other hand, the military engineer, charged with the supervision of important construction projects with which he is not himself thoroughly familiar as a result of practical experience, will have need and will be wise to avail himself of the advice and assistance of officers with civil experience along the lines of the work in question.

Construction in time of war is the field for the meeting of the "military" mind and the "non-military" mind. If these two minds can be combined in one individual, even to a limited extent, many dangerous mistakes in practice may be avoided. To develop such composite minds for the future service of our country, is the purpose of our present system of engineering training for regular officers, our military training for the Reserve Corps and R. O. T. C. And it is, moreover, a prime function of the Society of American Military Engineers and of this Journal.

Wanted—Suggestions!

The Society of American Military Engineers now has a membership of more than 3,600, covering a wide field of engineering activities. The bulk of the membership is drawn from the Engineer Officers' Reserve Corps.

It is the aim of THE MILITARY ENGINEER to publish articles that will appeal to the membership at large as being well worth reading. It must be borne in mind, however, that the *raison d'etre* of the Society and its journal is PREPAREDNESS, and in the interests of preparedness the most important function of the Society and its journal is the provision of a meeting ground for those engaged in the military service and those now engaged in civil pursuits who will be called into military service in time of emergency. The development on the part of each of these bodies of a knowledge and appreciation of the problems and the point of view of the other, will greatly facilitate their amalgamation in time of emergency into a single body capable of devoting the maximum engineering effort to the common cause.

The military field will furnish material for many articles that would be of great interest to those in the military service, and the civil field will yield data of vital interest to practising engineers; but the purely military field is covered by official publications and Army educational institutions, and the technical press covers all the requirements of the civilian engineer. The aim of THE MILITARY ENGINEER is to provide a connecting link between these two fields, which is obviously a more difficult task than it would be to present merely an assortment of articles, partly military and partly civil in nature.

The Editor is not a mind reader; if he were, securing articles for publication would be comparatively simple. A request to a definite person for an article on a specific subject usually meets with a willing response. When anyone is merely asked to "write an article," he always asks, "What shall I write about?"

In order to answer this frequent and insistent question—"What shall I write about"—it is purposed to publish occasionally in THE MILITARY ENGINEER a list of subjects upon which articles are desired. This list will be compiled from suggestions received from the members of the Society.

It is believed that the publication of such a list, with such additions and revisions as appear from time to time advisable, will serve as an incentive to our readers to contribute by furnishing them a definite starting point, and will also help to insure that articles published are such as will help in the accomplishment of the objects for which the Society and its journal were founded.

Digitized by Google

Please write your suggestions on the form on page 196 and send it at once.

The following are some of the subjects that have been suggested:

"Water Supply in Mobile Engineer Operations."

"Construction and Maintenance of Ponton Bridges under Battle Conditions in France."

"Military Railway Transportation."

"Universal Service."

"Effect of Sea Water on Reinforced Concrete."

"Problem requiring the establishment of an Advanced Engineer Depot, showing Organization of Office, Methods of Purchasing from Local Sources, Methods of Storage and Issue of Material."

"*Esprit de corps* among Reserve Officers."

"Developments in Methods of Using Explosives During the War."

"Methods of Administration, Cost Analysis and Progress Reports on Engineer Construction Work."

"Roads and Road Making in Battle Areas."

"Maintaining Interest in Local Posts of the S. A. M. E."

"Proportions of Men Skilled in Advanced Trades Required for a Well-balanced Divisional Engineer Regiment."

The R. O. T. C.

THERE is perhaps no more important item in our present policy of national preparedness for war, nor one more deserving of support, than the Reserve Officers' Training Corps, popularly known as the R. O. T. C. The primary object of the Reserve Officers' Training Corps is to provide systematic military training at civil educational institutions for the purpose of qualifying selected students of such institutions as reserve officers in the military forces of the United States. It is intended to attain this object during the time that students are pursuing their general or professional studies with the least practicable interference with their civil careers, by employing methods designed to fit men physically, mentally and morally for pursuits of peace as well as pursuits of war. There can be no doubt that such military training properly conducted and properly correlated with the primary objects of the institutions concerned will contribute greatly to the development of better citizens.

In a recent statement, President-elect Harding expressed his appreciation of the usefulness and importance of the R. O. T. C. and his belief that it should be improved and extended. Members of Congress have also recognized the value of this movement. In his discussion of the Army Appropriation Bill in the House of Representatives, the chairman of the sub-committee, Mr. Anthony, stated that the bill provides $3,000,000 for the continuation of this work. He stated that his committee proposed to grant sufficient funds to keep up this activity to the fullest extent.

In the event of war our greatest need is for trained officers to supplement our regular force. In the late conflict some 200,000 were employed. It is our present policy to establish a large Officers' Reserve Corps from which a considerable part of the need may be filled. At present the Reserve Corps includes a large number of men who saw service in the World War. But as time goes on, the number of such will become progressively less.

To have even a list of men who are probably eligible to become officers is of some value, to be sure, but such a list does not take the place of a reservoir of really trained officers. To administer practical training to Reserve Corps officers, all busily engaged in their normal vocations, will be a most difficult matter, and since the end of the war nothing of the kind has been practicable. Plans for training are now being prepared by the War Department, but the execution of these plans is contingent upon the appropriation of the necessary funds by Congress. To assemble the men alone will be exceedingly expensive.

Present plans contemplate calling out Reserve Officers for only two weeks' field traiing each year, *provided funds are available.* This is all the time that men in civil pursuits can be expected to devote to active military training, and even this will be an embarrassment in many cases. Yet it is manifestly insufficient time for producing trained officers. Adequate fundamental military training must be provided before the officer enters the Reserve Corps, and his annual two weeks' training periods will then serve to keep him in close touch with military affairs, and to guide his voluntary study of military subjects. The R. O. T. C. is the chief agency for providing the necessary fundamental military training; without it there would be grave danger that the Reserve Corps would eventually become merely a "paper organization."

The R. O. T. C. course includes from three to five hours per week of theoretical and practical instruction during the first two years of college and five hours per week during the last two years. The instruction at the institutions is supplemented by a summer instruction camp of six weeks' duration. The Engineer summer camp has been described by Capt. W. D. Styer, C. E., in a recent issue. The instruction in all institutions is given by selected officers and non-commissioned officers of the regular army, and is closely supervised and directed by the General Staff and the chiefs of the various services.

The present strength of the "senior" (college) branch of the R. O. T. C. is approximately 50,000, and training for all the combatant arms, including engineers, is provided. There are now 3,000 students enrolled in the 19 engineer units in prominent engineering institutions of the country.

The R. O. T. C. has the great advantage that the military training is administered without interference with civil activities, and at a very low cost. Moreover, the advantages derived from the training are not limited to its military application. Enrollment in the R. O. T. C. is primarily a patriotic duty, but the subjects taught and the methods of instruction followed should appeal to the faculty and the student body, not only as a contribution to the national defense, but also as an educational measure of direct utilitarian value in a civil career. The R. O. T. C. enriches the educational resources of colleges and schools by contributing new methods, problems, equipment and applications.

The civil application and value of such courses as Hygiene and Sanitation, Physical Training, Military Law and Administration, Map Reading, Roads, Railroads and Bridges, will be readily apparent. Moreover discipline is just as essential in a construction camp or an industrial or commercial organization as in a military unit, and the fundamental principles of organization apply equally to civil and military service. The basic principles of administration and supply are common to peace and war. The time devoted to a well-balanced course of military training will not be lost, even should the student never be called to do his share in the defense of his country.

From this reservoir of trained young men most of the "recruits" for the Officers' Reserve Corps will in future be drawn. It will be conceded that no more effective and economical plan of providing at least partly trained officers to meet the emergency of war, is possible under the admittedly weak military policy dictated by the temper of the American people.

Prize Article

THE MILITARY ENGINEER offers a prize of $100.00 for the best article appearing in its columns during 1921.

The article may be on any subject, either civil or military, which will be of interest to the members of the Society of American Military Engineers. The subject need not be taken from the published list of suggestions.

The articles submitted will be judged according to their professional interest and literary merits, but especially by the extent to which they advance the aims and purposes of the Society.

Articles should be not less than four nor more than seven magazine pages (5,000 to 8,500 words) in length. Drawings, if submitted, should be on tracing cloth or white paper, ready for reproduction. (Titles of drawings should not be included in the border, but written in pencil outside).

The articles will be judged by a board consisting of not less than three nor more than seven officers, a majority of whom shall be Reserve Corps or former emergency officers.

The contest is open to all members and associate members of the Society.

The Society Emblem

The membership of the Society of American Military Engineers will be gratified to learn that the Society emblem has now reached the production stage. The illustration above is a cut of a plaster cast of the insignia drawn from a mold under the direction of the sculptor. Due, however, to the medium and to mechanical limitations incidental to reproduction in this form, the cut does justice neither to the design itself nor to the workmanship embodied in the master die. The lines of the emblem when finished in metal will be sharper, cleaner and altogether more virile than can be indicated on the flat surface of this page. The device being built up from rim to center, will have a pronounced relief, will contain a very desirable weight of metal and will avoid the objectionable appearance of stamped tin, so frequently encountered in insignia of this kind. As compared with the drawing published on the front page of the last number of this journal, the lines of the head and wings of the eagle have been improved in the sculptor's model. Minor changes have also been made with a view to enhancing the appearance of the emblem when reproduced in metal.

The symbolism of the emblem has been indicated in previous issues of this journal, and need not be repeated here. Every effort has been made to maintain the correct heraldic significance of the various elements. The number thirteen, symbolic of the original thirteen colonies from which this nation has been derived, is repeated not only in the bars on the shield, but also in the leaves of the olive branch and in the sheaf of arrows grasped by the eagle. It is again repeated in the number of berries on the laurel wreath surrounding the shield. The castle is correct in every detail, having been modeled on the lines of the original drawing, which was made about 1840, when, in its present form, it was first authorized for wear on the uniform of the Corps of Engineers. Incidentally, it may be observed that the chenelles, or embrasures at the tops of the three towers and in the curtain walls between them, also number thirteen. Whatever may have been the origin of the superstition which attaches to this number as one of ill omen, it certainly can have no terrors for the United States—sprung from thirteen independent, weak little settlements on the Atlantic Coast and now welded into a single united nation, the greatest in the world, with potentialities undeveloped.

For the present the Society emblem will be produced in bronze or in gold, according to individual tastes. It will be supplied for wear as a lapel button or as a charm for the watch chain. It can also be furnished with a security brooch-pin if so desired, though this entails a small extra charge. It will be five-eighths of an inch in diameter, or practically the size of the Victory Button and one-third the size of the cut herewith. At some time in the future it may be possible to produce the emblem in miniature form should a demand develop for a smaller size. It will, however, scarcely be practicable to enamel the surface of the shield in red, white and blue as has been sometimes suggested. On account of the superimposition of the castle, it will be difficult to apply the enamel satisfactorily to the small surfaces on the shield available for enamel of each of the three colors.

Orders may now be placed with the Secretary of the Society for emblems in accordance with following prices, viz:

Material	*Button or Charm*	*Brooch-pin*
Bronze	$0.75 each	$1.00 each
10k Solid Gold	5.00 each	5.50 each
14k Solid Gold	6.00 each	6.50 each

In ordering, specify carefully the form of the emblem—that is to say, whether desired as a lapel button, as a watch charm or equipped with security brooch-pin device. Orders will be filled as rapidly as conditions of production permit.

The emblem will also be made up in silver, but not for sale, as it is purposed issuing a silver emblem free of cost to every present member who secures three new members. A letter containing this offer and three application blanks will shortly be sent to all members.

The emblem is handsome and distinctive in appearance and one which can be worn with pride by every member of the Society as the symbol of a rational belief in the wisdom of a foresighted constructive policy of national defense.

Annual Meeting of the Society of American Military Engineers
January 14, 1921—Minutes

1. The Annual Meeting of the Society of American Military Engineers having been called for the fourteenth of January, 1921, in accordance with the provisions of Article VIII, Paragraph 1, of the By-Laws, the meeting was called to order by the temporary President, Gen. Wm. M. Black, at 2.15 P. M., in the Blue Triangle Club House, 20th and B Streets, N. W., Washington, D. C.

2. Seventy-five members of the Society were present.

3. The meeting was conducted in accordance with Article XI of the By-Laws.

(1) The reading of minutes of the preceding meeting was dispensed with, as this was the first annual meeting.

(2) Report of the Board of Directors, by Maj. Gen. W. M. Black, President:

Digitized by Google

a. On November 1, 1919, a board of officers was appointed by the Acting Chief of Engineers, U. S. Army, to effect an organization for an Association of Engineers in the Military Service.

b. The first meeting of this Board was held on November 28, 1919. At the meeting the name of the association was fixed as "The Association of American Military Engineers," and the Association was authorized to publish a bi-monthly periodical to be named THE MILITARY ENGINEER, which publication was to take the place of the PROFESSIONAL MEMOIRS, published by an informal association within the Corps of Engineers. A committee was appointed to draft a constitution for the Association.

c. Meetings were held on December 30, 1919, and on January 14, 1920, at which drafts of the constitution were considered. The name of the Association was changed to "The Society of American Military Engineers." On January 14 Major Bond was authorized to solicit membership in the first publication of THE MILITARY ENGINEER.

d. The printing plant and assets of THE PROFESSIONAL MEMOIRS (valued at about $12,000) were turned over to THE MILITARY ENGINEER as a publishing plant and not to the Society. This gave the publication of the Society an excellent start. THE MILITARY ENGINEER set up its printing plant and started to publish the journal.

e. In the spring of 1920 a canvass was taken of the regular and emergency officers serving in the Corps of Engineers to ascertain their attitude toward the new Society. Of those who replied, 226 regular officers were in favor of the Society and 8 were not; and 85 emergency officers were in favor, and 2 were not.

f. On May 28, 1920, a number of members of the Society who, it was thought, would take a live interest and who represented the various classes of members were invited to join the Board of Officers, appointed on November 1, 1919.

g. The first meeting of this new Board was held on June 2, 1920. At this meeting a temporary organization was perfected and temporary officers were elected to carry on the work of the Society until the first annual meeting, when regular elections would be held. A Committee on Development was appointed with Major Bond as chairman, and a Committee on the Design of Emblem or Badge with Colonel Youngberg as chairman.

h. The design for an Emblem for the Society was finally settled, by the temporary Board of Directors, by a letter vote taken in December, 1921. The design appears on the January-February, 1921, issue of THE MILITARY ENGINEER.

i. In September, Colonel Bond recommended to the Executive Committee that because of the expense of operation, the printing plant operated by THE MILITARY ENGINEER be sold, and that the journal be printed by contract. The Executive Committee consented, and, finally, arrangements were made whereby the plant was sold, and a contract was entered into for printing the journal for a period of five years.

With the issue of November-December, 1920, the journal of our Society, THE MILITARY ENGINEER, closes its first successful year. Born under conditions most discouraging and difficult from a financial and other points of view, it has been a worthy organ of our Society, a strong bond of union between our members. Probably more than any other single influence it has contributed to the healthy growth of the organization. Its columns have included handsomely illustrated articles on a wide variety of civil and military subjects, of great interest to all engineers. The contributors to its pages have included many men who won undying fame in the World War, as well as many who have achieved national distinction in civil engineering. But in particular our journal has fulfilled its mission and earned the praise of all who have seen it, because it has truly interpreted and represented the *spirit of service* of the engineer to his country. Its columns have breathed enthusiasm and devotion to duty. No periodical can have a higher aim than this.

That advertisers have appreciated the influence of THE MILITARY ENGINEER is indicated by the growth in the number of its advertising pages from thirteen in its first issue to thirty-five in the issue of November-December, 1920.

All of our members, whose support alone has rendered possible our progress, should feel a just satisfaction and pride in the excellent results thus far achieved and the bright outlook for the future. Less than one year from the time when our Society first took form in the minds of a few men, finds it a strong and flourishing organization of some 3,592 members, supporting and publishing its own journal with local sections established in most of the leading cities, and growing at a rapid and steady rate. Truly this is a most satisfactory result for so short a period. I offer my heartiest congratulations to all our members, and I look confidently forward to greater progress during the coming year.

W. M. BLACK,
Major General, U. S. Army (Retired),
President, Society of American Military Engineers.

(3) Report of the Secretary, Maj. D. L. Weart:

a. Total number of applicants for admission 3,301
This includes 500 applicants who did not remit check with application.
b. Number of applications passed by Membership Committee .. 2,059
This includes 2 life members, 1,962 active members and 95 associate members.
c. Number of applications awaiting action of membership committee 742
d. Number of other paid subscriptions to THE MILITARY ENGINEER 375
e. Total number of subscribers to THE MILITARY ENGINEER .. 3,676
f. Number of copies of THE MILITARY ENGINEER sent to advertisers, exchanges, etc. 137
g. Total circulation of THE MILITARY ENGINEER 3,813
h. Number of organized local posts of the Society 16

REPORT OF THE TREASURER.

Washington, D. C., January 1, 1921.

To the Acting Treasurer,
The Society of American Military Engineers.

Sir: In compliance with the provisions of Article V, By-Laws, I submit herewith my report for the year 1920 as acting Assistant Treasurer of the Society. I have been actively connected with the Society since June 22, 1920, but have incorporated within my report all transactions for the entire year.

The funds of the Society have been kept by and in the name of THE MILITARY ENGINEER at The Washington Loan & Trust Company during the months of January and February and at the Federal National Bank during the balance of the year. Disbursements have been made by myself under the direction of the Managing Editor and by the preceding Business Manager.

Membership dues during the year have been fixed at

Digitized by Google

$4.50, but drives have been made which allowed trial subscription to our Journal for $1.00 or $1.50. During four months of the year we maintained and operated a printing plant at 423 G St., N. W., which did our own printing as well as other commercial work, such as printing two numbers of ARMY ORDNANCE.

There follows a list of our assets and liabilities at the close of business December 31, 1920:

ASSETS.

Two Bonds—Chicago City Railway Co., 5 per cent—Nos. 5476-7; Maturing 1927; Interest February and August	$2,000.00
Two Bonds—Maryland Electric Railway Co., 5 per cent—Nos. 4787-8; Maturing 1931; Interest April and October	2,000.00
One Bond—Chattanooga Electric Railway Co., 5 per cent—Matured 1918; Entered for Collection Federal National Bank	1,000.00
Accrued Interest on above Bond	115.00
Five Notes—Frank T. Fuller and Wm. Busey, bearing 4 per cent Interest; Due October 1st of each year beginning 1921	7,500.00
Property and Furniture (approximately)	650.00
Accounts Receivable (approximately)	3,500.00
Cash on Hand, Federal National Bank	1,246.71
Total	$18,011.71

LIABILITIES.

Due D. L. Ward Co., for paper	$746.45
Due E. C. Gramm, for electrical work	361.00
Due Standard Engraving Co., for cuts	199.63
Due Ault and Wiborg, for ink	10.10
Due Acheson Ink Co., for ink	10.00
Outstanding checks	127.85
Total	1,455.03
Balance	16,556.68
Total	$18,011.71

THE MILITARY ENGINEER is at present under a two-year contract, dating from April, 1920, with Messrs. Escaville and Mackay for advertising. They have contracted to get at least 20 pages of advertising for the present and 30 pages starting with the May-June, 1921, issue, at the rate of $40.00 per page net to us, or about $7,200.00 per year. We have from our old advertisers about 6 pages of advertising at $81.00 per page per issue, or $2,916.00 per year. The success of our advertising depends upon our circulation, but it is fair to expect $10,000 per year from it.

Dues are at present fixed at the rate of $4.50 per year, including subscription to the Journal. Applicants for membership, mostly eligible, and members number about 3,500. and with a continuation of the present enthusiasm our number should not fall lower than 3,500 for the year. Their subscriptions expire about as follows:

700 expire with the January-February number.
500 expire with the March-April number.
200 expire with the May-June number.
200 expire with the July-August number.
300 expire with the September-October number.
1,600 expire with the November-December number.

(It is thought that all subscriptions should be made to expire at the end of the year.)

These members would pay as dues a total of $15,750.00 for the year.

On October 1, 1920, we sold to Frank T. Fuller and Wm. Busey our printing plant at 423 G Street, Northwest. They gave us in return $7,500.00 in notes, payable $1,500.00 yearly for five years with 4 per cent interest, and I have recorded with the Recorder of Deeds a chattel mortgage on the property until the final note is paid in October, 1925. Fuller and Busey have also contracted to do our printing of THE MILITARY ENGINEER for the same period of time, the contract price to be adjusted each six monhs. At present the price is $2,161.50 for 3.000 numbers, with 80 pages text and 4 pages cover. Our increased circulation demands about 4,000 copies at present, and our increased advertising warrants about 96 pages text with 4 pages cover. The price of this, including cuts and halftones, should not exceed $18,000.00 per year, or $3,000.00 per issue.

From these figures we have:

Probable income—	
Advertising	$10,000.00
Subscriptions	15,750.00
Note due October 1, 1921	1,500.00
Interest on notes and bonds	260.00
Total	$27,510.00
Probable expenditures—	
Printing journal	$18,000.00
Clerical work	3,000.00
Jobwork, drives	1,500.00
Postage	1,000.00
Rent	300.00
Outstanding indebtedness	1,350.00
Total	$25,150.00

RECEIPTS AND DISBURSEMENTS FOR THE YEAR 1920.

Period Brought Forward	Subscriptions	Advertisers	Jobwork	Miscellaneous	Total receipts	Balance	Disbursements
Balance on hand January 1, 1920						$4,240.36	
January	$580.90	$134.74	$7.00	$2,054.92	$2,777.56	$813.64	$6,204.28
February	389.78	5.00		67.40	462.18	340.65	935.17
March	798.36	195.49		387.26	1,381.11	266.25	1,455.51

January 12, 1921. Audited and found correct

H. R. RICHARDS, *Member,*
Chairman of Auditing Committee.

W. O. TUFTS, *Member.*
FRANK T. FULLER, *Member.*

These are fair estimates for the year 1921, and under the By-Laws of the Society it is the duty of the Treasurer for the year 1921 to acquaint the Board of Directors with any deviation from these figures if they are adopted. Our first year closes with our Society on a firm financial footing and with the best prospects for the future, but the hearty cooperation of the officers, members and editorial staff must be forthcoming to make our body perpetual.

Respectfully submitted,

JOSEPH J. TWITTY,

January 14, 1921. *Acting Asst. Treasurer.*

To the Secretary of the Society
of American Military Engineers.

Approved and transmitted for your information.

W. O. TUFTS,
Acting Treasurer.

(4) Election of Officers and Directors.

The following election tellers were appointed by the President:

Col. G. B. Pillsbury and Col. A. H. Brooks.

(5-6) Reports of Standing and Special Committees; no reports.

(7) Miscellaneous business; none.

(8) Report of Election Tellers—total votes cast, 958:

For President

Maj. Gen. W. M. Black	954

For First Vice-President

Col. Wm. Barclay Parsons	949

For Second Vice-President

Col. Charles Keller	950

FOR DIRECTORS

Regular Army

Maj. Gen. W. C. Langfitt	949
Col. Mason M. Patrick	950
Col. Wm. V. Judson	950
Col. Harley B. Ferguson	945
Lt. Col. G. A. Youngberg	944
Maj. Richard Park	940

Reserve Corps

Col. Chas. A. McKenny	955
Col. Perley F. Walker	951
Lt. Col. J. H. Finney	951
Col. C. Van Deventer	948
Lt. Col. Harris P. Ralston	947
Maj. Percy E. Barbour	949
Maj. Joseph H. Wheat	949

Membership at Large

Col. C. H. Birdseye	948
Col. F. G. Jonah	950
Col. F. A. Molitor	939
Maj. W. O. Tufts	944
Maj. Geo. O. Totten	946

(9) Announcement of election of new Officers and Directors. The Ballot was elected.

(10) Literary and Social Program.

As the meeting was preceded by a luncheon and an address by the Assistant Secretary of War, Mr. William R. Williams, whose article, "The Council of National Defense and Industrial Preparedness," appears in this issue, no further program was prepared.

(11) The meeting adjourned at 2.45 P. M.

D. L. WEART, *Secretary.*
Major, Corps of Engineers.

MEETING OF BOARD OF DIRECTORS

1. A meeting of the Board of Directors having been called to meet immediately after the Annual Meeting of the Society, the meeting was called to order by the President at 2.50 P. M., at the Blue Triangle Club House, 20th and B Streets, N. W., Washington, D. C.

2. Present:

Gen. William M. Black	Col. Chas. A. McKenney
Col. Charles Keller	Maj. J. H. Wheat
Col. Mason M. Patrick	Col. C. H. Birdseye
Lieut. Col. G. A. Youngberg	Maj. W. O. Tufts

3. Absent:

Col. Wm. Barclay Parsons	Lieut. Col. H. P. Ralston
Gen. W. C. Langfitt	Maj. P. E. Barbour
Col. Wm. V. Judson	Col. F. G. Jonah
Col. Harley B. Ferguson	Col. F. A. Molitor
Maj. Richard Park	Col. C. Van Deventer
Col. P. F. Walker	Maj. G. O. Totten
Lieut. Col. J. H. Finney	

4. The following business was presented to the Board by the President:

(a) Appointment of Secretary for year 1921.

1. In accordance with Article II, Paragraph 5, of the By-Laws, Capt. H. B. Richards was appointed Secretary for the year 1921.

(b) Election of Treasurer.

1. In accordance with Article II, Paragraph 5, of the By-Laws, Maj. W. O. Tufts was elected Treasurer for the pear 1921.

(c) Term of office for members of Board of Directors.

1. In accordance with Article VIII, Paragraph 3, of the By-Laws, Directors were selected by lot to serve for 1, 2 and 3-year terms. Col. Mason M. Patrick was directed to draw the lots. The result of the drawing is as follows:

For Directors

Regular Army

	Years
Maj. Gen. W. C. Langfitt	3
Col. Mason M. Patrick	1
Col. Wm. V. Judson	1
Col. Harley B. Ferguson	3
Lt. Col. G. A. Youngberg	2
Maj. Richard Park	2
Col. Chas. A. McKenny	3

Reserve Corps

	Years
Col. Perley F. Walker	1
Lt. Col. J. H. Finney	2
Lt. Col. Harris P. Ralston	1
Maj. Percy E. Barbour	2
Maj. Joseph H. Wheat	3

Membership at Large

	Years
Col. C. H. Birdseye	3
Col. F. G. Jonah	1
Col. F. A. Molitor	1
Maj. Geo. O. Totten	3
Maj. W. O. Tufts	2
Col. C. Van Deventer	2

(d) Election of members for Executive Committee.

1. In accordance with Article III, Paragraph 2, of the By-Laws, the following members of the Board of Directors were elected to serve on the Executive Committee:

Maj. J. H. Wheat — Col. C. H. Birdseye
Col. Mason M. Patrick

(e) Budget for year 1921.

1. In accordance with Article V, Paragraph 4, of the By-Laws, the budget which is included in the report of the Treasurer, submitted at the Annual Meeting, was tentatively accepted for the year 1921.

(f) Resolution of Chicago Post. "Junior Membership."

Action: A committee consisting of Col. G. A. Youngberg, Col. C. H. Birdseye and Maj. W. O. Tufts was appointed to consider the resolution and report to the Board.

(g) Change in date of the Annual Meeting suggested by Col. F. C. Jonah.

Action: The Secretary was directed to write to Colonel Jonah and inform him that Article XII, Paragraph 2, of the By-Laws, provides for amendments to the By-Laws, and that if he will submit his suggestion in the manner required, the Board will be pleased to consider the proposal.

(h) Resolution of the New York Post, proposing that travel orders be issued by the War Department for Army Officers addressing Posts on subjects of military nature.

Action: It was decided that no formal action could be taken on the Resolution. The Secretary was directed to inform the Posts that if they desired to have Army officers address them on military matters, they should apply to the Secretary, stating the subject which they wished to have covered, and then an effort would be made, in an informal way, to provide a speaker.

5. The Board adjourned at 3.15 P. M., to be reconvened at the call of the President.

D. L. WEART, *Post Secretary,*
Major, Corps of Engineers.

Permeability of concrete

Tests by the Bureau of Standards indicate that concrete is far more impermeable to water than the limestones and sandstones employed for building purposes. Stone slabs from 1¼ to 2½ inches in thickness were penetrated in from 10 seconds to 19 minutes by water at 60-pound pressure. A slab of 1.6 Portland cement mortar, 2 inches thick, resisted penetration for 3½ hours. A slab of 1:1½:2 concrete was penetrated to a depth of ½-inch in 24 hours.

New York Post Endorses Bill for Retiring Emergency Officers on Regular Basis

The annual meeting of the New York Post of the Society of American Military Engineers was held at a Beefsteak Dinner at Keen's Chop House, in New York, on the night of January 26. There were sixty-five present.

The tellers appointed to canvass the votes on the ticket nominated by the Nominating Committee reported the election of the following officers and directors:

Gen. W. C. Langfitt, President; Col. A. S. Dwight, Vice-President; Maj. Percy Barbour, Secretary; Maj. E. G. Sherwood, Assistant Secretary; Maj. P. B. Fleming, Treasurer; Col. R. D. Black, Col. F. E. Humphrey, Col. T. T. P. Luquer and Col. Geo. A. Johnson, Directors.

The Secretary was instructed, by unanimous vote, to wire Hon. John J. Esch, of the House of Representatives, in support of the bill providing for the retirement of disabled emergency officers on the same basis as Regular Army officers.

The dinner was then given over entirely to social features, including humorous speeches by many of the incoming and outgoing officers, interspersed with music furnished by professional entertainers and songs by the Post.

New York Post, Society of American Military Engineers, Launches Membership Drive

At a recent meeting of the board of directors of the New York Post, Society of American Military Engineers, the membership committee was enlarged as the first step in an intensive campaign to bring into the organization ex-service men and others interested in the national defense. There are now 111 members in the Post, and it is estimated that in New York and vicinity there are from 800 to 1,000 ex-service engineers eligible to membership.

The new membership committee, which still retains as its chairman the chairman of the old committee—Col. T. C. Clarke— is composed of the following men: Cols. O. B. Perry and E. S. Shaughnessy; Lieut. Cols. Philander Betts, J. P. Hogan and Evarts Tracey; Majors J. P. Hallihan, Chandler Davis, E. C. Church, Irving V. A. Huie, W. J. Hammer, A. C. Harper, J. W. Mark and E. E. Sherwood, and Lieut. A. D. Fitzgerald.

Federalization of 22nd Engineers, National Guard, New York

Five former colonels and the New York Post of the Society of American Military Engineers were the guests of honor at the military review of the 22nd Engineers, given at 8.30 P. M., November 15, at the regiment's armory, 168th Street and Fort Washington Avenue, New York City.

The 22d Engineers is the first National Guard engineer unit to become federalized, the completion of its federalization taking place November 5. It was partly in celebration of this event, and partly as an honor to the retiring colonel of the regiment, that the review was held. Col. George D. Snyder, the retiring colonel, acted as reviewing officer. Col. F. E. Humphreys, a graduate of West Point, but who is not now in the Regular Army, is the 22nd's new commanding officer.

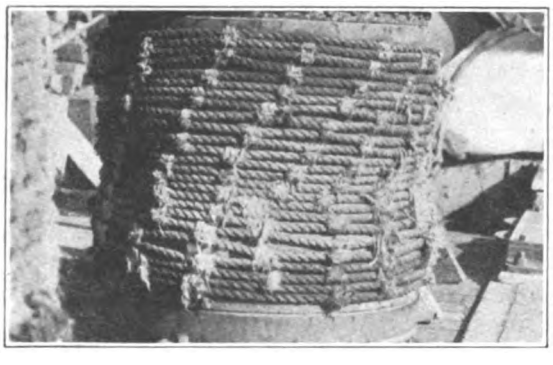
Rope Mat Reinforcement for Dredge Sleeves

By

J. H. Polhemus

General Manager, Port of Portland, Oregon

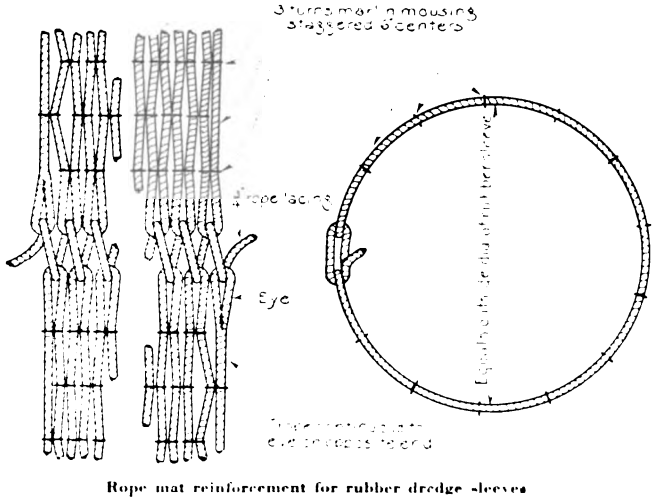


(Continued from Page 119)

For the information of pipe-line, hydraulic dredge operators there is submitted the design and description of a rope mat reinforcement for the rubber sleeves at the flexible joints in the discharge pipe line, or what is generally termed "the floating or ponton pipe line."

The Port of Portland for the past 22 years has been operating, on a large scale, hydraulic pipe-line dredges, and the cost of rubber sleeves has been as always, a very serious question, especially on the very high powered, 30-inch dredges.

Metal flexible joints of several different types for the pipe line have been tried at times, but they were not found satisfactory or suitable for the ponton pipe line.



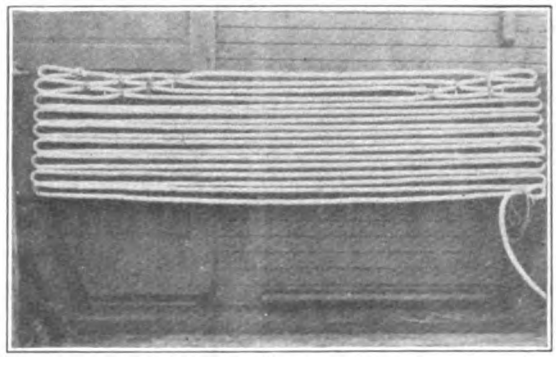
The first reinforcement for the rubber sleeves was tried about ten years ago on our dredges. This was an iron ring clamp around the middle of the sleeve. This, however, cut

the sleeve and also would slip to the end when the pump was stopped. Chains were next used, but with little more success.

The sleeves were later served with rope, but this was not entirely successful, as the rope would not stay in place.

The rope mat as now used very successfully on all of our dredges, and the two 24-inch dredges of the U. S. Engineer Department in this district, was first designed and used by Captain Johnson on The Port of Portland's 30-inch dredge *Tualatin* in 1917.

Rope mat reinforcement for rubber dredge sleeves



This mat is made of old rope stretched over a rack and tied with rope yarn. The mat is then placed on the rubber sleeve and laced in place. The accompanying drawing clearly shows how the rope mat is made. Old rope makes a better mat than new rope, due to the fact that the stretch has been taken out.

The picture shows one of the spare 30-inch rubber sleeves fitted with a rope mat, and the pegs or templet on which the mat is made.

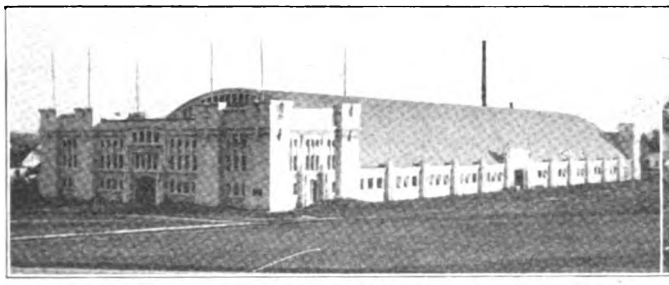
The material handled by these dredges varies from coarse, heavy, sharp sand to heavy gravel. Some clay is encountered at various locations in the harbor and is awkward to handle. It has been found necessary at times to shut the dredge down as many as fifty times during a 24-hour day to clean the pump but, of course, this is unusual.

The average harbor dredging conditions require a 3,500-foot pipe line and 30-foot lift from water surface to top of fill, the pipe line pressures running as high as 50 pounds per square inch.

The average life of the 10-ply, 30-inch rubber sleeve, such as we have been using, served with rope mats, under average dredging conditions, is 300 working days. The average life of the same sleeve under like service without the mats is 150 working days. Hence we have doubled the life of our

rubber ponton pipe-line sleeves by the use of this simple and inexpensive rope mat. Also the wear and tear is much more severe on the large 30-inch dredges than on the 20-inch dredges, and the sleeves are subject to more accidents, making the rope mat protection the more necessary.

Concrete Construction in the Tropics



That the tropics, where Jack Frost is conspicuous by his absence, is the ideal place for the use of concrete in building construction, has long been appreciated. Yet American manufacturers have apparently thus far failed to develop the possibilities of this market. We have not advertised our products.

Because of the presence of wood-eating ants no wood construction in the tropics has any great degree of permanence; and wood is at least twice as costly as in the United States. Concrete, on the other hand, is cheaper and more durable in the tropics than in the temperate zone.

Our architects have failed to adapt concrete construction to the needs of the dweller in the tropics. A modified New York house is not suitable for Central America. More window space is needed, and a greater capacity per occupant.

A distinctive design, adapting concrete construction to the characteristic dwelling of the tropics is needed, and the tropics look to America to provide such designs.—*Concrete.*

Engineer Reserve Officers' Training Corps

Instruction at Educational Institutions

By

Patrick H. Tansey
Captain, Corps of Engineers

SO extensive is the scope of activities with which the Corps of Engineers is charged in time of war, that the few officers holding permanent commissions therein must be assisted in the execution of their numerous and studendous tasks when the emergency of war exists. The urgent need for an Engineer Reserve Corps was recognized shortly before the World War, and at the entry of the United States into the conflict there were almost four hundred engineers enrolled in the Engineer Reserve Corps. Among this number there were very, very few who knew anything of military engineering, of the fundamental economic principles of construction in war, and limited opportunities only were afforded them for adding to their scant military education. Shortly after the declaration of war by the United States, Engineer officers' training camps were organized, and even up to Armistice Day Engineer officers were receiving a short, intensive course to fit them for duty either in the field of operations or service of supply in France. Oftentimes engineers with only several weeks' training were ordered away from the camps to active duty along lines of endeavor which they had followed in their civilian pursuits. How well they accomplished their duties history tells; nevertheless in consideration of shortage of officers during the war and the loss of time in training them while the war was raging Congress finally decided that something was radically wrong with our system of national defense.

To provide for well-trained officers in future emergencies the R. O. T. C. has been established. The primary object of the Engineer R. O. T. C. is to provide systematic training in military engineering at civil educational institutions for students actually enrolled in engineering courses at the institution, and to build up a strong and energetic Engineer Reserve Corps in which the members will not be officers merely "by Act of Congress," but also by virtue of the fact that they have been carefully selected as leaders and have been trained in military engineering and the art of war. Fortunately, this training is carried on when the students taking it are in a receptive mood; their minds and bodies are young and undeveloped; their characters are not yet formed; they are filled with intense interest and enthusiasm and the military instructors concerned are not confronted with the proposition of "teaching an old dog new tricks," as were some of the officers on duty as instructors at the Engineer Officers' Training Camps during the war.

In the article, "Summer Camps of Instruction for Engineer R. O. T. C.," Sept.-Oct., 1920, number of THE MILITARY ENGINEER, Captain Steyer stated that "The chief disadvantage of the training (training at college) or the greatest difficulty under which it labors, is that, because of the limited time and facilities available, the instruction with the exception of Infantry drill, is too largely theoretical and too little practical. This is especially true of engineering instruction. The average engineering college has very inadequate facilities for practical instruction in engineering." The above statement no doubt carried to the minds of all the Engineer officers who read that article that the work of Engineer Units at colleges is almost entirely theoretical and very little practical. The spirit of this article is to show what the work at colleges actually comprises in Military Engineering and to demonstrate that the courses are not too largely theoretical. It is contemplated that the following paragraphs shall prove a sequel or rather a supplement to Captain Styer's excellent article on Engineer R. O. T. C. camp training, and that the two articles combined will outline in a comprehensive manner the ideals, purposes, and accomplishments of the Engineer R. O. T. C. All reserve officers, no doubt, are interested to know just how their corps is to be increased and all officers of the Corps of Engineers to find out just what training their fellow reserve officers will have undergone when they join forces to meet the next national emergency.

The course of military engineering requires four college years for its completion, and the final reward for successfully passing through the four years is a commission as second lieutenant, Engineer Reserve Corps. In general this course comprises a thorough ground work in the fundamentals of military science and of engineering art as applied to war; in a word, the instruction given in engineer units at college is calculated to turn out graduates competent to perform the duties of a second lieutenant of Engineers, in garrison or in the field.

Digitized by Google

The schedules of training are prescribed within limits by the War Department; however, they are very flexible, so that they may be applied in any college or any clime, and fit in harmoniously with local conditions and local curricula.

To make my point clear, the same schedule could not be applied in Oregon, the land of eternal rain, as might prove a success in California, where the sun is ever smiling; Boston could not follow a course of training adopted in Alabama; colleges in the heart of a city do not offer the same advantages for outdoor practical work as colleges in the country. Wisely has the War Department left to the Engineer officers in charge of Engineer R. O. T. C. units the duty of arranging the schedules of instruction as best to harmonize with local conditions, customs and traditions.

The courses as developed for Engineer units have been made very attractive and interesting, and as such have appealed strongly not only to the students, but to the faculties of our leading colleges and universities; to the students because they feel they are getting some practical good, something of an immediate utilitarian value in their own line of engineering; to the faculty because they see their own courses of engineering amplified and extended with engineering problems of a military nature, and seeing such valuable extension work accomplished, they feel compelled to co-operate with the Department of Military Engineering in every way.

As a freshman an engineering student enrolls in the course in military engineering a private of engineers, his status is distinctly that of a private; his duties and obligations, his rights and privileges within the military sphere of activities are those of a private (the fact that he is a "plebe" or "rook" or what-not, accentuates that fact also). His course of instruction under the military department for the first year is progressive and conducts his education, step by step, through the military fundamentals and such technical knowledge as an intelligent and efficient private of Engineers should have. Normally at the end of the first year of military training the private attends an Engineer basic camp, where the knowledge and training already attained are extended to include practical work. (This attendance is voluntary.) In the fall he returns to college and again registers in the Military Department. During the second year, however, he is appointed either a corporal or a lance corporal and his duties are those of a corporal in all practical work. The theoretical course of instruction during this year is calculated to render him an accomplished soldier—efficient, smart and reasonably qualified to perform the duties exacted of a "non-com" in a company of Engineers. If his work has been satisfactory during the first two years of training and he appears to have the "makings" of a soldier and engineer, he is selected to take the advanced course, which leads to a commission in the Engineer Reserve Corps. Selected as "good timber" for an officer, he enrolls in the advanced course, and during the first year of that course he is trained in the duties which a master sergeant of Engineers would ordinarily be called upon to perform. Between the third and fourth year, he attends the Engineer Advanced Camp, where he actually performs the duties of master sergeant and junior officer in the company, on the drill field, and in the solution of military engineering problems of his own selection, along the lines of his civil education. In the last year of the course he is taught the duties of a junior officer, and at the completion of his four years' course in military engineering he is reasonably qualified to perform the duties of a platoon commander in a company of Engineers. Having been graduated from the college and from the R. O. T. C. and promoted to second lieutenant, Engineer Reserve Corps, he may request to be placed upon active duty as temporary officer in the Engineers.

The object of this period of training with the Regular Army is to acquaint the reserve officer with service in the Regular Army and to enable the Government to ascertain his qualifications for future promotion by thus providing a probationary period of training under the immediate supervision of officers and with units of the Regular Army.*

If a student follows out the entire course as outlined above and in addition has had six months' training as a "shave-tail" in the Regular Army, he certainly is qualified to perform the duties of a second lieutenant of Engineers. His subsequent rank will depend upon his military engineering activities after graduation. During his entire course in the last two years each student is closely observed in all his work and is carefully rated on that work. At the training camps also he is rated upon his proficiency and his personal characteristics. During his voluntary six months' probationary period in the regular service his qualifications for future promotion as an Engineer officer are carefully ascertained by his immediate commanding officer. His record as an R. O. T. C. student and as a temporary lieutenant of Engineers, together with the record of his activities in the engineering world, after graduation, will determine in large part the nature of his duties and his rank in the next war emergency.

Now, if his four years' training at college is too largely theoretical he will be far from a practical engineer when he receives his coveted sheepskin, for after all an engineer manual does not make an engineer "by a long shot." The statement of Captain Styer to the effect "that the instruction, with the exception of Infantry drill is too largely theoretical" was once a sad truth, but that unhappy day is passing. To-day, as far as practicable, our embryo Engineer reserve officers are learning the art of military engineering by *doing*. The theoretical work is becoming more and more harmoniously balanced with the practical work in the field, and in the laboratory or drafting room. In Engineer units Infantry instruction is limited to 17 per cent of the entire four years' course, and that is largely practical; engineering is emphatically stressed. Previous to the year 1920-21, the basic course for Engineers, that is, the first two years, was largely given to infantry instruction, but under the new schedules of training as outlined above the engineer instruction begins as soon as the student enrolls in the Engineer unit at the college, and in that engineer instruction the *practical* is emphasized. The R. O. T. C. officer of the Ninth Corps Area, an Engineer of long and extended practice, demands that engineer instruction be *practical*. Certain features about a college militate against the practical, since most of the courses are largely theoretical; however, that fact alone makes an Engineer unit an interesting attraction on the college campus, if outdoor practical methods are predominant in engineer instruction.

I will show briefly how practical instruction is being effected in certain institutions where Engineer units exist. In the bridge course, bridges are actually constructed to normal scale. Some units have been compelled to construct bridges one-half and one-third size. Such construction is valuable experience to the youthful military engineer, and he actually does something—creates an engineering structure that undergoes stress that he read about in some theoretical treatise. The course in military railways has been vitalized by actual survey and location in

*The number of reserve officers called into active service with the Regular Army will of course depend upon the amount of the appropriation made by Congress for that purpose.—Ed.

Digitized by Google

one institution. A combat railway was located under an assumed situation of warfare. This problem in the field was executed after the student was thoroughly conversant with the requirements of a combat railway, its functions and its limitations. Fortification, when practicable, is taught by actually laying out and digging trench systems; putting in the revetments; constructing barbed-wire entanglements, etc. In conjunction with such instruction a certain amount of theoretical study is necessary; however, if the practical method is followed, a student will look up all his duties even though the allotted time for home study is very short. When the student is taught hippology, he is actually brought in contact with live horseflesh, after he has studied the anatomy of the horse from a large chart furnished by the surgeon general, and perused mimeograph sheets issued to him for home study. Some institutions are fortunate enough to have the light ponton equipment; no better instruction in ponton work can be given than actual construction of the bridge on water. Practical instruction in demolitions is given by Engineer units which are blessed with facilities for storage and handling of explosives. The last few sentences show the extensive field open to practical work in Engineer units; however, the course of general construction work affords far more opportunities for practical problems in the field, laboratory and drafting room. The location of a site for a divisional cantonment, its general layout, the design of its water supply, power supply, sewerage system, sewage disposal, preliminary location of roads and railroads, mechanical installations, the design of portable power plants, etc., all these afford a vast source for actual work in the field, that can be executed just about as well at college as at the training camps, and this source is being drawn upon by the Engineer units to the gratification of the Chief of Engineers, to great satisfaction of the engineer college students, and to the growing interest of the college faculties.

The Chief of Engineers is whole-heartedly behind this practical work; the allowance of equipment is almost unlimited, if it can be shown that same can be used efficaciously in engineer instruction. Carpenter, demolition, drafting, map reproduction, photographic, pioneer, reconnaissance, surveying, office, and ponton equipment and supplies are authorized, but the Engineer unit commanders are directed to look upon this equipment as an investment and secure a reasonable return by way of increased efficiency, interest and esprit de corps of the unit. In addition two pounds of explosive are in general allowed every student taking the fortification course, provided, of course, that facilities are available for handling and storage of explosives. Authority is also granted Engineer units to make local purchases of expendable articles for use in drills and practical work in field engineering. Funds are obtained by requisition and may not exceed $300.00 for the first 50 students enrolled and $2.00 for each additional student. The above statements show the stand of the Chief of Engineers upon the Engineer R. O. T. C. training problem. One Corps Area commander of prominence and renown stated recently in an official manner that the most important work under operation in his area was the R. O. T. C. work. No doubt the force of this statement will bring home to the officers of the Corps of Engineers the vast importance of the R. O. T. C. work at colleges.

Notwithstanding the great importance of camp training in the R. O. T. C. instruction schedules, the college work cannot be overestimated. At camps, organization, administration and supply problems are easily solved, while at colleges these present many difficulties never dreamt of in a camp. At camp the atmosphere is purely military; at colleges a military atmosphere must be created. At camps discipline is easy of enforcement; at colleges it is quite a problem. And so the comparison runs down the line with the disadvantages on the college side. The officer on R. O. T. C. duty must ever play the role of the actor, the psychologist, the instructor and the diplomat; and his most difficult problems are by no means his problems of instruction.

In present-day methods of conducting warfare every science and every branch of engineering plays its part. Fundamentally military engineering problems are the same as those of any other branch of engineering, perhaps simpler, yet so extensive is the scope of military engineering that it demands wide range of knowledge in all engineering subjects. All branches of engineering send students to the Engineer units for instruction; it is therefore the duty of the Engineer instructor to show these various students just how their civil education can be put to military use in case of a war emergency, and extend that education by fitting problems of a military nature, where the fundamental principles of war economics must be applied. In addition to the solution of these military problems, the engineer students must also be trained in purely military engineering, which may include all improvisations calculated to accomplish a purpose with the swiftest dispatch. While engineering structures in the field of operations are required to be erected with great speed, and with the labor and materials available, and are in many cases makeshift structures, engineering construction in the zone of communications (the S. O. S.) and mobilization camps, etc., require the same skill and precision demanded in the world of civil engineering. In order to fit engineer students for the attack of such problems the R. O. T. C. Engineer units exist.

The Engineer R. O. T. C. is still in its infancy; modifications take place from year to year, but the policy is set and does not change, and all Engineer officers on this duty are endeavoring to carry out the policy of the War Department in this regard.

The author is of the opinion that the ideal will just about be reached when the basic course for engineer units is largely the Practical Military Engineering course at West Point with all its practical features, in conjunction with training in the military fundamentals; and the advanced course, in which the problems partake of the nature of the problems given at the Engineer School, U. S. Army, in the basic and advanced courses for Engineer officers.

The great success of the Engineer R. O. T. C. cannot be fully realized until its products are actually used in the service. Any officer is valuable inasmuch as he can relieve his immediate superior of responsibilities; in years to come when some of these embryo officers, products of the R. O. T. C., are serving in some future emergency as junior officers under the readers of this article, then can judgment be passed upon the efficiency of the Engineer R. O. T. C. As the years roll on the progress of the R. O. T. C. will continue, and a large and patriotic Engineer Reserve Corps will be established, so that in time of war the Corps of Engineers can turn with pride and confidence to its growing reserve and choose selected experts and proficient Engineer officers to carry out the tasks which war imposes.

The state of Wyoming is contemplating the installation of small beacons along its roads, to warn motorists of railroad crossings and dangerous curves. These beacons will be of the "flashing" type, 8 feet high, with a visibility of 3 miles. There will be distinctive colors for crossings and curves.—*Eng. News-Record.*

The Council of National Defense and the Mobilization of Industry

A paper read at the informal luncheon preceding the annual meeting of the Society of American Military Engineers, at Washington, D. C., January 14, 1921, by W. R. Williams, Assistant Secretary of War

A STUDY of the history of the activities of the War Industries Board during the World War shows conclusively that not only this organization, but also the allied units of the Food Administration, Fuel Administration, Railroad Administration and War Trade Board, were created to deal with the conditions of confusion in supply existing in the early days of the war. These conditions arose because of our lack of a plan for the supply of the forces we then brought into existence. The various stages of the growth of these bodies, and especially the War Industries Board, furnish impressive evidence in support of the above conclusion.

The Act of Congress creating the Council of National Defense in 1916 was an item of constructive legislation toward national preparedness that stands preeminent in the progress toward national security. However, the Council was created such a short time before the entry of this country into the World War that it was impossible to work out a well-planned organization. It is safe to say that if the Council had been given the power of direction and control it would have evolved sub-divisions of its organization to perform the work of the War Industries Board, the Fuel Administration, the War Trade Board and the other organizations that were created to meet the necessities of war.

No amount of preparation will enable us to dispense with some organizations exercising in war the functions of the War Industries Board, because, despite the most careful plans, contingencies will arise requiring the intervention of such an authority.

In connection with any pre-war plans for the mobilization of industry, a central body acting in the capacity of a national General Staff is indispensable. Without such an organization to initiate, co-ordinate and direct the study made in the several executive departments no definite results can be attained.

While conditions existing during the World War made necessary the formation of the various units referred to above, or at least justified their organization, it is asserted that it will be fundamentally faulty to include in the preparation of plans for another industrial mobilization a body to be brought into existence for the exercise of the functions of the War Industries Board, after the emergency has arisen, or even when it is seen to be imminent. The plans should include the utilization of an existing agency, if there be any such, or, if not, necessary steps must be taken to secure legislation creating a body capable of doing its part in peace-time preparation, and in time of war of executing such of the functions of the War Industries Board and allied organizations as may be then necessary.

Fortunately, there is no necessity for the creation of a new agency. The law creating the Council of National Defense assigns to that body functions that make it peculiarly suitable as the co-ordinating agency in formulating plans for the industrial mobilization of the country for war or other great emergency, and in war of exercising such executive functions as may be necessary. The organization of this body, therefore, should have two objects—first, to perform its part in the work of preparation, and second, to allow for an orderly and immediate expansion to meet the war demands that may be made upon it. With such an organization the only action necessary to enable it to execute its war-time functions will be an executive order. Such order can only be issued pursuant to legislative authority similar to that contained in the so-called Overman Act, but it is assumed that such legislation will be enacted.

A brief consideration of the organic law and its obvious method of application will show the essential part that the Council must take in any plans for industrial mobilization. The Act approved August 29, 1916 (Bulletin 33, War Department, 1916), provides, among other things, as follows:

> That it shall be the duty of the Council of National Defense to supervise and direct investigations and make recommendations to the President and the heads of executive departments as to the location of railroads with reference to the frontier of the United States so as to render possible expeditious concentration of troops and supplies at points of defense; the co-ordination of military, industrial, and commercial purposes in the location of extensive highways and branch lines of railroad; the utilization of waterways; the mobilization of military and naval resources for defense; the increase of domestic production of articles and materials essential to the support of armies and of the people during the interruption of foreign commerce; the development of seagoing transportation; data as to amounts, location, method and means of production, and advisability of military supplies; the giving of information to producers and manufacturers as to the class of supplies needed by the military and other services of the Government, the requirements relating thereto, and the creation of relations which will render possible in time of need the immediate concentration and utilization of the resources of the Nation.

It should be noted that the Council is composed of the heads of six of the Executive Departments. These six departments may be divided into two classes—first, those which represent the great users in war time, the War and Navy Departments, and second, those that represent the productive capacity of the country, Agriculture, Commerce, Interior and Labor. The Council is the great co-ordinating agency in the preparation of plans for industrial mobilization to meet a national emergency. By virtue of its membership, it can assemble statements of requirements, data as to sources of supply, and after a comparison of the former with the latter, reach conclusions as to allocation of facilities to satisfy needs. Such allocations can be made by the Council acting for the President, and will enable the various requiring units to proceed in an orderly manner to make their detailed plans for securing the necessary supplies. In cases where facilities are inadequate to meet requirements, the Council is the proper agency to study the problem, determine the measures necessary to meet the deficiency and intitiate the proper action.

Digitized by Google

The Council consists of the Council proper and the Advisory Commission. After the dissolution of the War Industries Board at the end of the war, the Council formed within itself a subordinate organization known as the Interdepartmental Defense Board. This is its real working unit. It consists of a representative of each of the Executive Departments whose heads form the Council proper and is under the chairmanship of the Director of the Council. Under a recently proposed reorganization of the Interdepartmental Defense Board it will have an Executive Committee consisting of the Director, the War Department representative, and the representative of the Navy. The advantages of such a Committee lie in its small personnel and in the fact that it has on it the representatives of the two Executive Departments which are the principal requirers in war and which are, therefore, most concerned with adequate war preparation.

The role assigned by law to the Council of National Defense does not contemplate or require a large organization. For its peace-time activities it can readily accomplish its task with a very limited personnel, relying on existing agencies to furnish the data needed for the development of plans of preparation. The degree of expansion to meet war conditions depends directly upon the completeness with which we solve our supply problems before the emergency arises.

On January 3, 1921, the House of Representatives, in the consideration of the Sundry Civil Bill, eliminated the item covering an appropriation of $75,000 for the next fiscal year for the support of the Council of National Defense. No fair-minded citizen can take exception to the desire of Congress to limit appropriations to essential governmental activities. Now, more than ever before, there is need for rigid economy. There is no economy, however, in eliminating an item for the support of an activity so important to the public welfare as is the Council of National Defense.

Information Concerning Appointments in the Army

Communication from The Adjutant General, U.S.A.

There are more than 4,000 vacancies in the commissioned personnel of the Army. When promotions under the reorganization law are completed, about 1,200 of these vacancies will be in the grade of first lieutenant, the remainder being in the grade of second lieutenant. While it is not proposed to fill all vacancies at present, the necessity for more officers for the Army requires that a portion of the vacancies be filled without delay. An examination for appointment will, therefore, be held April 25, 1921. This examination will be competitive for 2,585 vacancies; the appointments to be distributed among the branches of the Army as follows:

Infantry	812
Cavalry	35
Field Artillery	600
Coast Artillery	268
Engineers	118
Air Service	400
Signal Corps	114
Quartermaster Corps	35
Ordnance Department	86
Chemical Warfare Service	32
Philippine Scouts	85

As a result of this examination no appointments are to be made in branches of the service other than those named above.

The date announced is that of the final examination. Prior to that date applications must be submitted and applicants must undergo a preliminary examination. All applications are to be received and acted upon by corps area commanders, who are also charged with conducting the preliminary and final examinations. Details of information concerning examinations for appointment are contained in regulations now being distributed, and application blanks may be obtained at any military post or station. Applications should be submitted by the applicant at the military post or station nearest his place of residence. Writing to The Adjutant General for information or for blanks will only cause delay.

It is contemplated that successful candidates will be announced and appointed, or nominated for appointment, about two months after the examination. Candidates attending schools or colleges will, therefore, have an opportunity to complete the present school year before being appointed.

All successful candidates will be arranged in their order of merit, as determined by the final examination, and will be appointed in the Army in such order. They will also be placed on the promotion list in such order without regard to the branch of the Army in which appointed. Those candidates who attain the highest marks on examination will, therefore, have priority in advancement to the vacancies existing as first lieutenant. To be informed as to the full details concerning examinations and appointment, it is necessary that candidates consult the regulations which are being sent to all military posts and stations. However, the prospective candidate's attention is directed to the following important points:

1. Eligibility for appointment is fixed by law, and requests for exceptions cannot, therefore, receive consideration by the War Department. The age at the time of appointment must be between 21 and 30 years. At the time of the final examination each candidate must be in one of the following classes:

(a) A warrant officer or enlisted man of the Regular Army having had not less than two years' service as such.

(b) A member of the Officers' Reserve Corps or the enlisted Reserve Corps.

(c) A member of the National Guard.

(d) A graduate of a technical institution approved by the Secretary of War.

Any civilian of the required age who passes the preliminary examination may readily become eligible to take the final examination and to be appointed by entering either Class (b) or (c) above.

2. The preliminary examination consists of an inquiry into the physical, moral and mental qualifications of an applicant to determine whether or not he has the requisite qualifications to justify his proceeding with the final examination. Such a preliminary examination will avoid inconveniences and unnecessary expense to both the applicant and the government in many cases.

3. The final examination is the same for all candidates, and to insure strict justice to all, the examination papers will be marked by central boards convened in the War Department. The scope of the mental examination is such as to insure the Army getting men of the required educational foundation to satisfactorily follow a career as an Army officer. The elementary part of this examination embraces the subjects of history, grammar, geography, arithmetic, algebra, geometry, trigonometry and physics. The advanced part of the examination consists of a large number of subjects, including mathematics, languages,

Digitized by Google

literature, electricity, chemistry, law and minor tactics. Examination is required in but three of the subjects of the advanced group to be selected by the candidate.

4. Candidates for appointment in the Air Service, Engineers, Signal Corps and Ordnance Department are required to satisfy certain technical requirements, either by examination or by having graduated from technical schools.

5. The regulations provide liberal exemptions from examination in various subjects according to the education, training and experience that the candidate has had. The granting of exemptions has been placed entirely in the hands of the examining boards, and requests for exemptions cannot, therefore, be considered by the War Department.

6. Each candidate is permitted to express one or two choices of the branch of the service in which he desires to be appointed. In making appointments, however, while the preferences of candidates will be given due consideration, the War Department reserves the right to assign thm to such branches of the service as may be necessary.

In consideration of all of the facts, it is apparent that the present offers an exceptional opportunity for appointment in the Army, and it is anticipated that no difficulty will be experienced in securing the number of good officers for which the examination is held. Should a number of candidates, in excess of those for which the examination is held, receive a passing mark on examination, those making the lowest mark will not be selected for appointment nor will they be placed on an eligible list for future appointment, as the experience of the War Department has been that such eligible lists are unsatisfactory, both to the Government and to the individual.

[*Note.*—See page 165 for further data regarding appointments in the Corps of Engineers, Regular Army.—Ed.]

More About Staff Control

[*Note.*—There is room for extended discussion on the important subject of staff control. Of course, as has been pointed out, "any system will work if good men are on the job." But we must have a system set up in advance which will work with average and often poor men "on the job," because that is what we shall always have in time of war. We accordingly present to our readers two more illuminating discussions on this much-discussed subject.—Ed.]

C. L. Hall
Major, Corps of Engineers

THE two articles in the November number of THE MILITARY ENGINEER on Staff Control approach the General Staff from two standpoints—one from above and one from below. Major Young, writing from the G. H. Q. end, states with the utmost clearness the principles of functional organization which must characterize any complete staff; Major Lee, writing from nearer the enemy's bullets, points out the difficulties of the functional system when the same set of G's are in continuous control of the same individuals. Each writer naturally puts his best foot forward. Each tries to upset the other. Possibly both are right.

To argue by analogy, consider a War Department publication prescribing something or other. It purports to be issued "by order of the Secretary of War," but everyone who receives it knows that official probably never saw it. It was prepared by some individual, or group of individuals, in the War Department who were selected for the job on account of their expertness in that particular line. It was read over and approved by some Assistant Chief of Staff. If the draft was concurred in by the bureau chiefs, and chiefs of combatant arms affected, the overworked Assistant Chief of Staff may not have read it at all. But the man who gets the order never thinks of contesting it. The only people who really knew who wrote the order are (1) the other people in the same General Staff Section, (2) the officers corresponding to the publication writers in the bureau chief's offices, (3) the corresponding G's in the Corps Areas—maybe. If they don't scrap among themselves, the authors of the order will remain anonymous, and the fact that such a coterie, all selected because of their professional reputation, are agreed, indicates that they are most probably right. If this group does quarrel, the dispute will be settled by a general officer of the General Staff, an officer always of long experience, *persona grata* to the Secretary of War, with whom a quarrel is a waste of time.

Take it at the other end—the battalion. Acting on the functional system, the battalion G-3 gets out an order that the company commanders think is bosh. Do the company commanders grin and bear it? They do not—they kick to the major. If the major backs up his G-3, and the captains appeal, does the colonel tell the regimental G-3 to settle it? He does not. He settles the affair on the carpet, between the major and the captains, and somebody goes home with his tail between his legs. There is about as much anonymity in the matter as there is in a murder trial.

Now, somewhere along this line there must be a break where we pass from the large headquarters where the work must be sub-divided functionally, and can be carried on with comparative anonymity, to the smaller office, where the commander can boss the job himself, and use his staff officers, not as referees on complicated matters, but as agents for doing something he has thought of doing himself. This break would seem to occur where the commander is as well acquainted with the powers and limitations of his individual line units as he is with the abilities of his staff officers; that is, where his subordinates and their organizations are reasonably fixed, and go where he goes. And similarly, the commander below is more willing to accept orders which he knows are anonymously prepared, when his organization is not an integral part of the higher commander's unit, but a pawn, to be here to-day and gone tomorrow.

In modern warfare such a break occurs when we pass from the corps to the division. The division commander not only stays with his division, but stays with every regiment, battery, and company of it, until he is relieved or promoted. He knows that Smith's regiment or Johnson's battery is good—at least he does if he's "on the job." Moreover, Smith knows, or thinks he knows, that the old man won't let the G-3 put one over on him. The G-3 knows that Smith knows who is responsible for a decision, and that if Smith doesn't like it, and feels himself in the right, there will be a fuss. But when it comes to the corps, all this is different. The corps and division commanders may be acquaintances of ante-bellum days, but the corps commander doesn't know, and can't know, intimately, how much the 13th Division is worth. It reported on D-2, and pulled out on D-3; and seems to have done fairly well. He may see it again in six months. If it got the proper orders, but did badly, no one will think of holding the corps commander responsible. At least, he will fully clear himself by recommending the division commander's relief. The subordinates who can make and break him are his staff officers. When someone says that the Nth Corps is no good, they don't mean that the organizations are not good; they mean that the staff doesn't function well. When they say the Nth Division is good, they aren't celebrating the virtues of the G's especially—the staff is but one element in

Digitized by Google

the estimate. In fact, one could hear in France of good divisions somewhat handicapped by poor staffs. Whoever heard of a good corps with a poor staff?

Another reason for a break from functional to direct control at the division is the relative performance of the headquarters of a corps. Functional staff organization is, in the nature of things, a somewhat intricate game. You have to know one another's telephone numbers to play it, and you have to know the corresponding G in the next higher unit. G-1 of a corps, for instance, is in almost as complete liaison with G-1 of his Army as he is with his own Chief of Staff. He has to be to make the machine work. If he is not able to solve his problems without bothering the corps commander, he loses his job. The corps is quite likely to stay in the same army for a long time. The G-1 gets to know the organization of Army Headquarters, and knows, by name, the fellow to call on the 'phone about every conceivable thing. Moreover, he knows his terrain. So true is this that in some foreign armies a corps didn't take over its job until it had been several days in a new area. Using electrical parlance, it was such a delicate piece of machinery that whenever it was set up in a new place it had to run a few days on no load before the lights could be turned on.

But the division is an altogether different matter. It is a fly-by-night affair; here to-day and gone to-morrow. The division staff officers know no more about the corresponding G's in the next higher unit than they know about the G's back in the S. O. S. They know no more of the terrain than do the line officers of the division. Their usefulness depends, not on the nicety with which functional questions are correlated, but on how much service they are to their own fighting men. They are chief cooks and bottle-washers for their division.

It may be said that a case has been made out for the possibility of a functional staff in the corps and higher units; but that no case has been made out for its necessity. The necessity arises from the huge size of the larger organizations. The bureaus criss-cross at so many points, and on so many different matters, that there is no brain capable of co-ordinating all the joint questions which arise among them. The Chief of Staff has to functionalize to get his work done. Major Young's example of the movement of a division by trucks from a front area to a front area in another sector is very apropos. Imagine that being arranged for, in its ultimate details, at a conference between Generals Pershing, Harbord, Bullard, and Liggett.

The above argument points to a General Staff, functionally arranged, above the division—and a command, with definite lines of personal responsibility, from there down. Undoubtedly, there must be a division Chief of Staff, because the division commander can't deal with the three brigade commanders and all of his bureau chiefs to boot. But the Chief of Staff ought to be the commander of the division staff, and not any particular lobe of the general's brain. And he should not functionally divide his office. If an assistant is necessary, let him be a general assistant, to take the night shift or the rear echelon. The right kind of man as Chief of Staff can co-ordinate his bureau chiefs with his own brain without dividing it into specialized human lobes.

Undoubtedly, there is one G who must be found in every fighting unit that has any kind of staff—namely, the Intelligence Officer. But that is not because the functional decisions with which Intelligence deals are the most ubiquitous, but because functional decisions, in the lower units, form so small a part of its task. It is primarily an operating service, doing things with its own personnel which would not be done without it. It is the least "staff-like" of the staff sections. With this one exception, the writer claims that the G-System, or the General Staff, as a means of controlling the Army functionally, is a necessity in the higher units, but has no place in organizations smaller than a corps.

Breton Somervell
Major, Corps of Engineers

Further discussion of Staff Control being in order, since it has been started by Major Hall, an attempt will be made to arrange some of the ideas which have already been advanced to answer the points he has brought out. The opinions given by officers who have had wide staff experience (I will not say by "highbrows," inasmuch as the latest definition of "highbrow" is "a person educated beyond his understanding") prove that the views expressed by Major Young are fundamentally sound. In addition to this, his exposition of his views is fortunately very clear, and not handicapped by a profusion of ambiguous terms such as co-ordinate, co-operate, etc. He has very clearly stated "in plain words" what the General Staff does, what is the nature and extent of General Staff Control.

Major Lee's main arguments are for direct control and responsibility, which are answered in toto by the statement that the General Staff gives orders and sees to their execution, and by the provision of direct channels for the transmission of these orders. The authority of the General Staff springs from its relation to the general, and not from the ranks of its members. So long as the authority exists and is recognized by all concerned it makes no difference in results.

Major Hall advances the theory that a question, though possible of division into elements when it is a large one, is not thus divisible when it is small. Is a gallon of water more susceptible of resolution into hydrogen and oxygen than a pint? Are not the questions relating to procurement, storage and sale present in a department store also present in a peanut stand? In an army a general must have a staff to handle these questions, whereas in a platoon the platoon leader or boss handles them all himself. Decisions in a division must be made more quickly, and consequently the division commander or his C. of S. should have to consult as few as possible in arriving at a proper settlement of a question. Imagine his consulting eight or ten bureau chiefs as suggested by Major Hall before issuing orders.

Taking up divisions of Major Young's article on Staff Control:

1. What does the General Staff do?

It advises its superiors and gives orders to its chief subordinates. It exists to give service, of course; we all belong to "The Service," no matter what our job is.

2. What is the character of General Staff control?

It is functional, and cannot be anything else.

In this connection, a discussion of the possible "functions" of an army should not be out of place. Due to the fact that some subordinate functions have grown to such large proportions, they are now placed as independent sections of the staff; and consent of the heads of these sections must be obtained by the person who is really charged with the responsibility for results to undertake any course of action. In other words, the tail is wagging the dog.

Any army's mission is to defeat the enemy in battle. To do this the commander must learn where the enemy is,

Digitized by Google

what his strength is, etc., and then use his men and weapons to put the enemy out of commission. This is the combat function, and in order that the person charged with drawing up plans for combat may do so intelligently, the intelligence section must be under the orders of the combat or operations officer. In time of peace, of course, there are no field operations, and the duties of this section are reduced to plans and training. The activities of the intelligence section should then be so directed as to enable the operations officer to make sound plans and training programs for possible operations.

In order that the fight may be successful, the army must have personnel, material, and communications. The only other function the army has is to provide itself with these auxiliaries to fighting. In our own Army there are also certain civil functions, but these have nothing to do with the organization of the Army as a fighting machine, and should not be allowed to interfere with its proper organization for the national defense.

The functions of the army as seen by the writer are, therefore, combatant, and administrative or non-combatant. The word "administrative" is badly chosen, but no other is known which explains the situation. This division of functions is not new or original; it is the fundamental organization of the British Staff and of the French. In larger units the French have created a Deputy Chief of Staff to control the 1st and 4th Bureaux and one to control the 2d and 3d Bureaux, as the simplest way of rectifying their previously faulty organization. They have failed, however, to put G-2 under G-3's orders in corps and divisions, as should be done.

All administrative functions except combat can and should be divided into those pertaining to personnel and those pertaining to material, and the sections handling these should have a common chief. Could not this staff organization be used from battalion to army, and would it not be the simplest?

3. What is the extent of General Staff control?

What is helpful interference and what is meddlesome interference?

This is the question which has caused the staff so much trouble, and the one that has made so many faulty organizations. At a time like the present, when the lessons learned in the World War are so fresh in our minds, it would seem that there should be a demand for organization along functional lines, and public sentiment should be such as to tear away the camouflage from specious arguments advanced by individuals and groups of individuals in the interest of personal advancement, and by those who swallow their propaganda—bait, hook, line and sinker. Unfortunately, most of those persons who draw up organization charts regard them not as a delimitation of functions, but as orders assigning themselves to special duties. Generally, if they are ambitious, they will wish to get as much power as possible, even at the expense of not making the organization a smooth working machine with all its gears in mesh.

The most bitter attacks on the General Staff, those mentioned by Major Young, come from the administrative corps and not from the line branches. Any system of bureaucracy based on the idea that all officers in the bureau are Class AA+1 is wrong. Whereas enough officers are not available to outfit the army with exceptionally good men in every job, enough are available to put such men on the General Staff. If such men are put on the General Staff, complaints as to "trash," "bull," "bunk," etc., circulated by the General Staff will not be well taken, inasmuch as the authors of General Staff writings will be the best, or as good as we have.

Considering the bureaus from the functional viewpoint, the Adjutant General's Department should be eliminated, as suggested by Gen. Fox Conner, and the others should be delimited so that no two will have the same duties, *i. e.*, reduce the twilight zone between bureaus to a geometrical line without breadth. No two should, for example, have construction. No one bureau charged with procurement and issue of supplies should control the operation of a utility, such as transportation, which is vital to the success of all the others as well as to itself.

Following the functional idea, all services except the combatant services would fall under the immediate jurisdiction of the non-combatant G, and there should be no doubt in any one's mind that such is the case. Many Engineer officers have had their feelings hurt because they were "put under a G" or "received orders" from a G, when their position on the staff entitled them to access to the Chief of Staff or the commanding general. Their position was badly taken because they were in exactly the same position as the Chief of Artillery and should have governed themselves accordingly.

The General Staff control extends to the same degree that any other direct control extends. If the superintendent on a project gives a foreman a job, he gives general instructions so that the foreman's work will fit in with the rest of the project, and only interferes when the latter falls down on the job. He then helps him with advice, if he can, or removes him.

Most engineers get into the wrong frame of mind by imagining themselves staff officers, when they are, in fact, line officers called on for advice, in much the same way as the Chief of Artillery is called on when their work affects the entire plan of the commander. An engineer is not always right, and should understand that the rest of the Army is his client. If he undertakes to produce something for his client, the latter will want results and not be interested in methods. The case is much the same as in civil life. A company wishes a bridge built to meet certain conditions. It is up to the engineer to meet the conditions and not tell the head of the firm that he does not want the bridge. On the other hand, unless the plan is fundamentally wrong he should do his best to make his plans to fit the general scheme.

In conclusion, the preponderance of opinion seems to be with Major Young, but there is in addition to his ideas, which are admittedly sound, a conviction that the staff corps should be reorganized to conform to the functional system, undue overlapping and duplication of effort being eliminated.

The World's Greatest Gas Engine. A giant gas engine made in Liege, Belgium, was in process of erection when the Germans captured the city in 1914. The Germans permitted the installation to continue, and as soon as assured of the success of the experiment they removed the engine to Derisburg, where it was in operation at the close of the war. It was then returned to its owners. This monstrous machine has four cylinders of 1.3 meters in diameter by 1.5 meters stroke, and develops 8,000 horsepower at 94 r. p. m.—*Journal Frank Inst.*

Army Engineers Need Railroad Training

By

L. A. Jenny

Formerly Major, Transportation Corps

THE writer read with a great deal of interest the article written by Col. G. A. Youngberg, which appeared in the January-February number of THE MILITARY ENGINEER.*

Colonel Youngberg explains at length the civil experience of the Army engineer who has had an opportunity to be connected with River and Harbor work. There is no doubt that many of these engineer officers are excellent executives and good engineers.

There are, however, many branches of engineering in which the Army engineer has no practical training; it would seem highly important that more attention should be given to some of these branches, and the writer wishes to refer particularly to railroad engineering and operation.

Although the writer may be considered the pioneer of the Transportation Corps, having been the first railroad engineer officially assigned to the A. E. F. and having sailed for France with General Pershing in the first expedition, he does not claim to be the originator of this Corps. This honor goes to Col. W. J. Wilgus, who was a member of the special commission which was sent to France ahead of General Pershing and who was assigned to the Chief Engineer, A. E. F., about a week after we had opened our headquarters at 149 Boulevard Hausman in Paris. Colonel Wilgus was appointed Director of Railways in August, 1917, and worked out the first comprehensive organization chart comprising engineering, construction and operating personnel for this Corps.

The writer therefore having been connected with this work from its infancy and having been designing engineer for the Transportation Corps throughout the war, charged with the preparation of all plans for railroad connections, railroad terminals, depots and port facilities, has had an opportunity to come in contact with many Army engineer officers of all ranks, and it is his opinion that comparatively few of these officers had any conception of railroad requirements.

Under railroad requirements the writer means railroad engineering in a broad sense, the proper co-ordination of railroad facilities, correct planning of yard layouts so as to facilitate yard movements, locomotive repair and coaling facilities, water stations, etc., all of which are highly important, may prove a serious menace during an engagement if not properly planned, and may result in the defeat of an army if supplies cannot be forwarded in sufficient quantities.

It would seem that future officers of the Corps should receive some instruction in this important branch of engineering from a practical railroad engineer, while at West Point. After graduation these officers should receive practical training in the engineering department or operating department of some modern railroad, or, if possible, receive some training in both of these departments.

It is not expected that the Army engineer should be an expert railroad engineer or operating official, but he should have a fundamental knowledge of this new branch of the service and, above all, he should have a clear conception of railroad requirements.

Discussion

Elbert A. Gibbs

Formerly Colonel, 15th Engineers (Ry.)

Major Jenny's contention that officers of the Corps should receive more instruction in railroad engineering and operation is believed to be met as far as practicable by the provision for sending officers to engineering schools and industrial organizations to complete their training.

Only fundamentals of railroad engineering can be taught, even in a purely technical school and could be included in the course of study at West Point only at the expense of other fundamentals more necessary in the training of an officer.

It should be kept in mind that we have an organized reserve which includes men especially experienced not only in railroad but in many other branches of engineering, who are available when needed. This is one reason for having an Engineer Reserve Corps. However, in order to be of the greatest service, the reserve officer should have a clear conception of the requirements of military engineering, and it is the writer's opinion, based on his own experience with the A. E. F., that the Reserve Officer has as much to learn as the regular engineer officer to make his more special knowledge of real value.

The military engineer in time of war can scarcely ever construct as the best engineering practice dictates, because, even assuming that he has the necessary material, the need would pass before he finishes his work. If he builds too poorly, his structure will break down under the strain. Men are generally more plentiful than material, and time, the all important consideration, is fixed by the plans of operation and cannot be altered without impairing their success. Therefore, the best military engineer is the officer who can sense just how little in labor and material can be made to answer the basic requirements of the situation and be ready to function when needed. Some Reserve Officers had this faculty developed more highly than others, which was likewise true of the regular officers, and in both classes their success was proportionate to this quality.

If the facility is to be used over an extended period, the same principle applies, but the layout should provide for expansion when needed. If the A. E. F. had provided all the construction that certain services, including the Transportation Corps, demanded as the minimum before they could begin to function, the war would have lasted at least a year longer. By building so that the particular facility would operate with the minimum amount of construction and provide for such future extension as might become nec-

*"The Civil Activities of the Corps of Engineers," page 73.

Digitized by Google

essary, the always inadequate supply of material and labor was made to answer all reasonable demands of the situation in its constantly changing phases.

It is believed that the question of experts was rather overdone during the war. We sent many special engineering units to France that would far better have been pioneer engineer units with a properly balanced personnel. These special units either found little work of their kind to do or were obliged to work under such crude conditions that their special training was more of a handicap than otherwise. Considering the class of men that will be obtained from civilian life, both for the commissioned and enlisted personnel, for engineer regiments in war time, the prime necessity is to give them sufficient military training to teach them what military engineering is and how to apply their knowledge to military operations. They already know more of their profession or trade than they will probably ever have opportunity to use.

C. W. Sturtevant

Colonel, E. O. R. C.; formerly Colonel, 15th Engineers (Ry.) M. Am. Soc. C. E.

Major Jenny's views on railway methods in France during the war have been read with much interest.

I am neither a military engineer nor a railway engineer, although I had charge of railway construction and some railway operation during my service in France as a member of the first railway regiment to arrive overseas. I do not understand why the commander of a railway regiment should be expected to be familiar with all the details of railway engineering any more than he should be able to direct the regimental surgeon how to perform an operation for appendicitis.

All of the railway regiments were organized and commanded at the outset by regular army engineer officers assisted by adjutants from the regular army, as they should have been, for the reason that there were few, if any, railway or civil engineers who were familiar with military organization and regulations or with military supply methods. The other officers were of the best that could be obtained from the engineering profession at large. These regiments were prepared to do any kind of engineering work except military field engineering.

In all of these regiments, after the field officers became familiar with military organization, the regular army officers were transferred to other duties, leaving the officers from civil life in command. The latter were in charge, as a rule, of the railway management, design and operation, while the strategic questions, such as the location of railroads, the amount and routing of the tonnage required to be moved were usually determined by regular army officers.

In time of war it is of course impossible, on account of scarcity of labor and materials, to build such luxuries as balloon tracks and four-way connections between yards and main lines. It seems to me that the French and some of the American railway officers from civil life did not understand "temporary" military railway construction in emergencies. It is very easy to sit in an office and design a complicated, elaborate railroad yard, but altogether a different proposition to build it in war time with the men and materials that may be available at the time. The failure of officers from civil life to appreciate the military emergency was unusual, but did sometimes occur. I remember one occasion when the railway operation department refused to take charge of two railroad yards that were already in operation, until coaling platforms and inspection pits were built. On another occasion they refused to operate 32 miles of repaired French railway destroyed by the Germans until the Signal Corps had installed telephones or telegraph lines. The construction engineer, however, handled all the freight offered by simply dividing the line into two 16-mile sections and placing one locomotive on each section with double crews, with orders not to leave that section under any circumstances. There were no collisions.

The suggestion that regular army officers failed in general to understand the scope or the requirements of military railways is evidently taken from some standpoint that I do not understand.

If some of the engineer officers, after leaving West Point, could take a 4-years' course in any of the civil, mining, mechanical or electrical engineering institutions, it would no doubt be valuable, but even then they would secure little or no actual experience.- In the same way civilian engineers can secure valuable military training by joining the Reserve Corps, but they will not attain actual experience unless there is a war.

The officers from civil life often felt hampered by military red tape, but when they broke through it and got results the regular officer was the first to condone it. I knew a regular army officer who placed all communications in his wastebasket that had passed beyond the tenth indorsement. Have you ever been out in a camp at night when all was still and heard the typewriters pounding away like machine guns in the distance? An army would now be impossible without typewriters, and there is much more office work than in the time of the Spanish-American War.

I think that everyone recognizes that engineer officers from civil life played an indispensable part in the great work of the American Army. The regular army officers have always given us credit for what we did, even if we did not speak the language, hold the salute, speak to our superior officers in the third person, and wear spurs while riding in automobiles. All of us, both regular and volunteer, took part in a great work, each as he saw his duty, and we can and will do it again whenever necessary. "Let's go!"

F. W. Green

Formerly Lieutenant Colonel, Transportation Service, A. E. F.; M. Am. Soc. C. E.; Vice-President St. Louis Southwestern Ry. (Cotton Belt)

Major Jenny's views, as expressed in his letter, reflect the ideas quite commonly held by engineers of civil experience as to the lack of technical perfection upon the part of army engineers of the regular establishment. It is quite natural that conclusions of this character should sometimes be reached. Most of us minister in one form or another to our *amour propre*. In comparing ourselves with our fellowmen, it is quite natural to compare their weaknesses with our own strong points rather than conversely.

The writer has had abundant opportunity to observe and compare the regular army engineer with the civilian engineer in military service, and in an honest effort to do exact justice to all has reached the following conclusions:

(1) That the training of the civilian engineer, coupled with his experience, undoubtedly enables him, in his own particular specialty, to function more efficiently than the regular army engineers. This is attributed entirely to the fact that with application and experience comes facility.

(2) That as military engineers the men with civilian experience are distinctly inferior to officers of corresponding rank in the regular service. This is attributed to the inability of the civil engineers to properly evaluate their

Digitized by Google

problem in military terms. They deliberate upon and consider the relative economies, efficiencies, etc., of the various types of fire-fighting apparatus, while, figuratively speaking, Rome burns. The military engineer dismisses all such considerations from his thought, impresses the first 200 or 300 men he comes across into service, improvises a bucket brigade and puts out the fire. This illustration is perhaps overdrawn; it is intended to present in rather sharp contrast the differences in mental attitude, and is not intended to be in any way unkind.

The training of the military engineer in matters of organization and administration is generally superior to that of the civilian engineer. This was repeatedly impressed upon the writer whenever a new project was to be organized. The military engineers apparently had been trained to estimate new situations and reach decisions, make dispositions, etc. The writer further noticed that as between civilian engineers of the rolling stone type and those who had maintained one employment throughout their experience, the former were about a mean proportional between the military engineers and the latter. In his own command the writer found it necessary to undertake the training of his officers to a proper appreciation of these fundamental requirements. This stressed the following points:

(a) What is the mission?
(b) How much time is there for its accomplishment?
(c) What personnel and matériel are available for the execution of the work within the time allowed?
(d) If there are two or more alternatives, select the one which will be most certain to provide the best means for obtaining the objective with the least expenditure, bearing in mind always the imperative necessity for winning the objective first, and counting the cost afterwards, and assuming that the authority naming the objective has duly weighed the benefits against the costs, and that the tactical responsibility in that respect attaches to such authority and not to the officer who is given the mission to perform.

As to the criticism that army engineer officers of all ranks have an inadequate conception of railroad requirements in connection with the design of railroad facilities, it may be said that they could hardly be expected to be expert railroad designers in view of the fact that their entire training has doubtless been to consider railroad facilities as a means to an end, and not something to be considered wholly by itself. Railroad engineering is a rather broad field, and it would hardly be within the scope of any average man to qualify as an expert in this and all other branches of engineering. The writer does not believe it would be practicable to train all army engineers as railroad engineers, but believes that a better plan would be that suggested by him about two years ago, when the army reorganization bill was in process of formulation. At that time he recommended that a certain number of officers of the Regular Army be detailed in peace time to duty with railroads, manufacturing establishments, etc., to study and observe the methods and practices followed, to the end that in case of war such officers could be assigned to duty appropriate to the respective specialties in which they had had experience during such peace-time training. At the same time he stated that railroads and manufacturing concerns would no doubt receive considerable benefit from such an arrangement, as the army officers would no doubt be able to discover and point out errors and defects in organization which their military training should enable them to do, and which would become apparent to them because of their entering into the situation with fresh and eager minds, untrammeled by precedent and unfettered by tradition. It is with some sense of gratification, therefore, that the writer notes that the present army organization bill has recognized the value of this recommendation and has provided means for its realization.

In closing, the writer feels that it is only just to state that his contact and association with engineer officers of the Regular Army has been of great value to him in contributing to his realization of the importance of things that are fundamental, as distinguished from things that are supplemental. In fact, the military service of many thousands of civilian officers during the late war has undoubtedly contributed to a material change in their habits of thought and action, and with much advantage to them upon their return to their civilian pursuits.

Personals

Col. FRANCIS A. POPE, Corps of Engineers, has been relieved from his present assignment at Duluth, Minn., and ordered to report to the Commanding General, Philippine Department, for duty with the 14th Engineers.

Col. MASON M. PATRICK, Corps of Engineers, has been relieved from his duties at Washington, D. C., and assigned to temporary duty at Camp Pike, Ark., in connection with the training and instruction of Engineer troops.

Col. CHARLES S. RICHE, Corps of Engineers, has been retired from active service upon his own application, after more than thirty-eight years' service.

The leave of absence previously granted to Lieut. Col. CLARENCE O. SHERRILL, Corps of Engineers, has been extended fifteen days.

Maj. MAX C. TYLER, Corps of Engineers, has been granted leave of absence for two months, effective on or about February 1, 1921, with permission to leave the continental limits of the United States.

Maj. JAMES G. STEESE, Corps of Engineers, whose retirement from active service had been ordered on account of disability incident thereto, has been placed on active military duty as President of the Board of Road Commissioners for Alaska. Major Steese has been ordered to report to the Chief of Engineers for temporary duty, upon the completion of which he will return to his proper station at Juneau, Alaska.

Maj. EDWIN H. MARKS, Corps of Engineers, has been relieved from his duties at Washington, D. C., and ordered to Duluth, Minn., for duty.

Maj. CRESWELL GARLINGTON, Corps of Engineers, has been assigned to duty and station in Washington, D. C.

The leave of absence granted Maj. OSCAR N. SOLBERT, Corps of Engineers, has been extended ten days.

Maj. JOHN E. HARRIS, Corps of Engineers, has been relieved from further observation and treatment at Walter Reed General Hospital, Takoma Park, D. C., and ordered to report to the Chief of Engineers for duty in his office.

Maj. WILLIAM F. TOMPKINS, Corps of Engineers, has been appointed an Acting Quartermaster for the purpose of issuing bills of lading in the office of the Chief of Engineers.

Maj. ARTHUR P. VON DEESTEN, Corps of Engineers, has been granted five days' leave of absence.

Maj. ERNEST GRAVES, Corps of Engineers, has been retired from active service on account of disability incident thereto.

The leave of absence on account of sickness granted Maj. ARTHUR R. EHRENBECK, Corps of Engineers, has been extended one month.

Maj. WILLIAM A. JOHNSON, Corps of Engineers, has been relieved from duty as Assistant to the Department Engineer, Hawaiian Department, but will retain station at Honolulu in connection with his duties pertaining to the District Engineer Office.

Maj. DANIEL DEE PULLEN, Corps of Engineers, in addition to his other duties, has been ordered to report to the Commanding General, Panama Canal Department, for assignment to duty with the 11th Engineers.

Maj. ALLEN P. COWGILL, Corps of Engineers, has been retired from active service on account of disability incident thereto.

Maj. HARRISON V. PITTMAN, Engneers, U. S. A., has been honorably dischargd from the service of the United States for the convenience of the Government.

Maj. LEON E. LYON, Corps of Engineers, in addition to his other duties, has been detailed to superintend the construction or repair of

Digitized by Google

any aid to navigation authorized by Congress in the fourth lighthouse district, relieving Col. WILLIAM B. LADUE, Corps of Engineers.

Maj. JAMES W. BAGLEY, Corps of Engineers, has been relieved from his duties in Washington, D. C., and ordered to McCook Field, Dayton, Ohio, for duty as representative of the Corps of Engineers in experimental work connected with the adaptation of aerial photography to mapping.

Maj. WILLIAM B. HARRISON, Corps of Engineers, has been relieved from his duties in Washington, D. C., and ordered to report to the Commanding General, Panama Canal Department, for duty with the 11th Engineers.

Maj. HENRY H. STICKNEY, JR., Chemical Warfare Service, has been ordered to Wilmington, Del., for duty.

Capt. SAMUEL R. IRWIN, Corps of Engineers, was granted leave of absence for ten days, effective February 19, 1921, upon the expiration of which his resignation as an officer of the Army was accepted by the President.

Capt. WALTER E. LORENCE, Corps of Engineers, has been relieved from his duties at the Engineer School, Camp A. A. Humphreys, Virginia, and detailed as Assistant Professor of Military Science and Tactics, Colorado School of Mines, Golden, Colorado.

Capt. PIER L. FOCARDI, Corps of Engineers, in addition to his other duties, has been assigned to duty as Assistant to the Engineer, First Corps Area.

Capt. CLIFFORD E. BLACK, Infantry, has been relieved from his duties at Nogales, Ariz., and ordered to report to Fort Bliss, Texas, for assignment to duty with the Eighth Engineers.

Capt. JAMES D. CLEARY, Quartermaster Corps, has been assigned to duty in the office of the Engineer of the Ninth Corps Area.

Capt. DAVID L. NEUMAN, Corps of Engineers, has been ordered transferred from the Panama Canal Zone and will report by letter to the Chief of Engineers upon his arrival in New York City for instructions.

Capt. EUGENE F. GAEBLER, Corps of Engineers, has been relieved from his duties at Fort Sheridan, Ill., and ordered to report to the Commanding General, Hawaiian Department, for duty with the Third Endineers.

Capt. RALPH E. CRUSE, Corps of Engineers, upon his arrival in the United States, has been ordered to report to Chicago, Ill., for duty.

Capt. HORACE H. BRAUN, Corps of Engineers, has been relieved from his duties at Camp Lewis, Wash., and ordered to report to the Commanding General, Philippine Department, for duty with the 14th Engineers.

Capt. HUGH P. ORAM, Corps of Engineers, has been relieved from his duties at Fort Bliss, Texas, and ordered to report to the Commanding General, Hawaiian Department, for assignment to duty with the Third Engineers.

Capt. ROLAND H. STOCK, Corps of Engineers, has been relieved from his duties at Camp Grant, Ill., and ordered to report to the Commanding General, Hawaiian Department, for duty with the Third Engineers.

Capt. EDWARD EVERETT HALL, Engineers, U. S. A., has been honorably discharged from the service of the United States for the convenience of the Government.

Capt. WILLIAM HENRY WARNECKE, Engineers, U. S. A., has been honorably discharged from the service for the convenience of the Government.

First Lieuts. FREDERICK H. MCDONALD and WILLIAM GASTON MARTIN, Engineers, have been honorably discharged from the service of the United States, their services being no longer required.

First Lieut. WILLIAM A. CALLAWAY, Corps of Engineers, has been ordered from Camp Grant, Illinois, to Camp Meade, Maryland, for duty with the 56th Infantry.

First Lieut. CHARLES W. BURLIN, Corps of Engineers, has been transferred from Norfolk, Va., to Washington, D. C.

First Lieut. FREDERICK W. CONANT, Corps of Engineers, has been relieved from his duties at Fort Sam Houston, Texas, and ordered to report to the Commanding General, Hawaiian Department, for duty with the Third Engineers.

First Lieut. LEE S. DILLON, Corps of Engineers, has been relieved from his duties at Camp A. A. Humphreys, Va., and ordered to report to the Commanding General, Panama Canal Department, for duty with the Eleventh Engineers.

First Lieut. JAMES F. C. HYDE, Corps of Engineers, has been relieved from his present duties at Fort Sheridan, Ill., and ordered to report to the Commanding General, Hawaiian Department, for duty with the Third Engineers.

First Lieut. GLENN H. STOUGH, Corps of Engineers, has been relieved from his duties at Camp Grant, Ill., and ordered to report to the Commanding General, Hawaiian Department, for duty with the Third Engineers.

First Lieut. HAROID J. ADAMS, Signal Corps (Corps of Engineers), has been relieved from further detail in the Signal Corps.

First Lieut. ARTHUR W. PENCE, Corps of Engineers, has been ordered from Camp A. A. Humphreys, Virginia, to Fort Howard, Maryland, for assignment to duty as Assistant to the Engineer, Third Corps Area.

First Lieut. ELMER H. PETRIE, Engineers, U. S. A., never having reported for duty and having been absent without leave for more than three months, has been dropped from the rolls of the Army.

First Lieut. BERNARD S. STEARNS, Corps of Engineers, has been ordered relieved from his present duties at Camp Dix, N. J., effective March 15, 1921, and ordered to proceed to Camp A. A. Humphreys, Virginia, for duty as student officer, basic course, 1921.

First Lieut. GLENN H. STOUGH, Corps of Engineers, has been relieved from further detail in the Ordnance Department.

Leave of absence for two days has been granted First Lieut. HEATH TWICHELL, Corps of Engineers.

The resignation of First Lieut. FRED SHEAFF WELLS, Corps of Engineers, of his commission as an officer of the Army has been accepted.

Second Lieuts JAMES W. CLARK and HARRY E. FISHER have been ordered relieved from their duties at the Engineer School, Camp A. A. Humphreys, Virginia, the former being ordered to Camp Jackson, S. C., for duty with the Seventh Engineers, and the latter to Camp Meade, Maryland, for duty with the Fifth Engineers.

Addresses Wanted

The Secretary of the Society would be pleased to receive any information concerning the present addresses of the following named members, whose mail has been returned unclaimed:

Capt. H. L. Baker, Woolwich, Me.
W. G. Baxter, 53 Eddy St., Providence, R. I.
C. Buechner, 1306 Mahoning Bank Bldg., Youngstown, Ohio.
Capt. Edward W. Bullard, Hastings, Mich.
Capt. B. R. Butt, Clarksburg, W. Va.
G. B. Byam, 1600 Q St., Washington, D. C.
Lieut. R. W. Cabell, Lakehurst Proving Grounds, Lakehurst, N. J.
Lieut. Col. J. Edward Cassidy, Office Chief of Engineers, Washington, D. C.
C. L. Catlin, 728 S. Denver St., Tulsa, Okla.
Maj. D. N. Chisholm, Jr., 917 18th St., Washington, D. C.
Capt. J. L. Church, Montana Club, Helena, Mont.
Maj. Robert S. Clemons, 1204 Mills Bldg., El Paso, Texas.
Lieut. E. S. Cloud, 1751 19th St., Cleveland, Ohio.
Mr. C. S. De Puy, 133 No. Maple Ave., East Orange, N. J.
Mr. J. D. Dixon, Chico, Calif.
Mr. D. J. Donovan, 316 19th St., Milwaukee, Wis.
J. L. Doyle, Box 732, Johnstown, Pa.
Mr. J. H. Feehan, 207 S. 45th St., Philadelphia, Pa.
Maj. H. W Ferris, 300 Gun Hill Road, New York City.
E. C. Garvin, Court House Bldg., Brunswick, Ga.
Lieut. N. Gerten, 41 Elmhurst Ave., Long Island, N. Y.
Capt. F. M. Gibson, 2273 83d St., New York City.
G. T. Granger, 1609 Cadiz, Dallas, Texas.
D. L. Greenleaf, 5463 Blackstone Ave., Chicago, Ill.
Capt. J. R. Hall, Oak Park, Ill.
S. L. Kuhn, 103 Real Estate Exchange Bldg., Detroit, Mich.
Capt. H. Loveridge, 1333 21st St., N. W., Washington, D. C.
Edward Lyndon, 136 W. 16th St., New York City.
H. H. Martindale, 3337 Hastings St., Pittsburgh, Pa.
Capt. George E. Milville, 9th Engineers, Camp Travis, San Antonio, Texas.
P. D. Mackie, Zona, La.
Lieut. C. R. Moore, C. E., 61 Princes Gate, London, S. W. 7
Capt. Kenneth M. Moore, 4th Engineers, Camp Dodge, Iowa.
F. J. O'Hara, 1010 Balboa Bldg., San Francisco, Calif.

ACTIVITIES OF OUR LOCAL POSTS

San Francisco, Cal.

Capt. D. W. Dodge, 733 Rialto Building

On June 15, 1920, a group of Engineer officers and former officers gathered at the U. S. Engineer Office in San Francisco. Col. E. E. Winslow, C. of E., presiding, outlined the history of the "Professional Memoirs" and its proposed broadening into the Society of American Military Engineers, and explained the purpose and policy of the latter. A committee consisting of Col. J. W. Williams, Chester K. Smith and Capt. D. W. Dodge drew up plans for the organization of a San Francisco Post of the Society, which were adopted at a meeting on June 29, 1920.

At this meeting Col. J. W. Williams, E. R. C., Chief Engineer of the Northwestern Pacific Railroad, addressed the meeting, outlining the purposes and scope of the parent Society, and emphasized the importance of local organization and co-operation on the part of former officers of the Army, engineers and civilians interested in military engineering. From an experience that gave him a broad insight into the deplorable conditions out of which the engineering forces were organized from civil life, he urged that every condition be improved toward greater preparedness for the future. From his experience he described the readiness and eagerness of the engineering profession generally to serve the Government at the moment of emergency, and the confusion and inefficiency engendered by the vague ideas on the part of the profession generally as to what was required in order to make their services valuable and effective for military needs. Colonel Williams presented the possibilities for co-ordination presented by such a society as was then proposed, stating that such confusion could be avoided in a large measure through the bringing together of army engineers and representatives of all branches of engineering into a society of this kind, where they would have the opportunity to consult and become acquainted with one another's problems and point of view, and through such association acquire the fundamental understanding of what would be required in case of emergency.

The Post was organized with a membership of twenty-two. The following officers were elected:

President, Col. Thomas H. Rees.
Vice-President, Lieut. Col. Chas. B. Wing.
Treasurer, Capt. J. D. Cleary.
Secretary, Capt. D. W. Dodge.
Assistant Treasurer, Col. J. W. Williams.

At the second meeting, on October 21, 1920, twelve applicants for membership were received and the organization completed.

Col. Thomas H. Rees outlined the proposed plan of presenting subjects and problems of military engineering interest at the monthly meetings. He spoke also of the principle purpose of the Society, the fostering of close relations between Engineer Reserve Officers, former officers and the Corps of Engineers.

Meetings have been held regularly since the organization of the Post. Col. Roger S. Fitch, U. S. A., gave a talk on "The Organization of the Ninth Corps Area." Mr. M. M. O'Shaughnessy, a member of the Post, discussed the Hetch Hetchy water project, which he supervises as City Engineer of San Francisco. Mr. William Hood, Chief Engineer of the Southern Pacific Railroad, will shortly address the Post, and Mr. A. B. Fletcher, Chief Engineer of the California Highway Commission, will discuss the value of the state highway system for military purposes.

The following is a list of the Post committees and their functions:

Activities Committee. To arrange Inspection and Observation Trips; Establish and Maintain Military Relations; Function in connection with courses of training or study.

Program Committee. To prepare the program of meetings and activities of the Post; arrange for the assignment of subjects, presentation of papers, addresses, etc.

Current Events Committee. To study and analyze the happenings of the month along Military Engineering and National Defense lines, and present a report at each meeting.

Publicity Committee. To record and maintain a file of the proceedings of meetings and activities of the Post and the reports of the Current Events Committee. Maintain the file of membership and record individual activities. To furnish papers and information to THE MILITARY ENGINEER. To give our Post and activities suitable local publicity. To develop a library covering Military Engineering.

Membership Committee. The need and function of which is apparent.

Entertainment Committee. To develop social relations to the fullest extent; arrange for outings, hikes, excursions, rifle-range practice, etc.

* * * * * * * *

The present membership of this Post is fifty-seven, with an approximate tentative membership of thirty additional, and it is reasonably anticipated that a total of one hundred will be reached within sixty days.

To all members of the parent Society resident in the vicinity of San Francisco, or temporarily in this city, a most cordial invitation is extended to attend our evening and luncheon meetings. Information as to time and place of meetings can be had by communication with the secretary, Douglas W. Dodge, 733 Rialto Building, San Francisco, Telephone Kearny 823; and to those in this vicinity who are members of the parent Society and not members of the Post, and to those eligible for such membership, an earnest invitation is held out to meet our members and to join with us.

Philadelphia Post

Lieut. Col. W. B. Ladue, 815 Witherspoon Building

At the January meeting (January 27) of the Philadelphia Post of the Society of American Military Engineers, Col. Mason M. Patrick (late Major General, A. E. F., Chief of Air Service and Director of Construction and Forestry in France) gave a very interesting and valuable paper on the "Duties and Status of the Engineer Reserve Officer."

At the February 24th meeting Col. J. Frank Barber gave a talk on "Experiences of a Regiment of Combat Engineers in connection with an Army Offensive."

Colonel Barber was in command of the 304th Regiment of Engineers in France.

The Philadelphia Post, which takes in the district about Philadelphia, meets every month at the Engineers' Club, and is contemplating excursions to various points of military interest.

St. Louis Post

Lieut. Col. John L. Buchanan, 7th and Clark Avenue

The annual meeting of the St. Louis Post of the Society of American Military Engineers was held at a luncheon at 12.30 P. M. on January 28, 1921, at the Missouri Athletic Association.

Digitized by Google

Maj. DeWitt C. Jones occupied the chair, and opened the meeting at 12.45 P. M., with submission of Treasurer's report by Major Skelly.

On motion made by Colonel Jonah, and duly seconded, the Treasurer's report was accepted as submitted, and is appended as part of this record.

Minutes of the previous meeting were read and duly approved.

The Chair called for a general discussion on the subject of programs and meetings. Colonel Jonah suggested meeting at dinner quarterly for renewal of acquaintances and discussion of general subjects pertaining to the Society. It was suggested that this would be an effective manner of keeping contact between the regular and civilian officers, and would keep the Society thoroughly alive to current issues.

In connection with the subject of frequency of meetings, a motion was made by Colonel Laird, and duly seconded and passed, that meetings be held once each quarter in January, April, July and October of each year.

Colonel Perkins suggested leaving the selection of noon or evening for meetings to the officers of the Society, and added that there should be some one present to give a line on current army affairs, either calling on Colonel Youngberg or someone he might select.

In further voting, it was determined that character of meetings, program, dinner or luncheon, etc., should be determined by the Executive Council.

In establishing dues for the year 1921, motion was made by Colonel Laird, duly seconded and carried, that the Post dues be $1.00 for the current year.

The Chair next called for nominations of officers for the year 1921, and made announcement that due to the certainty of him making a change in situation later in the year, he considered it advisable that the Society consider someone else. Upon motion of Colonel Perkins, same being seconded and unanimously passed, Col. F. G. Jonah was elected President.

Other officers were elected as follows:

Vice-President, Maj. A. K. B. Lyman, C. of E.
Secretary, Lieut. Col. John L. Buchanan.
Treasurer, Maj. J. W. Skelly.
Assistant Treasurer, Maj. W. W. Burden.

Colonel Jonah read minutes of meeting of the National Society, and discussed a possible change in the annual meeting date in order to coincide more closely with the American Society of Civil Engineers in New York.

A discussion then followed on ways and means to enlarge the Society, and it was the general opinion that this matter should be worked out by the officers and carried out in a systematic manner by them.

Motion made, duly seconded and passed, calling for adjournment, subject to call of the President.

The following were in attendance at the annual meeting:

Col. A. T. Perkins, Col. N. L. Howard, Col. F. G. Jonah, Col. John A. Laird, Col. John L. Buchanan, Maj. D. C. Jones, Maj. R. J. Lockwood (Prospective Member), Maj. J. W. Skelly, Capt. Chas. Thorburn (Prospective Member), Capt. T. B. Perry, Capt. R. P. Garret, Lieut. A. W. Buckingham (Prospective Member), Lieut. A. O. Schleiffarth (Prospective Member), Lieut. W. B. Frost, Master Eng. L. G. Webber (Prospective Member).

New Orleans Post

Capt. E. H. COLEMAN, 1018 Hibernia Building

The following officers have been elected for the current year:

President, Arthur M. Shaw.
Vice-President, A. W. Jackman.
Secretary-Treasurer, E. H. Coleman.
Director (2 years), H. P. Ralston.
Director (1 year), Lester F. Alexander.

Plans are being made to start a campaign for new members among the large number of ex-service men in this locality who are eligible.

Cleveland Post

Capt. JAMES H. REDING, 1727 Bryn Mawr Road, East Cleveland

This Post has started to work. The temporary organization was called together January 27, and on February 10 a Constitution and By-Laws were adopted and permanent officers elected as follows:

President, Col. John R. McQuigg.
First Vice-President, Capt. Fred S. Curtis.
Second Vice-President, Capt. Harold McGeorge.
Secretary, Capt. James H. Reding.
Treasurer, Capt. Jos. C. Gilliland.
Director (2 years), Col. Elliott H. Whitlock.
Director (2 years), W. E. Stark.
Director (1 year), John Eisemann.
Director (1 year), First Lieut. Chas. W. Everson.

Both meetings were held at Central Armory in the headquarters of the 112th Engineers. The next meeting is to be held February 28 at the rooms of the Cleveland Engineering Society, when a special effort will be made to have a large attendance of eligibles.

We have 31 signatures on the charter application now. This we desire to keep open for at least thirty days longer.

New York Post

Maj. PERCY E. BARBOUR, 29 West 39th Street

At a meeting of the New York Post, S. A. M. E., a committee was appointed to protest against the pro-German meeting in Madison Square Garden on February 28. The following resolution was adopted, and copies of it were sent to the authorities, the American Legion, the Veterans of Foreign Wars, and several other organizations, for the purpose of bringing about closer co-operation between the various patriotic organizations with a view to combating objectionable propaganda:

RESOLUTION

Whereas, a meeting was held in New York City, at Madison Square Garden, on the evening of Monday, February 28, ostensibly for the purpose of protesting against the maintenance of black troops by the French Government on the Rhine, and

Whereas, Maj. Gen. Henry J. Allen, commanding the American Army of Occupation, has stated that there have been no French black troops on the Rhine since June, 1920, and

Whereas, the United States of America is still technically at war with Germany, and there is no present prospect for the conclusion of a satisfactory peace, and

Whereas, it is evident that the published reason for this meeting was fictitious, and that it was merely a gathering of numerous disloyal elements for the purpose of issuing false propaganda against our former Allies and in the interests of an enemy country,

Resolved, That in the opinion of the members of the New York Post of the Society of American Military Engineers, the holding of such meeting was a disgrace to the City of New York and an affront to all loyal Americans, and

Resolved, That this occurrence be brought to the attention of the Department of Justice of the United States, the

Digitized by Google

Governor of New York and the Mayor of New York City, with a view of expressing the protest of the members of this Post that such a disloyal demonstration was permitted to be held, and to demand that proper measures be taken to prevent a recurrence.

Signed:

JOHN P. HOGAN,
GEORGE H. GIFFORD,
R. S. TILDEN,
Committee on Resolutions.

Los Angeles Post

Capt. BURT HARMON, 745 West Ocean Avenue, Long Beach, Calif.

At a meeting of the Los Angeles Post on February 1, Capt. Hans Kramer, C. of E., in charge of the Engineer R. O. T. C. unit at the California Institute of Technology, Pasadena, gave an interesting talk on "The Engineer Reserve Officers' Training Corps." Many of the members were not familiar with the valuable work that is being done by the Engineer R. O. T. C. units now established at nineteen of the important technical institutions of the country, and Captain Kramer's talk called forth much interesting discussion.

It is believed that all local Posts would do well to interest themselves in the work of the Engineer units of the R. O. T. C. in their neighborhood, as these units are now training the men who will be the Engineer Reserve Officers of the future.

List of Applicants for Membership

(This list contains only those applicants from whom formal applications have been received since Jan. 1, 1921.)

Acher, A. H., 1523 Kimball Hall, 25 E. Jackson Blvd., Chicago, Ill.
Alvis, Raymond, Fishburne Military School, Waynesboro, Va.
Anderson, Christian, 466 Tenth St., Portland, Oreg.
Avery, Guy T., 9737 Prairie Ave., Chicago, Ill.
Barnes, Paul M., care Dakota Eng. and Const. Co., Valley City, N. Dak.
Boardman, Charles S., Lackawanna Steel Co., Buffalo N. Y.
Brand, P. H., 608 Marion St., Oak Park, Ill.
Breuer, Wm., 2736 W. Montgomery Ave., Philadelphia, Pa.
Capelle, George C., 99 Chauncy St., Boston, Mass.
Carson, C. E., 112 W. Adams St., Chicago, Ill.
Childs, Jas. H., Box 401, Hermosa Beach, Calif.
Clark, Frank J., 42 Cedar St., Dobbs Ferry, N. Y.
Coffin, Samuel P., 12 Remington St., Cambridge, Mass.
Covert, John F., National City, Calif.
Cueller, Arthur E., 307 S. Johnson St., Ada, Ohio.
Cylkowski, V. D., 6943 Calumet Ave., Chicago, Ill.
Dean, Bertram D., 1711 Ravanna Blvd., Seattle, Wash.
Dillman, George L., 14 Montgomery St., San Francisco, Calif.
Ellis, Edmund P., 2007 O St., Washington, D. C.
Ely, Carl B., 80 Maiden Lane, New York City.
Estabrook, Chas. W., A. & N. Club, New York City.

New Engineering Society

On September 22, 1920, the American Society of Lubrication Engineers was formed, with headquarters in the Monadnock Building, Chicago. The purpose of the Society is "To promote a better understanding of the problems of lubrication and the use of liquid fuels, including all problems of application and conservation." Oil companies, manufacturers of equipment, and users of lubricants and liquid fuel will, through the medium of this Society, co-operate for the dissemination of scientific data and useful information.

Progress in Organization of National Guard Engineer Units

Based on information secured from the Militia Bureau

THE work of reorganization following the passage of the act of June 4, 1920, has progressed far enough to enable us to appreciate the size of the task that confronts those who are charged with the duty of forming Engineer units for National Guard Service.

As is well known, there have been allotted to each of the nine Corps Areas within the continental limits of the United States two National Guard Infantry divisions. With each division is included the unit to be known henceforth as a Combat Engineer regiment, having a prescribed aggregate peace strength of 31 officers (including four medical) and 762 enlisted men. Four Cavalry divisions have likewise been allotted to the entire nine Corps Areas, each division including a Combat Engineer battalion, mounted, with a prescribed peace and war strength of 17 officers (including two medical) and 340 enlisted men.

The remaining components of the Regular Army Engineer organization as discussed in Major Wilby's article in the January-February issue of THE MILITARY ENGINEER will be duplicated in the National Guard Service, the main units being three Auxiliary Engineer battalions (which may be composed of colored troops) and a Corps Engineer regiment with each Corps Headquarters, and six Auxiliary battalions, together with three Army Engineer regiments with each Army Headquarters.

Under the law, the task of organizing the National Guard forces is to be undertaken in annual increments over a period ending June 30, 1923. For the fiscal year ending June 30 next, the following table indicates the allotments of Engineer units that have been made, as well as the status of existing units on January 31, 1921:

State	Division Troops	Corps Troops	Recognized as Nat. Guard
New York	1 regiment	1 regt. and 1 aux. bn.	1 regt. (divisional)
Pennsylvania	1 regiment		
Ohio	1 regiment		1 company
Texas	1 regiment	1 aux. battalion	
Massachusetts	1 regiment		1 regiment
New Jersey	1 battalion,		
District of Columbia	1 battalion, 1 hdqrs. & service co.	1 aux. company	Hdqrs. and service company and 2 companies of the battalion formed by conversion of existing infantry units.
Indiana	1 battalion,		
Iowa	1 battalion,		
Oklahoma	1 battalion,		
Tennessee	1 company		
Mississippi	1 company		
North Carolina	2 companies		
Oregon	1 company		1 company
Nevada		1 battalion, 1 hdqrs. and service co.	

It will be observed that no great progress in organization can be claimed for Engineer units during the past two years, for, aside from the conversion of the Infantry companies of the District of Columbia, only two regiments and a couple of companies out of the eleven regiments allotted have met the requirements for Federal recognition. This observation as to slow progress may, of course, be applied to the National Guard as a whole, but in lesser degree than to the Engineer branch alone, for on January 31, 1921, the Guard enrolled a total enlisted strength of 78,000 out of an allotment of about 208,000.

There have been many explanations offered for the exceedingly slow increase in the strength of the National Guard, but these cannot be discussed within the limits of this article. It may be said, however, that the two statements most frequently made in National Guard circles are these: That Congress by delaying the passage of necessary legislation was handicapping the development of the Guard, and that the high minimum strength required for the recognition of units prevented the presentation of a large number of companies that could not be recruited to the Regular Army prescribed strength until Federal recognition had been extended to a group that could thereafter act as a nucleus of a larger organization. By the passage of the act of June 4 last, Congress removed the legislative barrier and furthermore expressly provided that National Guard companies may be recognized with a minimum strength of fifty men regardless of the previously prescribed strength. With these two handicaps removed it might reasonably have been expected that a great boom in recruiting would follow, but the results have certainly failed to justify any such expectation. It is true that a small spurt in recruiting took place in June and July which added 13,000 men to the net strength of the Guard, but some of this increase must be credited to the fact that enlistments in the National Guard always "pick up" just before the season for the summer encampments. Between July 31 last and January 1 of this year the monthly net gain in strength has only ranged from 2,500 to 4,500 for the entire United States, and the rate of increase tends to grow smaller rather than larger. During the month of January the Guard did not gain in strength, due to the large number of units disbanded.

Assuming that there will be no great revival in the popularity of the National Guard within the reasonably near future (and nothing else is justified either by past experience or present prospects), it is not difficult to prove that on the basis of the monthly rate of increase given above the Guard cannot enroll by June 30, 1923, more than 195,000, as compared with the prescribed minimum of 424,800.

The engineer branch of the National Guard reflects the effects of the widespread apathy toward military service in general, but in addition our branch has acquired a reputation all its own that renders it the slowest of all organizations in recruiting. The cause of this situation is not far to seek, though the writer is reluctant to refer to it. However, it has been cited so consistently throughout the recruiting service of the National Guard that it seems to have a foundation in truth, in which case it is wisest to face the situation. The truth appears to be that the engineer service is

Digitized by Google

decidedly less popular han other branches, as a result of the fact that engineer soldiers were so largely employed as manual laborers during the A. E. F. operations.

Those officers who were so fortunate as to serve with an engineer regiment attached to a combatant division and whose commands consequently saw more or less active service may be inclined to dispute this statement, but such men are few in number and they are easily voted down by the far greater number of officers and the great bulk of the enlisted engineers who were consistently employed on construction work far behind the lines in France and who saw no frontline service. Even those members of divisional regiments of engineers whose battle experiences were limited to carrying on bridge and road work under long-range artillery fire cannot be expected to become enthusiastic over the chances for glory in an engineer regiment.

It may be repeated that the truth appears to be that during the World War the enlisted engineer had to swing the hammer or the pick or ply the saw to such an extent and so far removed from the zone of combat—the field of Death and Glory—that the popularity of that branch of the service has suffered to a marked degree. The mass of demobilized engineer soldiers throughout the country are not boosting our stock with thrilling accounts of trench raids put over, of machine-gun nests bombed off the map, and of prisoners of war gathered in by the hundred. The Adjutants General of most of the 48 states agree that the engineers are trailing the popularity procession, and some of them have been embarrassed by being called upon to explain that these units do not deserve the name of "Safety First Outfits."

In this case it is easier to describe the symptoms than to prescribe a remedy for the disease. Furthermore, the trouble is complicated by the fact that most of the doctors will agree that in times of peace the useful constructive work required of engineers is a source of greatest satisfaction and benefit to both officers and enlisted men. Presumably the situation will improve as the new generation of men comes on, men whose preconceived notions of war are not as faulty as those who "went in" during the recent conflict and who suffered the bitter pangs of disillusionment when they found that engineering in war is still engineering—only more so. Poets and historians have ever depicted war as a romantic adventure, and even the engineer, who is fundamentally an adventurer, loves romance. The agent who advertises for engineer recruits nowadays must watch his step. He must be a word painter of no mean ability and, in any event, he cannot afford to be as baldly direct in his methods of salesmanship as the old darky down South whose shingle read, "We bury others, why not you?"

The authorities, both at G. H. Q. and in the S. O. S., recognized that conditions surrounding the necessary engineer work in the A. E. F. were not such as to appeal to those who loved the smell of burning powder. A study was indeed made as to the possibility of "rotating" the service in the combat zone, but the war ended before the plans could be matured.

We are prone to draw conclusions from our experiences in the World War and to disregard all previous experience as well as to overlook other factors which will have a bearing on future operations. Just as the World War differed radically from all wars that preceded it, so it is reasonably certain that our next war will be very unlike that just finished. There will, no doubt, be a tremendous demand for engineering service, but in a new theatre of operations and under new conditions of warfare one may safely venture the prediction that no small part of the engineering work will be done under conditions that will contain the necessary spice of romance, and will furnish that modicum of truth essential to tales of high adventure and heroic daring.

The Military Mind

The discussion between Colonel Graves and Major Keesler in the last issue is surely an encouraging sign. The spirit shown between both principals in this "go" is the kind we need to bring about the desired results. The regular and emergency men are getting together all right. Just give the emergency fellows a chance to unload some of their ideas, especially those who have had the experience, and we will get these and the "Military Mind" boiled down and consolidated into perfect form for future use.

Just as the regulars had the opportunity to lead and instruct us in the methods and mysteries of the Military Mind while we were in the Service, now we have the opportunity to teach them a few things while we are out of the Service. Those who had to do with operations involving men and material in civil life surely have things worth while, especially after their experience in the Service, to bring before the men of the regular army.

The "Military Mind" needs a "tail piece" to meet the emergencies of these times, the integral parts to be supplied by "all concerned." Much of this material can be supplied by the emergency men of the late war and it is our duty to do so in a constructive manner for the good of the Service. There is one point we should bear in mind—we *all* faced an unusual emergency at the same time and had to learn a lot of things together.—B. W. VALLAT, *formerly Major 107th and 6th Engineers, A. E. F.*

Detroit, Mich.

Chicago Bascule Bridge

Many new features of construction were incorporated in the new double-deck double-leaf fixed-counterweight trunnion bascule highway bridge of 256-foot span over the Chicago River at Michigan Avenue, which was opened in May, 1920. It is believed to be the only double-deck bridge ever built having highways on both levels in order to provide for a separation of fast and slow traffic. Viaduct approaches connect the street level of the avenue with the upper roadway of the bridge, the lower roadway being for the slow and heavy traffic between various industries, terminals and steamship docks in the vicinity of the river. At the ends of the bridge the approaches are widened to form broad and ornamental plazas.

With a span of 256 feet c. to c. of trunnions, the structure provides a clear channel width of 220 feet. Its navigation headroom was required by the War Department to be 16½ feet from water line (city datum) for 80 per cent of the channel width with the bridge closed, and 120 feet for the entire width of channel with the bridge open. The lower deck has a traffic clearance height of 13½ feet, while the upper deck is free of overhead obstruction. Both floors are paved with creosoted yellow-pine block paving on transverse planking bolted to the I-beam stringers. Back of the trunnions, however, the lower deck has sandstone block paving on concrete on a buckle-plate floor, in order to add weight to the tail and to give a better footing for teams on the 3 per cent grade from the street. Provision is made for the future construction of two street car tracks on the lower deck.—*Eng. News-Record.*

Mobile Printing Train of A.E.F. Now with 2d Engineers

[The experimental mobile printing train of the A. E. F., sometimes spoken of as the "traveling circus," aroused so much interest and created so much comment in France that our readers will be interested to learn something about the train and also that it is still in existence.—ED.]

THE printing train now with the Second Engineers has had a varied experience. After being assembled in the United States during the war with Germany, it was sent overseas and assigned to G-2, of the Third Army. When the Armistice was signed it was sent into Germany with the troops. At this time the personnel consisted of two hundred and fifty selected men. Each man was a specialist in some department of printing, photography, or lithography. It remained in Coblenz some time, and was then sent to the United States to Camp Humphreys, Virginia. In February, 1920, it was decided to send the train to the Second Engineers at Camp Travis, Texas. It arrived there in May, rather the worse for its two thousand mile trip.

The train consists of eighteen trucks, one machine shop, three searchlight trucks for light and operating power, and three tank trucks. The first truck is the composing room. In it are type cabinets for hand composition and also a linotype machine. From this truck the work to be printed is passed on to truck two or three. Large jobs, when many copies are required, go to Kelly press in truck number two. while the smaller jobs go to the job press in truck three. This last truck also contains a multigraph, a stitcher, and a folding machine.

From printing we pass on to lithography, and truck number four contains a small rotary press where the finished zinc plates are printed. The next truck contains the apparatus and chemicals for sensitizing the zinc plates. In truck number six the zinc plates are exposed under a vacuum frame; in nine they are etched, and in seven they are rolled up and prepared for the rotary press. The work goes first to truck number six where the sensitized plates from five are exposed. Then this plate goes to nine; then to five and seven, and finally to four for printing.

Truck number eight contains a large wet plate camera capable of taking pictures 20 by 24 inches. This is used in photographing the maps and reducing them to exact dimension. The exposed plates go to truck number thirteen to be developed. The plates when finished are sent to truck number six, where they are printed to the sensitized zinc plates.

In truck number ten there is a routing machine where zinc cuts are made for the Kelly press or job presses, and are routed out and made clear.

Truck number eleven is now being used as a drafting room, and truck number sixteen as an office. However, number eleven was originally intended for aerial restitution work. No work of this kind is being done at present.

There are two supply trucks, one containing the paper supply and also a hand cutter for trimming the paper. The other contains the supply of chemicals and other materials used about the train.

There are two trucks used in connection with dry plate photography, which contain a small rotary press similar to the one in number four.

The train is capable of printing all kinds of matter; orders, circulars, letters, booklets, or newspapers; of photography; of printing posters; of all types of photography and of restitution from aerial photos.

The operation of the train is somewhat hampered at present by the lack of skilled men. When it first arrived in May there were only two men on hand who knew anything about handling it. Master Engineer Rodgers, from Headquarters Detachment, 2d Engineers, had served with the train throughout its tour in France and Germany, and was invaluable in helping to put it into operation here. The second man was Mr. Goedike, formerly a Captain in the Engineers, who was with the train in France and Germany. He was employed by the Government for a year to put the plant in operation and then to act as technical advisor for the officer in charge. The men are detailed from the 2d Engineers. They are, as a rule, untrained when they are first detailed, but they rapidly acquire a working knowledge of the departments of the train to which they are assigned by actually doing the work. It is not a school in the usual sense of the word, but rather a producing plant where the soldier learns by observing the results of his work.

Tightening Up a Wooden Block Pavement

An ingenious solution of paving difficulties was found in St. Louis last summer. Due to exaporation the wooden blocks had shrunk, which allowed them to rock under traffic, the pitch filler tending to work down under the blocks. Instead of taking up and relaying, which would have cost $10,000 for 7,500 square yards, and would have stopped traffic, the pavement was cut across its width (22 feet) at intervals of 150 to 250 feet, and jack frames carrying short trench braces inserted flush with the pavement. By tightening on the jack screws during hot weather the pavement was moved and tightly closed for a distance of 75 to 125 feet each way from the jacks. Under maximum temperatures (July, 1919) of 81 to 93 degrees, the total movement varied from 30 inches at a point 5 feet from the jacks, to 1 inch at a point 100 feet from the jacks. Movement in the direction against traffic was somewhat greater than in the direction of traffic, as the tractive effort of tires on the one-way street helped to push the pavement in the direction opposite to traffic. Three men manipulated 16 openings whenever the temperature conditions were favorable and obtained a total spread, between June 14 and September 14, of 23½ feet, or about 1 per cent of the original surface length. The openings were temporarily filled with blocks and the jack screw slots covered with small steel plates in order to accommodate the traffic during the course of the work. The cost was $1,200 for labor and supervision, $200 for material, a total of $1,400, as against $10,000 for repaving.

The new practice in paving is to use greater compression in laying the blocks in order to avoid a recurrence of trouble due to shrinkage.—*Eng. News-Record.*

Wire Drag Sounding Line

Construction. Assuming the depths to be measured in the particular case are from 18 feet to 33 feet, the line is constructed as follows: Starting with an ordinary 8-pound sounding lead fitted with a short leather thong, attach one piece of No. 14 galvanized wire with a small eye in the free end, to make over-all length from lower end of lead to the eye at free end 18 feet, then 7 lengths of No. 14 galvanized wire, each 1 foot long over their eyes, making an over-all length of 25 feet. In the last eye (25 feet) bend in 10-foot length of shrunken ¼-inch cotton line, making total over-all length 35 feet. The line is then marked thus: At the 18-foot, 24-foot and 30-foot distances, small pieces of black muslin are tied in the eyes or sewed on the line. At 21 feet, 27 feet and 33 feet, small pieces of red muslin are tied in the eyes or sewed on the line. At all the other foot marks, small pieces of white muslin are tied in the eyes or sewed on the line. The eyes in the wire should be made no larger than is necessary to allow hinge action, and the markings should be no longer than is necessary for the leadsman to see readily, because the eyes and markings all offer resistance to currents and tend to cause sag in the line. Tenths-of-foot between the foot marks can, after a little practice, be quite accurately estimated. Lines to measure lesser or greater depths are made on the same principle, viz: Wire length at maximum and rope length at minimum. The rope length serves as a handle, enabling the leadsman to obtain a satisfactory grip on the line without cutting his hands on the wire.

Use. The leadsman stands on the stern of the sounding boat, preferably a row boat, holding the line overboard continuously with the lead a foot or so above the river bottom. The boat is propelled at a rate of 2 to 3 miles an hour, and when soundings are required the line is lowered to the bottom, the foot mark above or below water line noted, the tenths estimated and added or subtracted from the noted foot mark below or above the water line, as the case may be. A forward and after swing of the leadsman's arm will usually bring the lead directly under the stern of the boat, making the measurement vertical, but in case this method does not give a truly vertical measurement the slant in the line is observed and the boat is checked and backed up, so that the line becomes truly vertical. The difference between the slant line and vertical-line soundings will give the error for slant-line sounding, which should be recorded for each line as is done with tide readings, and applied to the observed soundings to reduce them to their proper datum values.

Rapidity and accuracy. With the wire line, soundings may be readily obtained at 10-foot intervals, and their accuracy in deep water exceeds those obtained from a sounding rod, due to increased sensitiveness of touch on the river bottom. The flotation of the sounding rod deadens the sensitiveness of touch, so that in soft material the heel of rod has to penetrate the soft mud before the leadsman is aware that he has touched bottom. In the method of the ordinary casting line, the soundings obtained are always excessive, due to the three principal errors of the method: (1) Line not vertical; (2) lead sinking in soft material or lying on its side; (3) the catenary form taken by the ¼-inch line due to its resistance to currents.

The wire line will consistently give 4 per cent to 8 per cent less than the ordinary casting line.

The wire sounding line for depths greater than 16 feet (for depths less than 16 feet a sounding rod is used) has been used exclusively in the Washington District for twenty years, not only for cross-sectioning dredge channels, but also over extensive water ways of miles in width and length. In the large waterways it is customary to have two sounding boats, one moving out taking soundings, the other coming in tow of a gas launch to next station with party at case, making a continuous operation for the locating parties. The location of soundings is obtained by tag line or instrumental trisection.— *W. B. Harrison, Major, Corps of Engineers.*

Substitutes for Wood Cross-ties

There is probably no subject to which the mind of the inventor has turned more frequently than that of a substitute for wooden cross-ties. Yet in all the history of railroading no satisfactory substitute has been produced. It was hardly to have been expected before the present time. Wood was cheap and satisfactory, and there was nothing that could compete with it. But now that wood is becoming constantly scarcer and more costly, it is to be hoped that the effective substitute will be forthcoming.

The American Railway Association believes that this substitute will be produced by progressive development rather than revolutionary design.

At present there are 3,000 billion feet board measure of standing timber in the United States. This increases at a rate of 35 billion feet per annum, and is destroyed or wasted at the same rate. The annual consumption amounts to about 100 billion feet. At present rates then, the visible supply will be exhausted in 30 years. It is to be expected, however, that there may be a decline in consumption and an increase in production as the cost increases. Also the railroads will be less "fussy" as to the kind of ties required. Accordingly, our forests will probably continue to supply cross-ties for at least 50 years. Before that time a substitute should be developed.

The report of the Committee on Ties of the American Railway Association gives some valuable hints to any who may wish to take up the study of substitute cross-ties.

Flood-check Dams Formed by Fill

To check the velocity of streams in flood times and to store the surplus water which flows down the sandy and porous California river beds, there have been built lately some special dams known as the "Pratt Porous Dams" after their designer and builder, A. A. Pratt, of Los Angeles, Cal. They consist of a gaged wire frame stretched across the dry bed of the stream behind which frame there builds up during a flood a mattress of debris which constitutes an effective barrier to the water.

Such a dam was built for the Water Conservation Association of Riverside, Cal., on the Santa Ana River. The dam is constructed of iron posts or angle irons set into the bed of the stream and standing about 6½ feet above the bed and about 3 feet deep. These posts are guyed upstream by heavy wires to anchors set in boulders in the bed of the stream. The lower line of posts for the supplemental sections is set on the bed of the stream but not below the surface. They are guyed upstream as in the main dam. Upon these posts transverse angle irons are bolted, forming a frame on which wire mesh is stretched. The mesh in this case was made of ¼-inch wire with 6-inch mesh. The wire mesh is carried upstream above the river bed for about 16 feet and boulders laid upon the apron so formed.—*Eng. News-Record.*

Functions of Division Engineers in War

[NOTE—The following is a proposed paragraph in the new Staff Manual. The paragraph has been prepared with a view of defining, for the information of all arms, the duties and functions of the Divisional Engineers in War. The Chief of Engineers would be pleased to receive criticisms from interested officers and former officers. It should be noted that the strength of the Engineer Regiment has been prescribed by higher authority.—ED.]

Combat Engineer Regiment for Infantry Division

(*a*) This consists of two battalions and one Headquarters and Service Company; each battalion of 3 companies of 106 enlisted men each. (Total strength, 806 enlisted.) It forms only 4.35 per cent of the strength of the Infantry division. It will be equipped with automatic rifles, a small amount of pack transportation and a small mounted platoon in the Headquarters and Service Company. In addition it has its ordinary Engineer equipment.

(*b*) Besides its combat training (see *k* and *l* below) the regiment should be trained for performing all military engineering duties required by the division. Specifically these duties include:

Topography—

1. The regiment prepares and reproduces such topographical maps as are needed by the division, and cannot be elsewhere obtained.

2. It reproduces the situation sketches and special diagrams required by the division general staff.

3. It procures and distributes all maps to the division.

Communications—

4. It examines routes of communication and supply during an advance, including bridges and water-crossings; and makes such repairs as are necessary.

5. It constructs and maintains, with the assistance of other troops when necessary, routes of communication (including roads, railroads, bridges or stream crossings) required by the division, except as they are maintained by Engineers belonging to higher units, or Cm. Z. troops.

6. It provides and places signs marking routes of communication and division headquarters; and provides other signs required by the division.

Organization of the Ground—

7. It marks on the ground such defensive positions in rear of the outpost position as are directed by higher authority; and constructs, or supervises the construction of the defensive works included in these positions.

8. It may be called upon (as an exceptional measure) to select, construct, or supervise the construction of defensive works in the outpost position. All the work on this position is usually carried out by its Infantry garrison, which always maintains the works it occupies, including the wire entanglements.

9. It executes the technical details of the more important field works required by the division, when such execution requires specialists or tools not available to the organization which is to occupy the work.

10. It assists in the selection of, and constructs, division O. P.'s and advanced P. C.'s.

Demolitions and Obstacles—

11. It removes or overcomes obstacles encountered on the march of a division, such as land mines, barricades, etc.

12. It executes all required military demolitions, including the destruction of military stores threatened with capture.

13. It recommends the means to be used in the removal or passage of obstacles encountered in the attack of, or raid upon a prepared enemy position; furnishing tools or equipment and the assistance of such technical specialists as are necessary.

Supply of Engineer Tools and Material—

14. It procures, stores, and issues Engineer supplies to the division. For facilitating the issue of entrenching equipment to the Infantry, the regimental transportation includes: 1 escort wagon (loaded with entrenching tools) for each Infantry battalion in the division.

Shelter and Water Supply—

15. It executes, with the assistance of other troops when necessary, all general construction work in a divisional area (including bath-houses and delousing stations) not done by Engineers of higher units, or Cm. Z. troops.

16. It operates the various utilities, such as electric light plants, water supply stations, etc., within an advanced area; and within a rear area where these are not controlled by Engineers belonging to higher units, or by Cm. Z. troops.

17. It assists in the selection and lay-out of camps for the division, when called on.

18. It furnishes an adequate water supply for the division when in contact with the enemy, and in rear areas where this is not arranged for by Engineers belonging to higher units, or Cm. Z. troops; except, that, in mobile warfare or on the march, as water must be obtained from widely scattered local sources, water supply points must frequently be located, inspected, and marked by each organization for its own use.

(*c*) Auxiliary labor is normally required in road work in stabilized warfare (clause 5 above); construction of defensive positions (clauses 7 and 8 above); and general construction work (clause 15 above). Such labor should be requisitioned from the division commander by the regimental commander and employed as provided in Army Regulations. It is desirable that the officers and men detailed be taken from organizations who will benefit directly from the work done, if such a course is practicable.

(*d*) Engineer troops should habitually work under the orders of their regimental commander. It may be advisable, under unusual conditions to attach Engineer units for work with regiments, or bridges, but it should always be understood that their work is under the direction of their regimental commander. The policy of attaching all the Engineers to different brigades, leaving no reserve in the bands of the regimental commander, is particularly to be condemned. The distribution of Engineer work can seldom be foreseen in mobile warfare, and, when need for this work arises, the division commander must have Engineers available to meet the situation promptly. The *method* of performing engineering work including the details as to

[Abbreviations: Cm. Z.—Communication Zone; O. P.—Observation Post; P. C.—Post of Command.—ED.]

Digitized by Google

the number of men required, will always be decided by Engineer officers.

(*e*) The commanding officer of the division combat Engineer regiment is also division Engineer. He should actively perform both duties. Whenever possible, his regimental headquarters should be at, or in the immediate vicinity of, division headquarters.

(*f*) Engineering work, no matter how skillfully conceived and executed is of no value, unless it is accomplished so as to serve the military purpose for which it was designed. It must, therefore, at all times, be planned, directed and carried out with the fullest knowledge of the military situation, of the technical aims of the commander, and of its relation to their fulfillment. To enable him to acquire this knowledge, the division Engineer must have free access to the Chief of Staff.

(*g*) The division Engineer should be consulted in connection with:

1. The training in military engineering of all arms in the division.
2. The selection of defensive positions by the division commander or his staff.
3. The preparation of those paragraphs of division orders which relate to the Engineers; to the method of overcoming obstacles in an attack; or to the consolidation of captured ground, or preparation of defensive works.
4. The organization and control of routes for traffic within a divisional area, including the preparation of traffic control maps.
5. The selection of target ranges insofar as they might endanger public utilities.
6. All general construction work for the division.

(*h*) The division Engineer, subject to the approval of the division commander, prescribes rules for traffic over bridges and water-crossings.

(*i*) The division Engineer maintains close liasion with his corps Engineer, in order that the work done by his regiment may fit in with the plans of the corps Engineer. He makes such technical reports direct to the corps Engineer as the latter may require; furnishing his division commander with copies of such reports, if written, and keeping him informed of the nature of any important verbal or telephonic reports.

(*j*) In a rear area, the division Engineer may be charged with maintaining laision with the Cm. Z. Engineers, with a view to facilitating the shelter and water supply of the division, and ensuring the efficient operation of local utilities.

(*k*) Divisional Engineers will be trained to fight as infantry. The training should be sufficiently thorough to enable them to be of real value, and to acquit themselves creditably when so employed. However, Engineers are to be used as infantry only in a real emergency. If the Engineers are unnecessarily depleted, due to being used as Infantry when no emergency exists, the division may suffer later due to lack of the skilled personnel for handling some technical work of vital importance to the entire command. The frittering away of the small technical personnel assigned to the division by unnecessary employment of the Engineers as Infantry is especially to be avoided. *The use of Engineers as infantry in an attack is seldom justifiable.*

(*l*) In the preparation of field orders, it is a pernicious practice to immobilize the divisional Engineers by assigning them to duty as a divisional reserve in a designated locality. The regiment is automatically a division reserve. Its assignment to a designated locality hampers its proper utilization as Engineers and such an immobilization should be postponed until it becomes probable that their services as Infantry will immediately be required. In field orders, the regiment should normally be placed at the disposal of the division Engineer in order to enable him to carry out his mission. This mission may or may not be outlined in a paragraph or appendix devoted to Engineer Operations.

A New System of Power Transmission

A new system of power transmission having a wide range of adaptability, but particularly useful in the driving of percussion tools, has been devised and is being introduced in England. It makes use of the very slight compressibility of water or other liquid to introduce in a liquid filled conduit, impulse transmissions that are received at the opposite end of the line and converted into useful energy. This differs from compressed air and hydraulic transmissions in that there is no actual flow of the power medium nor is there required a source of supply of that medium and a corresponding waste of that medium at the power-using end. Just as direct current electricity has its analogy in hydraulics, this wave system of power transmission has its analogy in alternating current electricity, the laws and formulae of the two coinciding to the extent that they are almost interchangeable. Thus the wave transmission system has its direct equivalents for volts, amperes, frequency, angle of phase, induction, inductance, capacity, resistance, condensers, transformers and single-phase and poly-phase phenomena. Features of both systems are generators, rotary and reciprocating motors, heating apparatus, transmission lines, etc. The wave system promises to come into more direct competition with compressed air than any of the other usual forms of power transmission. In a comparison of costs between the two as applied to rock drilling operations, for instance, the promoters of the wave system claim savings of 80 per cent in power, two-thirds of the expense for maintenance, and one-third on the initial cost of the installation.—*Railway Review.*

French Government to Regulate River Rhone

Probably the most important and gigantic engineering work now being planned in France is the development of the Rhone River from Lake Geneva (Lac Leman) to the sea. The proposed development is to be in the three-fold interest of waterpower, navigation and irrigation. The upper Rhone is practically non-navigable, and is essentially a torrential stream. Beyond Lyons the river is full of rapids but has been rendered navigable by certain regulatory works mentioned below. The present plan calls for the immediate development of the water powers of the section above Lyons. These will be readily utilized at a minimum of expense, and the revenues and power derived from them will be of aid in constructing the remaining works. Briefly, the plan contemplates: (1) Rendering the river entirely navigable by the construction of canalized passes around the most objectionable rapids; (2) The development of power at the dams placed at the heads of these passes; (3) the use of some of the water for irrigation, which will be pumped by some of the electric power developed. It is believed that the total undertaking will cost in the neighborhood of 1,530 millions of francs ($295,290,000), of which 1,320 millions is for development of electrical energy and 210 millions for accessory works (passes, etc.) to render the stream navigable.—*Eng. News-Record.*

The Army Mule in the World War

ONE contributing force in the success of the World War which has received but scant recognition is that hybrid, the mule. The part played by the mule in the American Expeditionary Forces is an outstanding feature.

A remarkable array of mules took part in the World War in the United States Army. There were 124,137 of them in the United States, and of that number 18,596 went overseas and actually took part in the war. Added to this lot were 11,036 from Spain, 8,992 from France and 6,794 from England, a total of 45,418. Many of the mules purchased from England and a number secured from the French had been bought in the United States by those countries. But those secured from Spain were the product of that country.

Literally there is no comparison between the small, poorly nourished mule secured in Spain, and those purchased in southern France, and the powerful, upstanding, mealy-nosed product of the Middle West. There was sharp criticism in some places of the class of animals which came up from Spain for duty on the battle front. But these little animals were able to haul machine gun carts, releasing the heavy animals for duty with the artillery and ammunition trains.

There were times during the final stage of the World War when it was impossible to give much needed rest to those animals. There were not enough to do the work which confronted them, and the result was that it was necessary to keep on the move, forty-eight, sixty, and sometimes seventy-two hours, with hardly a pause. Then it was possible to feed only a small amount of grain, and a few handsful of hay. Under this strain the mule went forward, giving his all uncomplainingly.

The recuperative powers which he showed were remarkable. Sometimes when engaged it would seem impossible to get him back to the front again, but his powerful constitution came to his rescue, and in a remarkably short time he was able to return to duty. The mule has always been given the credit of having his full quota of brains, but at times it seemed he had more than his share. He may run when hitched to a wagon, but invariably does no harm to himself or the wagon. When tired he makes his condition known by quitting. However, this quality did not come to the fore during the days of St. Mihiel and in the Argonne.

There are some interesting figures shown in the percentage of losses by death among mules as compared with horses during the World War. From July 1, 1917, when the United States Army first received animals in France up to November 11, 1918, the percentage of losses among mules was 10.88 per cent, while the losses among horses reached 25.37 per cent. The losses from July 1, 1917, to June 28, 1919, the date of the signing of peace, among mules were 13.12 per cent, while it ran to 27.97 per cent among horses. Figures compiled on both horses and mules from July 1, 1917, to August 31, 1919, when the American forces in Germany had disposed of practically all of their surplus animals, show a loss of 26.1 per cent. A further comparison shows that even though animals are not exposed to the rigors of campaigns that replacements in rather large figures are essential to the upkeep of the Army. From April 6, 1917, to November 11, 1917, the loss among horses was 9.5 per cent, while among mules it was only 3.7 per cent. From the beginning of the war to June 28, mules they were 4.6 per cent or less by 10.3 per cent among mules than among horses.

The record of the mule through the World War has been such as to reflect much credit upon the dam, the farm mare of the United States, as well as upon the long-eared, loose-jointed progenitor of that hybrid—an animal indispensable to the success of our Army in the field.

The mule, a hybrid, is the offspring of two distinct species—dam of the horse kind, and burro, known in Biblical history as the ass. The ass, a quadruped of the horse kind, but smaller, and having long ears, and as distinct from the attributes accredited to the horse, is defined as dull, stupid, slow and stubborn, but withal not lacking in strength and courage—a combination peculiar to the hybrid-mule.

In his wild or natural state the horse travels in bands or droves, and in distinction the ass or burro travels in single file, or step of its fellow. Again, the habitat of the horse by natural selection is high table land, and, in the case of the burro, hilly or mountainous sections. Hence the opportunity for fleetness in the horse and the acquired disposition of the burro to climb. The one prefers rich grasses, while the other is content to browse on the hillside. Due to the distinct traits, the horse is best adapted as a saddle or riding animal, and the burro and mule as a burden carrier, and were so employed by man before the introduction of the wheel. Many instances may be related of the traits or peculiarities of the mule, inherited from the burro. In a free or wild state the action of the mule is free, at the walk and trot, but when placed in harness or carrying a burden, the nature of the animal, by inclination, changes from a free to a stubborn, slow and stupid gait.

The horse is by nature an impulsive animal, whereas the mule by inclination is the reverse of impulsive. Again, the horse will resist abuse with the whip or club, or may spring into action, while the mule may receive abuse without protest, and lacks the impulse to action which must be induced by the liberal use of the whip or club.

The question has been asked, "Why does the mule show such attachment for the horse?" All nature loves the mother, and the animal mule is not an exception. It is nursed and cared for by the dam of the horse kind, and attachment is a natural sequence. The attachment of the mule for the horse has led to the employment of the latter to lead a train of pack mules; that is, mules carrying a burden. A train may consist of any number of mules, and may be likened to a railroad train. The horse leads in the same manner as the engine propels, and the mules are content to follow in the step of the horse, without regard to sex or color. During travel, when the horse may be out of sight, a bell with a strap attached is placed around the neck of the horse to indicate that the horse is in the lead, and the mules are content to follow. Should the tinkle of the bell not be heard and the horse be out of sight for some time, they show uneasiness by constant braying. Some mules show more fondness for the horse than their fellows, and as they become attached they follow in the step of the horse in consecutive order, and in no instance will one mule

Digitized by Google

permit the other to advance out of its regular order. In the attempt to do so it is fought down the line until it regains its former position.

During the year 1882, while stationed with a pack train at old Fort Cummings, New Mexico, the "bell" horse, due to age, was sold for a song to the manager of the stage line from Cummings to Silver City, and another horse was supplied by the commanding officer. The animals, when taken to herd-ground for grazing, noticed the stranger and advanced for inspection by sense of smell and immediately protested by kicking at the stranger, braying and running around at a terrible rate, much like a child in search of its mother. A few days later while traveling with the train from Cummings to Fort Bayard, while passing the stage, old 'Vic," the former "bell" horse, recognizing the sound of the bell, began to whinny. The pack mules in turn recognized the cry of their old favorite and gathered about the stage in numbers that compelled the driver to stop. The passengers, noting the commotion, got out to witness so unusual a scene. Seemingly, each mule in turn had to approach old 'Vic," rest the head on his neck, and bray with lusty token of recognition, the braying continuing for some time after separation.

During the year 1866, while packing supplies to the mining camps in the upper Kootenais, British Columbia, while crossing the Dog Tooth Mountains, the bell horse had a leg broken and had to be shot. On the return trip, in passing the scene of the accident, the animals one and all gathered about the body of their old comrade, and with heads bent and mouth open, brayed in seemingly intense misery.

Another peculiar trait of the mule, inherited from the burro, is shown in a disposition to distinguish by sense of smell the trail of its fellows of one band or "Mulado," from another, as well as that of man—white from Indian. The mule also may be credited with sagacity, and even cunning. His sense of danger is unerring, as he will not attempt to enter bad or dangerous places, and it is well for the rider or driver to pay heed to the admonition.

Instances have been known where a pack mule would loaf about the army kitchen while the cook was baking bread until he observed the cook busy at some other duty, when he would approach the fire, raise one foot and paw off the lid of the Dutch oven, grab the hot loaf within, and make off with it on the run. He would do the same if he observed a hunk of bacon within easy reach.

Another instance was that of a messenger's saddle mule at the old corral adjoining the Alamo at San Antonio, Texas, before the advent of Fort Sam Houston. At noon time, on the toll of the bell, he would approach the gateway, and with his nose raise the latch that held the wicket and enter, then turn and with his nose push the wicket closed, go to the stall where his noon-day meal was ready.—*War Department News Bureau.*

Book Reviews

THE AMERICAN ENGINEERS IN FRANCE. By William Barclay Parsons, late Colonel, Eleventh U. S. Engineers. D. Appleton and Company.

Colonel Parsons is eminently well fitted to draw the general picture of the important part which the Engineers of our country were called upon to perform in the greatest task which has confronted civilized man in the past century, that of overcoming the aspirations and results of the false and debasing teachings of German Kultur. Not only was Colonel Parsons one of the prime factors in securing the law under which was made possible the organization for national defense of our resources of trained technical men in civil life as reserve officers of the Army, but also he was the first engineer to receive a commission, and the Lieutenant Colonel of the first volunteer regiment formed, the 11th U. S. Engineers, the second volunteer regiment sent abroad for service. His own service in the Engineer Commission ordered to France in May, 1917, and subsequently with his regiment throughout the war gave him the opportunity to obtain the comprehensive grasp of the situation which he has portrayed so graphically in the book just issued from the press.

The table of contents shows how wide was the scope of Engineer activities. Colonel Parsons does not attempt detailed descriptions of any individual works. His book is not an engineer text-book, nor is it the story of any campaign. It is, however, a clear statement of the tasks confronting Engineers in modern war, and of the methods followed by France, England and the United States in carrying on the work to a successful termination. The reader cannot fail to be impressed by the fact that in war, as in peace, transportation is one of the factors essential in the life of today.

Though the book is a tale of great accomplishments and of duty well done, the reader throughout sees how costly, if not actually criminal, is our traditional policy of unpreparedness.

BATTLE STUDIES. By Col. Ardant du Picq. With a foreword by Marshal Foch and a preface by Frank H. Simonds. Edited by Col. John N. Greely, F. A., U. S. A., and Maj. Robert C. Cotton, G. S., U. S. A. Cloth. $2.50. Macmillans.

Of this book Marshal Foch says: ". . . a very valuable work . . . amply verified in the experience of the American Army during the last war . . ."

Of this book Frank H. Simonds says: ". . . although he died in 1870, du Picq lives, through his book, as one of the most useful guides to a proper understanding of a war fought nearly half a century later . . ."

These two quotations are enough to establish the applicability of this old French military classic to the warfare of to-day, and to explain the first appearance of an English translation, made by two officers who fought in France in 1918.

The studies were made half a century ago by an obscure French colonel, who gave in them a luminous statement of the fundamental principles of warfare, the neglect of which led to Gravelotte and the first Sedan. He belonged to an army which was defeated, and fell on the eve of a battle which not only gave France over to the enemy, but disclosed a leadership so inept as to awaken the suspicion of treason.

Nowhere can be found a clearer statement of the bases of battle, a better analysis of the all-important human element in war, than in the paragraphs of Ardant du Picq. Reading him, "one understands something of the soul as well as the science of combat." Every American soldier reader will somewhere say, "That's Gospel truth," or "That reminds me of the day . . ."

Reunion of the 29th Engineers

Sixty-two officers and men of the Twenty-ninth Engineers met at their annual reunion on February 18th at the Cosmos Club, Washington, D. C. Major General Beach was unable to attend, and Brig. Gen. Harry Taylor was the guest of honor. General Pershing and Brig. Gen. Dennis Nolan sent their regrets at not being able to attend.

Lieut. Col. Alfred H. Brooks presided, and Col. Gilbert

Digitized by Google

Youngberg gave a valuable and interesting address on the plans for the Reserve Corps organization. Letters were read from Col. R. G. Alexander, now on duty at West Point, and Captain Ardon, the former French liaison officer, who is now engaged in private engineering work in the Federated Malay States. Humorous anecdotes and a vivid moving picture of A. E. F. life occupied the balance of the evening. Comrades attending came from as far as Connecticut and New York City for the purpose. Capt. R. T. Evans was the chairman of the committee of arrangements.

Lieut. Col. Augustus Trowbridge, formerly with the General Staff in the A. E. F., and in charge of Sound and Flash Ranging Organizations, is in charge of the Division of Physics at the National Research Council in Washington, D. C., for this year.

Maj. Theodore Lyman, formerly in command of the 2d Battalion of the 29th Engineers, later the 74th Engineers, is with the Jefferson Physical Laboratory at Harvard University.

Capt. George S. Young, formerly of the 29th Engineers, is with the General Petroleum Corporation in San Francisco, and hopes to have a reunion of about 75 members of the organization from the Coast in March.

Lieut. Col. W. W. Kirby, of the 29th Engineers, is now a Major of Engineers in the Regular Army and is in charge of the Engineer Reproduction Plant at Washington Barracks, D. C.

Maj. H. R. Richards, after a severe illness of some months' duration, is Business Manager of THE MILITARY ENGINEER and Secretary of the Society.

Lieut. Col. G. S. Smith, of the 29th Engineers, is now out of uniform, though still in the Reserve Corps. He has charge of surveys being made by the Republic of Santo Domingo.

Capt. O. G. Taylor, of the 29th Engineers, is now Resident Engineer of Yosemite National Park.

Capt. Stuart P. Penick, of the 29th Engineers, is now Technical Assistant in the Reclamation Department of the State of Texas.

Col. J. P. Hogan, Maj. L. B. Roberts and Capt. C. H. Davey, of the 29th Engineers, are with Parsons, Klapp, Brinckerhoff and Douglas, in New York water-power investigation.

Lieut. John W. Brashears, Jr., formerly with the 29th Engineers, is touring the Southern States in a Dodge car, converted into a comfortable and home-like dwelling on wheels.

Capt. A. P. Meade, of the 29th Engineers, is conducting a lithographic establishment in New York City.

Lieut. McKinley W. Kreigh, formerly of the 29th Engineers, is practicing law in Springfield, Mo.

The Military Mind

In THE MILITARY ENGINEER for November-December, 1920, we published a brief discussion of the workings of the Military and the Non-Military Mind. The violent reaction after the Armistice against all things military was, in the main, a manifestation of war fatigue, which is a condition fairly well recognized as the aftermath of every war. It is undoubtedly true that one of the factors contributing to the intensity of the war fatigue following the World War was the failure of the military and the non-military mind "to go along," one with the other, during the war. An impartial verdict would lay the blame in some measure on both sides, and thus a further consideration of the operations of these types of mind should prove illuminating to the respective possessors thereof on the Burns principle, that it is well to "see ourselves as others see us." The following from a member of our Society is a non-military point of view on military appointments and some things to be avoided in connection therewith:

The last issue of the Journal contained some very interesting articles, and in reading about the "Military and Non-Military Mind" it occurs to me that the Army should try to understand the "Non-Military" mind in some cases, particularly with reference to obtaining recruits and new officers.

The writer recently journeyed some hundred miles or more to Camp Meade, for examination for a commission in the Regular Army. Nothing further was heard of the matter until a telegram (delivered two days late) advised of an appointment in one grade below that applied for by the writer. The A. G. Dept. gave me two days to send in my acceptance, and I believe ten days to report for duty.

Now, a civilian with any kind of a position at all is not going to leave his company on short notice, when doing so will seriously handicap the organization with which he may have enjoyed many years of pleasant association. The non-military point of view would be to remain for at least thirty days with his company, or until some one could be secured to handle his work. Furthermore, before accepting a commission in a lower grade than expected, a civilian would like to have several questions answered, but the two-day limit prohibited anything other than "take it or leave it," without understanding the new listing system or any of the other changes which may have been made since the World War.

The above may explain why the War Department itself prevented some officers from accepting commissions in the Regular Army. It goes without saying that no one would take the trouble to be examined if he were not interested in the proposition.

Characteristics of the German Long Range Gun

The German long range guns used in bombarding Paris were constructed from worn out 15-inch, 45-caliber naval guns, mounted on concrete emplacements. The converted guns were of two parts; the main section was 98.5 feet long, and the forward section 19.7 feet. The 15-inch gun was bored out, and a heavy uniformly-rifled tube 8.26 inches in diameter inserted, 42.3 feet of this tube projecting beyond the muzzle of the gun. Over this projecting portion a hoop was shrunk. The muzzle section, 23.6 feet in length, was screwed to the end of this hoop tube. This forward tube was unrifled and was probably added to impart additional lineal velocity and better align the axis of the projectile with that of the bore of the gun. The reliners used in this gun were of such a thickness that when worn out they could be rebored to 9.3 inches, and then to 9.93 inches. Up to the time the firing on Paris ceased, at least one of the seven guns constructed had been rebored and was firing 9.3 inch projectiles.

A comparison of the general characteristics of this gun with our 14-inch naval gun, model 1920, is shown below.

Source of information: Ordnance Department.

Comparison of German Long Range Gun and American 14-inch Navy Gun.

	German 8.26-inch	American 14-inch Navy
Muzzle Energy, foot tons	467,250	85,750
Range, yards	132,000	39,000
Length, feet	118.2	59.7
Weight, pounds	318,000	180,395
Muzzle Velocity, feet per second	4,760	2,800
Elevation degrees (maximum)	55	38
Chamber Pressure, pounds per sq. in.	44,000	40,000
Length of Projectile, feet	3.44	5.09
Accuracy Life, rounds	50	250
Weight of Projectile, pounds	264	1,400

River Bank Protection by Sedimentation

The Mississippi was forced to build its own dike for the protection of a sliding bank at Natchez, Miss., by W. C. Curd, drainage engineer for the Missouri Pacific System of railroads.

A 125-foot bank, composed of conglomerate near low water, overlain by sand and clay strata, was being cut away by undermining in the sand at high water, thus endangering the railroad on top of the bank. Owing to the excessive cost of obtaining material for fill, it was decided to retard the current so as to bring about the formation of a silt deposit upon which permanent concrete paving could be placed. A mud-cell dike 1100 feet long and 23 feet high was built in 1912, at a distance of 75 to 100 feet from the foot of the hill, so as to give a 2 to 1 slope to the top of the hill. The mud cells were made from live brush and poles. A brush mattress 1 foot thick and 30 feet wide was formed of bundles or fascines, wired together and anchored to deadmen at the foot of the hill. Tiers of cells 5 by 5 feet were then built on the mattress by placing single rows of brush and poles at right angles to each other, very much after the fashion of a log cabin. Five tiers of cells, each 5 feet high were built; the bottom tier was 5 cells wide, and each superimposed tier was one cell narrower; the settled height was 23 feet. The cells were bound with wire and cable to the foundation mattress, anchored to the deadmen at the foot of the hill, and ballasted with conglomerate.

The downstream end of the dike was joined to an abandoned transfer barge sunk in line during high water. Six lateral mud-cell dikes, or baffles, 15 feet wide by 100 feet long, were connected into the main dike and run up the hill to Gauge 40, to prevent parallel currents and eddies in the area where sedimentation was being sought. The head of the mud-cell dike was protected against head-water by a pile dike 600 feet long, extending from a point upstream to an outside lap connection. Cypress piles 32 to 62 feet long were driven 16 to 20 feet into the conglomerate. The upstream 112 feet had a single row of piles, the next 216 feet a double row, and the lower 272 feet a triple row. The piles were spaced 8 feet center to center, staggered and braced; 3½ by 10-inch white oak sheeting formed the outer or river face of the dike.

By low water of 1916 the enclosed area was practically filled with sediment and decay had set in among the brush and poles forming the mud-cells. A concrete toe wall, reinforced with galvanized mesh, was started at a depth of 3 to 5 feet below the surface of the conglomerate, to afford protection against under-scour, and carried up to a gauge height of 14 feet, at which height concrete slabs were connected to it and laid on a 3 to 1 slope back to the hill. The slabs were 4 inches thick, 54 inches wide and 14 feet long, reinforced with galvanized mesh. Some filling was necessary to give proper support to these paving slabs. The paving amounted to 39,774 square feet, being 46 feet wide on the slope and 864 feet long. The total cost of the work was:

Mud-cell dike	$9,292
Permanent pile dike	10,604
Concrete paving and wall	18,845
Total	$38,741

The volume of material recovered by sedimentation was estimated at 56,000 cubic yards, at a cost of 16.6 cents per cubic yard, very much less than would have been required in that location by any other method.

In spite of frequent interruptions caused by high water, nature worked hand in hand with the engineers.—*Eng & Cont.*

Derrick Boom Supports Leads for Steam Hammer Driving Batter Piles

In the construction of the barge canal terminal in Flushing Bay, Flushing, Long Island, the McHarg-Barton Co., New York City, has driven a large number of long foundation piles, including several hundred spur piles, 17 to 19 inches in diameter and 80 to 85 feet long, battered 1:3, by the use of the swinging leads supported by a derrick boom. Piles are driven to an average penetration of 55 feet through mud, clay and mud strata, to bearing in a heavy blue clay, without the use of a pile driver tower or the elaborate mechanism often employed for driving battered piles.

The piles are set in position by a floating derrick and penetrate the mud several feet by their own weight. The tops are guyed and pulled into position, giving approximately the required angle at which they are maintained by the guy ropes while the pile is driven by a No. 7 McKiernan-Terry double-acting steam hammer making about 225 strokes per minute. The hammer weighs 5,000 pounds, and the striking part weighs 800 pounds, giving it a high efficiency which drives the piles at an average rate of 32 per 8-hour shift.

The pile hammer operates in a pair of 6 by 6-inch swinging timber leads, with 2-inch planking extending about 8 feet below the butt of the pile, thereby affording a batter support. The leads and hammer are handled by a hoisting tackle operated from the end of a 78-foot derrick boom which is very quickly adjusted to the required position for successive piles.—*Eng. News-Record.*

Using Large Size Aggregate

Provided it can be readily secured so that the cost of transportation is not governing, large stone makes the most economical aggregate for mass concrete, particularly when strength necessities are so low that the leaner mixtures can be used. The main reason why stone above the standard 3 or 4 inches is not more generally used is the fear that the ordinary concrete machinery will not handle it. Nevertheless, in an increasing number of cases it is being proved that regular mixing and chuting equipment, with only a few changes to provide proper clearance, will stand up under the battering of the big stones and deliver a well-mixed concrete. The latest instance is the Stevenson dam work. Here there was an ample gravel supply handy to the site, a condition which often exists but is not always utilized, and the engineers estimate that about $250,000 was saved in the concrete cost due to the decision to use the gravel even up to the 6-inch rejections, which means some irregular pieces of larger dimensions. Furthermore, they testify that the maintenance charge and out-of-order time losses were little if any greater than with stock material. The practice is well worth consideration for other jobs. —*Eng. News-Record.*

Spring Meeting, American Association, M. E.

May 23 through 26 has been set as the date of the Spring Meeting of The American Society of Mechanical Engineers. It will be held in Chicago at the Congress Hotel.

Sessions are planned by the Professional Sections on Aeronautics, Fuels, Management, Material Handling, Machine Shop, Power, Forest Products and Railroads.

Training of Reserve Officers

The Adjutant General has published the following information on the subject under date of March 14, 1921:

1. The following policy will be observed and will be brought to the attention of reserve officers who tender their resignations before acceptance of such resignations. It is desired that it be given as much publicity as practicable:

(*a*) On account of the necessity for economy in expenditures and other considerations, it will be possible, in the immediate future, to call but a very small number of reserve officers to active duty for training purposes. Prior to June 30, 1922, no reserve officer will be called to active duty for training without his consent. Available funds and other considerations will probably make it impossible to call all those officers who request active duty for short periods of training.

(*b*) During the time specified, to June 30, 1922, the organization of units of the Organized Reserve and the assignment of reserve officers thereto will be proceeded with. Such assignments will not demand a material amount of time of reserve officers.

(*c*) The present number of reserve officers is insufficient. Those who now hold commissions are urged to defer any withdrawal from the reserve contemplated by them until the Organized Reserve has been formed and definite policies for its training formulated. When such has been done, and regulations governing the Officers' Reserve Corps have been published, reserve officers will have a better understanding of their obligations, duties and privileges and will be better qualified to determine whether or not other interests necessitate their withdrawal from the Officers' Reserve Corps. The present reserve consists of veteran officers of the World War whose moral and material assistance in the building up of the Organized Reserve will be a very material factor in the efficiency of that force and the state of preparedness of our reserve forces.

By order of the SECRETARY OF WAR:

(Signed) T. H. LOWE,
Adjutant General.

Reserve Officers' Instruction Department Proposed for The Military Engineer

Plans are under consideration for the establishment in THE MILITARY ENGINEER of a department devoted entirely to the instruction of Engineer Reserve Officers, who make up the bulk of the membership of the Society of American Military Engineers.

It is planned to have the Engineer School at Camp Humphreys, Va., assume control of the department. Instruction will probably be carried on under three general headings, viz:

a. Military Administration, including administration, supply, military law, military courtesy, etc.

b. Minor tactics.

c. Military Engineering, or engineering problems based on tactical situations.

The material presented under each subject will be logically progressive—references, illustrations, and cuts will be included, and each issue will contain approved solutions of problems presented in the previous issue.

Plans in detail will be published at a later date. It is hoped that such a department can be instituted beginning with the May-June issue of the journal.

Notice to Subscribers

In order to simplify the accounts of the Society, bills for dues or subscriptions will henceforth be made out for a period expiring with the November-December issue of each year. Those whose dues expire during the first half of the current year will be billed for the remainder of the current year only. Those whose dues expire between June and December of this year will be billed for the remainder of this year and for all of next year. The amounts in the latter case will exceed the annual subscription price, but it is requested that remittances be made in accordance with the bills sent out, in order to reduce the time and expense of accounting.

Utilization of Tidal Energy. The scarcity of fuel has turned the attention of both French and British to the possibility of deriving power from the tides, which have a very great range on the coasts of France and Britain. The power obtainable from a given area is proportional to the square of the tidal range, the cost of machinery also decreasing as the operating head of water increases. At some localities spring tides have a range of over 40 feet, neap tides being somewhat less than half. With a tidal range of only 20 feet for springs and 10 feet for neaps, operating on both rise and fall, each square mile of basin area can, without storage, produce a daily average of 110,000 horsepower.

The most difficult problem is the equalization and saving of power by storage. Accumulators are too expensive, and the most feasible suggestion is to utilize the surplus power to pump water to a high level reservoir, from which power may be drawn as needed.—*Journal Frank Inst.*

The Operation of Motor Trucks in War

(Continued from Page 103)

Discussion

James G. Harbord

Major General, U. S. Army; formerly Chief of Staff, A. E. F., Commanding General, 2d Division, and Commanding General Service of Supply, A. E. F.

During the war the energies of the Motor Transport Corps were centered on the assignment and distribution of motor vehicles. The assignment and distribution of the vehicles included a comprehensive plan of convoy operation, as the distribution of assigned vehicles to combat organizations and sections of the A. E. F. and convoy work were inseparable. Both entailed the movement of transportation from Base Ports to the intermediate and forward areas.

Except in the sections of the Services of Supply, the question of the operation of these vehicles, after their assignment and distribution, was generally left to the judgment of the motor transport officer attached to the organization to which the vehicles were assigned. This arrangement was far from satisfactory, and was the result of the lack of a comprehensive plan of operation of the vehicles. The question of either permanent assignment or pooling was still in the stages of discussion, and the result was that where the training of the officer in charge of the transportation led him to believe that best results were to be secured from pooling the transportation, or by assignment, the method which he believed correct was used.

The urgent demands for motor transportation overshadowed the questions of operation of the transportation after assignment to units, and the constant cry of "More transportation" drowned efforts to satisfactorily work out a definite plan of operation, except in the Services of Supply.

After the armistice the assignment and distribution fell off to a marked degree, and in proportion to the decrease in activities pertinent to assignment, grew the opportunities for development along the lines of controlled operation.

Inspectors were sent out for the purpose of studying the methods of operation in use at the different motor transport activities within the Services of Supply, and the recommendations resulting from these inspections had for their purpose more efficient operation of motor transportation, and the result was more concentrated pool operation and greater efforts toward proper traffic control.

Traffic control is the foundation of efficient operation, regardless of the merits of either assigned or pooled transportation; without traffic control neither system can function with efficiency.

In taking up here the subject of traffic control, it is believed advisable to explain the expression "traffic control." Traffic control does not consist entirely of directing transportation while it is moving, but in reality consists of studied disposition of trucks so that the maximum efficiency in their use will result.

Perhaps the traffic control of motor transportation may best be compared with traffic control as exercised in railroad activities, i. e., properly allotting the cars with a view to requiring their full capacity to be utilized between whatever points the cars may be operated, thus avoiding an empty back haul.

With proper traffic control, the number of motor trucks necessary to perform certain work would be cut down to 60 per cent of the number of trucks used when there is no traffic control exercised. It is safe to say that with proper control, the apparent shortage of motor transportation in the United States Army would disappear.

Further, with the decrease in the number of vehicles operated, would come the decrease in maintenance, with its problems of replacements, spare parts and money cost.

So it is seen that whatever method of handling transportation is used, whether it be pooled or assigned, the solution to satisfactory service lies in proper operation.

So strong is the writer's belief in the efficiency of pooled transportation over the method of individual assignment that it is not considered worth while to discuss here the relative conveniences which assignment transportation is said to give.

Our experiences in the war showed us conclusively the advisability of pooling transportation, and this method followed by the French demonstrated the superiority of such a system. With far less motor transportation than we possessed, the French were able to meet all emergencies requiring the use of motor vehicles, and their system was exclusively one of pooled operation.

Behind the French Armies were placed at strategic points, groups of motor transportation, each having a given radius of operation. Should the high command direct the movement of troops or material from one point to another, the motor group nearest to the body to be moved would be informed as to the amount of tonnage to be carried, and would direct the requisite amount of transportation to effect the movement to report to the organization, transport it from its position to the desired point, and upon completion of the movement the transportation would return to its group, ready for further work.

By the foregoing method the French were enabled to shift the transportation where the need was greatest, and so avoid the embarrassing situation of having one unit of its army sorely in need of transportation while another boasted a "sufficient" number of vehicles.

It is a matter of opinion among many students of motor transport problems that the success which the French had with their transportation was due entirely to its efficient operation. This successful operation had for its basis proper traffic control. Again, it is sometimes alleged that one of our war failures was that our demands for motor transportation could not be met, with the result that we were always short on the amount of motor transportation needed, so short that at the signing of the armistice we were but little more than 50 per cent equipped. This is true only if we consider as a basis the amount of motor transportation allotted by tables of organization then in force.

The writer is of the opinion that the difficulty lay not so much in the shortage of motor transportation as in the absence of a comprehensive plan of operation of the vehicles on hand. So, too, we may say that the shortage of spare parts could be partly traced to this same lack, as the improper operation of the vehicles precluded the possibility of establishing any sort of a reserve, and without a reserve it is impossible to discontinue operating certain trucks for even minor repairs; and continuous operation of a given number of trucks, which must be the case where no reserve exists, will eventually break down the allotted number.

Undoubtedly the new tables of organization now in process of completion will contain many interesting changes resulting from our experience in the war, and with these changes should come a well-defined plan for standardized operation of pooled transportation.

M. L. Walker

Colonel, Corps of Engineers; formerly Brigadier General, Chief of the Motor Transport Corps, A. E. F.

This excellent paper deals largely with the question which stirred the A. E. F. as much as any other one thing, *i. e.*, "The Pooling of Motor Transport." Many differing opinions were apparently held concerning "pooling," but it is a fact that whenever the situation got tight a resort to practical "pooling" was forced, whether admitted or not.

A commander is assigned a mission, and is given certain instruments for its accomplishment, among others a limited amount of motor transportation. No matter what tabular assignment of this motor transport is made, the officer who measures up to the requirements of a commander is going to use it as he deems best to carry out his mission.

Knowing that conditions are practically certain to arise which will render the massing of motor transport and its operation in large units necessary, it seems logical to adopt an organization which will render such employment most feasible, viz, standard units and a standard system of training and control. This was all that was desired and recommended by the M. T. C., A. E. F., together with the policy that, as set forth in Major Young's article, there should be a minimum of motor transport permanently assigned and the remainder would be attached whenever or wherever most needed, its operation to be controlled by the local commander through his own Motor Transport Officers as long as it was at his disposal. The recommendations which Major Young made following a meeting of the Military Board of Supply were the same recommendations which the Motor Transport Corps had been making almost from its inception, but without success in getting them adopted.

The above method of dealing with motor transport worked in the S. O. S., and it will work in the Combat Zone. In the S. O. S. each Base Section Commander was given certain transportation, and this he distributed through his area and operated through his own Motor Transport Officers. H. Q., S. O. S., never entered the area except to increase the transportation by additional allowance upon approved requests of the Base Commander, or to make withdrawals when more pressing needs elsewhere rendered such action necessary. In case of withdrawals the Base Section Commander was informed that he must give up a certain number of truck tons; where he should take it out and the making of necessary re-adjustments were left entirely to him.

It was due to the following of such policy in the S. O. S. that we were able in August, 1918, to pull out 2,500 truck tons for immediate employment in the St. Mihiel offensive, and a month later produce an additional 1,500 tons for the Meuse-Argonne Campaign. But the S. O. S. was no magician's bag from which such large quantities of motor transport could be produced without visible disturbance. The stoppage of many construction projects of vital importance, if the war were to carry over the coming winter, was necessitated. The C-in-C was informed personally by the C. G., S. O. S., as to the effect produced, and wisely decided to gamble on an earlier termination of the war.

The problem of traffic control was never solved in the A. E. F., nor were the systems of either France or Great Britain above criticism—certainly neither one should have been adopted by us bodily.

The French system grew, like Topsy, from the scheme for handling motor transport during the Verdun campaign, developed by Commandant Dumenc, which led to the creation of the French "Service Automobile" and left the handling of such traffic, and all other on the controlled roads, in the hands of this organization. The French never claimed that their system was perfect, but they did claim, and justly, that it worked. Personally, it has seemed to me that the French solution was a good one. Whenever traffic becomes so dense as to need control, motor transportation is going to be the dominant consideration, and the control should be exercised by personnel thoroughly conversant with the operation of such transport. However, there are good arguments for placing traffic control under the Military Police, who must cover all roads for police work, and also for placing it under the Engineers, who build and maintain the roads and must know more than anyone else the traffic possibilities of these roads. I have never been able to decide that traffic control *must* go to any particular agency, but I am sure that the personnel actually doing this work must, above all else, be fully informed concerning the operation of motor transportation in large masses.

The scheme for traffic control put forth in the fall of 1918 by G-4, G. H. Q., would have worked—anything will work if intelligent and loyal people get behind it and make it go—but it was fundamentally wrong, in that G-4 was planning to operate directly and thus go outside of its legitimate sphere as a section of the General Staff. I have always understood that what prevented the actual carrying into effect of the traffic control order mentioned, was not the coming of the Armistice, as stated, but the violent opposition of at least one other of the General Staff Sections at G. H. Q.

Malin Craig

Brigadier General, U. S. Army; formerly Chief of Staff, 1st Corps and 3d Army, A. E. F.

Major Young, the writer of this article, was afforded perhaps the greatest opportunity given to any officer of the American Expeditionary Forces to study the question of motor transport in war from a broad, unbiased viewpoint. His conclusions are accordingly deserving of serious consideration.

The pooling of motor transport was absolutely the result of necessity. It is believed that the maximum efficiency of truck-carrying capacity is obtained when the vehicles can be run practically continuously, withdrawal being necessary only for disability due to accident or for periodical general overhauling. Pooling permits of the foregoing, while the permanent assignment results in all vehicles being run but part of the time and many of them being laid up in reserve, loaded or unloaded, most of the time. There is no question in my mind that had the First Corps failed to pool its motor transport its successes in point of time and distance would have been greatly diminished. It is to be regretted that the author did not include in his paper a discussion of the capacity of trucks, as it is believed that those of greater than one and one-half tons cargo capacity have no place in the transport (supply or combat) of divisions, except special vehicles. Furthermore it was demonstrated during the three great campaigns of the A. E. F. that the single cargo truck can handle with practically equal facility ammunition, supplies, combat personnel, as well as evacuating sick and wounded and salvage. Many officers of the Artillery Service claim that they must have special vehicles under their own control to handle artillery ammunition. It is believed that they base this claim on too narrow a view of the entire situation. Their arguments are certainly controverted by experience, as we habitually used the ordinary cargo trucks for the artillery ammunition

The Strength of the Pyramids

For centuries the Pyramids have stood with an endurance founded on solid, rugged strength. As these inanimate structures have endured through strength, so must an organization of men endure; and of the elements of strength, Service is the greatest, the most rugged, the most imperishable.

The strength of the American Association of Engineers lies largely in the service it renders to engineers. The 154 chapters of the Association supply non-technical educational courses, means for properly directed citizenship duties, opportunity for one to acquire experience in organization direction, business offices with interests of engineers as their principal endeavor, compensation and employment service, and the stimulating fellowship of other engineers.

Among such national activities as the publishing to the profession of a Code of Ethics, written for A. A. E. by the late Isham Randolph, the maintenance of a Practice Committee to enforce the Code, a great compensation service conducted in accordance with professional ethics, the Service Department stands in the forefront.

The positions filled during July saved members $35,000 which commercial agencies would have charged to place them in the same positions. This is more than two times the total monthly dues of the 21,000 members of the Association. Furthermore, the department did not fill all the positions on its list. It has 200 vacancies a month for mechanical engineers.

You should know more about the service rendered by this young, virile society. Send the coupon for a copy of our handsome new booklet entitled "An Ideal Which Has Become an Institution."

American Association of Engineers

BAYER Valves

BAYER Valves are made in heavy-pattern regrinding globe, angle and check types, screw and flanged ends—all good for working pressures up to 225 lbs. Each one is guaranteed to meet the metal composition requirements of U. S. Navy Department specifications 46-B-8, June 20th, 1913, covering valve bronzes or composition "M."

Body walls are of liberal thickness, with a uniform distribution of metal. Valve seats are radial, and can be ground continually, thus prolonging the life of the valve indefinitely. Discs are made of a hard bronze composition; stems are unusually heavy with a greater number of accurately cut threads than usually found in valves of this type.

Naturally, continued satisfaction is the only logical result that can follow adherence to the BAYER standard. Send for our book "The BAYER Valve."

service and there was never any just cause for complaint on this score. There must, of course, be artillery specialists at the dump for fusing and other technical operations incident to the character of the cargo.

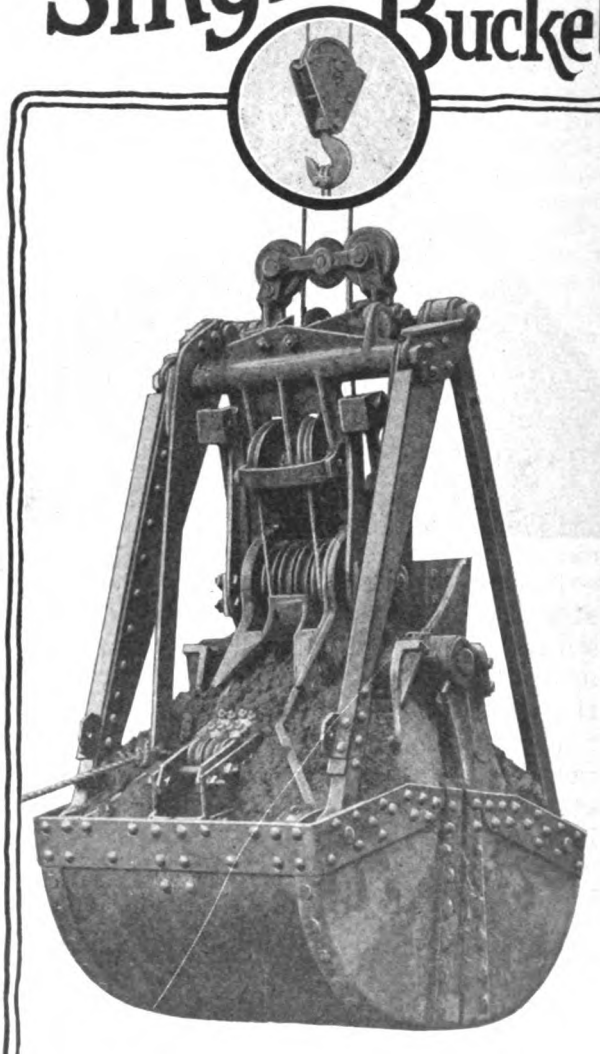
Another matter not touched upon is the fact that in the general case trucks are not properly loaded, or loaded to capacity. This is frequently so in the case of single vehicles, and is practically always so in the case of companies or trains. I refer, of course, to conditions as they existed in the zone of the armies in the A. E. F. This matter has a great bearing on road space and traffic control, as well as the truck tonnage allotted as the minimum for units. There seems to be every argument based on results in actual practice in favor of pooling, both in peace, in garrison and in war at corps, army and probably general headquarters.

H. C. Smither

Colonel, General Staff, U. S. Army; formerly Chief of Staff, G-4 S. O. S., A. E. F.

Amongst those who, during the war, viewed all activities in simultaneous operations, I think there can remain no doubt as to the soundness of the theory of pool transportation. The theory of fixed assignment is largely dictated by convenience. Pooled effort is dictated by economy in the use of limited resources. In a struggle of such proportions as the late war there can never be an over-abundance of that type of equipment on which the mobility of units and the speed of their operation must depend.

In this article Major Young is partly in error with reference to 1,200 "truck tons" supplied for the St. Mihiel operations. In this case the S. O. S. had, in anticipation of such a need, assembled the trucks in question at Dijon to act as a reserve to meet the unexpected developments of the St. Mihiel operations. The need for a system of equalizing reservoirs became early apparent in the S. O. S., which, as Major Young states, was kept practically stripped by reason of the urgent needs of combat troops. There was, in consequence, never a time when automotive capacity approximated meeting the routine load and reserves were always in use.



Geo. P. Tyner

Lieutenant Colonel, General Staff, U. S. Army; formerly Colonel, Assistant Chief of Staff, G-4, 2d and 3d Armies, A. E. F.

Major Young's efficient handling of the distribution of the limited supply of motor trucks in the Zone of the Armies, under the stress of battle and of conflicting demands from all directions, was such that the writer hesitates to attempt any criticism.

It might not be amiss to describe briefly the transportation within a division. This transportation consisted of two kinds, that belonging to regiments and that belonging to the division. The regimental transportation consisted of the field train carrying the two days' field and the one day's reserve rations, and the regimental combat train carrying the regimental reserve ammunition. Both of these trains were supposed to be animal drawn. Under the control of the division commander were the supply train, carrying two days' field rations for the command, and the ammunition train carrying the division's reserve supply of small arms and artillery ammunition. Prior to the war the supply train was animal drawn, but as Major Young describes, it was motorized for service in France. In the tables for European service, the division ammunition train was also largely motorized, only a small percentage of it remaining animal drawn. Due to the shortage of animals in France, no divisions other than the First and Second ever

BLAW Single Line Buckets

As they need for complete operation merely a single hoisting line or hook, Blaw Single Line Buckets can be in installed on any type of derrick, overhead crane, locomotive crane, monorail crane, dredge, steam shovel, railroad ditching machine, etc.

There's a Blaw Bucket of a type and size suitable for your hoisting equipment which will take care of all of your requirements.

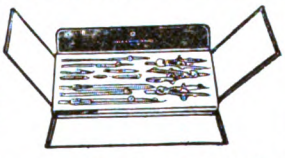
PEASE

PEERLESS BLUE PRINTING EQUIPMENT

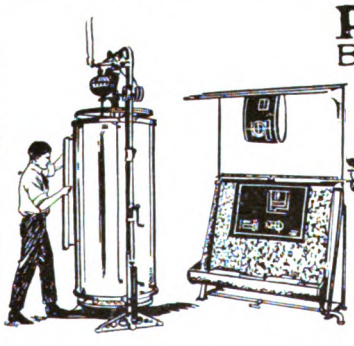
One boy and a Pease Peerless Automatic-Continuous Blue Printing Equipment can print, wash and dry more and better blue prints than four experienced men can turn out with any other equipment using independent methods of washing and drying.

A Pease Peerless will make up to one hundred yards of perfect blue prints every hour at any hour of the day or night, and do it at a lower cost per square foot of finished blue print than is possible by any other method.



If you wish to know more about this drafting room labor saver, write for Catalog No. P-21.

DRAFTING ROOM FURNITURE



Catalog F-20 contains many illustrations of modern drafting room furniture. Steel and wood, horizontal drawer, sectional filing cabinets; a vertical steel plan-safe for blue prints, maps, etc.; drawing tables, drawing boards, draftsmen's stools and ruling attachments are a few of the many pieces shown. If you are contemplating the purchase of drafting tables or stools, you will be interested in the complete assortments illustrated. We will gladly send you a copy of this catalog for your files on request.

DRAWING INSTRUMENTS

Pease "Chicago Made" Drawing Instruments are not surpassed for accuracy, finish and quality by any other line, either domestic or imported. Write for Catalog D-21, which contains prices of complete sets and separate instruments.

PEASE VERTICAL BLUE PRINTING MACHINE

If the demand for blue prints does not warrant installation of the automatic equipment illustrated above, a Pease Vertical Blue Printing Machine and Sheet Washer can be installed in a corner of your drafting room, and will furnish a constant supply of perfect blue or negative prints whether the sun shines or not.

Write for descriptive booklet.

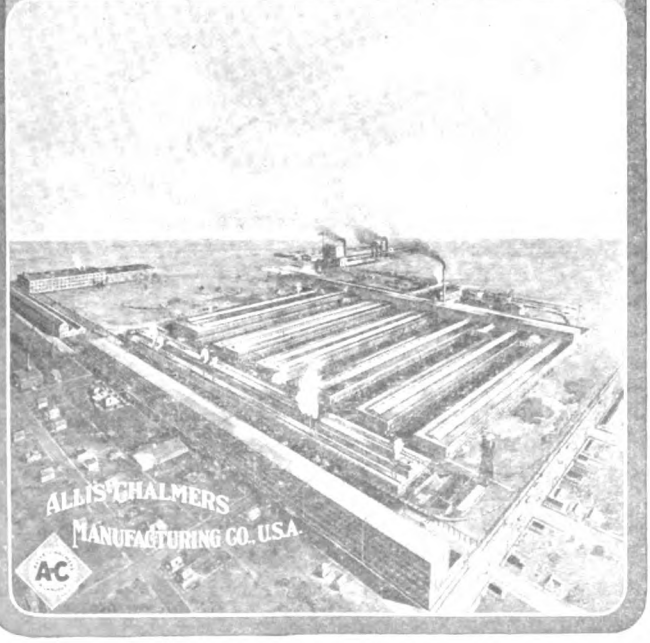
WEST ALLIS WORKS

The largest of the three plants of the Allis-Chalmers Manufacturing Company, known as the West Allis Works, is located at West Allis, Wisconsin, a suburb of Milwaukee.

The bird's eye view of the West Allis Works depicts the layout of this plant. Specific products are made in each of the six machine shops, extending East and West and at right angles to the three long buildings shown in the cut, each machine shop having its proportion of pattern shop, foundry and erecting shop. From the west end of the plant, patterns travel in one direction to the foundry, and the finished castings through the machine shops in the direction of the erecting shop, where they are assembled, loaded and shipped out at the extreme opposite or east end of the plant.



An idea of the size of the Plant is obtained from the following:

Principal Products:

Air Brakes
Air Compressors
Cement Machinery
Centrifugal Pumps
Condensers
Crushing Machinery
Electric Hoists
Electrical Machinery
Farm Tractors
Flour Mill Machinery
Forgings
Gas Engines
Hydraulic Machinery
Oil Engines
Reciprocating Pumps
Rolling Mill Machinery
Steam Engines
Steam Hoists
Steam Turbines
Sugar Machinery

Total floor area of plant, square feet, 2,381,947.
Total ground area, acres, 116.
Plant boiler horsepower, 10,700.
Miles of railway track, 17.
Number of locomotives, 3.
Length of overhead flask unloading track, 2,604 feet 9 inches.
Reservoir for condensing water for power plant (size 200 feet by 360 feet by 15 feet 6 inches), capacity 4,650,000 gallons.
Number of cranes, 143.
Total capacity of cranes (tons), 3,000.
Foundry day capacity (tons), 350.
Heaviest casting produced, 130 tons.

ALLIS-CHALMERS
MILWAUKEE, WIS. U.S.A.

approached a state where the animal-drawn vehicles described above were furnished with horses. Consequently the demands made upon the motorized supply train were all the greater.

I believe that the shortcomings described in Major Young's article have been corrected in the Tables of Organization, approved by the War Department on August 31, 1920. Under these approved tables all field and combat trains of regiments and similar independent organizations, are animal drawn. The infantry division, whose war strength is now slightly over 19,000, has a supply train of four truck companies of 1½-ton trucks, 27 trucks to a company, and two mule-drawn wagon companies, of 60 escort wagons each. The allowance of rations in the field remains unchanged, but the number in the division supply train, now known as the division train, is reduced to one day. This train also carries all ammunition except that for the Field Artillery. The Field Artillery ammunition is carried by one truck company, which is part of the Field Artillery brigade of the division.

Major Young's argument for pooling in commands higher than a division has been met by the assignment of 12 truck companies, each of 27 3-ton trucks, to the corps commander, which, together with a wagon train of 270 wagons, mule drawn, gives the corps Commander the pool necessary to augment the divisional transportation of any of his divisions requiring assistance. As an additional pool, we have in the new organization under each army commander, 18 truck companies, each of 27 3-ton trucks. The approved report upon the re-organization of the Army also contains the statement that traffic control will be a function of G-4, using the military police under the direction of G-1.

It is well to remember that the probability of our having sector warfare within the territorial limits of the United States is very remote. The situation in Europe was a well-defined line with one flank on the ocean and the other upon a neutral state. The chances are small of our having a war in this country where both flanks are impassable. In view of these conditions, our divisions must be so organized that they can carry on a war of movement over roads found in any part of this country.

For this reason our troops must always have as part of their organization sufficient transport to carry such equipment as the troops will inevitably need whenever the enemy is encountered during maneuver.

L. D. Gasser

Lieutenant Colonel, Infantry, U. S. Army; formerly with Motor Transport Section, G-4, G. H. Q., A. E. F.

Major Young portrays very accurately the history of our difficulties in supplying and operating motor transportation in France.

Economy and efficiency both demand the pooling of motor transportation; this was recognized by both the First and Second American Armies in France, where the pooling system was partly placed in effect prior to the Armistice.

Ammunition trucks were left out of the tentative organization of the motor transport reserve, mainly on account of the claim of the technical character of the cargo to be handled and transported. There are many widely divergent opinions on this subject, and I have no intention of discussing them here, except to state that the principle of motor transport pooling, which recognized economy and efficiency in the problem of transporting troops and supplies, evacuation of the battlefield, etc., would, it is believed, also increase the efficiency of ammunition supply in large commands.

I concur in Major Young's conclusions. It was on this

Digitized by Google

basis that the tentative motor transport reserve regulations were prepared, *i. e.*, limiting the permanent assignment of motor transportation in divisions to the barest necessities, leaving to the motor transport reserve the larger problems of supply of the whole force, or when special missions were assigned to divisions, of furnishing sufficient transportation to enable them to carry out their missions.

The problem of traffic control, which is essential to the proper utilization of the highways in the theatre of operations, is one which has never been satisfactorily worked out in our service. It will be even more difficult in this country than it was in France, owing to the character of the roads, and the fact that there will also be a smaller number of roads within any given theatre of operations, rendering heavy concentration of troops a far more difficult problem. This is a function of the military police in our service, but the system of dispatching and controlling traffic has not been fixed, and one function cannot be separated from the other with the expectation of efficient results.

Coincident with the principle of unit control, comes the question of which General Staff section should co-ordinate and control traffic. It would seem that the best results would be obtained if the section of the General Staff charged with the supervision of roads would also have charge of the supervision of the traffic thereon, in the same manner as it has charge of the supervision of railroads, both as to roadbed and operation of the rolling stock.

J. Edward Cassidy

Formerly Lieutenant Colonel, Engineers

The two theories of handling trucks in operations has been discussed in this article, and the good and bad features of each pointed out. There are some of the conclusions I cannot agree with, however. The matter of use of trucks for military transportation is comparatively new, but the principle dates back to antiquity. There are two essential features necessary for the successful conduct of an operation, *i. e.*, men and *materiel*. It has been amply demonstrated in modern warfare that men alone cannot combat *materiel* successfully, and to win success in battle the enemy's *materiel* must be neutralized. The greater the degree of mobility of men and *materiel* available for an operation, the greater the chances of success will be. Motor transport has two important functions, one the transport of *materiel* and the other the transport of men. The movement of whole divisions by means of motor transport was a feature developed during the World War, but the principle is old. In one of his campaigns against the Indians, General Miles could not keep his infantry in contact, so he used ponies in order to give them a mobility equal to the Indians. The dragoon of other days was merely a more mobile infantryman. The development of internal combustion engines made possible new variations of the old principles.

The author of this article appears to conclude that it was better to wait until a standardized truck could be produced in this country than to use trucks which were already on a quantity production basis, and while the theory is all right, it did not work out practically. The American Army in the beginning of the Argonne-Meuse offensive had approximately 20 per cent of its proper motor equipment, and on November 11, 1918, was approximately 10 per cent equipped with such transport. (Report of Lieut. Gen. Hunter Liggett.) The available supply consisted of all sorts, kinds, and classes, and almost every make—with few repair parts available. We might as well have had a variety of trucks of our own make as to have had a conglomeration

Appointments in the Corps of Engineers

[Editor's Note]

The foregoing circular from The Adjutant General deals with appointments to the Regular Army to the number of nearly 2,600; of these, 118 will be in the Corps of Engineers, all in the grade of second lieutenant, but promotion to the next grade will follow at an early date for those who pass examinations with a high mark. No prediction can be made as to the rate of promotion above the grade of first lieutenant.

The following information will be of interest to engineers who contemplate taking the examinations:

The preliminary examination will be mainly physical, and for graduates of and senior students in engineering institutions of acknowledged excellence the mental part will be nominal.

The final examination will be fairly comprehensive in its scope, but exemptions will be allowed under certain conditions, so that anyone who has graduated or who, within six months of the date set for the examination, will graduate in the upper fourth of his class at one of the leading technical educational institutions of the United States need take examination only in one of the four following subjects, viz, Analytical Geometry, Calculus, Advanced Mechanics or Surveying. The choice rests with the candidate and his place on the list will depend upon the marks made in examination. Men who did not graduate in the upper fourth of their classes, and non-graduates, are also eligible to compete for appointment, but they will be examined in the subjects prescribed.

Senior students at engineering institutions who will graduate this year should note that the minimum age requirement (21 years) applies not to the date of final examination (April 25), but to the date of appointment, which it is contemplated will be about two months after the examination.

It might be inferred from the circular that senior students in college may become eligible for the final examination only by enlisting in the National Guard or the Organized Reserve, but Par. 9 of the new Army Regulations No. 605-5, Dec. 9, 1920, states that—

"Any candidate who has graduated from, or who will graduate within six months from a technical course in any recognized college, university, or technical school, may, for the purpose of taking the final examination, be considered eligible for appointment. Upon receipt of examination reports in individual cases, decision will be made by the Secretary of War whether or not the institution and the course therein are approved as making the candidate eligible for the appointment he seeks."

Successful applicants will be allowed to continue their studies until graduation.

Civilians not graduates of an approved technical institution and not members of the Officers' Reserve Corps may, after passing the preliminary examination, become eligible for the final by enlisting in either the enlisted Reserve Corps or in the National Guard, or by securing an appointment in the Officers' Reserve Corps.

Officers commissioned in the Corps of Engineers can be assured of a varied and interesting career. Service will consist of duty with troops, duty as instructors and inspectors with the Organized Reserves and on construction work connected with fortifications and improvement of rivers and harbors. The annual pay of a second lieutenant is $1,700 with a bonus of $420 per annum, supplemented by allowances for quarters, medical attendance, an annuity upon retirement from active service by reason of age or physical disability in line of duty, and other perquisites. The pay is increased by 10 per cent of the base pay in each grade for each five years' of service, but not to exceed 40 per cent after twenty years' service.

Members of the Society of American Military Engineers will render a kindness to their young acquaintances engaged in or preparing for the practice of engineering by bringing this information to the attention of such as they believe would be interested in army service. All who desire to compete will receive full information upon application in person or by mail to the Commanding Officer at the nearest Army Post or Corps Area. Corps Area Headquarters are located at Boston, Mass.; Governors Island, New York City; Ft. Howard, Md.; Ft. McPherson, Ga.; Ft. Benjamin Harrison, Ind.; Ft. Sheridan, Ill.; Ft. Crook, Nebr.; Ft. Sam Houston, Texas; and San Francisco, Calif.

Strength of Aged Cement

Because of cement shortage in the District of Columbia the Corps of Engineers has proposed to use some cement which has been in storage about eighteen months. In order to determine the proper strength assumptions for concrete made of such cement the Bureau of Standards made a number of tests on it. The cement as received was first put through a sieving process to remove the lumps. The cement after sieving, as well as the crushed lumps, were then made into separate concretes which were compared with concrete made from cement recently purchased in the local market. It was found that a 1:1¼:2½ mix of the old cement would give approximately the same strength as a 1:2:4 mix of fresh cement, and it was recommended that the lumps be sieved out of the old cement before using. Similar tests were conducted on aged cements submitted by the U. S. Engineer Office at Vicksburg, Miss. The results indicated that a 1:2¼:4½ mix of the aged cements gave approximately the same strength as a 1:3:6 mix of fresh cement.—*Eng. News-Record.*

Tractors Replace Teams for Scrapers

Two 5-ton tractors, each hauling three wheeled scrapers, are used for grading work by the American Cement Plaster Co. at its plant at Acme, Tex. The two tractors are doing as much work as twelve wheeler teams according to the superintendent of the company. With a maximum haul of about 1,200 feet the two machine outfits are moving about 400 cubic yards per day. The excavation is 12 feet in depth and the dump is on the surface of the ground, so that the machines run up hill and down hill all day. The tractors load the scrapers on low gear, haul them to the dump on direct drive, and return to the pit on high gear when the ground is sufficiently level. Each machine uses an average of 25 gallons of gasoline per 10-hour day, and about a gallon of lubricating oil, besides cup grease. The maintenance on the machines has been very small—*Eng. News-Record.*

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

Sauerman Bros.

1145 Monadnock Bldg., Chicago

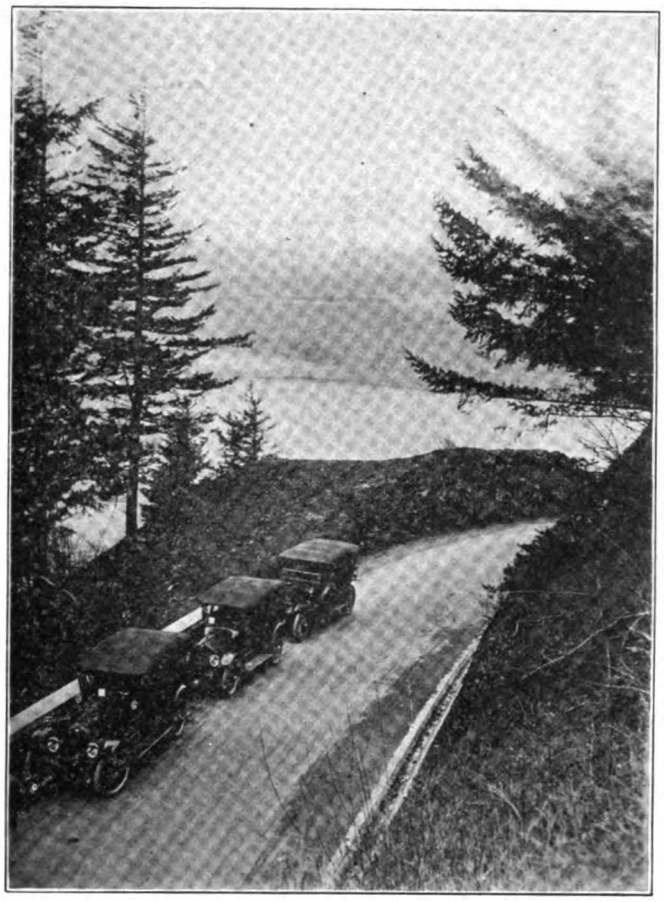
(Continued from Page 163)

of foreign trucks, many of which were trucks which had been practically discarded by the British and French Armies. Valuable time was lost after the declaration of war in experimenting with machine guns, airplanes, trucks, and other impedimenta of war instead of getting busy on *materiel* which could have been placed on quantity production basis at once. We adopted a rifle which was largely used by our forces, which was very inferior to the U. S. Magazine Rifle, Model 1903, usually termed the Springfield, because the Springfield was not on a quantity production basis while the other was. This same system should have been applied to trucks and other classes of equipment. Once the pressing needs of the army had been supplied, then the work of producing standardized equipment could have gone forward. Of course, the British Navy and the French and British Armies were between ourselves and trouble, so nobody seemed to be in any great hurry to get properly equipped for making war. Had we been faced with the same situation Great Britain faced in 1914, our methods would undoubtedly have been changed.

I do not agree with the contention that the motor industries of this country could not have supplied the necessary motor equipment working on an enlarged commercial basis, and could not under present conditions supply the needs of any armies we might have to raise. The time to prepare data for the utilization of industries in the time of war is not after war has been declared, but before. The motto on many of our coins—"In God we trust"—has been applied too literally to the matter of our national defense during the entire history of the country, and while it is well to put your trust in God, the nation that keeps its powder dry and a little reserve stock on hand for special occasions, is more liable to survive in the contest of nations than the nation which trusts to God alone to preserve its integrity.

The American system of handling trucks in France was a sort of hybrid affair, and from rather long intimate contact with it, fails to arouse any enthusiasm in the writer. Still this system cannot be used as a criterion because of the fact that at no time was there sufficient motor equipment available to make definite systems possible. Had the war lasted a year or two longer we would undoubtedly have gotten out of the amateur into the professional class in the art of making war.

Conclusions drawn from detailed observations and experiences on British, French and American fronts, lead me to believe that the French motor transport system, with various modifications, is about as good as can be found. I am not a believer in a Motor Transport Corps in any sense of the word, except possibly a small unit in the Service of the Rear for use as a co-ordinating unit in arranging a supply of trucks with the zone of the interior. I found too often when truck units were drawn from the Motor Transport Corps, the personnel were more interested in the operation from the standpoint of the M. T. C. than they were in the good of the military operations going on, apparently feeling that their first allegiance was to their own Corps. It was the old story, "The operation was successful, but the patient died."



I believe a good organization for the motor-truck service would be found in the following general outline:

(a) Combat units to be supplied with a fixed truck capacity sufficient for their average needs. This equipment to be entirely under control of the various units. By combat units in this case, I refer to regiments and independent battalions operating in divisions and corps.

(b) Divisions to be equipped with truck trains for average supply, and for reserve—the ordinary supply to be in the hands of an officer acting under G-4; the Reserve being under the control of G-1.

(c) Corps units, such as the Corps Engineer Regiment, to be on the same footing as the divisional units. There should be an ample truck reserve in the corps and under G-1 of the corps, which would be used

The Field Artillery Journal

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bi-monthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

to supply the extraordinary demands of the divisions in the corps and to move troops within the corps for tactical purposes.

(d) Army units will, of course, be provided with a fixed supply for average requirements. In addition, the army must have an army reserve sufficient to move entire divisions for tactical purposes, and to take care of extraordinary supply when occasion demands. The army reserve would be called on to replace the fixed truck capacity of the divisions when depleted by battle losses. As in the corps and division, I contend that the proper place for the control of this truck reserve is not in G-4 or a Motor Transport Corps, but under G-1. The army reserve to be replenished from the S. O. S.

The control of motor transport must be in the hands of a staff section which is directly interested in operations, and my experiences lead me to believe that G-1 is the proper place for such activities.

In addition to the distribution and handling of motor trucks, there must be adequate control of roads and classes of transportation. Road control in the American Army in France was a joke, and supervision of the impedimenta moved forward with the divisions in combat operations received little attention, as a result divisions carried forward everything, including the "piano and kitchen stove," blocking the roads with a great deal of transport which should have been left behind and brought up later. As regards road control, I have seen division and corps M. P.'s stationed within forty feet of each other with widely different instructions, and as these were so contradictory, the officers or men usually paid little attention to them. I think the highest ranking officer on road control I ever saw in France was a major, and only one of him—the M. P. private usually being the only representative of the road control and most generally he knew little or nothing about roads, so it is not surprising that things did not function very well. Inasmuch as the American Army was only in existence for a period of four months during active operations in the war, it is not surprising that we were still in the amateur stage when the Armistice was signed.

There should be a Chief of Roads for each army, and this officer should not just be picked because he has a certain rank, but he should be picked solely for his qualifications, and these specifications should also apply to the corps chief of Roads. Chief of Roads of the army and the Chief of Roads in each corps should be under G-1, and each have a competent staff of specially picked officers. The Chief of Roads of the corps should be vested with full authority over road plans and traffic control. An assistant to the Chief of Roads of the corps should be with each division working with the Division G-1. Proper supervision should be exercised over classification of materials and supplies, and the Assistant Chief of Roads in the divisions should be supplied with steel disc markers to be carried by each truck, indicating the class of road. For instance, a round, steel disc painted red might be used for priority materials or supplies, this disc to have a circular, countersunk area painted with luminous paint for night indication. The truck to carry four markers, two front and two rear, these markers to show the extremities of the truck. With the luminous markers, the movement of traffic at night in areas where lights could not be allowed would accelerate traffic movement 50 per cent. The adoption of such a system would result in an accelerated movement of necessities instead of the roads being cluttered up with useless stuff, which might as well be brought up later when things are slack.

The necessary impedimenta for a modern army is so great that all unnecessary material must be kept off the roads to the greatest possible extent, and it is morally certain that the supervision must be done by corps agencies and not left to the divisions.

Another thing vitally essential is that motor-truck units

Wickes Blueprint System

FOR DISTINCTNESS

Above all else a blueprint must be distinct---a single decimal point or figure misinterpreted may result in a catastrophe.
Protect your job, your workmen and yourself by getting absolutely distinct Prints.
Use the WICKES SYSTEM. It is consistently reliable in accuracy, distinctness and clearness. No blotches or faded lines, to mar its strength of tone.

drawn from a reserve, whether corps or army, and sent for duty to a certain organization, must remain under control of the unit to which it is ordered to report until it is released to the reserve again by proper authority. My experience with Motor Transport Corps units sent for special duty with my regiment, was that these units felt that they were in no sense under my command and that they were free to come and go as they pleased, as their first allegiance was to the M. T. C. This was not due primarily to the individual units, but to the lack of proper control.

Jno. F. Franklin

Major, Infantry, U. S. Army; formerly Motor Transport Corps, A. E. F.

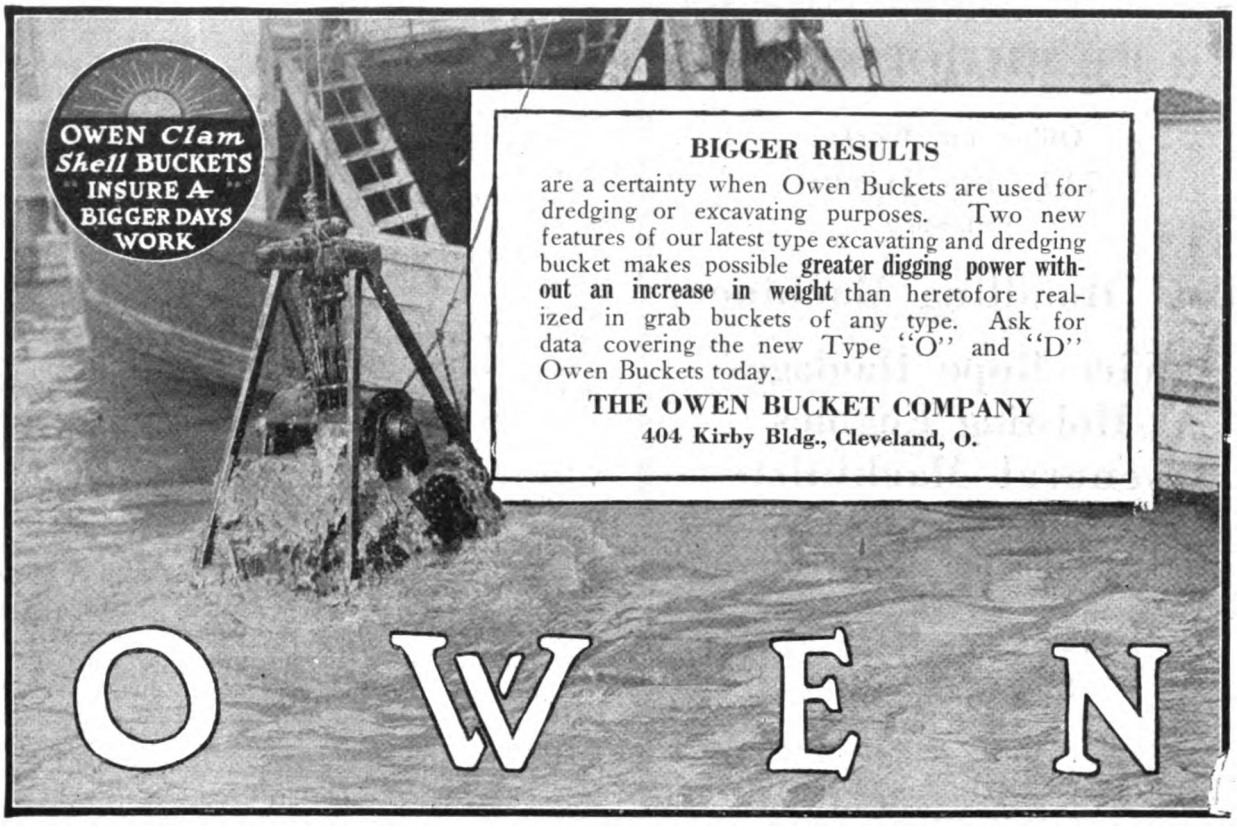
Major Young presents a very able discussion of this subject from a broad point of view. I heartily agree with the conclusions drawn, though I am sure they would meet with considerable opposition in the service if put into effect.

The only criticism that I have of the article is that he has not sufficiently stressed the advantages of his plan of operation over those of the "fixed assignment" in the maintenance of the equipment. When an army is equipped with proper motor transportation, the efficient operation of the work is only begun. The real job is the maintenance of that equipment. If this subject is not given the proper thought and the work properly organized, the army will be crippled for lack of proper transportation in a surprisingly short time.

The advantages in maintenance of the "pooled system" over the "fixed assignment" are obvious.

Marmion D. Mills

Major, Engineer Reserve Corps; formerly in charge of Transportation Branch G-4, 1st Army, A. E. F.



In the interest of a higher efficiency in the supply service of future armies in the field it is to be hoped that Major Young's admirable article will be widely discussed from the viewpoint not only of those who saw the Motor Transport problem in the A. E. F. from the operating side, but also of those who saw it as a means to an end, *i. e.*, the movement of men, supplies and munitions.

Probably no division commander would wish thrust upon him the operation of a railroad within his area, simply because he depended upon that railroad for his supply. He would realize that the operation of the road was a highly technical matter, and as long as his supplies were received when and where wanted, and that he was assured that the road could meet an emergency promptly, his interest in the actual operating problems would be nil. He would have enough troubles of his own.

The operation of motor transport in the area of a modern army in an active sector is as highly technical a problem as is the operation of a railroad. One operates trains of cars drawn by power units between certain points over a previously laid track, and by means of a dispatching system or traffic control is able to handle a maximum tonnage or passenger movement in both directions. The other operates convoys of separate cargo or passenger-carrying power units between points over an existing road system and by means of a centralized traffic control, *and by this means only*, is enabled to insure the maximum movement of tonnage in both directions.

The loose operation of separate convoys from various corps and divisional units over a road system by which a large force is supplied, not only is a primary cause for traffic jams, but it represents an ineffectual use of available transportation. During the early phases of the Meuse-Argonne operation when the various corps were making
