

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

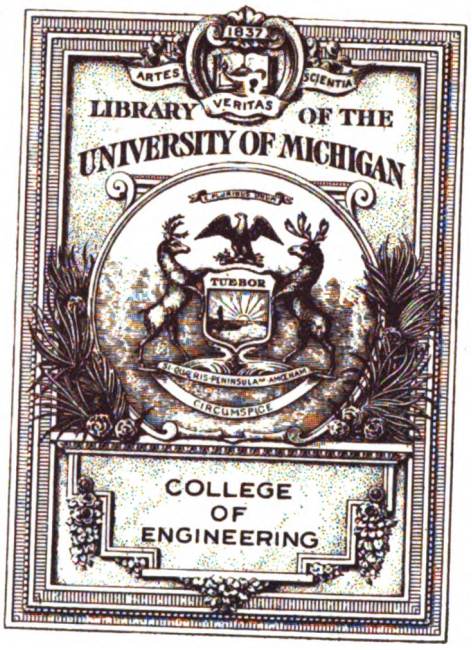
Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.



+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

UNITED STATES ARMY builder of MEN

TEN years ago it was necessary for the United States Army to argue men into its ranks.

But to-day the Army, like every other great university, points with pride to its graduates.

Four million of the nation's choicest young men were entrusted to the Army's care.

MOST of them are back in the ranks of industry to-day; and every parent in America, every employer, every teacher knows that they are better, abler men for their experience.

They stand straight upon their feet, a symbol of physical fitness.

They have learned how to execute orders, and how to give them.

THERE is, in their characters, a maturity beyond their years, a vision and a self-confidence that are fundamentals of success.

The months that they gave to the Army were not lost months; the records of the future will show more rapid progress for them because of the qualities which those months developed.

THE United States Army is open for enlistments today. It wants no inferior applicants; it seeks young men of character and purpose; and it promises those young men that the term of their enlistment will be fruitful years.

They will come back to civil life in perfect health—their muscles, their eyes, their bearing all evidencing the finest professional care.

IT IS the purpose of the War Department to develop in the American soldier those qualities which are the essentials to success in any trade or business and are the prime requisites in an American citizen.

Congress has appropriated $2,000,000.00 to be used in Educational work in the Army Schools. In many camps and posts men are being trained in the skilled trades and at practically all Army stations, schools are in operation in which the soldier can improve his education.

Through enlistment the United States Army offers opportunities to travel. It provides good food, good clothes and good care. It gives a training which brings health—physical development — mental quickness and self-confidence. It sends you back to civil life better equipped for American citizenship than when you enlisted.

A PERSONAL INTERVIEW INVOLVES NO OBLIGATION

Engineer Construction in France

Work of the Division of Construction and Forestry, A. E. F.

By

Lieut. Col. J. A. Woodruff

Corps of Engineers, U. S. Army

Discussion and Comment by Maj. Gen. W. C. Langfitt, Maj. Gen. M. M. Patrick Brig. Gen. Edgar Jadwin, Col. J. B. Cavanaugh, Col. Ernest Graves, and an Extract from the Final Report of General Pershing

[See Index Map, Page 67]

WITH the exception of a few barracks erected in the Gondrécourt area by troops of the 1st Division immediately after their arrival in their training area, the actual work of construction by the American forces in France was commenced by the 15th (Railway) Engineers, Col. Edgar Jadwin, C. E., commanding. This regiment was one of those raised in May, 1917, as a result of the Joffre Mission to the United States. It arrived at Vierzon July 28, 1917; its equipment, which consisted of about a trainload of tools and plant brought from America, also arrived promptly. The regiment at once began surveys, and construction detachments were distributed without delay to Issoudun, Bordeaux, Gondrécourt, and other important points between the Atlantic ports and the combat sectors.

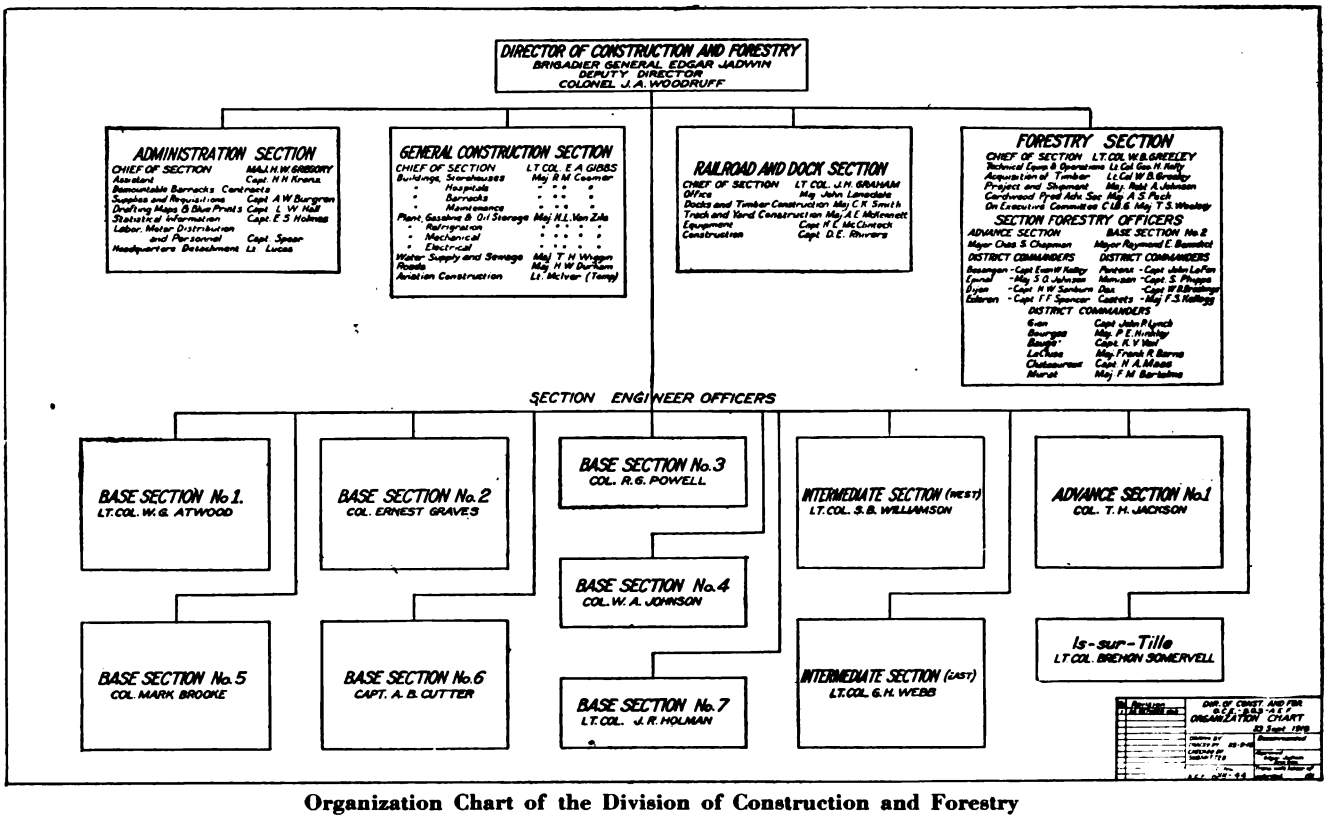
The 17th Engineers (Railway), Col. J. S. Sewell, Engineers, commanding, arrived at St. Nazaire August 17, 1917; the 16th Engineers (Railway) Col. Harry Burgess, C. E., commanding, arrived at Is-sur-Tille August 26, 1917; the 18th Engineers (Railway), Col. J. B. Cavanaugh, C. E., commanding, arrived at Bordeaux August 20, 1917; the 10th Engineers, (Forestry), Col. J. A. Woodruff, C. E., commanding, arrived at Nevers October 9, 1917 (later consolidated with the 20th Engineers, Forestry). Other regiments, such as the 11th, 23d, 25th, 33d, 55th, 32d, 106th, 109th, 309th, 311th, 312th, 318th, 319th, and many other regiments and battalions performed valuable service during the time they were in the S. O. S., but the 15th, 16th, 17th, 18th, 10th and 20th, by virtue of their early arrival and long service may be considered as having formed the backbone of the field construction forces of the Services of Supply.

The organization as modified by General Jadwin in May, 1918, consisted of a central office at Tours, the headquarters of the Services of Supply, organized into four sections, viz: Administration, General Construction, Railroads and Docks, and Forestry, all in charge of a deputy director.

The construction work in the field was carried on through Section Engineer Officers whose territory corresponded with that of the sections of services of supply and consisted of an advance section, an intermediate section (divided into two construction sections on account of its extent) and seven base sections, each embracing the territory around a port of debarkation.

The forestry work in the field was carried on through district commanders, each of whom also com-

[The Division of Construction and Forestry in France in its final form was one of the four great departments of the engineer organization under the Chief Engineer of the American Expeditionary Forces. Its history began with the arrival of General Pershing in France when General Taylor, the Chief Engineer, assigned to one of his assistants the duty of directing the construction immediately necessary and planning for that ultimately to be required by the American forces.



In August of 1917 the Lines of Communication were formally organized to handle all phases of supply, housing and transportation in rear of combat sectors. Construction devolved upon the Chief Engineer of the Lines of Communication and was so continued until by a reorganization in February of 1918, the Lines of Communication were designated as the Services of Supply. This included as one of its great operating divisions, a Service of Utilities, with Maj. Gen. William C. Langfitt at its head as Chief of Utilities. This service included among other functions a Department of Construction and Forestry and a Department of Light Railways and Roads. In July of 1918, the Service of Utilities was discontinued as such and the two departments named were merged with the previously existing Engineer Department. The chief of utilities became the head of the consolidated department and succeeded to the title of the Chief Engineer, A. E. F. The previously existing activities connected with military engineering operations, engineer supply, construction and forestry, and light railways and roads, were continued as operating divisions of the new and enlarged engineer organization with a director at the head of each.

For brief periods in the summer months of 1917, Col. C. W. Kutz and Brig. Gen. C. H. McKinstry served successively as Chief Engineer, Lines of Communication. Brig. Gen. M. M. Patrick was appointed Chief Engineer, Lines of Communication, in September, 1917, and discharged the duties of the position until May 22, 1918, the title having been changed in the meantime to that of Director of Construction and Forestry, with no material change in duties. General Patrick having been appointed Chief of the Air Service, A. E. F., he was succeeded as Director of Construction and Forestry by Brig. Gen. Edgar Jadwin, who remained in charge of the construction work of the A. E. F. until demobilization of the forces had been practically completed in July, 1919.—Ed.]

Digitized by Google

manded a battalion of the forestry troops which operated from two to eight saw-mills. The districts in the advance section and those in Base Section No. 2, where most of the forestry operations were located, were combined under a section forestry officer. These officers acted directly under the central office for production and shipments outside their own section, but filled local requisitions on orders of the section engineer officer in whose section they were located.

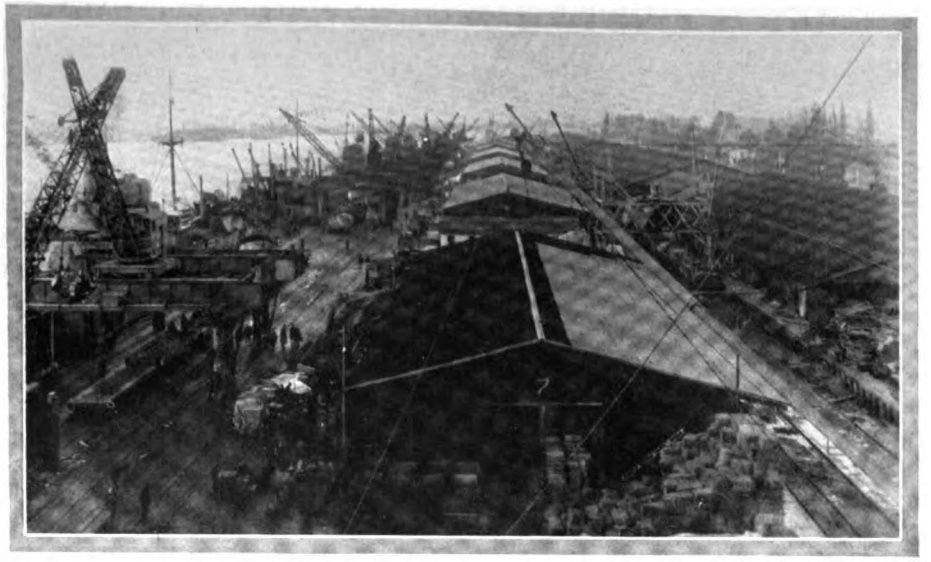
The changing and rapidly increasing force, together with the size which it had attained at the time of the armistice—150,823 men, of which 127,000 were

Organization Chart of the Division of Construction and Forestry

available for work—and its wide distribution, called for an elastic and adaptable organization and methods.

This was obtained by means of a decentralized organization and the use of type plans as far as practicable. The work was handled by the Director of Construction and Forestry with a central office at Tours, operating through a section engineer officer in each of the sections. General instructions were originally given to the S. E. officers, who were supported consistently so long as they observed the general policies of the director and of higher authority. Every possible help was given them by the central office in the securing of men and materials. The central office, under the immediate charge of the deputy director, carried on continuously along established policies and precedents. The director was thereby enabled to spend considerable time in inspections and consultations with the officers in the field, and the consideration of special suggestions, recommendations and requests made by the various section engineer officers and others concerned.

The results confirm this as a satisfactory type of organization for handling a large construction force under such varying and trying conditions.



Throughout the entire period of construction the labor forces available were inadequate. There was in particular a shortage of technical troops. It was necessary to use combatant troops and general labor organizations to perform special construction work. Such technical troops as were available were necessarily used for purpose of supervision. Requests were repeatedly made on the United States for the selection and organization of technical troops, but the need for them and combatant troops at the front and the inadequate transportation facilities made it impossible to obtain adequate technical troops and common labor. The use of civilian labor recruited from men not physically suited for service at the front was not a success. Because of this constant shortage, it was necessary to curtail the construction program at all times and to limit it to bare necessities.

The various classes of construction work carried on may be sub-divided into—

(1) *Shelter for troops,* including camps of various types such as rest and depot division areas, embarkation camps, camps for stevedores, women's camps, enclosures for American prisoners and prisoners of

Some of the Works of the American Engineers in France

The great docks at Bassens with up-to-date facilities—built and equipped by American engineers at a speed that caused the French to marvel

The great refrigerating plant at Gievres under construction. Capacity 7,500 tons of meat, and 500 tons of ice daily

Saveney dam, 40 feet high, 6,000 yards concrete, 10,000,000 gallons storage

The railroad bridge at Nevers. Built in "jig-time" to carry the heaviest loads

Great engineering projects of every kind are indispensable to victory in modern war. The Engineers with the A. E. F. undertook vast works of every conceivable class, including water and rail terminals, docks, light and standard railways, bridges, roads, buildings of all kinds and all materials, machine shops, dams, water supply, sewerage, electrical installations, refrigeration, etc. With unlimited zeal, enthusiasm and patriotism, joyously surmounting all the difficulties resulting from inadequate personnel, plant and materials, and the necessity of conducting difficult work in a foreign land across the seas, they rapidly and successfully accomplished every task assigned to them, and contributed to the great victory of civilization.

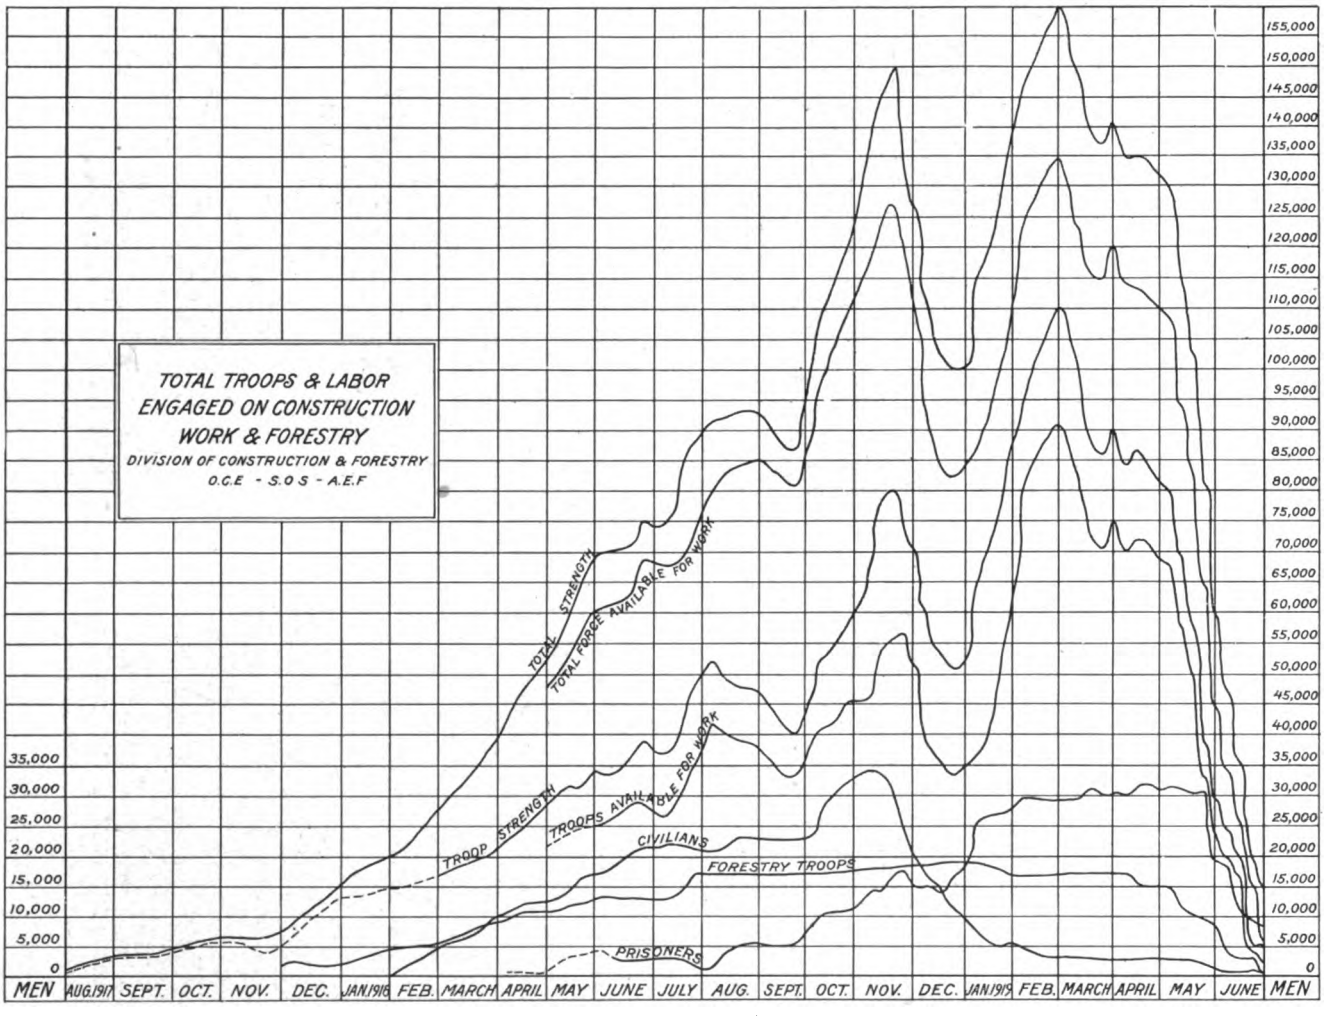
war, instruction centers and schools for army, corps, artillery, aviation, tank, motor transport, ordnance, chemical warfare service, etc.

(2) *Hospitalization*, consisting of base, camp, evacuation and red cross hospitals and convalescent camps.

(3) *Ports*, comprising the construction of docks and warehouses thereon, railroad connections, and lighters.

(4) *Railroads*, including engine terminals, regulating stations, double-tracking at various congested points, cut-offs, receiving, classification and departure yards and tracks in storage depots, and their connections with the ports.

(5) *Storage depots*, including large storage depots required at the ports and in the intermediate and advance sections; also special ammunition and aviation depots, coal storage yards, gasoline and oil stations, motor transport centers, remount depots, veterinary hospitals, refrigerating plants and salvage plants.



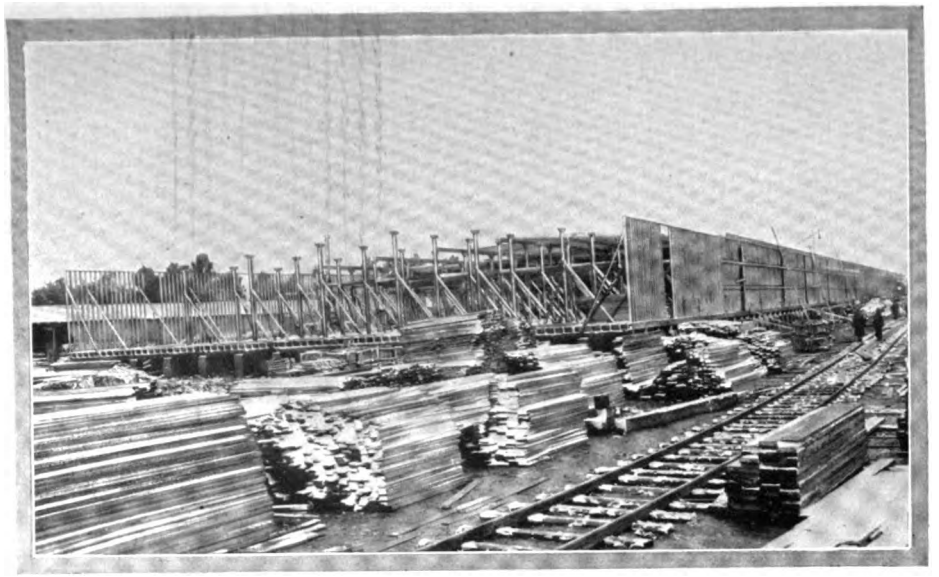
(6) *Roads*.

All of the above work was in sole charge of the D. C. & F. from its beginning, except the following:

(*a*) Railroad construction, which was in charge of the C. E., L. of C., up to September 14, 1917, when it was turned over to the transportation department. It was again placed under the D. C. & F. on March 12, 1918. Of the 1,035 miles of railroad constructed, 62 miles, or 6 per cent, were constructed while the work was in charge of the transportation department.

(*b*) Air service construction, taken over by the D. C. & F. on December 31, 1917, when approximately 7 per cent of the total work had been completed.

(*c*) Ordnance construction, assumed by the D. C. & F. on January 17, 1918. About 1 per cent of this work had been completed before that date.



Shelter for Troops

Both in scope and general character of construction, the problem of providing shelter for troops had many features in common with the one of building hospitals. In fact, it was generally the erection of demountable barracks that served to initiate engineer troops newly arrived in France into actual construction work on foreign soil. Towns were flooded far beyond their billeting capacity as the stream of American soldiers came to flow inland from base ports, so that additional

accommodations on a large scale in the form of camps of various types had to be furnished. The engineer department undertook the task of supplying barracks for one-third of the United States troops in France, assuming that the remainder would be billeted.

According to G. O. No. 46, G. H. Q., A. E. F., 1917, prescribing the allowance for troops as 20 square feet per man, in addition to kitchens and mess halls, 16 barracks 20 by 100 feet were required for 1,000 men. Contracts were made for demountable barracks with the French and British governments and with civilian contractors in France and Switzerland. A total of approximately 23,000 barracks were contracted for, of which 15,000, including 4,500 hospital barracks, were delivered. Most of these were of the demountable type. Deliveries were very slow except during August, September, and October, 1918, when over 1,000 barracks per month were received. On account of these slow deliveries, it was necessary to construct barracks in place from lumber furnished by forestry troops. Two types of barracks were developed, utilizing the minimum of lumber. Type "B" barracks required only 6,100 feet b. m. of lumber, and the type "C" barracks using corrugated iron roof and sides, with frame of wood, requiring only 1,600 feet b. m. of lumber. These barracks were furnished with 4-man bunks and would accommodate about 100 men.

A total of approximately 17,120 barracks were erected, which represents 324 miles of barracks.

The largest camp involving the construction of barracks and other facilities was the Pontanezen Camp at Brest, for 80,000 men—25,000 in tents and 55,000 in barracks—for which over 500 barracks for officers and men were constructed. There were also constructed for this camp 15 mess halls and kitchens, each with a rated capacity for 4,500 men per hour; a complete bathing, delousing and laundry plant and numerous administration, storage and welfare buildings. The tendency at the larger concentration and embarkation camps has been towards large kitchens operated by permanent personnel. There have been several types of these kitchens developed, the largest of which are those at Pontanezen camp, where, although these have a rated capacity of 4,500 men per hour, one of these kitchens has a record of 7,000 men served in 58 minutes.

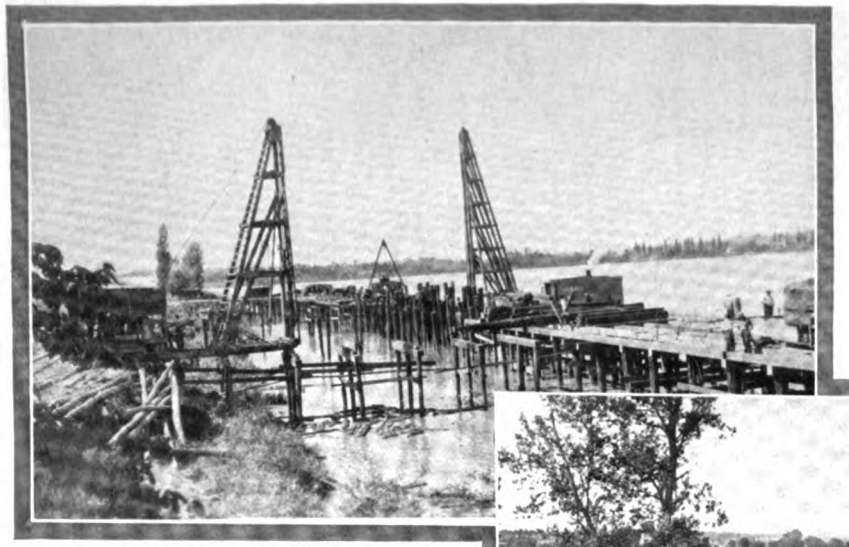
Hospitalization

In August, 1917, instructions were issued to provide for hospitalization on the lines of communication for 300,000 men. In September, 1917, nine French hospitals were taken over, each of which was a nucleus for a hospital center, the original total capacity being about 6,000 beds, which were finally developed into about 34,800 beds.

During the fall of 1917 it was found impossible to obtain many existing hospitals from the French, so that preparations were made to construct a large number of barrack hospitals. Meanwhile, hospitalization had been tentatively authorized for 10 per cent of the strength of the A. E. F. A great deal of time was consumed in determining upon the sites, due to the necessity of meeting the conditions proposed by French and American services interested. Plans of the standard type barrack hospital were developed. A type "A" standard hospital provided for 1,000 normal beds and 1,000 beds by crisis-expansion in tentage, and a type "B" camp hospital provided 300 beds.

The experiences of both the French and English were freely consulted in original type plans and much attention given in the preparation of revised plans to economy of materials and personnel. For further economy in personnel, administration, and supply, hospitals were grouped, as far as local conditions would permit, into centers of hospitalization. Those centers were usually developed in multiples of the Type "A" 1,000-bed base-hospital to any size required.

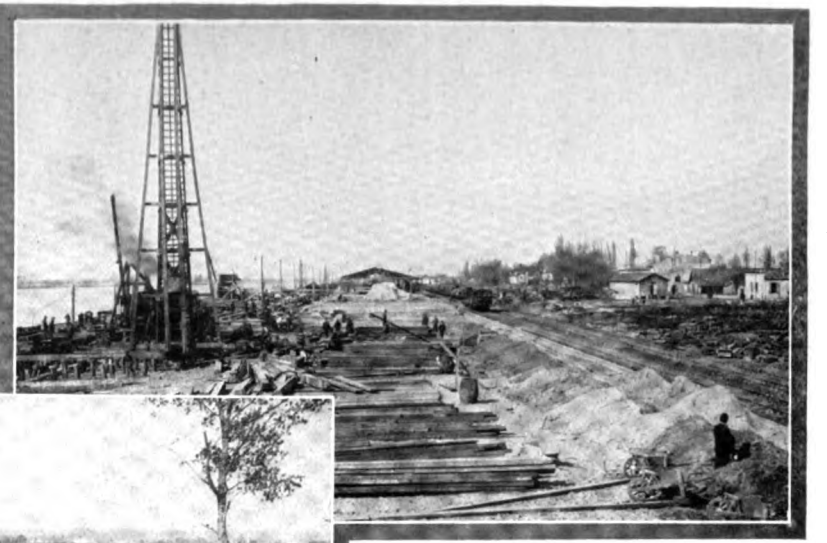
Contracts were at once made for hospital barracks, but deliveries were slow and resort was had to construction in place, using materials most available. Most hospitals were constructed of lumber, but in some cases light masonry walls and concrete floors were used. At first a number of contracts for this work were let, as the contractors were then able to obtain materials, supplies and labor not available to the A. E. F. This advantage steadily decreased during 1918 as the A. E. F. obtained access to all markets for materials and as the quantity of troop-labor increased, while at the same time it became increasingly difficult for the contractors to get labor and materials and to obtain transportation.



In May, 1918, the rate of troop arrivals was doubled and on June 1, 1918, the commander-in-chief directed that there be maintained an actual current bed status aggregating 15 per cent of the A. E. F. strength in Europe. The immediate effect was to triple the necessary rate of hospital construction. This increased rate was more than met.

On November 14, 1918, due to the cessation of hostilities, the authorized capacity of hospitalization was reduced to 7½ per cent. At that date bed space had been provided for 280,000, or 14.2 per cent of the strength of the A. E. F.

Of the hospital space of 280,000 beds provided on armistice day, 139,000 beds were in French buildings, and space for 141,000 beds had been provided by construction. In other words, slightly over one-half of the total hospitalization was provided by construction. This amounted to 7,700 hospital barracks, which represents 127 miles of wards.



In the 1,000-bed base hospitals spacing of beds provided for 3 feet 4 inches between beds. This gave

1,000 patients per unit; unit consisting of 20 ward buildings and other buildings necessary for administration, feeding, operating, etc., and 13 buildings for personnel.

As indicated above, the D. C. & F. was always able to keep ahead of the number of patients on the standard basis, taking into consideration the French hospitals secured and tents erected. The standard 1,000 bed hospital unit contemplated tentage to the same amount, so that 2,000 men would be handled in these units in emergencies with the same general facilities intended, in normal times, for 1,000. Due to the lack of sufficient medical personnel and equipment to operate all the hospitals, particularly those in French buildings, and to the shortage of tents, there were frequently more than 1,000 men placed per unit of the base hospitals, as those units enabled the largest number of men to be taken care of with the minimum medical personnel. At times the number thus handled per unit was as great as 1,500.

Wooden barrack buildings at Camp No. 4, near Bordeaux

Type of steel-frame warehouse; corrugated-iron roofing and siding, employed at Montoir yards

The maximum number of beds occupied by sick, wounded, and convalescent never exceeded 10 per cent, and the available bed space since the first week in July, 1918, was at all times at least 50,000 beds in excess of the number of beds occupied, although tentage for crisis expansion and operating personnel was not provided in sufficient amount to match the bed space provided by construction.

The large scale of hospital construction is typified by the 20,000 bed type "A" base hospital centers at Mars and Mesves

The Airplane in Surveying and Mapping

By

Col. E. Lester Jones[1]
Superintendent U. S. Coast and Geodetic Survey

IT is not believed that the aeroplane unsupported by other surveying can give the final accuracy required in original surveys; but by its means can be made a map that will be much better than the maps which may be in existence today in the areas which have not been topographically mapped. In order that the remaining 60 per cent of the country might be mapped by aeroplane it would be necessary to have a great amount of triangulation and traverse run with a view to furnishing the horizontal control for the photographs to be made by the aeroplane. With this control, it would be possible to fit the photographs on the map into their proper positions.

It is not possible to run many miles with aeroplane photographs and expect to have a very high degree of accuracy in the resulting maps and here I wish to give a word of caution to the advocates of aeroplane mapping, that everything can not be expected of aeroplane mapping. The development of this science will undoubtedly be rather slow for a few years. After it has been developed methods must, of course, be thoroughly tested before they can be adopted. It is well that this is so, for otherwise haste might cause mistakes which would discredit the method to such an extent that it would take years to recover.

. . . . . .

From the experience of the engineers of the Coast and Geodetic Survey the revision of an area that does not need contouring is almost as expensive and takes almost as much time as the original survey, for it is necessary to make a test of the position of each feature. It is here that the aeroplane will be of the greatest service, for if a portion of the shore line should be inspected with a view to learning whether or not the map of it should be revised, we could have a series of photographs made by an aeroplane along the coast and a comparison of the photographs with the original map would enable one to locate definitely each area within which there are new features or where old ones have changed. It is believed that in most cases the details on an airplane photograph could be placed on the map from the photograph with all the accuracy that is needed in the topography shown on the coast charts.

It is a debatable question as to whether the aeroplane photograph made over a water area will show any outline of dangers to navigation when the plates are developed. If they are shown, there is a vast field for the aeroplane in making photographs over water areas where it is known that many obstructions exist. With the usual surveying methods, it is difficult at times to locate every obstruction. One or more on any chart might be missed. The fact has been proved a number of times in a most disastrous way by vessels running on uncharted rocks both along our eastern and our western coasts and especially in Alaska.

The Coast and Geodetic Survey is now making wire drag surveys of all doubtful areas along the coast but it will be many years before the bureau can assure the navigating public that all obstructions have been found and accurately charted.

It may be possible that an aeroplane photograph will indicate submerged rocks or other dangers that are close to the surface of the water. It would be a question of differences in shade in the photograph. If such a detection of danger can be made then one must be very cautious to make the photographs only on perfectly clear days. Otherwise, the cloud passing over makes its shadow on the water which might show on the photograph and cause uncertainty as to whether the spot is a cloud or an actual obstruction.

There are many hundreds of square miles of area along the coast that consist of salt marshes with many streams of little or no importance but which should be shown in their proper relation to other topographic features. These marshes can be photographed from aeroplanes and the streams running through them would probably show in such a way that they could be fitted into the map from the photograph. Here might be a large saving of time for the surveyor in the field.

There are other cases where there are extensive mud flats, when the tide is low, as in Jamaica Bay, New York. To survey the outline for these flats is rather laborious, with the usual instrumental methods, but it is believed that it might be possible to photograph them from an aeroplane and have the results placed on charts. It will undoubtedly be possible to get

[1]Extracts from an address delivered before the Second Pan-American Aeronautic Convention at Atlantic City, New Jersey. Reprinted by permission, from the *Journal of The Engineers' Club of St. Louis*, May-June, 1919.

Digitized by Google

these located on the chart from aeroplane photographs with all the accuracy that is necessary for the navigator.

In making photographs from the water, for the purpose of discovering obstructions to navigation at low tide it will be necessary to have some means to properly locate photographic features on the chart. This probably can be done by anchoring two or three small boats within the area of the photograph and locating them with relation to triangulation stations. The location could be done in the usual way in which the sounding boat is today given its position, that is, by taking two sextant angles simultaneously from a boat to three control points. It can readily be seen that if two or three accurately located boats are clearly shown on the aeroplane photograph, it will be possible to place the topographic details on the map in their proper positions.

I do not wish to convey the idea that the aeroplane photography will supersede the usual methods of hydrographic surveying, but it would supplement those methods by making it possible to discover channels running through mud flats, also coral heads, shoals, and other obstructions which might be close to the surface of the water and which may be missed by the usual methods of conducting hydrographic surveying.

There has been a rather positive statement made above that the aeroplane can be used to advantage in the work of the Coast and Geodetic Survey. This is undoubtedly true but only time and the development of the methods can show just how much the aeroplane can be used by this Bureau.

. . . It is hoped that aeroplane surveying can be developed at least to supplement the usual surveyors' methods in mapping the interior on a comparatively large scale map with high accuracy.

It would appear that if the aeroplane photograph will be of so much assistance in the topographic work along the shores of the country that it would really be of some value in the interior.

Whether or not it is possible to make contours from aeroplane photographs is a question that has not yet been decided. Many persons who have studied the question claim that it is impossible to locate accurately contours from aeroplane photographs. Others claim that they can be located with great accuracy. The chances are that some mean position will be found to be the true one. It is possible that the stereoscopic method can be applied to two photographs taken by two cameras on the same airplane or by cameras on two different airplanes together to obtain a rough idea of the configuration of the country.

With regard to surveying the interior of the country for the purpose of making an accurate large scale, contoured map, I may say that here the aeroplane photographs can undoubtedly supplement the usual surveying methods, but can not entirely supplant them.

. . . . . .

It seems to be absolutely necessary in making the contoured survey to do the work with the present methods. One can readily understand that it would be impossible to show contours at intervals of 20 feet (that is, the difference between two contours will be that amount) over a wooded area, where trees in different parts of the forest varied in height. The area photographed will not show the difference of elevations of trees in a wood, for the low trees and bushes, not more than 20 feet in height, would show about the the same on a photograph as a primitive forest where the trees may be 70 to 100 feet high.

The contoured map must be of such accuracy as to enable the highway engineers, and engineers engaged on irrigation projects, to lay out their work accurately. It can be readily seen that with an accurately contoured map, the engineer could plan the railway, the highway, etc., from one place to another, and not make great mistakes in grades and alignment. It is believed that this would be impossible from contoured maps made from aero-photographs. It is possible that some method may be discovered by which the difference in elevation between two points shown on each of two separate photographs can be computed, but if one considers that the work involved, if it can be done at all, will be very great, he will see that it will probably be more economical to put the contours on the map by the usual methods, than to compute innumerable elevations from photographs.

The possible method of computing distances and elevations from photographs may be supplemented by using the stereoscopic method which would give one an idea of the configuration of the ground. This would enable the draftsman in the office to select critical points whose elevation could be determined. Such critical points would be crests of hills or ridges and the bottoms of slopes. If the elevations of critical points are determined then contours could be interpolated between them.

I am giving these statements with a good deal of reservation on my part, for the method of contouring by aeroplane photography has not been developed and it may be that very little can be accomplished where accurate contouring is desired.

But this accurate large-scale contoured map can undoubtedly be made by combining the usual methods of surveying with the aero-photographs. The aero-photograph will usually give a great deal of detail which may facilitate the progress of the map by the topographer using the plane table. It will be necessary of course for the topographer to select a number of definite points on his map, such as road crossings, large buildings, groups of buildings, bridges and other features which can be identified from photographs. Those features would serve as control points for the topographic details shown on the photographs. Without such points located by the

Digitized by Google

usual methods, it would be necessary to place certain conspicuous objects on the ground near the triangulation and traverse stations. Most any kind of object that would show in the photograph, and have a distinct shape, could be used. But the placing of these objects would be expensive. It is believed that the location of the conspicuous features referred to above could be done by the topographer at a much smaller cost than the cost of placing objects for the aero-photographs, at the triangulation and traverse stations.

It is possible that the topographer would be able to place the topographic details on his map from the photographs before going into the field to do the contouring. Much of the work of the topographer by the usual methods consists in placing the topographic features on the map in their proper locations, but a great deal of this might be obviated by the use of the photographs. Then he could go into the field and place the contours with greater rapidity than if he attempted to do so previous to using the details of the photographs.

. . . I feel confident in stating that even on the highest grade of topographic maps the aero-photographs can be used to a great degree in revising and bringing up to date maps of that character which have already been made. . . .

. . . In order to test such a map and learn whether it was up to date, it would be necessary, by the usual methods, to send a surveyor into the field to go over the area in great detail. Of course an inspection could be made of an area by driving over it, but many changes might be overlooked by this method of inspection.

How much simpler and more reliable it would be to send an airplane over the area in question and make a series of photographs. These photographs would show, at a glance, the exact areas where changes in the features had occurred, and if the changes were not too complicated it is possible that we would be able to place the new features on the map directly from the photographs. The process would be to fit in the new features between unchanged old features, which of course would also be shown on the photographs.

. . . . . .

I feel that the aeroplane can now furnish maps of a low order of accuracy, so far as scale and position of features are concerned, which will be of considerable value in many branches of industry and commerce. They will undoubtedly be extensively used in unmapped areas in this and other countries in the very near future, in these reconnaissance surveys and maps. But I hope they may be of great use in more accurate work.

Aeroplane Photography as an Adjunct to Military Mapping

By

Maj. J. H. Wheat

Engineers, U. S. A.; Topographic Engineer
U. S. Geological Survey

THERE is no doubt whatever of the great value of air photographs as an adjunct to map making in war. Accurate large scale maps were absolutely necessary for the type of fighting developed by the war with Germany. It was soon realized that the ordinary methods of surveying the battle area could not be carried out.

Special instruments were constructed and numerous methods were tried out to find means by which accurate maps of enemy works could be made from ground positions. All proved inadequate for the degree of accuracy required. Finally, the air photograph solved the problem so far as detail was concerned. The French *Plans Directeurs* furnished the base for control and the vertical photograph gave all the detail necessary for any map scale required.

The rectification or restitution of the photograph to eliminate the errors due to tilt of the photographic negative from the horizontal plane, during exposure proved to be somewhat of a problem. This problem developed three general methods for restitution: One, which was used by map makers of all the armies, is a graphical method. Four points are selected on the photographic print which are common to both photograph and map. These points are connected by straight lines forming a quadrilateral. By means of the intersection formed by the diagonals and with the apices of the triangles, this figure can be divided into as many small triangles as will be found necessary for the amount of detail desired. The same number of lines and figures must be drawn on both map and photograph. The features on the photograph are then transferred to the map by compilation.

An optical method by which the image of the pho-

Digitized by Google

tograph is reflected by means of a prism upon the base map was also used where small bits of detail were needed.

A third method involved the use of an enlarging and reducing camera equipped with special adjustments by means of which an oblique image from the negative of the tilted vertical photograph could be superimposed upon the base map or a tracing of control points. This oblique copy represents a correct image of the ground such as the original photograph would have done if the camera had been rigidly vertical at the time of exposure.

There is a tendency toward misconception of the value of air photographs in regard to maps. This impression is received through various articles published in popular magazines and newspapers. The mere pasting together of a number of photographs to form a "mosaic" does not make a map. The errors arising from tilt and relief must be considered, and then corrected by restitution and adjusted to proper control.

The air photograph needs control to fix its correct position on the planimetry. Therefore where no base maps are available, it will be necessary to do a certain amount of triangulation and from this primary control to establish a secondary control graphically, by means of the plane table, locating road junctions, church spires, bridges, etc., which may be easily identified on the photographs. The restitution of the photograph may then be accomplished.

There is a limitation of the air photograph, other than the one of control, which should be noted. An ordinary vertical photograph shows the width and direction of roads, lines of railways and course and width of streams, with the size and density of woods on their banks. It also shows the boundaries of swamp areas, the shore line of lakes and ponds and the demarcation of woodland borders. In the case of wooded areas, such details as the relative heights of trees, density of growth, glades within heavily wooded country and brush are easy to pick out, but when the relief of the terrain, in the sense of accurate elevation is needed, the vertical photograph fails.

It is true that shadows will show steep slopes; indicating hills or valleys and that sometimes the furrows of cultivated land will indicate the contour form (a hairpin-shaped road or the alignmnt of a railway will also indicate slopes), while elongated shadows cast by trees growing on hill slopes are also to be noted.

With the use of the stereoscope a fairly good "form" map may be shown, either by means of shading or hachures.

A combination with the plane table seems to be about the only way by which contour sketching can be carried on with vertical photographs. By means of the plane table, intersections of salient points and vertical angle elevations to the same, could be obtained and the details of form drawn in from the photograph. Major Brock, of the Canadian Survey, suggests a combination of the photo-topographic method with aerial photography or a combination of all three, plane table, photo-topography and aerial photography, depending upon the character of the varying topographic features encountered in area to be mapped.

This matter of the limitations of the vertical photograph in regard to relief applies of course only to ground forms. The plans of all objects on the ground are well shown and their shapes indicated by their shadows. It is also possible to note their dimensions by comparison with other objects of known size.

It is apparent that in making use of the air photograph for map construction, the personnel must be specially trained for rapid and accurate work. A thorough knowledge of interpretation and the methods of restitution is required. It is a waste of good material to distribute photographs to those who cannot read them and who generally look upon them merely as souvenirs. For accurate topographic mapping well trained and experienced topographic engineers are required.

The Army Surveying and Printing Battalion is the logical organization to take up all work pertaining to map making. During the war this organization furnished topographers, and the personnel for the restitution of aerial photographs to armies, corps and divisions. In the division the map making was confined to compilation of new work on existing French maps or those furnished by the Base Printing Plant. This was done by divisional G-2-C.[1] If exigencies should arise requiring new surveys a detail from the army topographic unit could be called upon to do the work.

It does not seem to be practicable to attempt the training of all Engineer troops in methods of accurate large scale map making. Too much time is required for such training and it would be to the detriment of other branches of military engineering for which their services are needed: furthermore a special technical education is necessary as a basis for training, and it will be difficult to get men with such qualifications.

The above suggestions are not intended, of course, to do away with ordinary map making such as all engineer troops should be able to do—road sketching, position sketching, traversing, etc. Every soldier should be able to read a map intelligently, and one way to become familiar with maps is to practice sketching them in the field. When considering future training for troops, special emphasis should be placed upon the subject of *map reading*. Experience in the Topographic Section of the Army Engineer Schools and the Army Intelligence School, A. E. F., proved the necessity of a more thorough training on this subject, which is a vitally important auxiliary to a soldier's education.

[1] G-2-C is the abbreviation for the Map Division of the Intelligence (2nd) Section of the General Staff.

Construction of Lock D, Cumberland River

By

Rufus W. Pafford

Junior Engineer

LOCK D is located 105 miles by river below Nashville, Tenn., and 87 miles above the mouth of the Cumberland River, and is one of six locks comprising the project for the improvement of that part of the river from Nashville to the mouth, called the "Lower Cumberland," by which a maximum stage of 6.5 feet is to be maintained throughout the year. Old Fort Donelson, which was captured from the Confederate Army by General Grant during the Civil War, is on a high hill immediately back of the lock.

Sand and gravel for making the concrete masonry were obtained from the river in the vicinity of the work by a suction dredge. The timber for building the storage bins for the sand and gravel was purchasd from a local sawmill and delivered on the job. Ties and poles suitable for trestles and rough lumber for temporary buildings were also obtained locally. Cement, coal, form lumber, machinery, supplies, etc., were either brought down from Nashville by boat to the site or by rail to Bear Spring, a point on the river about 7 miles above the lock, and either hauled through the country with teams or brought down the river from there in boats. The contractors built a switch from the tracks of the Tennessee and Cumberland River Railroad at Bear Spring to the river, a distance of about ½ mile. This switch was used for delivering cement, coal, lumber, and supplies to the river when boats could operate from this point to the lock, but on account of the difficulty of getting over the Dover shoals at low water, and because of the fact that the 1913 working season, when most of this work was done, was very dry, it became necessary to haul all supplies from Bear Spring, the terminus of the Tennessee and Cumberland River Railroad, a distance of about 6 miles.

Lack of funds prevented the award of one contract for the completion of this lock and dam, so it was decided to ask for bids for building the lock walls, upper and lower guide walls, guard wall, and for the removal of about 6,000 cubic yards of rock from the lower approach. The contract for accomplishing this work was signed February 25, 1913. This article will have to do with the part of the work covered by the first contract only.

The contract mentioned above was awarded to the Foster-Creighton-Gould Company, who immediately after signing the contract began to overhaul their old machinery and to purchase new equipment suitable for doing the work covered by this contract. A steamboat, two barges, a derrickboat, and a gasoline towboat were bought and three barges and a sand dredge were built by the company.

About the middle of March, 1913, the work of towing the plant, together with lumber and other supplies, from the company's headquarters at Nashville, was begun; the boat having landed at the lock site on March 20 on her first trip. The small gang of men which came at this time was employed for the first few weeks in clearing the site, building tool-houses, temporary quarters for the men, and a house for the inspectors which is to be used later for a dwelling for one of the men operating the lock. As soon as the river was low enough to be out of the way of the laying of tracks, construction of trestles and sand and gravel bins, and the erection of derricks and general plant construction, the work was started.

A study of the gage readings in the vicinity of the work for the 6 years just prior to the advertising for bids would indicate that the contractor could count on from 190 to 250 days per year during which the river would be below the top of the cofferdam, plans of which were exhibited with the rest of the plans for the lock when bids were being asked. The records kept on the work show that the river conditions since the contract was let have been just about what one might have expected or forecasted from the hydrographs of the river for the 6 or 7 years previous to that time.

The following is a list of the quantities of the work, as estimated by the engineers previous to advertising for bids, compared with the actual quantities of work performed by the contractors:

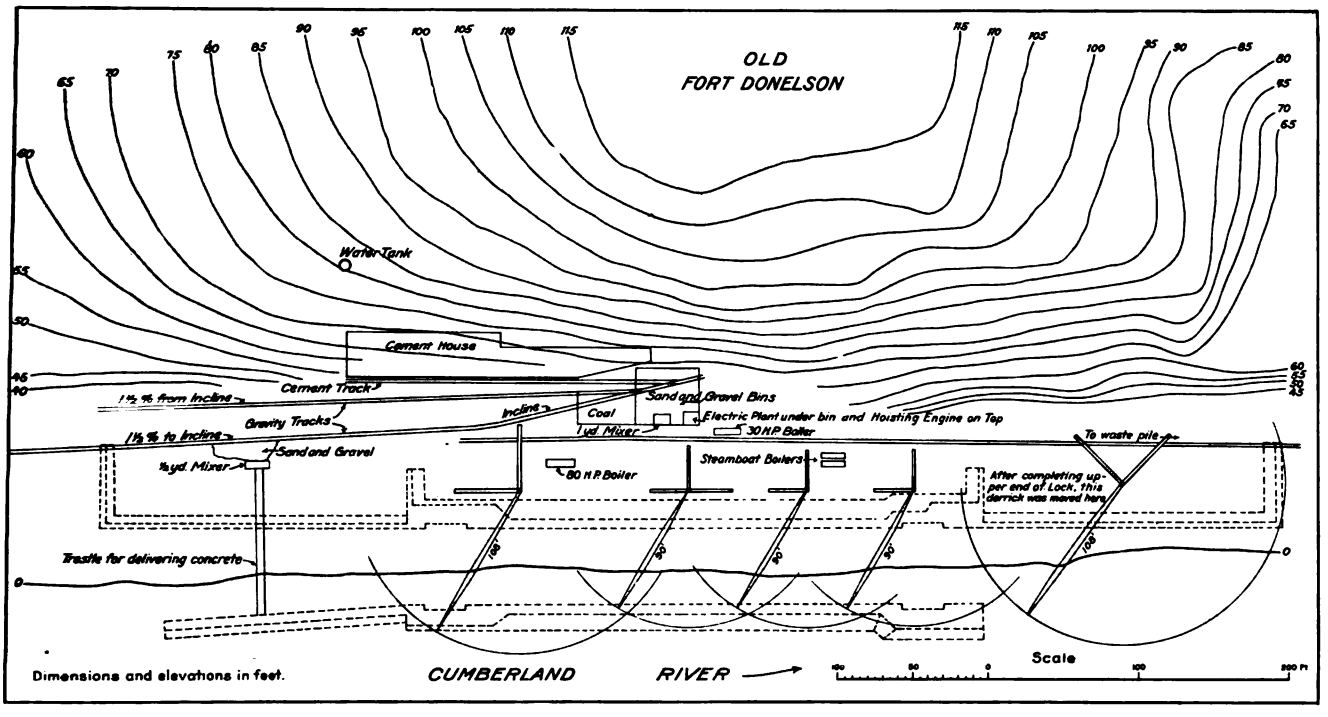
Digitized by Google

Classification.	Quantities as per office estimate	Actual quantities
Earth excavation .....cu. yd...	4,000	6,387
Rock excavation—		
Inside cofferdam.....cu. yd...	8,900	8,781
Outside cofferdam.....cu. yd...	6,900	6,980
Backfill .....cu. yd...	9,000	10,061
Concrete—		
In lock .....cu. yd...	13,100	13,312
In guard and guide walls.cu. yd.	4,500	4,353
Puddling .....cu. yd...	500	138
Cofferdam.....lin. ft...	650	654
Bolt holes.....lin. ft...	300	607
Handling and placing iron..ton..	62	73
Inspector's house.....No...	1	1

It can be seen, at a glance, that the office estimate was very near in most cases to the actual quantities. The extra amount of earth excavation was due principally to sediment in the cofferdam, payment for which was allowed as earth excavation. The differences in the figures on iron and steel, puddling, and bolt holes was due to slight changes in plan, which cause was possibly also responsible for the difference in the case of backfill.

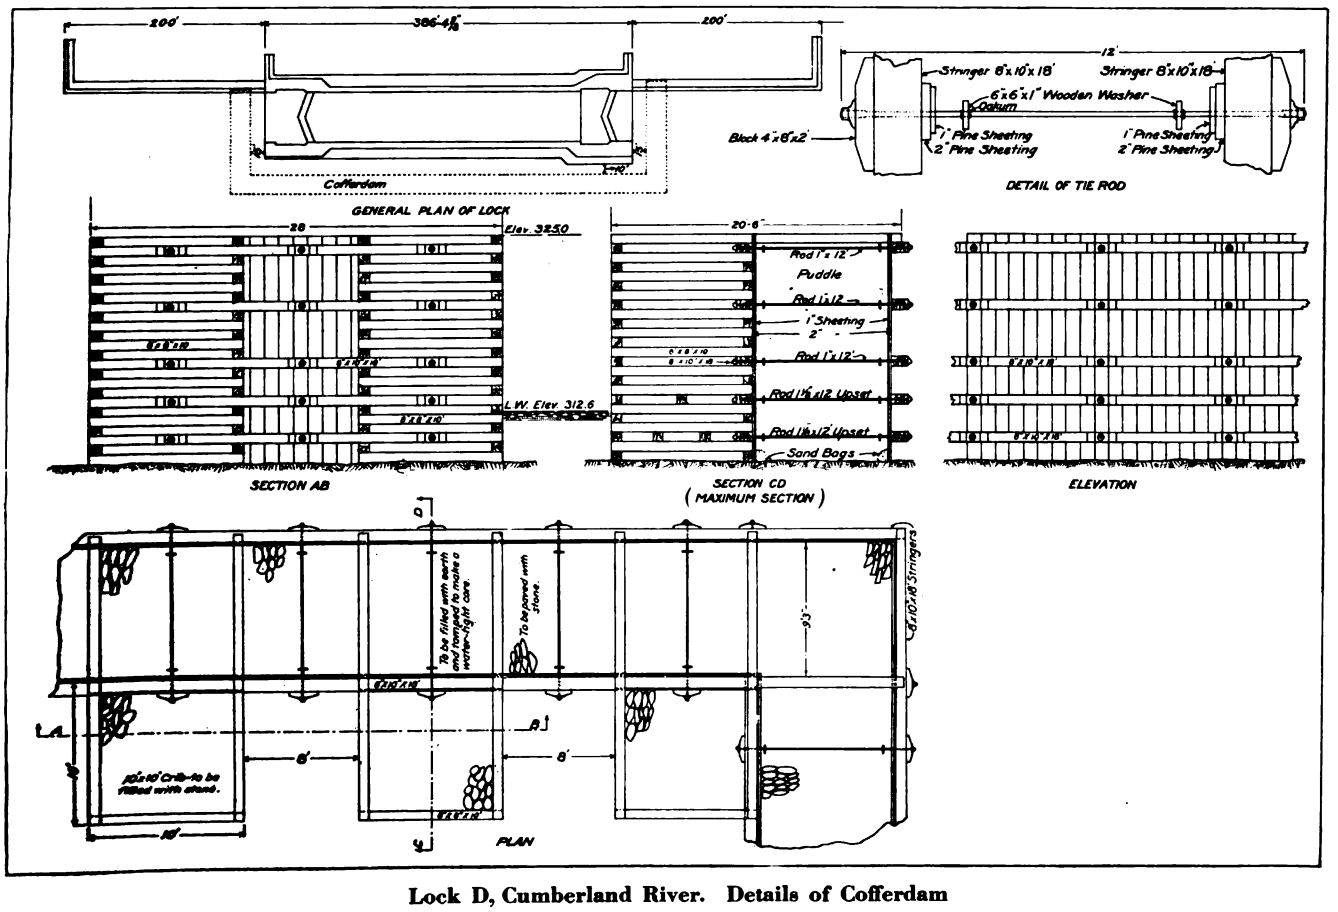
A very thorough examination was made of the foundations for the different parts of the work covered by this contract, borings being made on two different occasions under the supervision of two different men. All investigations showed the foundation to be rock of a very solid and dependable character, with no crevices or earth seams. After the excavation had been carried to the elevation which the plans called for in each foundation, test holes were put down several feet, and in no case was any condition encountered which was not considered most satisfactory.

The contractors' plant consisted of one steam towboat, one gasoline towboat, one sand dredge, two 80 by 20 foot barges, one 22 by 120 foot barge, one 18 by 65 foot barge, one 14 by 40 foot barge, one derrickboat, two 10-inch centrifugal pumps, two 6-inch centrifugal pumps, two steamboat boilers, three locomotive type boilers (one 40, one 50, and one 80 horsepower), one steel derrick with 60-foot mast and 108-ft. boom, 3 timber derricks with 30-ft. masts and 90-foot steel booms, one timber derrick with 30-foot mast and 60-foot boom (used for unloading material from barges), one timber derrick with 30-foot mast and 40-foot boom—each derrick being supplied with hoisting engine—one channeler with engine complete, one dynamo with engine complete, one 1-yard concrete mixer with engine complete, one ½-yard mixer with engine complete, two haulage engines, one duplex supply pump and 4,000-gallon water tank, one diving outfit complete, two 1-yard steel-bottom dump concrete buckets, three steam drills, and two air drills, besides a sufficient supply of home-made flat cars, side-dump cars and skips, and steel tilting-derrick buckets to handle the earth and rock.



The time specified in the contract for completing the work was 3 years. With the plant that was on the job, the contractors should have have had no difficulty in completing the work in 2 years. The delay in completing the work was due to the fact that the cofferdam around the lower approach excavation was insufficient. This is responsible for the unfinished condition of the excavation in the lower approach now, and was the cause of the lower guide wall not being built earlier.

The first contract work to be started was earth excavation for the land wall of the lock, which was begun early in May, 1913. This excavation was light, and as no derricks had been placed in commission yet, it was done with wheelbarrows. The waste material was wheeled up the bank and deposited back of its original position to be used later as backfill behind the wall. This was a slow and expensive operation, but was considered profitable, inasmuch as the material could be placed as backfill very cheaply when the wall was built. Some of this work was done with a skip and derrickboat by fastening a snatch block to a stump on the bank above where it was intended to deposit the material. The skip was brought back by a line from one drum of the hoisting engine on the derrickboat.



About two weeks after the earth excavation was started a beginning was made on the rock excavation for the land wall of the lock. Although the cofferdam had not been built, the stage of the river made this work possible. As no steam drills had been received on the job, this work was started with churn drills. The holes were loaded with small charges, so as not to scatter the stone so badly nor shatter it too finely. The excavated stone was piled along the edge of the water, where it could be reached conveniently later for use as filling in the stone compartments of the cofferdam.

While the river was too high to start actual construction of the cofferdam, the contractors' steamboat and barges were being used to take advantage of the favorable towing conditions and bring cofferdam timber down from Nashville. This timber was unloaded with flat cars on an incline on the top of the bank and stored about 300 feet up the river from where the upper end of the cofferdam was to be built. These cars were operated with the derrick-boat by putting down a "dead man" on top of the bank and fastening a snatch-block to it. This incline, though a temporary affair, was allowed to remain here and the timber was carried back down the bank where it was needed for use in the cofferdam over this track. In order to facilitate construction of the cofferdam when the stage of the river should become favorable, it was decided to frame the timber on the bank, so this work was started on May 10th. Actual construction of the cofferdam was started June 5th, when the first crib of the upper bank corner was placed and filled with

Lock D, Cumberland River. General Plan and Layout of Plant

Lock D, Cumberland River. Details of Cofferdam

Digitized by Google

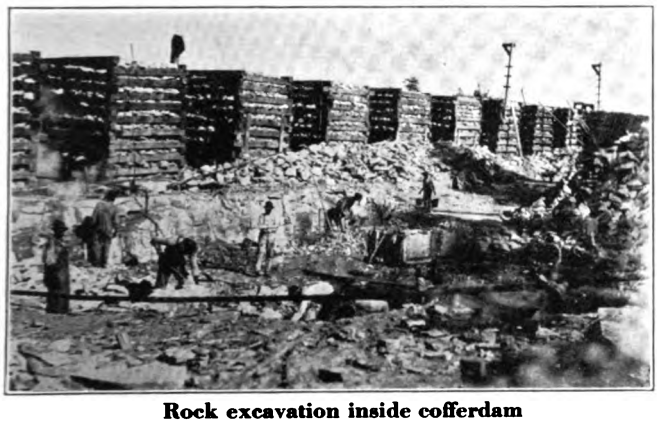
stone. However, in a day or two the river had risen until the surface of the water was higher than the proposed cofferdam, and the work of placing cribs was ncessarily suspended. After about one week, though, the river fell sufficiently, and this work was resumed and carried to completion without any further interruption caused by high water. Before placing any of the cribs a sufficient number of boats and barges were tied together and drawn up on the edge of the crib lines and the lines of sheathing to reach their entire length. The corners of the cribs that came on this line were located and accurate soundings taken; then the boats were moved to the next line and the crib corners located and sounded. When the cribs had been sounded, the points under the rods on the two lines of sheathing were sounded, as the sheathing on both lines that the rods pass through must be bored and put on the rods as the cribs are built and before the stringers are put on After these soundings were taken, a sketch of the bottom of each crib was made and the amount of blocking necessary to make the crib set level when it rested on the bottom of the river was determined.

The cribs were built on a gently sloping part of the bank just above the site of the lock and at the foot ot the incline that had been used to unload the cofferdam timber, which made the work of transferring the material to the proper place a very cheap and fairly rapid operation. Several of these cribs were built together, the connections being made while that part of the crib was above water. As timber was added, forcing the cribs on the bottom, they would be pushed farther out into the river where the water was deeper. When they were as high as it was thought they could be floated into place without any of them hanging on the bottom, they would be checked down the river to their positions next to the ones that had previously been set, lined with an instrumnt, weighted down with heavy stone until they rested on the bottom, the remainder of the timbers required to bring the cribs to the proper elevations drifted on, the tops leveled by dapping out, and this section connected to the one previously set. The principal reason for building several cribs in one section before they were set was in order that the connections between cribs could be made above water as much as possible. When this had to be done under water, it proved to be a difficult proposition and one that only a diver could handle satisfactorily.

The cribs were filled with the stone excavated from the foundation of the land wall of the lock referred to above. As a considerable amount of this had been piled along the edge of the water for the entire length of the cofferdam, it was an easy matter to deposit the stone in the cribs by the use of the derrick-boat and a tilting bucket of 1-yard capacity, since the stone pile was at no point farther than 70 feet from the cribs. Wheelbarrows were used in filling the cribs across the lower end of the cofferdam, as the derrick-boat had to be removed from the cofferdam before the closure was made. After the stone filling in the cribs was above the surface of the water, an effort was made to have it as compact as possible by using two men in the cribs to place the stone by hand as it was dumped from the bucket.

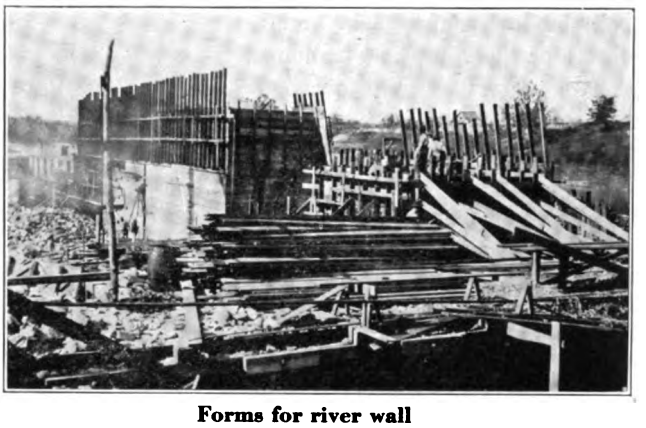
Great care was exercised in putting the sheathing on the puddle compartment. Where the depth of water would permit, the carpenters would examine the bottom, which was practically all rock, with their bare feet, and if this was not possible, careful soundings were made on both sides of the plank which was about to be placed, so that the proper slope of the bottom could be determined, and just prior to nailing the plank was sharpened and struck several blows on the end with a large hammer, in order to broom the bottom and thereby secure a closer joint between the sheathing and the rock bottom. Another precaution taken to seal this joint was to place a continuous line of cement bags about half-filled with sand along each side of the puddle compartment on the bottom before placing the clay puddle. Practically all of the bags of sand were placed by a diver, who worked as a carpenter when he was not in the diving suit.

After digging test holes in a number of different places, it was found that clay suitable for making the puddle for the cofferdam could be gotten from the river bank only a short distance from the government reservation on the up-river side, provided a small amount of the top soil be stripped.



A string of pile bents about 100 feet long was driven in the river near the proposed clay pit with the top of the caps well below the floor of the clay pit and wide enough to allow a barge to float in under the bents and between the piles. Two 36-inch gage tracks were laid from the clay pit out to these bents. As previously stated, these tracks sloped to the river. Two home-made side-dump 1-yard cars were operated on these tracks, and by fastening one end of a line of the proper length to each car and passing the bight of it through a snatch-block fastened to a "dead man" at the back of the clay pit, the loaded car going to the trestle would pull the empty car back into the pit. By dumping these cars from both tracks, the barges could be loaded without doing any shovel work at all. The clay in the pit was loosened by shooting with black powder and was loaded into the cars with shovels. As soon as a barge was loaded, it was towed by the contractor's boat to the cofferdam to be unloaded, and an empty barge put in its place, so that the operation was continuous. For a portion of the time that this puddle work was going on, three 8-hour shifts were employed. At first these barges were unloaded with shovels, but this method was soon abandoned and the derrick-boat with ½-yard clam-shell bucket was used. The clam-shell was operated with a two-drum hoist by working the derrick with a fixed boom and moving the

Digitized by Google



boat instead of the boom. A supply pump was kept running all the time when clay was being unloaded, and a continuous stream of water played on the dry clay. In addition to this, men were kept puddling the clay with their feet while it was being placed.

After the puddle had been allowed a few days in which to dry out and stiffen up, it was covered with riprap ranging in thickness from 12 to 18 inches, consisting mainly of 1-man stone set on edge with some spalls and smaller stone to fill the voids.

The cofferdam was finished July 31 and pumped out on that same day without any trouble whatever. No leaks of any consequence developed, and the work of unwatering covered only a few hours. It is the opinion of the writer that 30 minutes per week of actual running for a 10-inch centrifugal pump would have taken care of the leakage from the day it was first pumped, July 31, until the following February, when it was flooded for the first time. Even after the river had risen almost to the top of the cofferdam, no leaks developed, and work could have been carried on inside the cofferdam until water actually began to flow over the top.

Rock excavation inside cofferdam

Forms for river wall

While the conditions here were very favorable for building a good cofferdam, on account of the rock foundation, and especially since the rock was not covered with gravel or earth, yet it is thought the design is very good; and, furthermore, the contractors exercised considerable care in the construction of the cofferdam and appeared anxious to obtain the very best results possible.

Immediately after completing the cofferdam and pumping out the water, a large force of men was put to work excavating the approximately 9,000 cubic yards of rock inside the inclosure. Four stiff-leg derricks had been erected on a line parallel to the axis of the lock and 25 feet back of the face of the land wall, and so spaced that with 90-foot booms on three of them and a 108-foot boom on the other, all of the excavation could be reached by them, as well as the 36-inch gauge track behind the line of derricks and parallel thereto. This track extended for the entire length of the cofferdam and also for several hundred feet down the river where the waste from this excavation was piled. Cars used on this track for disposing of this material were built on the job and had detachable bodies, which served as skips and were used in connection with the derricks for hoisting the rock from the cofferdam. A train of four of these cars was operated by means of rope haulage, which was driven by a 6¼ by 10 inch reversible haulage engine from the derricks to the dump, where they were unloaded in the same manner as an ordinary side-dump car.

It is believed that a dinkey could have handled this waste from rock excavation much more economically than did the haulage engine. In the case of the haulage engine, the track must be straight, the long and expensive line must be bought, maintained, and installed, and after the material piles up to the track it must be shoveled or moved from the track by hand, causing a heavy expense; whereas, the dinkey track could be made as crooked as necessary and could be kept on the edge of the dump where the cars could be unloaded easily and without rehandling any of the material.

It is thought that some time was lost in breaking the stone unnecessarily fine, a large per cent of it being handled with shovels both into the skips and away from the track at the dump. Another practice which is thought lost the contractors money on this excavation was the congesting of the men instead of scattering them so that each man would have ample room to work. Three of the four derricks which handled this excavation were equipped with home-made swinging appliances, which required one or two extra men to operate. These same derricks were used to place the concrete with the same extra force. The money paid these men would have gone far toward equipping these derricks with steam swinging appliances.

Another feature of this rock excavation which gave considerable trouble was channeling. The specifications required that the vertical surface on the land side of the rock cut from the upper end of the lock to

Digitized by Google

the lower end of the lower guide wall should be made with a channeler. The stone was very hard and had pockets of flint in it which increased the difficulties of the channeling. When one of these pockets was encountered, the bits would slide to one side of it and make a crooked cut. After the channel had been cut a few feet deep, it was so crooked that it became practically impossible to operate the machine until the stone in front was shot out of the way as far down as it had been channeled, and then the machine was started again. Progress on this part of the work was slow, an average of thirteen and a fraction square feet being cut per eight-hour shift; besides the results were unsatisfactory. With this hard flinty limestone, it is impossible to get even fairly good alignment, and, besides, a large amount of work must be done in bringing the top of the rock to a line on the showing edge, as it breaks off unevenly where the channeler is started. In the case of the lower guide wall, the contractor asked to be allowed to remove the rock for two feet back of the face of the wall and down to the grade of the lower approach, and replace same with concrete at their expense in lieu of the channeling. The change in plan was approved by Major H. Burgess, Corps of Engineers, the officer in charge, and it is the opinion of the writer that all parties concerned profited thereby. The contractors saved money and did the work much more quickly, and the job is just as good and much neater in appearance.

However, as a whole, rock excavation progressed very satisfactorily during the month of August; in fact, nothing else of much consequence was being attempted at this time, and a large force of men was employed. At one time during this month the force ran up to 240, which was the largest number employed on the work at any one time. At the time when the force was largest, two shifts were being worked on rock excavation. In addition to the stone that was taken out, a large amount was piled along the center line of the lock pit, to be used later as plums in the concrete for the walls. These plum stones were to be handled into the forms with the same derricks as were used to place the concrete. This operation was carried on successfully and profitably from the contractors' viewpoint, as the stone was quarried in the pit and could be placed in the concrete practically, if not quite, as cheaply as it could be disposed of in the usual manner. When the rock excavation had progressed to the point where it was thought advisable to do so, the work of placing concrete was started. A large part of the force was changed to form building and mixing and placing concrete, which naturally caused the rock work to progress much more slowly during the remainder of the year. However, it was carried on when river conditions were favorable until the part inside the cofferdam was completed.

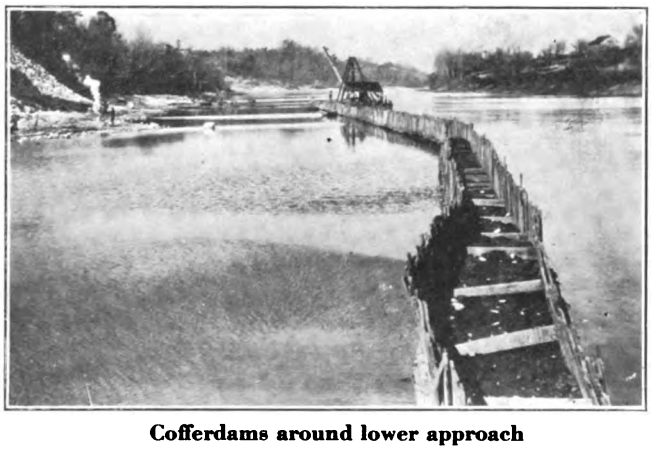
The rock excavation for the upper guide wall, guard wall, and upper approach was handled differently. No derricks were used for handling this waste material. The foundations for the upper guide wall and the upper approach were high and could be prepared without cofferdams. This material was wheeled toward the river and dumped so as to keep the waste pile as much as one foot below the upper miter sill. While the foundation for the guard wall was considerably lower than these other two just mentioned, no provisions were made in the specifications for a cofferdam. Work on this wall was not started until the river had gotten very low and only a small coffer was necessary. The one built was of 8-foot tie lumber, with 4 by 4 inch wales, and the two sides were held together with wire, forming a puddle space of about 4 feet. Practically no excavation was necessary here, as the rock was found to be clean and solid when the water was pumped from the cofferdam, and no definite grade was required for the foundation.

The lower approach has proven the most troublesome and most productive of delay of any part of the excavation. Here also the specifications did not provide for any cofferdam, but allowed the contractors to build whatever in their judgment the case demanded in the way of a cofferdam. The season of 1913, when this cofferdam was built, was a very dry one, and the river was exceptionally low, which is thought to be largely responsible for the light cofferdam that was built and for the fact that this work, as well as the entire contract, was not completed at least two years ago. This cofferdam was constructed of two thicknesses of 1 inch by 8 foot oak lumber, nailed to two lines of 4 by 4-inch wales. The two sides of the 4-foot puddle compartment were held together with wire. This dam was probably adequate for the stage of water when it was built, and had this excavation work been pushed to completion that season, it is possible that it might have served its purpose very well; but it was allowed to drag while an extra effort was being made to get the concrete work on the lock walls above an ordinary winter stage so that it could be carried on during the winter, and it proved to be a very expensive mistake, as no such season as 1913 has been had since that time, and this work yet remains to be completed. Several efforts have been made since that season to complete this part of the contract, but always the river rises and floods the cofferdam before it is finished. The foundation for the lower guide wall is included within this coffer. Excavation for this wall was done in the latter part of the season of 1914. Excavation for the entire lower guide wall foundation was handled to the haulage track with the steel derrick having the 108-foot boom, which had been set opposite the middle of the wall and between it and the haulage track. This derrick, which is one of the four from the line back of the lock wall, has also handled a large part of the earth and rock that

Digitized by Google

have been excavated from the lower approach and wasted from the haulage track. However, some of it has been hauled with wagons and deposited several hundred feet below the property of the United States, and a small amount of the rock excavation has been loaded on barges with a derrick-boat, towed to deep water and unloaded.

The forms used for the concrete work consisted of 1⅝-inch pine sheathing, dressed on four sides; 2 by 8-inch studs, dressed on two sides, and spaced 30 inches center to center; 4 by 8-inch wales, rough, spaced 48 inches center to center vertically, with 8-inch dimension horizontally; and ⅝-inch tie rods, spaced 60 inches horizontally, and placed in the forms diagonally, having a sleeve nut at each side of the forms and at least 2 inches inside of the wall, for the purpose of removing the part of the rod that is outside of the concrete work. This can very easily be done by breaking the bond on this 2 inches of concrete and screwing the rod out of the sleeve nut. These rods not only held the forms together, but, by using horizontal struts in connection with them, it was possible to get very good alignment of the forms. For lock walls, guard wall, and upper guide wall, the sheathing was put on continuously, and the forms torn down and rebuilt after they had been filled and the concrete had been given time to set properly. In the case of the lower guide wall, it was necessary for the water to be low on account of the low and insufficient coffer which inclosed this wall along with the lower approach. Owing to the fact that it was necessary to build the forms very rapidly when a suitable stage of the river should be reached, the contractors requested permission to use panel forms and were allowed to do so. Accordingly, during the summer of 1914, while the water was too high to start the foundation work for the wall, quite a number of panels 10 by 15 feet were made, and in November of that year, when the river did get low enough, the contractors were enabled to place all the foundation for this wall and to then proceed with the work even if the river was high. The same system of rodding and strutting was used with the panels as had been used with the other style of forms. The plan of building continuous forms and tearing them down and rebuilding with the system of bracing and rodding used on this work gives splendid results. The sheathing was used an average of about three times. Good results were obtained with the panels also, but they were not used so extensively, and it is difficult to compare the two methods of forming. However, where a derrick is convenient for handling the panels, the writer is inclined to think that they would be preferable in point of speed and economy, but is not so sure about the results.



Forms for lower guide walls

Concrete for the lock walls and the lower guide wall was mixed in a 1-yard Ransome mixer, which was arranged under the sand and gravel bin and near enough to the cement house, so that these materials could be placed into it by gravity, and it was also in such a position relative to the 36-inch track back of the line of derricks, referred to above, that the concrete could be deposited directly from the mixer into buckets set on flat cars on this track. After the bucket was filled with concrete the car was moved until it was in reach of the derrick being used; then the bucket was raised and brought over the forms, lowered to the proper elevation and dumped. The flat cars used for this purpose were large enough to accommodate two buckets, and while one was being dumped the other was carried back to the mixer on the car and was filled with another batch of concrete. Two of the derricks were so near to the mixer that the car could be dispensed with and the buckets handled directly from the mixer into the forms. The buckets used were of the Insley bottom-dump type, of 1-yard capacity. It is thus seen that the same derricks and

Digitized by Google

haulage outfit that disposed of the rock excavation from the cofferdam delivered and placed the concrete in the lock walls and lower guide wall. Concrete for the upper guide wall and the guard wall was mixed in a ½-yard cube mixer and delivered to the forms in Ransome 2-wheel concrete carts drawn by men.

The concrete was a 1 : 3 : 5 mixture, made from river sand and gravel and Speed Portland cement. The sand and gravel were dug from the bed of the river near the lock site with a 10-inch suction dredge. The dredge was built for this job and was provided with means of screening and washing the material, so that it could go directly from the dredge to the storage bins ready for use in concrete. The chutes from the screens on the dredge were so arranged that sand could be loaded into a barge on one side of it and gravel into another on the other side. These barges, loaded with sand and gravel, were towed to the job by the contractors' boats. Considerable difficulty was experienced in getting coarse aggregate of the proper size, as most of the bars in this locality furnished a material too small to meet the requirements of the specifications, which called for a coarse aggregate that would pass through a screen having 2½-inch holes, and be retained on one having ¼-inch holes. However, by adding an extra screen and wasting some of the small or pea gravel, a very good quality of coarse aggregate was obtained.

Cofferdams around lower approach

The walls were built in blocks of about 30 feet in length, the full width of the wall, and at least 5 feet in height; the first run being made in block No. 3 of the river wall of the lock on September 9, 1913. In accordance with the specifications, alternate blocks were built, leaving the omitted block to be built in later without end forms. This plan required that more form lumber be tied up on account of forming for the wall continuously and allowing the omitted block to get behind; however, by having the work scattered in this way over different parts of the job, it enabled the carpenters to keep forms built so that the concrete gang could work continuously. Only about 5 suitable working days were lost from the time the concrete work started, September 9, until February 3, when the cofferdam was flooded for the first time. The largest number of batches of concrete placed during any one eight-hour day was 120. Better progress was made for shorter periods of time, but more than that amount was never placed in eight hours. The trouble seemed to be in getting the concrete gang to work eight hours at a hitch. This was seldom done for various reasons, such as frozen steam and water pipes in the morning, lack of steam during the day, mixer breakdowns, failure to clean out forms, etc.

For a job similar to this, where the specifications allowed the use of chutes, it is the opinion of the writer that it would be a better plan for handling the concrete. It is thought, at least, that they offer fewer chances for delay to the work.

While the daily output was not so great, yet, as has been stated, the mixer ran practically every day for several months; in fact, both mixers ran almost every day for some time, and very good progress was made, the best month being October, 1913, when 2,600 cubic yards of concrete were placed. The plan of placing some concrete every day is favored, in preference to making one or two big runs each week, and not placing any the rest of the time. The upper guide wall was finished during the fall of 1913, and the guard wall was practically so, but the lock was not completed until August of 1914; and the concrete work on the lower guide wall was not started until November of that same year, on account of the necessity for low water to get to the foundation. This wall was finished in April, 1915, which completed the concrete work for this contract.

The valves used for emptying and filling this lock chamber are called cylindrical valves, from their shape. This valve consists of a cylindrical ring 5 ft. in diameter and about 18 in. high, sliding up and down in a second ring above the latter having a closed and water-tight cover. The seat is set before the concrete forming the floor of the valve chamber is placed, and this concrete is finished level with the top of the seat so that when the valve is closed it rests on this ring or valve seat and cuts off the water. The valve is opened by pulling the ring up into the covered second ring by means of machinery on the lock wall. The joint between these two rings is made water-tight by a leather packing-ring.

Four of these valves are used to fill the pit and four to empty it. The ones used for filling are located opposite the gate recesses at the upper end of the walls, and each one has a separate culvert leading under the

Engineer Duties in the Field in War

By

Col. R. R. Ralston

Engineers, U. S. A., Corps Engineer, 4th Corps, A. E. F.

IN 1912 the Board on Engineer Troops was directed by the Chief of Engineers to make a comprehensive study of the proper organization, equipment, and training of engineer troops for the United States Army, and to submit their recommendations thereon, basing the latter on the needs of the engineer service in case of war with a first-class power. The board completed this work in 1913, and its recommendations on these and other related matters were approved by the general staff with minor modifications on being submitted to that body as representing the views of the Chief of Engineers. The engineer regimental and mounted battalion organizations authorized by the National Defense Act of June 3, 1916, were as recommended by the board, and the board's recommendations as to the duties of engineers in war resulted in C. A. R. No. 46, which placed on them duties of general construction and railway construction and operation in the theatre of war which hitherto had not been definitely assigned to any branch of the service.

The board's recommendations formed the basis of the policy of the Corps of Engineers relative to military preparedness for the mobile army prior to the war with Germany; but, as was to be expected in a pre-war study of this kind, it was deficient in a number of features, due to an inadequate conception of the magnitude of engineer operations incident to modern warfare; and further to the fact that it was based on a defensive war in the United States, as the carrying of an offensive war to European soil was considered at that time to be beyond the bounds of probability. The great engineering undertakings incident to the service of supply in the American Expeditionary Forces, it was assumed, would, in a theatre of operations in the United States, be carried out largely by civil means, and the organization of special military units for this purpose would not be necessary. The recommendations of the board relative to engineer troops were accordingly limited to divisional engineer troops, except that a tentative organization was recommended for engineer railway troops for the operation of railroads under military control.

Division Engineers

It is generally conceded by engineer officers that our regimental organization during the late war was satisfactory, and it has been favorably commented on by engineer officers of foreign services. The only part of the divisional engineer organization that did not function exactly as contemplated was the engineer train, and it is believed that results would be more satisfactory if it were made part of the regiment, forming a supply company as part of regimental headquarters. With this arrangement, engineer supply of the division and general supply of the engineer regiment will be better co-ordinated.

The strength of divisional engineers recommended by the board in 1913 for an infantry division was 6 per cent of infantry strength; but with the divisional reorganization during the emergency it was nearly double this figure, or about 6 per cent of the strength of the whole division. Experience does not indicate that the number of divisional engineers was excessive, and should the divisional organization authorized by the national defense act be substantially retained, the addition of a third battalion of three companies to the engineer regiment would seem to be justified.

Duties

The pre-war conception as to the duties of divisional engineers in the field was very well substantiated by the experience of the late war, with one or two exceptions, one of which was the duty of map-making and reproduction. This work in Europe, where the topography is so well recorded already, consisted in the addition of cultural changes and the reproduction of new issues of maps on so large a scale as to require for the latter work a special organization of engineers.

Aeroplane photography secured much of the data required for the preparation of the new maps, and, in my opinion, in future military operations, even in poorly mapped countries, the basic means of securing information for the production of maps will be this agency; the maps themselves being produced by a central plant well in rear. There is, of course, much information requisite to a good military map that can not be secured by aeroplane photography, and resort to the usual former topographical methods will be necessary. Furthermore, much topographical work will be required where the usual methods will be obligatory, and for these reasons topographical work will still be a duty of divisional engineers and one for which they must be prepared by having a suitably trained personnel and adequate equipment. I do not believe, however, that map reproduction within di-

Digitized by Google

visions will be of sufficient extent or importance to warrant the training of any personnel of the division engineers in lithography, or to justify the retention of the rather cumbersome lithographic equipment.

The war as conducted in Europe did not demonstrate that searchlights can be used to advantage in field operations; but that their use was practically confined to anti-aircraft defense of important centers. It would accordingly seem that for future military operations no provision need be made for the use of searchlights by divisional engineers, or engineers of higher units. In fact, it may be argued that the operation of searchlights is a function of the artillery assigned to anti-aircraft defense, rather than a function of engineers, as the status is similar to the use of searchlights in coast defense by the coast artillery.

On the other hand, the need of electric lighting plants for division headquarters and such other localities where they are necessary, the use of electrified obstacles, and the supervision of power plants and lines in territory under military control, as demonstrated by the war, requires that the divisional engineers possess an adequate personnel with a practical knowledge of electricity.

Field fortification was an important duty of divisional engineers during the war and will continue to be such. While it was contemplated that infantry should be capable of constructing their defensive works, the general experience of the war seems to have been that the engineers, in co-operation with infantry and machine-gun officers, should lay out the defensive works and initiate and push forward the construction of the remaining works. Divisional engineers must, accordingly, be prepared to lay out defensive works and to initiate and push forward to completion the most important elements of such works. After the main features have been established, elaboration of the works and their maintenance may be placed in the hands of the infantry, with enough engineer supervision to insure continuity, and the work of the engineers transferred to the construction of the remaining elements of the defenses, for the construction of which they are better qualified than the infantry.

Affiliated with field fortification is the subject of camouflage. This is an activity which should be included in the training of all combat arms, but it should be specially thorough in the case of engineers, in order that they may be prepared to insure effective work by other arms. During the war detachments were assigned to sectors of the front from the engineer camouflage regiment, who made inspections and recommendations in order to improve the camouflage work of corps and divisional troops, and in some cases directed the same. This system worked satisfactorily, but it is believed that it would be preferable in future operations to have those who are responsible for effective camouflage work by division or corps troops members of the division or corps; and it is believed that this will be the duty of divisional and corps engineers. One officer in each divisional or corps engineer regiment with a small number of selected enlisted men should be designated to look after this work exclusively.

Road and bridge work will constitute one of the most important and extensive duties of divisional engineers in military operations. In a rapid advance to a limited objective such work as a rule need only be sufficient to insure the passage of foot troops over streams and the lighter transport over the roads; but with the stabilization of lines it will be necessary to provide means for the movement of the heavy artillery and supply trains without interruption. In the various offensives undertaken by the United States Army in France, work of road repair and construction was often greatly hampered by inadequate traffic control on the roads on which work was under way. It has been suggested, in order to obviate this difficulty, that engineers in charge of road repair be given authority to regulate traffic over such roads, so that in an advance they would act as military police for traffic control purposes in front of a fixed line, turning such roads over to the military police as soon as repairs are completed. Paragraph 103, Field Service Regulations, gives the engineers such authority in the case of military bridges, and it is believed that the same authority over roads under repair would be desirable.

Our ponton equipage needs revision to adapt it to the heavier loads which will be met with in future military operations, and also to provide for the use of tractor draft; but the present equipage can still be used to advantage in military operations, and should be retained until worn out. I do not believe that any more equipage of the present type should be built, however, provided a new equipage can be made available in a reasonably short time.

In the training of engineer troops in the future more time should be devoted to the construction of heavy fixed bridges, standard types of which should be adopted. Spar bridges, which have been so assiduously practiced in the past, should not be entirely eliminated from the training of our divisional engineers, as they can still serve valuable purposes under many conditions; but the limitations as to their use should be clearly defined.

In connection with road work, the experience in Europe, not only during offensive operations, but also on the march into Germany and in occupied territory, made it apparent that divisional engineers should be provided with one or more caterpillar tractors for the purpose of removing ditched trucks that are obstructing roads, and to assist trucks up steep slippery hills when necessary.

Demolitions and the handling of high explosive, in wire cutting, removal of enemy traps and mines, and the destruction of "duds" was a duty that gen-

Digitized by Google

erally fell to the engineers during the war, and is one for which they must continue to be equipped and trained.

General construction duties devolved upon divisional engineers to a large extent in the A. E. F. in training and rest areas, and also in certain sectors of the front. In the army of occupation a great deal of general construction work, consisting of mess halls and kitchens, amusement halls, baths, delousers, stables, horse-dipping vats, corrals, etc., was carried on, as well as a great variety of smaller jobs that came up from time to time. The character of this type of construction indicates the need in an engineer unit of carpenters, blacksmiths, plumbers, concrete men, electricians, and allied trades, as well as a good proportion of "handy men."

In the army of occupation it became necessary for divisional engineers to take over to a greater or less extent work of road repair and maintenance, including direction and payment of German civilians engaged on this work. Direction was usually through the regular German road officials, with additional supervision by engineers, and means of transportation for road materials was furnished by the engineers, as the Germans were practically without transportation.

Supervision over public utilities, such as gas, electric light, and water supply systems, also became necessary, owing to the increased load put upon these utilities by reason of the army of occupation. Supervisors of public utilities in each town where they existed and where troops were stationed were appointed from the engineers, and any extensions of service handled through them, so as to prevent any overloading of plant.

Infantry Duties

Our Field Service Regulations, par. 126, indicate that engineers are to be used in the attacking line only in exceptional cases, and this is generally understood by division commanders. The engineers were used both in attack and defense during the war in a number of cases, and it is my opinion that they will be so used frequently in future military operations, and for this reason their infantry training should be of a high order. It is also believed that they should be armed with the automatic rifle in the same proportion as the infantry, so that they can make use of the same tactical dispositions. Any tendency to sacrifice thorough infantry training to engineer training should be suppressed; for with competent engineer officers, engineer work in the field can be carried on with a disciplined and soldierly organization, even though it is somewhat lacking in engineer training. In time of peace in our regular army time is available to give the enlisted men both military and engineer training; but at outbreak of war, when a large number of new troops must be raised, as in the case of our national army, I believe it preferable to devote the larger part of the available time to making the men trained and disciplined soldiers. Men entering the regular army in peace times usually require engineer training to make them fit for engineer work, but the material available in the national army required much less instruction to carry on engineer work in the field.

On the whole, I believe that our methods of training in time of peace, and the qualifications which are considered necessary for the personnel of a divisional engineer unit, as we conceived them prior to the war, are both sound and leave little to be desired.

Corps Engineers

The corps as organized in the A. E. F. corresponds to the field army of our Field Service Regulations. By tables of organization, it consisted of six divisions, four of which were combat divisions, and certain auxiliary or corps troops, whose aggregate strength was nearly that of a division. Included in the corps troops was a regiment of engineers, and also a regiment of pioneer infantry, from which additional details for engineer work could be secured, if necessary. The corps, particularly in position warfare, constituted what was practically a permanent sector personnel, which remained in position as divisions came and went, and was thus intended to insure continuity of policy in the corps sector.

The corps engineer troops usually consisted of a sapper regiment and train, which had been the engineer troops of a replacement division and had been transferred intact to duty as corps troops. Special engineer regiments, for duty as corps engineer troops, had been organized in the United States, but, except in one or two cases, they were not used as such, being diverted to other duty. The corps troops as a whole were at a disadvantage, in not possessing the same unity of organization as a division, due to the fact that they were gathered together from a number of different sources and had never served together until assigned to duty as corps troops, and then were scattered over so large an area that it was not practicable to secure the same cohesion as in a division. This lack of unity was shown by the fact that some of the units of the corps troops were not aware of the functions of the corps engineer troops, and were uncertain as to the proper means of arranging for the execution of their engineer work or for the procurement of engineer supplies.

The 4th Corps engineer troops—301st Regiment and Train—joined the 4th Corps on the day preceding the St. Mihiel offensive, and during that operation were engaged on the reconstruction of the Flirey-Essey road over the old trench systems north of Flirey. They continued on road repair work in the corps sector for about a month after the offensive, when the work of road repair on which they were being used was practically all taken over by the 2nd Army engineer troops. In this work they were assist-

Digitized by Google

ed at first by one and, later, by two battalions of the corps pioneer infantry regiment, and these troops continued on road work practically till the armistice. During this period the corps engineers also constructed two corps ammunition dumps and did some work on a third for the corps munitions officer. The two dumps completed were located in woods, and each involved a loop of one-way plank road several hundred feet in length, providing an entrance and an exit on a main road and a roadway suitable for ammunition trucks. These dumps were also provided with powder and fuze houses, and the approaches were camouflaged where required. Light railway connections were extended to them by the light railway engineer regiment.

As soon as it could be relieved from road work, the corps engineer regiment took up the work of preparing the second defensive position, which had been approximately fixed by army and corps orders; and the preparation of which in the corps sector had been assigned to the corps engineer. The work of wiring this position from the left of the corps sector to a point where it connected with an old French position near the right of the sector, was practically completed at the time of the armistice.

After the beginning of the Meuse-Argonne offensive the combat divisions in the 4th Corps were changed quite rapidly; in fact, one division took over a sector of the front line and was withdrawn in a week. This made progress on the consolidation of the first position slow and unsatisfactory, as there was hardly time for a division to get oriented before it was withdrawn, let alone doing any effective work on the consolidation of the first line. Some changes in the first lines had been ordered since they were first established, but in a number of places where no change had taken place the wiring was incomplete and progress of consolidation was quite unsatisfactory. Under these conditions it seemed necessary to place a part of the corps engineers on first position consolidation work, and the regiment was disposed with this end in view; but as the divisions then occupying the front line were not moved, actual work did not become necessary

In the offensive of the 2nd Army, ordered for November 10, 1918, it was planned to establish a one-way motor truck circulation route for the use of ammunition and supply trains, with an "out" and an "in" route over the trench systems, and several cross connecting routes in rear of the German lines, to be used in succession as the advance progressed. The preparation of this route within our own lines had been undertaken as far to the front as possible as soon as it was decided on, and the corps engineer regiment, assisted by 2 battalions of the pioneer infantry regiment was designated to prepare it for truck traffic following up the advance of the divisions. One battalion of engineers and a battalion of pioneer infantry were accordingly placed in position well to the front by zero hour on the 10th of November near both the "out" and "in" routes, prepared to undertake this work as soon as the advance permitted. Sufficient distance was not gained, however, prior to the armistice to make any work by these corps troops necessary, but from the amount of high explosives afterwards removed from culverts along these roads, plenty of work would have been needed.

On October 10th corps headquarters moved from Menil-la-Tour to Boucq, where, under direction of the corps engineer, a number of portable barracks had been erected and camouflaged for office use by a company of the 5th Engineers, then in corps reserve. After about two weeks at this locality it was decided to move to Wainville, and a company of the corps engineer regiment was designated to remove the barracks, etc., and re-erect them at the latter place.

The direction of the corps engineer and pioneer infantry regiments of the 4th Corps on the march into Germany was, by corps orders, assigned to the corps engineer; but no engineer operations of any consequence were required on the march. On reaching Trier the duty of guarding railroads from that point to the Rhine was assigned to the 4th Corps and turned over to the corps engineer. The pioneer infantry regiment was distributed along the railroad from Trier to Coblenz, taking over from the divisions as they advanced. The corps engineer regiment took over the railroad east of the Moselle and after the Rhine was reached and the sector east of the Moselle taken over by the French, the regiment was concentrated at Brohl on the Rhine, it being considered desirable to have the regiment here, in case a crossing of the river became necessary. The chief engineer of the 3rd Army, on arrival at Coblenz, arranged through a German contractor for the construction of a bridge of German ponton equipage across the Moselle about 40 kilometers above Coblenz, where the valley road crosses the river by a ferry. After construction it was turned over to the corps engineer, 4th Corps, for maintenance, and one company of the corps engineer regiment was stationed at the bridge for this purpose, the companies being changed from time to time in order to give as many as possible experience in this work. This bridge was maintained continuously, except for short interruptions on account of high water, ice, and the carrying out of about half of the structure by a ferry-boat that had gone adrift on a fairly high stage of water.

Soon after the units of the army of occupation reached their destinations numerous requests for general construction work began to be received, and a considerable amount of work of this kind was done for corps troops by details from the corps engineer regiment, though in a number of cases it was done by the troops themselves after they received the necessary materials. The corps regiment also rendered assistance at times to divisional engineers of the corps in

William Murray Black

Major General, U. S. Army; Member American Society of Civil Engineers
Chief of Engineers, March 7, 1916-October 31, 1919

[By direction of the President, and on his own application after more than 46 years of service, General William Murray Black, Chief of Engineers, U. S. Army, was placed on the retired list October 31, 1919]

WILLIAM MURRAY BLACK was born at Lancaster, Pa., November 8, 1855, the son of James and Eliza Murray Black. His father, James Black, was a prominent lawyer of Lancaster County.

He graduated from Lancaster High School at the age of 14, and from Franklin and Marshall College at 17. Forty years later his alma mater conferred on him the honorary degree of Doctor of Science.

He entered the U. S. Military Academy at West Point in 1873 and graduated at the head of his class in 1877. While at West Point he was Adjutant of the Corps of Cadets, then, as now, a recognition of soldierly distinction. Among his classmates were Cols. W. L. Fisk and S. W. Roessler of the Corps of Engineers, and Gens. Thos. A. Barry and Edwin F. Glenn.

General Black's entire service has been with the Corps of Engineers. The following is a very brief statement of the principal events in his long, varied and distinguished career of public duty:

1877—Assistant instructor at the Military Academy.

1877-1880—On duty with the Battalion of Engineers and Engineer School of Application at Willets Point, N. Y.

1880—Promoted to 1st Lieutenant, Corps of Engineers.

1880-1882—Assistant on engineering work to Col. W. P. Craighill, Maj. W. E. Merrill, and Capt. Wm. Ludlow.

1882-1886—Instructor in Practical Military Engineering at the Military Academy.

1886—Promoted to Captain, Corps of Engineers.

1886-1891—Assistant and District Engineer, St. Augustine, Fla., on river and harbor and fortification work.

1891-1895—Commanding Co. C, Engrs., and Instructor at Engineer School of Application, Willets Point, N. Y. Engaged in submarine mining development. Author of "Public Works of the United States."

1895-1897—On duty in Office of Chief of Engineers, in charge of fortification and personnel matters.

1897-1898—Engineer Commissioner of the District of Columbia. Assisted in development of highways and planned the elimination of railroad grade crossings in the district.

1898—Promoted to Major, Corps of Engineers.

1898—Lieut. Col. of Engineers in Spanish-American War. Chief Engineer, 3d Army Corps and 5th Army Corps. Took part in Porto Rican expedition.

1899-1901—Chief Engineer, Dept. of Havana, Chief Engineer, Division of Cuba, under Maj. Gen. Leonard Wood. Re-organized the Dept. of Public Works of Cuba. In this capacity Colonel Black "cleaned up" the city of Havana, including its water supply, sewerage and paving, and improved the highways of the island.

1901-1903—Commanding the Engineer School, Willets Point, N. Y. Transferred this school and re-established it at Washington Barracks, D. C. Pioneer in the establishment of "trade schools" for vocational training in the army.

1903-1904—On duty in Panama with the Isthmian Canal Commission.

1905—Promoted to Lieutenant Colonel, Corps of Engineers.

1904-1906—District engineer at Portland, Me.

1906-1909—Director of Public Works in Cuba during the American Intervention. During this period Colonel Black continued and extended the work he had inaugurated at the time of the Spanish War.

1908—Promoted to Colonel, Corps of Engineers.

1909—District Engineer, 1st District, New York City, Dept. Engineer, Dept. of the East, Division Engineer of the Northeastern Division. During this period he was chiefly engaged with the improvement of New York harbor and the Hudson River. Chairman of the Board of Engineer Officers appointed to raise the wreck of the *Maine* in Havana harbor.

1916-1919—Brigadier General, Major General and Chief of Engineers, U. S. Army. General Black commanded the Corps of Engineers and directed the Engineer activities of the American army throughout the great war. He also performed during this period a multitude of public duties of many kinds, and was awarded the distinguished service medal in recognition of his accomplishments.

1919—Having completed the demobilization of the engineer forces after the war, General Black retired on October 31, 1919.

The dominating motive, the outstanding characteristic of General Black's long and intensely active career, has been his compelling sense of duty. This has been the guide and support that has enabled him to go forward unwavering through every combination of adverse circumstances, and every period of disappointment and discouragement.

Richly endowed by nature with a keen analytical mind, a vivid imagination, exceptional reasoning powers, a faculty for organization, an iron constitution, indefatigable energy and enthusiasm, and great strength of character and decisiveness, General Black possesses in a marked degree most of the qualities that make the constructive engineer and the leader of men. He has been a powerful influence in every project with which he has been connected.

Though engaged during a large part of his career in engineering problems connected with the public works, General Black was above all a *soldier*, and never for an instant lost his keen interest in all affairs military. He believed that a thorough knowledge of the art of war is indispensable to the effective application of engineering science to armed conflict, and he constantly strove to impress this idea upon the Corps and the engineering profession. Perhaps his greatest efforts were those he devoted to the improvement in education and training for the younger officers of the Corps. It was his constant purpose to provide them with the broad and solid foundation upon which they might build their careers as military engineers of the highest type. The glorious record of the Engineers in the World War is the justification of his judgment and the crowning reward of his labors.

General Black leaves the army not to retire, which his restless energy forbids, but to enter other fields of activity and usefulness.

Conspicuous in the long list of public men who have served their country with intelligence, enthusiasm and devotion, stands for all time the name of WILLIAM MURRAY BLACK.

Engineer Units in the National Guard

By

Col. H. A. Finch

Engineers, U. S. Army

FOR the past three months the writer has been watching the condition of the National Guard throughout the country but there have been few encouraging features to dwell upon and the strain on the observer's first-line trenches of optimism has been heavy enough to justify calling up the reserves.

Judging from surface indications the situation is certainly not such as to elicit loud cheers because the facts are that only a few more than half of the States have signified their intention of attempting to organize their allotment of troops for the year 1919-20, and out of 126,000 men contemplated for the enrollment during the present fiscal year only 35,000 were actually enrolled up to October 15, 1919. At that time only one Engineer organization was in existence in the Guard—a battalion which was organized in Arkansas too late to be accepted for service overseas.

So much for the pessimistic features of the situation. Reflection on this subject suffices to bring out certain hopeful thoughts, but more than reflection is required to solve the problem of the Guard's reorganization. Co-operation is what is needed or both the Regular Army and the National Guard will suffer.

There is a point here that frequently appears to be missed, i. e., since a militia is expressly provided for in our Constitution, the National Guard, in some form, is here to stay unless an amendment—a very remote possibility—puts an end to its existence. However much some of us may regret this apparent dispersion of strength, whatever, in our opinion, may be the weakness of the dual military system thereby imposed upon our country, no good can come from an attitude either of aloofness or of opposition on the part of regular army officers in their relations with the national guard. The weakness of the combination is centered more in in the form than in the substance, since American stock is the same throughout. But the opportunity for jealousy and misunderstanding to get in their work is the real defect of the system, and here our duty as officers is clear, i. e., since strength comes only from unity we should work to promote unity by every means within our power.

It is certain that not only the national guard but the regular army as well is at present in the doldrums. A countrywide apathy toward military service in any form is very evident, but what could be a more natural reaction, considering what the men in our country, eligible for military duty, have recently passed through? The same condition on a small scale was observed following the Spanish-American War.

Having met the demands of patriotism in the most critical time of war it would indeed be surprising if our young men showed eagerness to rush into peace time military service without first having had a period for relaxation and for a readjustment of their personal affairs.

The Militia Bureau recognizes this present widespread indifference as the main cause for the slow recruiting of the National Guard but it also recognizes other causes which may be listed in the order of their importance as follows:

(1) Delay on the part of Congress in acting on military legislation, thereby failing to establish definitely a military policy for our country.

(2) A decided Micawber-like tendency on the part of some officials to wait for conditions to become better without making any effort to improve these conditions in the meantime.

(3) A dislike for strike or riot duty which at this juncture appears to be the guardsman's inevitable portion.

(4) The hostility, either latent or active, of the labor unions toward military service.

Most national guardsmen, having seen from two to three years of active service, had to go to work at once to re-establish themselves. This they are doing, and a reasonable period having elapsed, there are many signs now visible of a revival of interest in the guard among eligible men. When the fate of the League of Nations is settled and our foreign obligations are thereupon determined, Congress may be expected to pass on army legislation and decide upon a definite policy for the military. Labor upheavals may be expected to subside gradually and with them will disappear the effects of the unions' hostility toward the guard. If in the meantime we can secure the liberal co-operation of the regular army, from the general staff down, then may we expect the realization of an efficient national guard; otherwise the reg-

Digitized by Google

ular army officers concerned with this task will continue to face a situation from which can come neither satisfaction to themselves nor credit to the regular service.

The newspapers to-day show that a certain proportion of former national guard officers are bitter toward the officers of the regular army, as a result of the attitude of superiority and intolerance sometimes assumed toward the guard by men of the regular establishment. This is most regrettable but the writer is far from believing that more than a very small number of regular officers offended in that respect. Impatience and intolerance destroy congeniality and efficient team work wherever they are found, and the unfortunate fact remains that these qualities in even one regular army regimental commander have the effect of causing 50 or more national guard or national army officers to become disgusted with the system which the colonel misrepresents.

There is no denying that there are certain inherent defects in the national guard system, especially in the opportunity it affords a certain group of its personnel to play politics, utilizing the national guard organization as a form of political machine. This type of man deserves the contempt that he receives whether in the national guard or elsewhere, but on actual association with officers serving with state troops it is gratifying to note how seldom this species is encountered and how often one finds business men of a high type who are giving up their time and pleasure from patriotic motives unmixed with any desire for gain to themselves.

The writer commanded from June until December, 1918, a regiment composed of former national guard officers and men. He was impressed with the fine spirit and the high average ability of the rank and file, and he also was given much food for thought in the statement of one of the officers who was "thankful that the Lord has sent them two regular army colonels in succession who were real human beings."

Criticism can of course be brought and has been brought against the military system which permits the existence of our national guard, but the officers of the regular army will be among the first to state that the national guard divisions fought exceedingly well in the recent war. The writer holds to the belief that all of our divisions fought bravely and, in most cases, well; bravely, because our men are born that way, and well or better, depending upon the training they had received and the spirit inculcated in them by their officers. But service on the Mexican border and prior training in armories and during encampments prepared the men of the national guard for a quicker departure overseas than would otherwise have been the case. In August, 1917, the national guard furnished for national defense 12,115 officers and 367,000 enlisted men—by no means thoroughly trained, of course, but with the foundation for their training prepared. To that extent, therefore, the system justified itself.

All of the above is by way of impressing upon officers of the Corps of Engineers the necessity for patience, tolerance, and the utmost co-operation on our part in dealing with national guardsmen whether in the service schools or in the field, or on duty as inspector-instructors.

The plans for the engineers in the national guard are comprehensive enough as prepared by Colonel F. B. Wilby, Corps of Engineers, during his recent tour of duty in the Militia Bureau. The scheme contemplates the following eventual organization for the National Guard Army on the assumption that it will consist of four corps comprising sixteen infantry divisions and one cavalry division:

	Minimum strength
27 pioneer regiments (2 battalions of 3 companies each) at 1,000 each	27,000
1 for each infantry division 16	
2 for each corps 8	
3 for the army 3	
Total 27	
1 mounted battalion for the cavalry division (3 companies)	300
5 ponton trains (3 heavy div. and ½ supply div. each) at 100 each	500
1 for each corps 4	
1 for the army 1	
Total 5	
The following additional army troops—	
1 camouflage battalion (2 companies)	300
1 flash-ranging battalion (2 companies)	300
1 sound-ranging battalion (7 companies)	400
1 searchlight battalion (3 companies)	425
1 surveying and printing battalion (3 companies)	425
1 surveying company	...
1 printing train company	...
1 base printing plant company	...
Total	29,650

The strengths given above are approximate minimum peace strength equal to about one-half the war strength of the organizations listed.

The following extract is taken from a memorandum by Colonel Wilby:

The above organizations will include all those recommended for divisional, corps, or army troops, in report dated April 7, 1919, submitted by Board on Organization of Engineers, convened by the Chief Engineer, A. E. F.,—except one water tank train, 18 service battalions, and a headquarters detachment for Chief Engineer of Army. It does *not* include any of the following special engineering organizations required on the lines of communication:

Construction regiments,
Forestry regiments,
Road regiments,
Light railroad regiments,
Railroad construction regiments,
Shop battalions,
Engineer depot detachments.

Digitized by Google

It is believed that none of these specialized engineer units for work on the line of communication would require peace time military training, but could be rapidly organized as needed in time of war.

To provide for the contemplated organizations the various states have been allotted the task of forming engineer units as shown in the table below. The table indicates both the allotment for the present fiscal year and the ultimate allotment which is supposed to be enrolled by June 30, 1924.

	1919-20 Allotment.	Ultimate allotment.
1 New York	1 regt. and train.	2 regiments.
		1 battalion (mtd.)
2 Pennsylvania	1 battalion	
	1 train	2 regiments.
3 Massachusetts	1 battalion	
	1 train	2 regiments.
New Jersey	1 battalion	1 battalion.
		1 hdqrs. company.
4 North Carolina	1 company	1 battalion.
	1 train	1 hdqrs. company.
Georgia	1 company	1 battalion.
		1 hdqrs. company.
South Carolina	1 company	1 battalion.
5 Ohio	1 battalion	
	1 train	1 regiment.
Indiana	1 battalion	1 battalion.
		1 hdqrs. company.
6 Illinois	1 battalion	
	1 train	2 regiments.
Wisconsin	1 company	1 regiment.
Michigan	2 companies	1 regiment.
7 Iowa	1 battalion	1 regiment.
Kansas	1 train	1 battalion.
		1 hdqrs. company.
Missouri	1 battalion	1 regiment
		1 battalion.
Colorado	1 company	1 battalion.
	1 train	1 hdqrs. company.
8 Arkansas	1 battalion	1 battalion.
Texas	1 company	1 battalion.
		1 hdqrs. company.
Oklahoma	1 company	1 battalion.
9 Oregon	1 company	1 battalion.
		1 hdqrs. company.
Idaho	1 company	1 battalion.
California	1 battalion	1 battalion.
Maryland	None	1 battalion.
Alabama	None	1 battalion.
Mississippi	None	1 battalion.
	None	1 hdqrs. company.
West Virginia	None	1 battalion.
Tennessee	None	1 regiment.
Minnesota	None	1 regiment.
Porto Rico	None	1 company.
Totals	1 regiment	15 regiments.
	10 battalions	18 battalions.
	11 companies	9 hdqrs. companies.
	8 trains	1 battalion (mtd.)
		1 company (Porto Rico.

The 18 battalions and the 9 headquarters companies provided for in the ultimate allotment are equivalent to 9 complete regiments, assuming that the headquarters company of the future regiment of engineers will include the train. The total of 24 regiments is enough to provide for the 16 divisions and the 4 corps, but it will be noted that no provision is made for the 3 pioneer regiments for the army nor for the 5 ponton trains and 5 special battalions recommended for the national guard. These units are to be allotted when the task of organizing the 24 pioneer regiments for the corps and divisions is farther advanced.

To provide engineer training and instruction for these units there will be required 9 engineer officers and 22 engineer sergeants for inspector and sergeant-instructors, for the first allotment (1919-20), and additional officers and sergeants at the rate of 1 officer and 2 sergeants for each new regiment formed.

These will be assigned to duty as follows to the groups of states having engineer units in their initial allotment. The assignment of territory will be shifted when necessary to take care of states forming new engineer units later.

Group No. 1—
Number of officers 1
Number of sergeants 2
Group No. 2—
Number of officers 1
Number of sergeants 1
Group No. 3—
Number of officers 1
Number of sergeants 2
Group No. 4—
Number of officers 1
Number of sergeants 3
Group No. 5—
Number of officers 1
Number of sergeants 2
Group No. 6—
Number of officers 1
Number of sergeants 3
Group No. 7—
Number of officers 1
Number of sergeants 3
Group No. 8—
Number of officers 1
Number of sergeants 3
Group No. 9—
Number of officers 1
Number of sergeants 3
Total, 9 officers; 22 sergeants.

So much for the plans.

The Corps of Engineers must be prepared to assume the obligation of training the engineer units of the national guard. It is understood that at this juncture the demands to be met by the corps are very heavy, including as they do the training of some 200 or more of the junior officers within our own ranks. Granting the importance of this task, it is clear that the detail of only nine officers for national guard duty

Digitized by Google

would cause no great derangement of the training program within the corps, and the experience gained by these officers would more than compensate for any temporary inconvenience caused by their detail.

The officers required for such service must under the law be drawn from the regular establishment. These men will hold positions of trust and responsibility not exceeded by those of any officers within the corps below the rank of lieutenant colonel, on duty with troops. They will gain greatly from the broadening effect of living and working with the American business man and soldier.

Duty with the national guard is very popular in other branches of the army, and wherever the Militia Bureau has a voice in the selection of inspector-instructors only the best officers are chosen.

It is clear that our country will gain from the national guard only in proportion to the time and talent devoted to its advancement; the regular army will likewise gain and in even greater measure, but only if the service assigns to this task officers who have a correct attitude toward their duties and an aptitude for working with men. In other words, we shall get back from the guard only what we put in it.

The responsibility of the Corps for the engineer service in the national guard is direct and can not be avoided. Some of the nine officers are needed *now* to start the work of assisting in the guard's reorganization. If we do not take up promptly our share of this task the Corps of Engineers will soon, for the first time in its history, be trailing the procession.

Discussion

Col. F. B. Wilby
Engineers, U. S. A.

Col. Finch's article should be of interest to every engineer officer as it presents clearly a subject concerning which the average engineer officer has only the haziest idea. Most of us are content to dismiss the subject with the remark that "the national guard system is wrong, and will soon disappear, and therefore why bother our minds with it?" Such an attitude is most deplorable for several reasons.

1st. We have all sworn to support and uphold the laws of the United States, and as long as the laws of the United States include the national guard as part of the national defense it is clearly the duty of every officer of the regular army to do his utmost to make the national guard as efficient and dependable as it is possible to make it with the resources available. As part of those resources, Congress has appropriated this year something like $16,000,000 for the support of the national guard. It is a poor soldier who, upon receiving an order from his commanding officer, fails to carry it out to the best of his ability simply because in his opinion the order should not have been given. Yet, isn't this exactly the attitude of the regular army officer who, having received a $16,000,000 order from Uncle Sam to support the national guard, spends his time and effort in decrying the national guard system and proclaiming the fact that Uncle Sam shouldn't have given him such an order?

2nd. Is the national guard system to disappear as soon as many regular army officers believe? Colonel Finch has called attention in his article to a provision of the constitution which may stand in the way of such a consummation, and until we have something better to take its place, it is certainly better than nothing,—possibly not very economical for results obtained, or as efficient as might be desired,—but certainly worthy of our best efforts to make it as efficient as possible.

3rd. With all its faults, the national guard system has one great advantage which must be perpetuated in any system which takes its place; i. e., the localization of units. The worst national guard unit has more esprit or pride in its organization, due to this localization, than can be found in many far more efficient regular army units. Of course the esprit due only to efficiency and resulting from demonstrated ability is the most valuable in the long run, but the spirit of pride engendered in units whose personnel is drawn from one locality, whether town, county, or state, is a most valuable foundation upon which to build efficiency, and should be preserved in any forces raised for national defense, whether under the national guard system, universal training system, or any other.

The figures given by Colonel Finch showing the engineer organizations contemplated in the national guard are of course only tentative, and simply show approximately what the national guard engineers will be if organized under existing law—the National Defense Act of 1916. This act is undoubtedly liable to be changed before the plans given can be carried into execution. However, until it is changed, it is clearly the duty of the Corps of Engineers to see that such national guard engineer units as are organized under that law receive the fullest possible co-operation and assistance. One form for that assistance is in the detail of capable and experienced engineer officers and noncommissioned officers as instructors.

Col. W. A. Mitchell
Engineers, U. S. A.

This article covers the subject quite thoroughly. I was in the Militia Bureau when the war started, and it was quite evident to me that the engineers had not shown a great deal of interest in the national guard. The results were not to our benefit; we were

Digitized by Google

forced to hurriedly form some engineer regiments, one of which was formed bodily by changing the name from infantry to engineers, and telling them that they were so. However, although they were not so immediately, they were quite earnest in their efforts and ultimately became very efficient as engineers.

As the national guard bids fair to remain a national force until we have compulsory service, and as no one can tell when we shall have that, it appears that the engineers should promptly take up their duties with the national guard as they have done in other works. If the Militia Bureau needs 9 officers and 22 sergeants, I feel sure that many of us are willing to add a little more work to the little more that we have already added in order that the Militia Bureau can have its wishes.

Col. Lansing H. Beach Appointed Chief of Engineers

The nomination of Colonel Lansing H. Beach, Corps of Engineers, to be Major General and Chief of Engineers, was sent by the President to the Senate, January 14, 1920.

Colonel Beach was born in Iowa, June 18, 1860. He graduated from the United States Military Academy number three in the class of 1882, and was assigned to the Corps of Engineers. He was appointed Additional Second Lieutenant, June 13, 1882, Second Lieutenant, June 30, 1882, First Lieutenant, January 10, 1884, Captain, October 4, 1894, Major, February 20, 1903, Lieutenant Colonel, February 28, 1908, and Colonel, February 27, 1913. He served with the Battalion of Engineers at Willets Point and West Point, N. Y., from 1882 to November, 1884, when he was assigned to river and harbor improvement work in Texas. From September, 1885, to November, 1888, he was a member of a commission to run and mark a portion of the boundary line between the state of Texas and the Indian Territory. For two years he was disbursing officer of this commission. At the same time, from December, 1885, to August, 1889, he was engaged upon works pertaining to the Ohio River and its tributaries.

He served four years at the United States Military Academy as Assistant Professor of Civil and Military Engineering, and in August, 1893, was assigned to river and harbor improvement work at Galveston, Texas.

He served at Washington as assistant to the Engineer Commissioner of the District of Columbia from November, 1894, until May, 1898, and as Engineer Commissioner of the District until November, 1901.

He was stationed at Detroit, Michigan, in charge of river and harbor work and the Eleventh Lighthouse District from November, 1901, to August, 1905, when he was detailed as Instructor of Engineering at the Army Staff College and Infantry and Cavalry School at Fort Leavenworth, Kansas. He was assistant commandant of these schools from November, 1906, to August, 1907, when he was assigned to fortification and river and harbor work at Jacksonville, Florida, in August, 1908, he was appointed Division Engineer, Gulf Division, New Orleans, La., and in August, 1912, was transferred to Baltimore, Md., in charge of fortification and river and harbor works. He was appointed Division Engineer, Central Division, with station at Cincinnati, Ohio, in August, 1915, where he has since served.

Colonel Beach has served as member of various Engineer commissions, including the Mississippi River Commission, and is a member of the American Society of Civil Engineers.

Proposed Huningue-Strasburg Canal

It is proposed to construct a canal running from Huningue to Strasburg, and to make a port on the river at the latter city. The canal will be 120 m. broad and 6 m. deep, and would be constructed so as to facilitate the erection of ten hydro-electric power stations with a total of about 700,000 hp., and costing one milliard francs.—*Eng. and Cont.*

Effects of Sea Water on Reinforced Concrete

German manufacturers, as a result of experiments extending over 20 years, make the following recommendations:

In order to obtain suitably strong structures in sea water, it is necessary to use cement which is as rich as possible in silicates, but poor in kaolin and iron oxide. Such cements, when at the same time they are rich in lime, can be considerably increased in value by adding certain quantities of trass. The decisive factor, however, for the permanence of concrete structures in the sea is the use of mixtures which are as dense as possible and impervious to sea water, while at the same time sufficient external hardening should be given to the substances before they are placed in the sea by exposing them to heat and to moist air. Concrete, the mortar of which contains more than 66⅔ per cent of sand, will generally not show the necessary density to enable it to stand attacks by sea water for any length of time.

Barge Canal Terminal, New York City

The largest of the terminals of the New York State Barge Canal is that recently completed at New York City. It includes piers Nos. 5 and 6, East River, near the foot of Broad Street. The dimensions of the piers are, respectively, 70 by 570 feet and 50 by 572 feet. They are of timber with reinforced concrete decks. The slips between these piers have a width of approximately 100 feet at the bulkheads and 200 feet at the entrance, and a minimum depth of 14 feet.

The piers are equipped with jib cranes of a semi-portable type and boom cranes specially designed, all operated by electric power.—*Eng. News-Rec.*

American Falls Dam, Idaho

A writer in *Eng. News-Record* states that the new dam of the Reclamation Service at American Falls will flood an area of 70,000 acres of land and create a storage of 3,000,000 acre feet, being the largest storage reservoir yet constructed.

Proposed Detroit River Bridge

The volume of traffic across the Detroit River necessitates a new bridge from Detroit to Windsor, Canada. The investigations for this bridge are in charge of Mr. Gustav Lindenthal and Mr. Charles Evans Fowler. It will be of the cantilever or suspension type with a clear span of 1,800 to 2,400 feet.—*Eng. World.*

Proposed Trans-Pacific Cable

In addition to the new proposed government trans-Pacific cable, private enterprise backed by the Western Union Co. proposes to lay a cable from Seattle to points in the Orient, by way of the Aleutian Islands. The proposed route will be only half the length of routes farther south, which it is said will double the speed of transmission.—*Eng. World.*

Soldiers First!

By

Col. J. C. H. Lee

Engineers, U. S. A., formerly Chief of Staff
89th Division

COLONEL SPALDING'S article on the divisional engineer officer, published in PROFESSIONAL MEMOIRS, September-October, 1919, puts the question so clearly before engineer officers that it is to be hoped everyone will read and re-read it and think over the comments.

The sound truth of the statement, that the engineer regiment is the divisional engineer, is splendid. Also there should be no doubt that the engineer regiment must train with and become an integral part of the division. Some may still disagree with this. However, they remain quiet on the subject.

Two matters, however, seem to have brought forth a considerable opposition, to-wit: first, splitting up the engineer regiment temporarily from time to time and assigning it according to the needs of the situation; and second, recognizing the authority of the brigade commander in his own theatre.

Oftimes, and I think in these comments, the various writers may be trying to express much the same idea. Each no doubt is perfectly sure in his own mind, but has difficulty in conveying his ideas to others.

There is apparently, however, a wide difference of opinion as to the responsibility for command of engineer troops in a combat division. A conservative group, as we may style them, seem to entertain the view that the division engineer must retain command of all his troops all of the time as a matter of principle. The other group believes in allotting the engineers as the situation may require, giving temporarily to each brigadier, who needs their services, his proper share according to the opinion of the division commander after consulting with the division engineer, and leaving under the direct control of the division engineer only such part of the regiment as the particular situation may justify.

Several of the officers making comments on this article have indicated their alignment on the conservative side. There were many engineer officers who followed the conservative principle during the late war. Some corps engineers even went so far as to give direct orders to the divisional engineers operating in their corps, apparently considering that the corps engineer commanded all the engineers serving under the corps commander. On two occasions that I know of, where this attitude was promptly resented by a division commander, the corps engineer's action was repudiated and he was required to make his suggestions, or convey his corps commander's orders, to the division commander, except in very great emergency which must justify the departure from routine.

I cite these incidents as they form a good analogy to the situation within the division, where the division commander has allotted certain engineer units to his brigades for use in a given situation and where the division engineer, before these units had been put back under his immediate orders, might try to control them.

No doubt the earnest desire on the part of the average engineer, to get engineering results, is a strong reason for his reluctance to give over the temporary command of any of his men to a layman, a line commander. If we meet the issue fairly, however, we see a tendency to strive for 100 per cent perfection in mere structural details when the attainment of such perfection is not the mission of the combat engineers.

In analyzing this question it is well to examine our premises, lest we neglect to consider certain fundamental principles on which depend the proper participation of the engineers as well as all other troops in the campaign, and success or failure of that campaign.

We are now considering the division engineers, the regiments trained for and used as the engineers of a combat division. The first fundamental consideration is that the mission of the division is to win battles. It must produce results in action. Its organization, its training, its habit of thought and performance must be based on this principle of producing its maximum effort in battle. The divisional engineers are only one part of this fighting organization. It is their mission to fit accurately, gracefully and cohesively into the fighting machine and deliver the maximum of assistance to the division in action or preparation therefor. The organization, training, and control of the engineers must accordingly be based on this principle. Any habit of thought or mental attitude which will increase efficiency in performing this mission should be fostered. On the other hand, any custom or method of control which apparently hinders or jeopardizes

Digitized by Google

the proper performance of this fighting mission should be scrutinized with suspicion, carefully analyzed and, if found unsound, ruthlessly eliminated.

The second fundamental principle we should consider is that of unity of command. In one theater of operation there can properly be but one commander if maximum efficiency is to be realized in fact. All the military means in that theater must be placed absolutely at the disposal of this *supreme* commander. He is held solely responsible for results and therefore must *command* without qualification or restriction, let or hindrance. From his next higher commander he receives his mission and his means. It is for him to produce results. This is organization, responsibility and command in their proper relation as proven by all military experience.

The third fundamental principle is that the fighting foot soldier in every war is the chief factor in success or failure. He suffers the greatest losses. He decides the issues of battle and campaign. In modern battles, supported by the powerful auxiliary arms, it is nevertheless he who must advance and clinch the victory, hold the gains, or lose them. He therefore is the guide. All other arms are auxiliary. The mission of these auxiliaries is to furnish the foot soldier with the maximum of real support. It is their only reason for being, their only excuse for not sharing equally his losses and hardships.

In order that the support of the many auxiliary branches may be given efficiently to the foot soldier there must be that condition of co-ordination and mutual confidence often so vaguely striven for and called *liaison*. However, this condition after all means only mutual knowedge, confidence, friendship and helpfulness between the infantryman and the other arms. If he knows and trusts them and they know and trust him, there will be liaison. He can then and only then really profit by their support.

Experience in the late war has no doubt had a tendency to lead us to false conclusions about the proper control of the auxiliary arms. I think this is due to the fact that many captains and majors of infantry and cavalry, after a decade or so of relative military inactivity, had fooled themselves into believing that they knew pretty nearly everything about the line soldier's job. These men were suddenly thrown into a situation where they commanded infantry regiments or brigades. The tremendous expansion, the routine work and the routine training of their troops required their best thought and effort. Many of these officers found themselves in action not only commanding their own regiments with the many new infantry weapons but having also at their disposal additional machine guns, field artillery, engineers, tanks, possibly gas and flame troops, and airplanes for reconnaissance. Not many minds can formulate new plans and accustom themselves to new conditions under the stress of battle. That many of our officers did learn in action and did handle these combined arms advantageously stands out to their great individual credit. That many failed to use these auxiliary arms advantageously was due to the fact that they never had the practice, they had never thought it out, they had never done it before. The division commanders usually were more fortunate in having as immediate assistants a fairly efficient staff assigned to them by law and who could at least advise individually along the lines of their respective experience. Brigade and regimental commanders, however, were fortunate if they had acquired staffs capable of merely supplying their troops and of writing out and distributing the plans and orders which the commanders themselves had to think out and dictate. Of course many brigade and regimental commanders failed to use properly the means placed at their disposal and made the engineers, for example, feel that their troops should never be placed under the orders of a line brigadier or colonel. Herein lies the danger of the deduction.

The division is the largest unit which has in its permanent organization the combined arms. This does not mean, however, that the combination of the various arms ceases in units smaller than a division. Far from it. In action either offensive or defensive—and we must consider success in action as the primary requisite—the infantrymen must be supported by the combined arms down to the smallest possible unit. Modern war has emphasized this, realizing the impracticability of attaching engineers and artillery to an infantry platoon, but giving them engineer tools and giving them increased fire power with the modern trench mortars and 1-pounder guns. However, where the situation justifies it, we give the assaulting infantry battalions the actual physical support of accompanying field pieces and the assistance of skilled engineers for passing obstacles. Probably the lowest infantry unit in the division to which are ordinarily assigned auxiliary troops, as such, is the battalion. This battalion may be defending a center of resistance, such as a fortified village or it may be moving forward in attack formation. It will probably have additional machine guns, possibly one company, and a platoon or even a battery of field artillery used either as anti-tank or close defense guns on the defensive, or as accompanying guns in the attack. It would have perhaps a platoon of engineers to work with the infantry in passing obstacles or, if on the defensive, in making obstacles, performing demolitions and assisting in the general preparations of the defensive organization. There may be also signal troops, gas and flame troops, and tanks, if in attack. However, in that center of resistance or in that attacking force there can be but one commander and he must command unequivocally all of the means put at his

Digitized by Google

disposal: infantry, machine guns, artillery, engineers —all. "Co-operation" is not the ideal—it is "absolute command," to guarantee unity of purpose and unity of effort.

If an infantry major is going to control properly these auxiliary arms in action, he must have had practice; he must have thought out similar problems during quiet times when his brain could work; he must have learned the capabilities of the various arms; and he should not only have learned how best to use them, but preferably how best to deal with the individual commanders. If he has known the engineer by months of association, depending on him, it will be to his great advantage in action to understand him, and to count on him. His officers and his men will know the engineer officer and his men. The same is true with the other arms. All of which does not mean that this platoon of engineers or this battery of artillery has always been serving under or indeed in close contact with the infantry battalion, of course not. The engineers have been trained as part of the engineer regiment in their proper duties as engineers even as the artillery has been trained in its brigade. However, in their training, and in their maneuvers, wherever this infantry battalion was to receive artillery support and engineer support, these particular artillery and engineer units would if possible be those assigned. Moreover, in the daily routine, this engineer unit would if possible be the one assigned to help the infantry battalion in its target range construction, improvement of its camp drainage, etc. In other words the infantry major will *know* his means thoroughly. They will be a real and integral part of his fighting machine and the team will have the best chances of success.

If an infantry major, such as we have described above, learns how to command his battalion and the proper proportion of auxiliary arms, he will probably make an excellent colonel or brigade commander. He will know what to do with his engineers and his artillery. Is it not therefore a fundamental duty on our part to see that the field officers of the line acquire the experience of handling the auxiliary arms, particularly the engineers, in the proper way? If we don't help them to learn how, we can not justly complain thereafter if things go wrong. The artillery has been trying to show the infantry officers how best to use the guns. Similarly, we must show them how best to handle the combat engineers.

It may not be economical engineering, particularly at first, to let the line commander control our detachments temporarily. However, we are not only observing the true principles of organization and respecting proper command within a "theater,"—but we are helping that commander train himself to think in terms of engineers. We are increasing the chances for success in battle—we are travelling true to our course, carrying out our mission as the engineers of a combat division.

If we are going to convince the line how engineers should be handled we must first convince ourselves that we are right. There is a wide divergence now. It behooves us to thresh out the question in the light of our best experience, not forgetting the fundamental principles that underlie our profession. As members of the Corps of Engineers we are soldiers first. Our function in war is to produce those results which will assist in the greatest possible way in the attainment and maintenance of military success. We are soldiers first and engineers second. Those who thus believe I term the progressive party, and the other group, which I have named "conservative," rightly merit being called engineers first and soldiers second. This condition cannot continue. We must become one party, but not by unsatisfactory compromise. The conservatives must join the ranks of the progressives. If the Corps of Engineers is to justify its existence as an inherently essential element in the Army of the United States it must take for its motto "Soldiers First!"

Dust Explosions

Dust explosions occur in grain elevators, feed grinding plants, flour and starch mills, sugar refineries, wood working plants, paper mills, etc.

They are due to ignition of the dust in the air from an external source under certain conditions of temperature and humidity. Fineness of the dust particles, high temperature, and low humidity, increase the probability of explosion and the destructive effect.

The principle causes of ignition are lighted matches, heat developed by friction, electrical sparks and static electrical discharges.

The flame of explosion is propagated at a rate of more than 6,000 feet per second and it is impracticable to construct buildings which will withstand the pressures thus developed.—*Canadian Engr.*

Inter-river Drainage District

The inter-river drainage district of Butler Co., Mo., between the Black and St. Francis Rivers, is one of the largest projects for reclamation of lands subject to overflow. It includes an area of 127,500 acres.

The project involves about 54 miles of levees along both rivers, varying in height from 10 to 14 feet, and requiring over 4 million yards of embankment. Detention reservoirs were considered as a possible solution, but rejected as less economical than the levee system. There will also be provided some 208 miles of drainage channels for the interior of the area, varying in size from 12 feet bottom width and 6 to 8 feet depth, up to 55 feet bottom width and 10 feet depth.

The plans for this work were prepared by the Morgan Engineering Co. of Memphis.

Contracts for the levee work have been let to the Callahan Construction Co. of St. Louis.—*Mun. & County Eng.*

EDITORIAL

Construction Work of the Engineers in France

IN this issue appears an account of the work of the Engineers of the U. S. Army in the theatre of the World War. It is a simple record in plain fact and actual figures, of one of the greatest and most varied construction tasks ever undertaken, and successfully accomplished by human energy. It describes briefly the achievements of the Corps of Engineers, without underrating the work of others who did their part, without attempting to decry their efficiency, impugn their motives, besmirch their good name or destroy their usefulness, although efforts to destroy the good name of the Corps of Engineers have recently appeared in certain contemporary publications.

The men who did this work, the officers of the Corps of Engineers, and the men from every branch of the American engineering profession who responded to the call, strove under many difficulties. They were not at home, working under conditions in some respects more favorable than those of peace, but abroad in a strange land, facing new and unknown conditions, amongst a foreign people, speaking an unfamiliar language, having different customs, a different mental attitude, and often a lack of sympathy and the will to co-operate, due to the lack of understanding. The material resources of the United States were not at hand and readily available, but 3,000 miles away, across an ocean infested with hostile submarines. Our engineers did not control the transportation facilities of France—the railroads which were essential to their task. They did not have at their backs the organized efficiency and patriotism of the skilled contractors of America.

It was, moreover, not a simple task of building construction which these men faced, but a complex and intricate project, involving every variety of structure and installation. In the beginning they lacked almost every thing necessary to the prosecution of their work, personnel, supplies, equipment, transportation, though happily they possessed an organization well adapted to the difficult situation and capable of expansion.

Almost everything they lacked, but not *everything.* For these men possessed a practical knowledge of the fundamental economics of warfare, which demand prompt results, stripped of all niceties and refinements, sufficient unto their purpose and no more than sufficient. But above all, our engineers had the will to conquer, the genius of achievement, the "never say die" spirit that always has surmounted and ever will surmount all material obstacles. Herein lay the certain guarantee of success.

The heavy task was accomplished, rapidly, efficiently and thoroughly done in face of all difficulties, and it constitutes a proud monument of achievement in the field of engineering and construction.

The record is a worthy one, and adds lustre to the reputation of the Corps of Engineers and the American engineering profession. And every American citizen whose soul is not dead within him, should thrill with a mighty pride in the magnificent work of the American Army Engineer in France.

A New Era

WITH this issue PROFESSIONAL MEMOIRS in a new form and under a new name enters a new era, on the occasion of its twelfth birthday. It must be an era of greater usefulness than that which has passed. We have a more important mission to perform, a larger clientele to whom we must appeal.

The scope of our efforts will be greatly increased. In this issue several new departments make their appearance and certain old ones have been abandoned. It is intended to add other departments in the near future. The news section, which now appears for the first time, is far from being complete or perfect. Still, we feel encouraged by a good beginning. This department has great possibilities of usefulness in keeping each of us in touch with what the others are doing.

Our change of name is in accordance with our change of policy. A "memoir" is a solemn chronicle of a task well done. But a magazine such as ours, to fulfill the mission we have set before us, should not be a mere archive of technical data and methods. It must be a living thing, pulsating with human emotion and interest.

To be instructive a magazine should be entertaining. The journal of a scientific institute, the "proceedings" of a technical society, do not serve the same purpose as a current periodical. They are in effect archives of technical knowledge, and our journal is not such. Our "body politic" consists chiefly of live human interests and passions, men who are doing things, and not "book-worms," or animated encyclopedias of impractical ideas. We aim to dispense and distribute enthusiasm as well as knowledge. Enthusiasm and knowledge combined win many battles where either alone would fail.

The aim of this journal is to promote the practical efficiency, the solidarity and the enthusiasm of the engineering profession, in the service of the country. It is not a mere recital of technical methods but a bond of union, sympathy and understanding between all engineers in civil or military life who are desirous that the profession shall be always prepared to render the most efficient possible service to the nation in case of need.

Accordingly THE MILITARY ENGINEER solicits from all its subscribers, from all engineers and from all military men, articles and news items which will help it to accomplish its mission. For since we have no staff of paid writers we are dependent for existence on the voluntary contributions of those who believe in our mission.

What is the class of articles that will best meet our needs? First, they must generally be current, up-to-date. Second, they must, in general, appeal to a relatively large number of our subscribers. Third, they must be of value for instruction. Fourth, to be read they must be readable. This generally requires a relatively short article. In each issue there should be a few articles of moderate length and a greater number of short articles or notes.

It is seldom wise to attempt in any article for a current publication to *tell all,* for that is generally tiresome. If the article be, for example, an account of the construction of a dam, it should not aim to be a complete guide with plans and instructions for others to follow in the future. For as such it will never be used. Neither should it be a history of the work. In some articles that have been submitted there has been included what was almost a journal of operations, which cannot possibly be of an interest to our readers proportionate to the space it occupies. Professional memoirs and technical instructions which are in effect text books, have their uses, but not in a current periodical. We need accounts of new and unusual things, new schemes, new difficulties encountered or new ways of overcoming old troubles. Some details are interesting and important. Others are merely tiresome to a reader. The latter should of course be omitted. Important statistics should be summarized when practicable.

The belief that monumental treatises were required has often served to deprive us of valuable contributions. An author having a valuable idea sometimes feels that he must expand it into a long-winded article. The effort required to do this is so great that often we lost a valuable idea that might have been suitably written up in a few hours or even a few minutes time. Some accounts are of most value when, for our purposes, complete and thorough. But the majority are most useful when presented in sketchy and picturesque style.

In any case it is *quality* rather than *quantity* that we need. The most valuable commodities usually come in the smallest packages.

In order to cover a wide field and to maintain an uncompromising standard of excellence in the material presented to our readers we should have plenty of contributions to select from in order that we may, so saying, skim the cream for each issue. The fact that an article is not published does not mean that it is not good, even excellent. It may simply mean that we are receiving many excellent contributions, all of which manifestly cannot be published. Also it is necessary that we present a "balanced ration," and the best of articles judged *per se* may not fill our needs at any given time. Not every shot of even the most expert marksman is a bullseye. And we want nothing but bullseyes.

If you have a valuable idea don't fail to let us have it simply because writing is not your forte. If your literary style is not in accord with our standards it is very easily re-dressed. It is much easier to adapt some-one else's work than to give birth to new ideas. We are glad to re-write the crudest article which contains valuable information—or have some one else do it. It is the substance rather than the appearance

Digitized by Google

that counts. To see that good ideas are properly and attractively presented is the editor's job. You need not be a finished writer to be a helpful contributor.

However, waste of time may often be avoided if authors before writing articles complete will send to the editor titles and brief outlines of topics they are prepared to contribute. If articles of any nature or on any subject are not needed at the time, the labor of preparing them may thus be saved. Also if several contemplate an article on one subject the editor can designate one to prepare the article and the others may be called on for comments. Thus duplication of work is avoided.

When an article on a particular subject is requested of a particular individual it will be quite plain that the article is specially needed and will most probably be published.

Comments or discussions of articles will never be called for unless it is fully intended to publish them. Literary style and logical arrangement are of less importance in discussions than in capital articles. Therefore when your comment is invited, help the cause by sending it in promptly.

From time to time the editorial columns will indicate articles needed, and those who are in a position to contribute them are urged to volunteer.

It is desired that subscribers suggest subjects that would be of interest. Our journal can be a success only if it continually presents live matter of interest to us all. So tell us what you want.

Increase in Price of Subscription

DURING the ten years that have just passed the costs of all items which enter into the make-up of a magazine have greatly increased. In some cases they have doubled.

Due to legislative restrictions it has become necessary to discontinue the printing of the journal at Washington Barracks and to contract with a commercial press for the work, with a very decided increase in costs of issue.

This occurs at the very time when we are endeavoring to improve the quality and extend the scope of our work.

As a consequence of these changed conditions the publication of the magazine will cost henceforth from four to five times as much as heretofore. We are accordingly reluctantly compelled to make for the first time in our history a small increase in our subscription price, from $3.00 to $4.50 per year. This increase in price will by no means cover the increased cost of production. This can be met only by a large increase in the number of new subscribers and the increase in advertisements which will naturally follow.

It is the intention to secure these additional subscribers by issuing from now henceforth a magazine which no engineer who is interested in the national defense can afford to be without.

Civil and Military Engineering

IT will be the policy of THE MILITARY ENGINEER in the future, as in the past, to include in each issue articles on both civil and military engineering.

Division of articles into "military" and "civil" engineering does not mean that such articles are of interest solely from a military or from a civil point of view, as the case may be. Most of the operations of modern military engineering are adaptations of civil practice to military needs. Military experience broadens the viewpoint and develops the resourcefulness of the engineer; military necessity results in the development of new and ingenious methods. This military experience cannot fail to promote the development of civil engineering. All branches of engineering, civil, mechanical, mining, electrical, etc., find their application in military operations. No military engineer, therefore, can be indifferent to developments in civil practice, any one of which may be employed in the future conduct of war. And no civilian engineer, however highly specialized his work, can be indifferent to the possible application of his knowledge and experience to the service of his country in time of war.

The defense of our country is a duty which any engineer may be called upon to perform. It is a duty quite as important and always more urgent and critical than the development of civilization and the creation of wealth in time of peace.

The obligation of service to the flag involves the duty of preparing ourselves efficiently to perform that service. Accordingly every engineer who is also a patriotic citizen, is interested in all developments in the field of engineering which may find an application to warfare.

A National Military Policy

SOMETHING over a year ago the Armistice terminated the greatest military conflict that this world has ever seen. In the course of the struggle millions of men gave up their lives and billions of wealth were destroyed. As a direct consequence of the war dynasties passed away and new nations came into being. Normal economic processes were interrupted and the conditions of life which obtained before the War will never be restored. But in this interplay of cause and effect the controlling factor—the elemental force dominating it all was not destroyed. In spite of the ordeal through which it has passed, human nature still remains the same. Individuals will continue to disagree and nations will not always find their aspirations in accord. There is

Digitized by Google

small hope that the World War will stand for all time as the last war of mankind. Even now the peace treaty, not yet fully consummated, exhibits a tendency to take its place with other historic scraps of paper.

Our own nation has not yet fought its last fight. That "splendid isolation" which has been our vaunted first line of defense against a foreign foe has been destroyed. The appearance off our coast of hostile submarines, the crossing of the Atlantic by air and our own performance of transporting to Europe within a space of six months' time one and one-half millions of men, are powerful demonstrations of the military situation which now confronts the nation.

In the rapid march of modern progress in transportation and communication, time and space in a military sense have been all but annihilated. Scant opportunity remains for the creation of a nation's defenses after diplomatic processes have failed to achieve results. More than ever before in history national preparedness is an issue and it can not be ignored, but the question now is not one of principle but one of means and methods. The great conflict has brought home to all the fact that professional armies, however well trained, however well equipped and however numerous, short of the total national resources, cannot meet the ultimate demands of modern warfare. Nations at war must be in fact nations-in-arms and their war power can be nothing less than their total strength in men, in matériel and in an invincible will to win—"men, munitions and morale." Obviously, however, no nation can afford to keep its total manpower under arms at all times, nor, on the other hand, can any nation afford to dispense entirely with some force which shall serve to hold the outer lines in the first assault and to cover the mobilization of its reserves. Some organization must be maintained by means of which the nation may generate its full fighting resources.

The World War was not fought in vain, but the United States will have failed to fully consolidate its success if it does not adopt a rational military policy in keeping with the genius of the American people which shall insure a continued existence of the fundamental principles of the nation. By reason of the participation of all its people in war activities the country as a whole is now informed and interested in our foreign policies and relationships. Through the various associations formed during the War and which are still in existence, educated public opinion has a means for expressing itself. Scattered throughout the land is a body of thinking men who have had actual experience and who can make themselves felt in national affairs. The events of the last two years in which they have taken a vital part have made preparedness a personal issue with each and every one of them.

This body has already through the American Legion announced its military policy as one of universal military obligation, with equal opportunity for all, to be secured by a national citizen army based on universal military training. It is opposed to compulsory military *service* in time of peace and to the establishment of any strong military caste. It favors a citizen army capable of rapid expansion, organized into suitable tactical units, trained, equipped and officered before rather than after the commencement of hostilities. This policy includes a small regular army with a general staff composed of citizen-soldier officers and regular army officers in suitable numbers.

This policy is true to the ideals enunciated by the founders of the republic. It is in harmony with the constitutional declaration of faith that "A well-regulated militia is necessary to the security of a free state"—for, to the founders of the nation, "a well-regulated militia" was a citizen-army, trained, armed, equipped and instantly ready to fight in defense of the nation. The "militia" as a *word* was in fact nothing more than a colonial colloquialism for the citizen-soldiery of the national forces. The Spirit of Valley Forge was its soul and the Minute Man of Concord was its embodiment. Through the compromises necessary to consolidate thirteen independent states into one sovereign power, and to give life and force to the national motto "E Pluribus Unum," through circumstance and conditions not then foreseen and through persistent failure to appreciate that, in war, offensive action is the most effective form of defense, the word "militia" has been subverted from its primal meaning of a national soldiery to that of a local constabulary.

In the one hundred and forty years of its existence the sovereign rights of the nation as against the local rights of its component states, have been fairly well determined in all spheres of national activity except in that one sovereign right and duty, paramount to all—the right of national existence and the duty to take measures to maintain that existence. That right and that duty, in the crisis through which we have just passed, were exercised by destroying the arbitrary distinctions between regulars, militia, volunteers and the selective service levies—they were all one, the *Army of the United States.* The contention of our foremost military experts in favor of one national army and only one is founded on experiences, and is now supported by the opinion of the well-informed and thoughtful average citizen; for the American Legion is none other than that citizen, no longer mute but with a voice to be heard. Its policy aims to provide a single unified national defensive force as opposed to a heterogeneous aggregation of regulars, national volunteers, state forces and conscripted contingents secured in varying numbers under some form of compulsory service. It proposes to form an army of the United States, one and indivisible. In this endeavor it is entitled to the support of all who have at heart the best interests of their country.

The Military Engineer

THOUGH the fighting foot-soldier has ever been the backbone of armies, engineering has always played a major rôle in the conduct of war, and with the advances made in modern times in metallurgy, chemistry and the various other sciences and arts, it has become in some of its many applied forms a controlling factor in the progress of military operations.

There is a strong family likeness in all engineering work and in many respects construction behind the lines in the theatre of war does not differ greatly from that often conducted under emergency circumstances in time of peace, but the governing conditions under which the work is executed are radically different. The purposes in view are not the same and considerations enter in military work which rarely find their analogy in civil constructon. Besides his technical equipment as an engineer, his knowledge of strains and stresses, his familiarity with the characteristics and uses of structural materials, his experience in the management of labor and in the utilization of construction equipment and appliances, the military engineer must be thoroughly familiar with other subjects of which the civilian has little knowledge and for which he normally has little use.

The engineer in war must be not only a competent engineer and an efficient manager, but he must be thoroughly versed in the art of war. He must have a full appreciation of strategy and tactics; of the employment and effect of artillery and infantry fire, and must be able to devise measures which shall reduce or wholly nullify their destructive action. He must be prepared at all times to direct his construction talents in support of military operations against the enemy. A ready resourcefulness and an ability to substitute or improvise must be dominating elements in his professional equipment for his heavy duties.

The engineer who accompanies the combat troops into action is essentially a military man. In the face of the enemy, when the nation's honor or its very existence are at stake, military considerations are paramount and all operations of every nature must directly contribute to military success. This means that time is of the essence, which is the fundamental economic principle of military engineering.

His technical engineering attainments must be supplemented further by a knowledge of army regulations and governmental business methods, restrictions and requirements. He must know the duties and responsibilities of the various staff departments and the relations that they bear to one another and to the combatant forces in the field. The trained military engineer is thus at one and the same time a general practitioner and a specialist in the engineering field. He applies general engineering to the very special purposes of war under unusual and abnormal circumstances and conditions, as judged from a peacetime point of view. He does not, as is sometimes supposed, disregard economic considerations, but to achieve success he must realize that the economics of war are not those of peace.

While military engineering is a specialty, it is by no means an occult science whose mysteries only a gifted few may hope to solve. It knows no horizons—it recognizes no limits. Its field is coterminous with that of human endeavor, for there is no activity of man which does not find its application in war in some form or other. The civilian engineer, therefore, will encounter no insurmountable barrier to prevent his becoming an able military engineer, but it can not be done by the mere act of accepting a commission, or donning a uniform. There is no royal road to learning, nor is there an asphalt highway to knowledge of the military engineer's art. This can be acquired only by study and practice. The civilian, however competent he may be as an engineer, will find himself at a loss in the military machine unless he is also a trained soldier with a soldier's appreciation of military conditions. To take his place in a national citizen army the civilian engineer must train himself in time of peace to apply economically and efficiently his art in war.

If the country abides by precedent we shall always have in the permanent military establishment a force of engineers, but this body, on a peace basis, can never be more than a mere nucleus of that vastly larger number needed in a national crisis. Its object will be to keep alive the best traditions and practices of military engineering, to note developments in commercial and industrial life and to study their applications to the art of war. Not the least important of its functions will be to furnish a medium through which the great number of engineers from civil life may be instructed in the military phases of their profession and to provide a channel through which they may in an emergency be incorporated in the defensive forces, organized and assigned to those positions and duties in which they can render the maximum service.

The Engineer Officers' Reserve Corps, authorized by the National Defense Act of 1916, affords at present the most direct means of accomplishing these objects through military channels. A great many officers who served in engineering capacities in the National Army during the World War have applied for commissions. Others are known to be waiting on legislation and their future course will depend upon the action of Congress in respect to universal training and its effect on the reserve corps.

However, the Engineer Officers Reserve Corps is now reasonably able to respond to an emergency provided, of course, that it does not take on the dimensions of another World War. Due to the limited number of officers available for the multitudinous

Digitized by Google

duties of the Corps of Engineers, it has been necessary to conduct the examination of records and requests for consideration with an altogether inadequate force. An attempt has been made in each instance to tender the commission with a rank appropriate to the actual capacity and service of the officer concerned. Since the records are voluminous, though in many cases incomplete, the work involved in determining the proper grade for officers who were not formally recommended, but whose experience demonstrates suitability is enormous, and unfortunately has produced an impression of delay or indifference. Notwithstanding these adverse circumstances, steady progress is being made in this work of reorganization.

Under the law commissions in one grade higher than those held by them during the war may be offered to former officers whose records warrant it, and every effort is being made by the Board of Review to accomplish this in all appropriate cases without additional correspondence.

On the first of December there were about 3,185 reserve officers classified as to their availability for immediate duty with combat engineer troops, or for duty with certain specialist engineer organizations. This total was distributed in grades approximately as follows: 15 colonels; 70 lieutenant colonels; 300 majors; 850 captains; 850 first lieutenants; 1,100 second lieutenants.

Every reserve officer is urged to keep his correct address on file in the Office of the Chief of Engineers to the end that communications may reach him without delay. Under plans now being made, it is anticipated that information of value will be sent to these officers from time to time in order to keep them in touch with military developments.

A Society of American Military Engineers

THE war left its mark on the engineering profession as a whole, for in some capacity or other, in the government service or in the industrial world, at home or abroad, all took part in it. On April 6, 1917, when the existence of a state of war with Germany was formally declared, the engineers available for immediate military service consisted of 256 officers and 2,228 soldiers. In November, nineteen months later, there were in the Engineering Department of the United States service 10,886 engineer officers and 292,300 soldiers. There were in addition in the Ordance Department, in the Construction Division, in the Chemical Warfare Service and in various other branches of the Government, a vast number concerning whom exact data are not now available. The engineers of the country bore well their part and when the final record is written no page will be more brilliant than that which chronicles their achievements. They are justly proud of their service and their contributions toward the winning of the war are too well known to need comment here. They are vivid in the memory of all and many of their accomplishments are perpetuated in the form of structures and devices which, though created for war, will continue to serve the purposes of peace for all time.

By far the greater number of these officers and men have long since returned to their former less spectacular if more beneficent labors. Some few of these thousands of engineers came out of the war perhaps with a just grievance and a mental resolve expressed by the slogan "Never again." Improper assignments were undoubtedly made—the square peg did not invariably get to the square hole. Promotions were slow in coming and were not always made with even-handed justice. Now and again some regular officer whose rank had outstripped his judgment, "dressed in a little brief authority" took undue advantage of his position, but with the passage of time the disappointments, the resentments, the bitter memories have faded and their once sharp outlines have been softened in the happier recollections of great achievements. Distance has cleared the vision and restored the sense of proportion, and the citizen soldier now judges the army, not by the markedly inefficient nor yet by the conspicuously able, not by the most arbitrary nor yet by the thoughtfully considerate. He has begun to apply the law of averages—he realizes that the regular army man is neither god nor devil, saint nor sinner, but combines the attributes of them all and the composite result is an individual on whom the country may place its reliance.

The thinking citizen everywhere has come to realize that in deflecting an unprepared nation from the paths of peace to those of war, mistakes will occur, that war itself is a dislocation of the normal processes of thought and normal lines of endeavor, that it breeds mistakes and that unpreparedness, such as was ours before the war, serves to multiply natural errors and omissions. He now appreciates that, in consideration of things as they really were before the war, results, by and large, were not so bad after all; he experiences in his inmost soul a keen sense of gratification that it was his privilege to have taken a man's part in upholding the standards of a free people.

Under the wholesome reaction that has set in, the citizen soldier has ceased to brood upon the trials and tribulations of a day that is passed, and in the light of his experience has turned to the solution of new problems which now confront the country. His previous resolution to avoid all military service is directed instead toward the maintenance of personal preparedness to do his part should the nation again require his services, toward the formation and adoption of a sound military policy for the nation, toward preventing a recurrence of national mistakes and toward

Digitized by Google

so training coming generations as to spare them the painful and humiliating blunders of the past. "Never again" will his country face a great conflict in behalf of liberty and justice, unprepared, if he can prevent it.

But these thousands of officers and men are no longer in the service and there exists no distinct agency to unite them as engineers in their common purpose or to direct their efforts to a common goal. There are, to be sure, great numbers of engineering societies, each with its specific purpose, and all thoroughly imbued with the most patriotic spirit. These societies include within their membership those professional men who by virtue of experience and training are now qualified as military engineers or who may so qualify hereafter. But there is no society which concerns itself consistently with questions of military engineering and allied military activities.

There is, therefore, a pronounced need for a society or an association of American Military Engineers. The reasons for its existence are primarily of a professional and patriotic nature and secondarily, only, of a social or sentimental character. Its first purpose should be to conserve the teachings of the World War in the field of military engineering and to maintain unimpaired the assets represented by our late experience. Its policies and aims should be of a positive and constructive nature looking to the needs of the future rather than the glories of the past. Such a society will provide a common meeting ground for those who in a future national emergency must shoulder the engineering burdens of the country. It will furnish a medium for the interchange of ideas and for the dissemination of professional information of military character.

Steps have been taken to form such a society and it is hoped that those whom the supreme need of the nation once welded into an effective instrument for the vindication of its ideals and the preservation of its sovereignty will, now that the bonds of military compulsion have been dissolved, unite voluntarily to maintain the ties of a common experience and preserve the heritage of their service in the cause of freedom and democracy.

The Aeroplane in Surveying and Mapping

THE extent to which the aeroplane may be used in mapping and the methods of its employment have been subjects of much speculation amongst all who are interested in maps, and that means most engineers. Many have hoped that it offered a large measure of relief from the laborious methods we have heretofore of necessity employed, have hoped in fact that the butterfly would now take over the functions of the ant. In this issue appears an article by two well-known authorities on this important subject, which must be of great interest to all our readers.

Essayons

EVERY ENGINEER OFFICER in our service wears over his heart, as well as at sundry other points on his person, a button bearing the seal of the Corps of Engineers. This emblem of a distinctive service is the oldest in the army. Its origin and the circumstances of its adoption are lost in the unrecorded history of the early days of the nation though we know it came to us from France with that little band of self-sacrificing but practical idealists who accompanied Lafayette or followed in his train.

Amongst these were Louis le Begue du Portail, who was the first Chief of Engineers in our service appointed by act of Congress (though the third to occupy the post), and the gifted L'Enfant, to whose artistic genius and far-sighted faith in the young republic we owe the present beauties of the national capital.

In consideration of the scholarly attainments of these ancients, their mastery of speech and the leisurely politeness of the times, we may not doubt that the simple motto "Essayons" adequately represented their ambitions, but we may not doubt on the other hand that our literal translation "Let us try" lamentably fails to express their high-souled hopes as signally justified by their actual achievements.

For them "Essayons" was not a mere polite phrase, it conveyed no sense of weak irresolute endeavor, it carried no suggestion of possible failure. It stood for a living fighting force, a determination to win through at all costs. Its real spirit was "let us try, we will not fail; let us do, and it will be done."

Our motto, "Essayons," has served the Corps of Engineers through long years of earnest endeavor and consistent achievement. We cherish it for its associations, for the memories it evokes, for the examples it calls to mind of engineer officers of other days who have essayed and won.

But fashions have changed; the lumbering coach-and-four has given way to the luxurious auto-limousine; the stately minuet has been replaced by the romping jazz; politeness has succumbed to "pep." While the spirit may be the same the polished phrase of other days has been done to death by the demand to "make it snappy."

During the past five years the French have had slogans, the verbal manifestations of their unconquerable spirit, breathing sentiments and determinations far above the simple "Essayons" which served their forebears and ours. The spirit is the same but finds its expression in other terms. In August, 1914, Viviani said, "We are here without reproach, we go forward without fear." At Verdun there came through set teeth, "They shall not pass." There was no hesitation, there was here no "if possible," no idea of "let us try,"—and trust to luck.

It is related that during one of the first engage-

Digitized by Google

ments of the American Expeditionary Forces, when the Germans were raiding our lines north of Toul, a French battery was sent in by the high command to support the regimental sector then being harassed. Around the American P. C. there was great excitement and confusion. The general locality was being "strafed," couriers rushed in and out, telephone messages gave garbled and exaggerated reports of the situation. The "buck-fever" of the tyro held sway for the moment.

The French battery came down the road, halted near a clump of woods while the French captain rode up to report at the American P. C.

The Frenchman stepped into the confused little office, stood quietly till he caught the eye of the commander, then saluted smartly and said "Nous sommes arrivés, mon Colonel." The youthful American colonel stammered: "Why yes, of course, we are glad to see you. A little bit hot around here." The Frenchman stood silent a moment, then said, "Positions?" The Americans collected their wits and showed him where they thought the guns could go. This determined, the Frenchman said, "Echelons?" They then showed him the places for picket lines, kitchens, etc. He then said, "Munitions?" and they told him he could draw ammunition supplies from the artillery munition dump. Each of these localities the Frenchman noted on his map. He then saluted, saying briefly, "Etendu" (understood), and left. Quietly, yet quickly, and in a manner that put calm and confidence into every American officer, this single French captain completed his work.

Now the only thing that the Frenchman said when he got "his job" was, "Understood." In English he might have said, "Very good sir." His short words, his alert attitude, inspired instant confidence. There was no doubt in his Commander's mind that the work would be done. He did not say, "I shall try," he did not raise in the mind of his commander a doubt as to his ability and full intention to do his task.

At one of our new division camps at the outbreak of the war the division commander called in his division engineer. "Now Colonel," he said pleasantly, "what is your regiment prepared to undertake?" "General," replied the young colonel, his lip trembling a little, "we will *do* anything you tell us to do."

In one of the branches of the engineer department there is a certain civilian employee, an old timer, who enjoys the enviable reputation of never admitting that there is anything he cannot do. He says that on a certain occasion his commanding officer asked him if he could perform a certain very difficult task. He was about to respond, "I shall try." Just then a large moving van rumbled past, and on its side, in enormous letters was the boast, "We move *anything.*" "Right there," says our friend, "I took for my motto 'I *do* anything.' They never ask me if I can do things now. They just tell me to go ahead." This man has apparently progressed beyond the "Essayons" stage.

The Corps of Engineers was created and is maintained for the primary and essential purpose of furnishing able military engineers for service in war. All of its activities and all of its work in peace time are the necessary means to this end. It is not enough that these officers should be men who will try, men who can be depended upon to do their best. They must be, and must be known to be, men who can and will "deliver the goods" in any circumstances. When the commander gives his engineer a task it is not enough that he should believe the engineer will *try*, or even that he will do it *if possible*. He must know absolutely that *it will be done*, and done promptly, efficiently and thoroughly; that if it proves impossible it will still be done, "because I told my engineer to do it."

We believe that the motto of any association of men should express its highest aspirations. Does not the literal translation, "Let us try," fall short of our ideal? Does it not even fall short of what *we have done* and *can do?* Do we need a higher ideal as the goal of our efforts?

Training for the Engineer Officers' Reserve Corps

THE National Defense Act of 1916, which established a Reserve Corps of officers of various arms of the service, prescribed that these officers should receive such training as necessary to fit them for the performance of their duties in case of war or other emergency.

The Engineer Officers' Reserve Corps was established and enrolled promptly upon the passage of the Act. Although our country was then at peace, the engineering profession responded to the call in numbers and with an enthusiasm that was most gratifying to those who have cherished a pride in the patriotism of the engineer. Many of the most eminent men in various branches of the profession applied at once for commissions. These applications continued to arrive in constantly increasing numbers after the declaration of war, until the Chief of Engineers was embarrassed with the wealth of talent placed at his disposal. The Engineer Department entered the war better equipped with available commissioned personnel than any other branch of the service.

The work done by the Engineer Reserve Officers during the war is now a matter of history and is a record of which the profession may well be proud.

When, in August, 1918, the various military forces were combined as the U. S. Army, the Reserve Corps as a distinct organization ceased to exist. Up to that time, 7,189 commissions had been issued in the Engineer Officers' Reserve Corps. In November, 1918, there were 11,174 engineer officers in the army, and during the period of the war nearly 14,000 origi-

Digitized by Google

nal commissions as engineer officers were issued.

Now that the war is over, the Engineer Officers' Reserve Corps has been re-established. It is no new, untried organization. It has behind it a glorious history, and a record of patriotism, devotion to duty and splendid achievement. Most of the men now in the corps took part in the war, where they all rendered meritorious service. The number already commissioned exceeds 3,000 and is constantly growing. Many other engineers are awaiting legislative action, establishing a definite policy with reference to our reserve forces, before making their applications for commissions. The prospects of such legislative action are excellent. (See Synopsis of Army Re-organization Bill elsewhere in this issue.)

So much for the present situation. What is to be the future policy with reference to the training of this corps? Many of its members, as we have pointed out, have already been well trained in the school of actual war. But we are not content to rest on our laurels. We live in a world of progress and we must "carry on." Moreover, new men, with no previous training in military engineering, will join in large numbers.

The War Department fully appreciates its responsibility in the matter. It must furnish the incentive, the leadership and the guidance necessary to reap the fullest benefits of the time and effort that will be given by the patriotic citizens who will constitute the reserve forces on which we must rely in the event of war. The Training Branch of the General Staff is now perfecting a policy and devising ways and means for the proper training of the Reserve Corps. These plans are not yet fully matured. As a first step, however, they contemplate the issue of instruction literature by the Training Sections of the various services at the War Department, in co-operation with the Service Schools at Fort Leavenworth, Camp Humphreys, etc. In this manner much valuable instruction may be given.

For engineer officers of the reserve corps no instruction in engineering is contemplated, since these officers are well versed in this subject, as they proved during the war. What is needed is instruction in military matters and the tactical application of engineering science.

To meet this need of the Engineer Reserve Corps for military training, which will enable them to apply their professional knowledge and experience to the best advantage of the National Defense, is one of the chief functions of the Society of American Military Engineers and of this periodical.

Our columns will contain articles and digests on military and engineering subjects which will be of special value to the reserve officer. Plans are under way for the establishment of a department of matters of particular interest to the reserve corps, which will be published in such manner that they may be clipped and filed for reference. It is contemplated to issue instruction courses similar in form and substance to the "Engineer Field Notes" of the American Expeditionary Forces, but of still wider scope.

To carry out these comprehensive plans is no small undertaking. It will require continuous and persistent effort in the face of difficulties. The contributions to our columns represent the voluntary effort of officers and others, all of whom have regular duties which require a full day's work every 24 hours. We shall need the support and assistance of all our subscribers and, in particular, we need the support and assistance of the officers of the Engineer Reserve Corps themselves. With this support we shall "carry on" to success and usefulness in promoting the efficiency of the Engineer Officers' Reserve Corps in the interest of national security and independence.

In this issue is a synopsis of a Bill for Army Reorganization, which will be presented to the Senate in the near future.

It is characterized by Secretary Baker as the most statesmanlike military legislation ever introduced in Congress, an opinion in which the army will concur.

It is gratifying to note that the lessons of the war and the advice of military men have not been wasted upon Congress.

Promotion by seniority from a single list, with elimination of the unfit, is approved by the vast majority of army officers, even including those who have hitherto favored promotion by selection in some form. It will be incumbent upon the army itself to justify the wisdom of Congress by an effective application of the law.

This provision will do more to eliminate hurtful politics and mutual jealousies and distrust, and to promote good feeling, efficiency and hearty co-operation amongst individuals and between different branches of the service, than any other which could have been devised. Most of the discontent, the jealousy, bitterness and recrimination, which have been known in the army, are due to the utterly unreasonable inequality of promotion, which the present bill would forever remove. The army would work as a unit, shoulder to shoulder, all moving forward with a common purpose and mutual interests.

A regular standing army of moderate size, and an effective reserve, created by Universal Training, are in accord with the lessons of experience and the advice of all military experts. They would give us for the first time in our history a sane, economic, fully effective military policy, as a sure guarantee of national independence.

Perusal of the provisions of this bill puts new hope into the flagging soul of the Army. To the apathy towards all things military which has followed the war, the efficiency of the Army, the Nation's only sure guarantee of law, order and independent existence, is being rapidly sacrified. The best of its personnel is swiftly melting away, under the cruel economic pressure forced upon them by the Nation's indifference towards the maintenance of its defenses. The morale of those who remain is rapidly approaching the vanishing point. Strong, resourceful, self-reliant men, the only men who can carry out the will of Congress in establishing an effective defense, are not content to live in poverty and uncertainty, deprived of everything which makes life worth the living. Men of this type are leaving the services by thousands, those in civil life cannot be attracted to the services under present circumstances.

To correct these deplorable conditions, to re-establish our shattered defenses before they are utterly destroyed, two important but simple measures are necessary: the enactment into law of this bill providing an adequate military policy, and the provision of a decent living wage for the nation's defenders. These measures, if not too long delayed, will save what remains of the wreck and insure its ultimate rehabilitation. But during every day of delay the Ship of State continues to pound on the rocks and suffer injuries which threaten its ruin. Shall our National Defense be sacrificed to a penny-wise economy? Is it a useless extravagance which should be eliminated? We believe that the American people, however great their apparent apathy, in the reaction from the war, will never again approve a makeshift, haphazard and niggardly policy of National Defense

"Through Military Channels"

By

Col. Ernest Graves

Engineers, U. S. A., formerly Section Engineer
Advance Section, S. O. S., A. E. F.

THE recent war was a most illuminating experience. The acid test of actual contact with a strong and resourceful foe dissolved many finely drawn pronouncements of the school room and many of the illusions evolved during a long term of peace. There is, however, one pernicious feature in the practice of the Army of the United States which appears to have gone unscathed, and is the more noticeable since the war did so much to improve army methods generally. In the matter of army correspondence procedure, that is to say the routing and handling of written matter, there appears to have been a retrogression rather than an advance.

In the groove (or rut) known as "military channels," a written communication must always pass from a subordinate through his various superiors to its final destination. As a matter of theory, the reason usually given for this requirement is that thus the superior is enabled to be familiar with what is going on. As a matter of fact, the only reason for following such a method is to maintain loyalty between subordinates and superiors. Theoretically, if a subordinate is not permitted to communicate except through his superior, no action can be taken without the recommendation of the superior. The two reasons given above are fundamentally wrong. The passing of a mass of written detail through the office of a superior does not keep him informed of what is going on. It has a tendency to do just the opposite; that is, to befog the vital issues or conceal them in a mass of unintelligible detail. Likewise, the routing of official communications can not keep loyalty where it belongs, because when a subordinate really wishes to overstep certain superiors, he simply addresses his communication "Dear Bill" or even "Dear General." The correspondence is then "privileged," and "Dear Bill" is so touched by being thus affectionately addressed that he has not the heart to do anything but answer in the same way. In addition, he is generally very glad to get information that he can rely on and that is not camouflaged under the courteous language of strict military etiquette.

In our operations in France, all the various organizations of supply, construction, and transport became so large that business simply could not be done under the old, out-of-date rules of correspondence. Nevertheless, people who were continually trying to get things done were always hampered by these rules and attempts to enforce them. The people who had common sense simply disregarded rules. Those who did not, suffered, or caused others to suffer, on account of the delays of correspondence.

One of the most conspicuous examples of the unworkability of the time-dishonored system of communication in the army was the relation in France between General Headquarters and the Advance Section of the Services of Supply. The Headquarters of the Advance Section, S. O. S., was at Neufchateau; G.H.Q. was at Chaumont, lying in the Advance Section, S. O. S.; Headquarters of the S. O. S. was at Tours. So, according to the Army system, when G. H. Q. wanted a sprinkler cart to sprinkle the dust down in front of the office of the Commander-in-Chief, word to that effect was sent to Tours, where it was relayed up to Headquarters, Advance Section, S. O. S., where in turn it was referred to the Section Engineer, Advance Section, who thereupon sent it to his local representative in Chaumont. By the time the sprinkler heard the news, it had rained and no sprinkler was necessary. This, of course, sounds extreme, but is an actual instance and serves to show the ponderosity of accepted methods governing army correspondence and the transmission of orders.

Whenever a general staff officer in one of the large headquarters received anything urgent, he did not dare entrust it to correspondence. Generally, he cut all channels and telephoned to the person who needed the information. One instance occurred in which a phone message put an officer on the lookout for necessary data, and he waited eight days for the letter with the data to pass through one headquarters. In another instance an officer was heard demanding of a messenger an explanation of the reasons why it had required seven days for a communication to pass from his hands to those of his chief clerk, who was in the next room.

In many instances the normal peace-time rules of routing correspondence were changed, but they were not sufficiently revised to permit business to go on without unnecessary and often disastrous delays. The fellow who was wrapped up in his job and was simply breaking his neck to produce results, found a large percentage of his time and ingenuity devoted to get-

Digitized by Google

ting through and around the rules of procedure which would wreck his job if he did not surmount them.

In addition to reform in prescribed military channels, there is vital need of revision in the manner of handling letters and indorsements. Necessary reform involves training of staff officers as well as general education in the army in the use of letter-writing. Since the typewriter came into common use, the waste of paper and ink and time has been enormous, and the proper performance of work has been really seriously injured without the seriousness of it being realized.

Our new staff organization came as a result of a vital need and it has come to stay. However, as yet, our officers have not generally become expert staff officers in the matter of correspondence, and it is very necessary that this feature of their training should not be neglected. The fellow who simply sits at a desk and is satisfied to pass papers along, should be eliminated. He should be taught that wherever possible papers should either be returned by him or put into the waste-basket. If he does not know enough to eliminate a large percentage of the useless correspondence that travels, he does not know his "job."

The fundamental reason for the passing round of letters that are either aimless or that request information, or require minor decisions, is the disinclination of an officer to accept the responsibility of giving a definite answer, no matter how unimportant the information or the decision required. This human weakness should be combatted in every way possible and certainly our Army officers ought to have it educated and trained out of them.

The average staff around the various headquarters during this war was much too large, and the members kept themselves busy by writing to each other, and by requiring the fellows in the field, who were trying to get work done, to render voluminous and useless reports that the staff could not understand. Usually, by the time the reports arrived, they were too late to permit of any correction in the method of work or in the kind of work being done. As histories, they are useless because the man in the field soon learned that they were often not even read, much less understood and he very properly devoted his energy to getting his work done rather than to composing eloquent eulogies on it.

All of the foregoing destructive criticism is of little value without some kind of constructive scheme of correction which is practical. Effective correction is very difficult to suggest. However, the following principles should be laid down in a general order and all officers should be urged to thus educate and train those under them. The principal reason that subordinate officers do not assume their proper responsibility is that superiors do not encourage or permit them to do so.

(*a*) Useless letter writing should be stopped by all commanding officers, who should instruct those under them never to send a letter without closely scrutinizing it to determine if it is really necessary for higher authority to be thus addressed in writing. Letters should never be written where the matter can be settled by personal conference.

(*b*) Staff officers are placed in their positions for the purpose of properly acting on papers received by them and they should never pass a letter on because they do not know what else to do with it. When necessary to forward a communication it is their chief function to know the exact place where the subject-matter of the letter can be attended to and to send it there by the shortest route. When useless letters are received they will be returned with censure. If offenses of this kind are repeated, disciplinary action will be taken.

(*c*) Where the subject-matter of a letter is such that the opinion or judgment of superior officers should be expressed, the communication should be forwarded through these superiors. No letter requiring a decision will ever be forwarded without a recommendation by each officer who signs the original or an indorsement. An officer will never forward anything upon which he can act himself. Where the subject-matter of a letter is such that a superior is not interested, the letter should go direct to the person most concerned. If a superior would be interested indirectly as a matter of information, a copy should be sent to him.

(*d*) The foregoing method of procedure must not be used to keep information away from a superior or in any way to promote disloyalty. A properly supervised organization can keep loyalty and information in proper channels without slowing up necessary business with cumbersome and clogging red-tape.

Of course, the above instructions must be followed up by a real and active supervision to stop viciously useless letter writing and to produce an actual improvement in military business methods. Every officer in the Army must shoulder his own responsibility, make his own recommendations, and be on the alert to keep himself from "passing the buck." He must likewise not permit his subordinates to pass the buck to him. In other words, let the Army, in this day of education, launch a campaign to teach its officers to shoulder each one his own responsibility and to assume all the responsibility that he can acquire, even if he occasionally gets into trouble by so doing. Keeping ourselves out of trouble is not, after all, our principal function.

The Key Bridge Cofferdams

By

John T. Talman
Assistant Engineer, U. S. Engineer Department at Large

THE Key Bridge (named after Francis Scott Key), in process of construction at Washington, D. C., is to extend across the Potomac River from Georgetown, D. C., to Rosslyn, Va. This new structure, being built by the United States Government to replace the old Aqueduct Bridge, is to be a concrete-arch bridge composed of seven spans varying in length from 85 to 208 feet. The total length of the bridge, including approaches, will be about 2,700 feet, and the length of the masonry structure proper about 1,450 feet.

The width of the deck from out-to-out will be 70 ft. 6 in., which allows for a double-track electric line, two 16-ft. roadways and two 8-ft. sidewalks.

The bridge will also be provided with two conduits located under the sidewalks in which cables, gas and water mains, etc., may be laid. The height of the deck of the bridge at mid-stream will be about 85 feet above mean low water, which will give an under clearance of 72 feet at the center span.

The plan shows alignment of the bridge and location of the four river piers. These piers are designed as abutment piers and are being founded upon solid rock. Prior to construction careful examinations were made of the foundations at the site of each pier and abutment.

This examination consisted of a series of soundings and probings taken on, and parallel to, the center line of the proposed structure from shore to shore. After the spans were decided upon, a floating template, the size of the proposed cofferdams, was placed at each pier position and three sets of soundings and probings were made around it. Borings were also made at each end of each pier position and a core removed to a depth of 20 feet into the rock.

The depth of water at these pier locations varies from 24 to 35 feet at mean low water, the average tide being about 2.9 feet. Floods in this river are not frequent, are of short duration and seldom raise the water level more than 6 feet above M. L. W.

The method of constructing these piers was given most careful study and it was finally decided to build them in open cofferdams. These cofferdams are timber frames surrounded by steel sheeting sealed to the rock bottom. The timber frames were erected on the Virginia shore upon launching-ways. They are 103 feet long, 45 feet wide and 24 feet deep, and composed of three longitudinal trusses 101 feet long and 24 feet deep, separated by series of 12 by 12 timbers, and two end-trusses 45 feet long and 24 feet deep, all connections being through-bolted. The reason for trussing these frames was to give them greater rigidity and prevent any chance of distortion in handling them from the ways to their location in the river.

These frames are supported upon nine shoes about 12 feet long, 3 feet wide and 2 feet high, each furnished with two sets of cast-iron rollers connected by steel axles. The rollers turn in grooves cut in the bottom of the shoes and drop off as the frame leaves the ways. They are later recovered and used again under the next frame. The rollers run in 7-inch channels spiked to the timber-ways. The shoes also function when the frame is in place by holding the lower timbers off the uneven bottom, thereby making it easier to level-up the frame.

These frames, after being launched, were lifted clear of the bottom by means of a scow at each end, and towed to their proper locations.

After being lowered into position and blocked up level by a diver, their height was increased 10 feet by superposing additional frames.

The sheeting of these coffers consists of ordinary 12-inch 31½-pound I-beams interlocked into two 7-inch channels, separated by wood filler blocks 5⅛-inch by 5⅛-inch in section, securely bolted together.

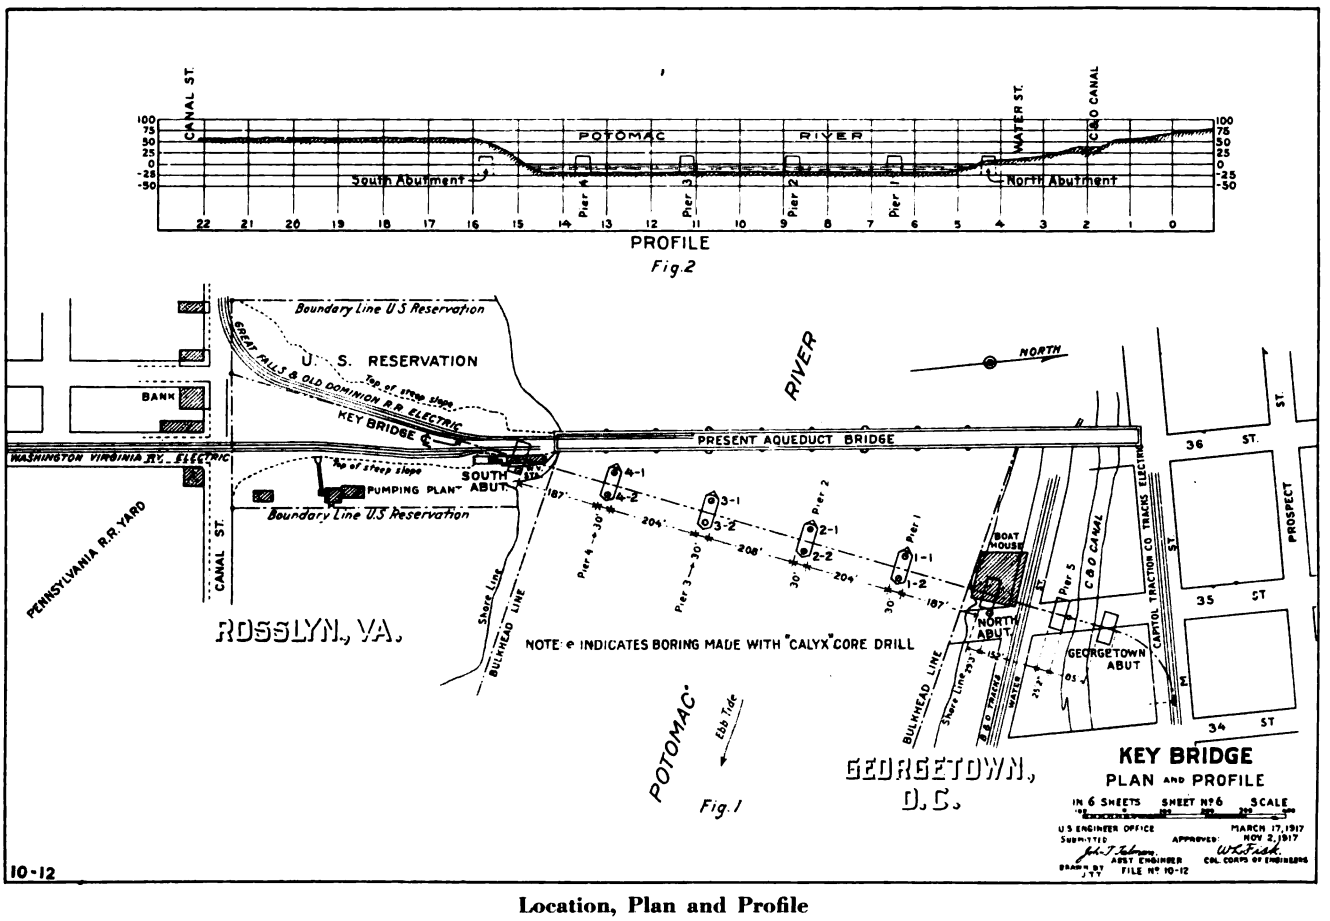
This sheeting was placed by a derrick-boat with swinging pile-driver leads. The sheets required very little hammering to force into place, as the small amount of mud that overlaid the rock had been removed by dredging prior to the placing of the frame. The only driving that was necessary was enough to overcome the friction of the interlock; many sheets dropping to place of their own weight.

A diver watched the sheets at the bottom to see that they hugged the frame and about every fifth sheet was secured to the frame at the top. About fifty sheets were placed in a single day of eight hours. At the corners 12-inch I-beams, bent 90 degrees, were used. The closures were formed by using wide channels bolted together and filled with concrete after being driven. Practically all the steel employed as

Digitized by Google

sheeting will be used later in the construction of the deck of the bridge.

The sealing of these dams was done by divers, and consisted in placing a sand-bag wall around the outside of the dam, about 4 feet from the steel. The top of this wall was brought up about 2 feet above the bottom of the steel sheets. The rock bottom of the trench formed by the bag wall and the walls of the dam was cleared of mud, sand, etc., by the use of an air jack or siphon.



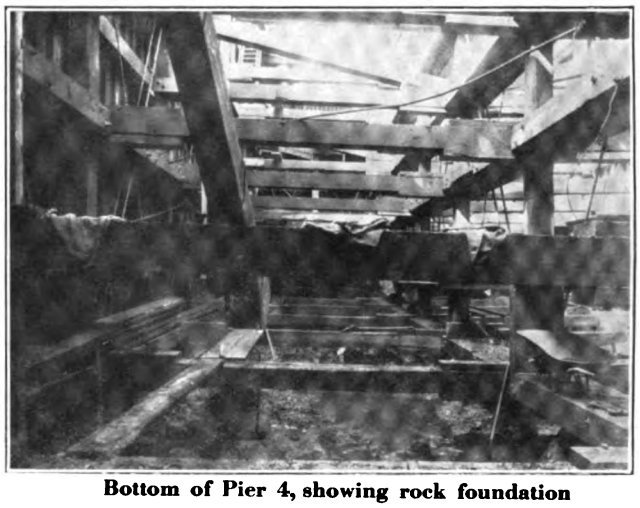
An air-jack is a long piece of 6-inch malleable pipe with a small air-pipe leading down outside to the bottom of the larger pipe and turned up into it. The jack is floated at its upper end just above the water and the air or operating end is moved from place to place by the diver. Compressed air is forced down the air-pipe into the base of the jack-pipe and lifts water, sand, mud, and even large cobbles to the discharge end. It is in effect a siphon.

As soon as the trench had been thoroughly cleaned, wedge-shaped forms, about 12 inches deep, were placed all around the dam, the forms being suspended by wires with their tops at the same level as the top of the bag wall. The trench was then filled with concrete placed through a trémie on a scow, the movements of the trémie being regulated by the diver. As soon as this concrete had set-up sufficiently, the wedge-shaped forms were removed and this groove was packed with a row of sand-bags. Upon these sand-bags rolling mats were placed. These were composed of canvas in long rolls, filled with straw, old burlap, manure and such other materials as could be secured at the time. The mats were about 12 inches in diameter with a flap 3 or 4 feet long. These rolling mats were placed as close to the steel as possible with the flap extending out over the concrete seal and weighted down with sand-bags.

The object of this pliable wedge was to take up the give in the timber frame caused by the pressure developed during dewatering. This inward movement would cause a crack to develop between the steel sheeting and the concrete seal.

As soon as the seal was perfected the pumps were started and cinders were dropped in small quantities down the outside of the sheeting. These cinders were drawn into any small leak that developed either in the sheeting or in the seal. The seal was then tested out for some time before any mud was banked around the dam, and on the dam just dewatered a head of about 15 feet was secured without any banking.

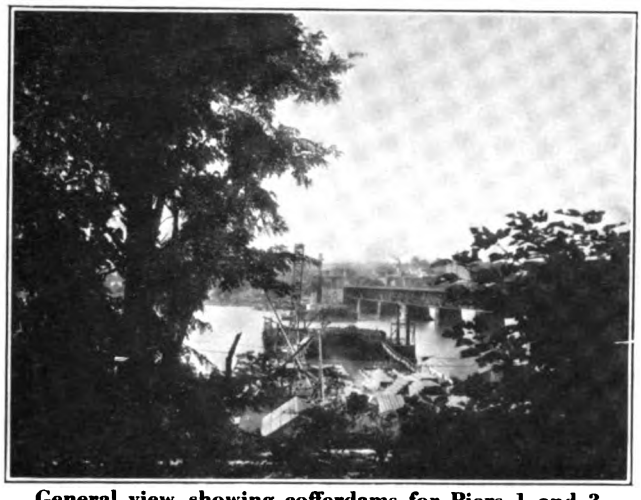
When the pumps had produced sufficient head on the dam, the diver made an examination of the seal and, at the same time, an examination was made by the use of a current-meter inside the dam to detect the location of leaks. These leaks are usually caused by sand or gravel deposits in rock seams, and may



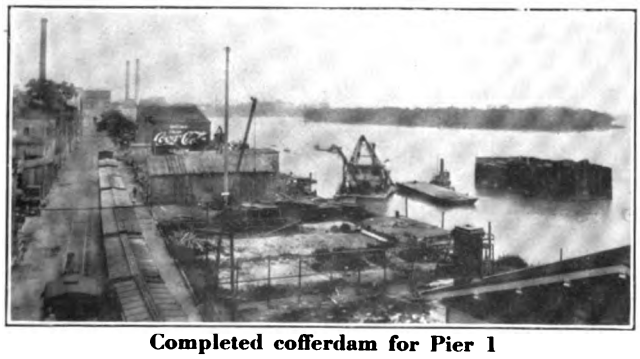
Location, Plan and Profile

Digitized by Google

Cofferdam-frame on ways ready for launching



Bottom of Pier 4, showing rock foundation



extend far out from the dam. The hardest leaks to detect are bottom leaks. So far they have given no trouble in these dams, but there is kept on hand a compressed-air grouting machine ready to meet such a condition should it arise.

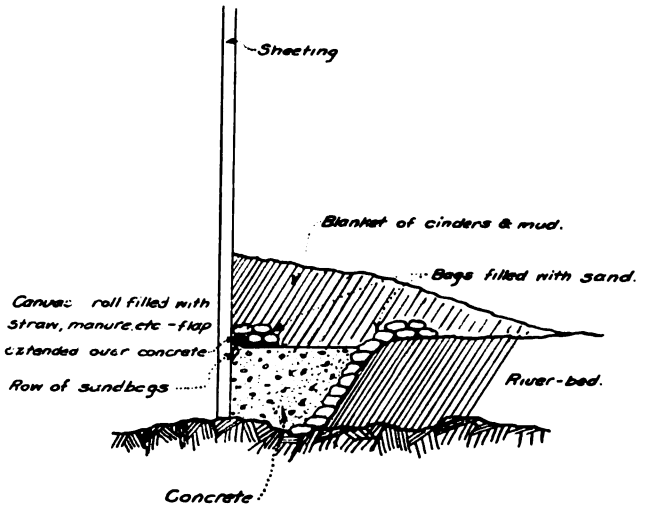
After the test of the seal, a mud bank from 6 to 10 feet high was placed around the dams.

The pumps used were two pulsometers and one Emerson steam pump. The Emerson pump has a capacity of 2,000 gallons per minute, one pulsometer 2,200 gallons and the second 750 per minute. The steam for these pumps is supplied from two 125-horse-power portable boilers, mounted upon a scow.

General view, showing cofferdams for Piers 1 and 3 and Pier 4 almost completed

Completed cofferdam for Pier 1

Three dams have already been placed and pumped out. The shortest time required to dewater a dam was in the case of No. 3, which was eleven days from the time the pumps were started. No. 1 dam required four weeks and No. 4 required 6 weeks.



Immediately after the dams had been dewatered, forms were placed 2 feet inside the lower wales, the rock thoroughly cleaned off and an inner concrete sealing ring placed. This ring extends from the rock to the under side of the lower wale and canvas was placed wherever possible against the steel sheeting to prevent the concrete from bonding with the steel and making the pulling of of the sheeting difficult.

Wherever lateral leaks existed, the water was carried through the inner seal by wood boxes or conduits, the concrete being poured around them, and when the concrete had set the conduits were plugged.

When the inner seal was completed the sealing forms were removed and the entire bottom of the dam was thoroughly cleared of mud and loose or disintegrated rock, and the surface scoured. The foundation was then ready for the base course of the pier which was poured up to the lower waling timbers. Above this point forms were set up and the pier was poured in the form of blocks 12 feet high between the timbers. When these blocks had set, the pressures on the lower section of the dams were taken by strutting against them and the lower inner timbers were removed. The space between the blocks was then filled with concrete and this process was continued to the top of the dam.

It has been found that the steel sheeting in these dams pulls remarkably well and is in excellent shape after using. Dam No. 4 was pulled and the steel redriven around Dam No. 3 without the loss of a single sheet and the frame re-erected for Dam No. 2, there being but few broken timbers requiring renewal.

Digitized by Google

Method of sealing cofferdam
Width of concrete, about 3 feet. Height is great enough to care for inequalities in height of bottom of sheeting.

These cofferdams have, to date, shown absolutely no indication of failure in any respect, although very roughly handled. This work, like all cofferdam work, required an infinite amount of patience.

At the time of writing pier No. 1 is completed above the water and the cofferdam sheeting is about half pulled; cofferdam frame No. 2 is in the river, but not yet placed; cofferdam No. 3 is dewatered and part of the inner seal is in place, and pier No. 4 is completed nearly to the deck and the cofferdam all removed.

This work is being done by day labor and Government owned plant.

[No special difficulties appear to have been encountered in this work, but it is a good example of standard practice in bridge-pier construction. No pains were spared to secure tight coffers and the results evidently justified the effort.—ED.]

New Infantry Howitzer for Army

The Infantry-Cavalry Equipment Board has, after careful study, determined the requirements for an Infantry accompanying gun. The requirements have been approved by the Chief of Staff and have been sent to the Chief of Ordnance for development. In order to avoid confusion the gun will be known hereafter as the Infantry howitzer and it will take the place of the 3-inch Stokes mortar and the 37-mm. gun, being arranged for both high angle and direct fire. It is believed the caliber will be about 2.75 inches and the range approximately 3,500 meters.—*A. & N. Journal.*

Light Mortars as a Cavalry Weapon

Stokes mortars and a moderate amount of ammunition (12 shells per load) may be carried on pack animals. Accordingly these weapons will be exceedingly useful for the exploits of mobile forces of cavalry, which are by no means obsolete for all time because they found little application in the World War.

An enemy intrenched can hold off cavalry armed only with rifle and machine gun. Perhaps they cannot even be reached by direct fire of artillery. But the Stokes mortar can seek them out.

The following equipment to accompany a squadron is proposed by an officer of the Indian army:

1 pack animal, gun and mounting.
2 pack animals, 24 rounds of ammunition.
3 pack animals, 36 rounds of ammunition.

Wireless Telephone in War

Prior to the European War no application of wireless telephony to military operations had been made. The most urgent demand for it is in aeroplane communication. Its disadvantages for this purpose are the weight and complexity of the apparatus and the lack of secrecy, but these are more than compensated by the speed of communication and the fact that the aviator need not be familiar with the difficult telegraph code.

The aeroplane wireless telephony set was developed by the Western Electric Co. under direction of the Signal Corps. The development proceeded rapidly. Several experimental sets were issued, great improvements effected and success was regarded as assured, but at the time of the armistice quantity production was not yet in process. Training of aviators for "voice command," using the experimental sets, was in progress, and excellent results had been obtained.

An interesting history of this development is given by Col. N. H. Slaughton (formerly Signal Corps) in *Journal of the Franklin Inst.*, Jan. 1920.

Gas Masks in Mining and Manufacture

The gas mask, a product of the World War, seems destined to a great field of usefulness in commercial life. In mining and mine rescue work a light, properly designed gas mask can take the place of the cumbersome oxygen helmet. In many industries it may be used to protect workers from noxious gases and fumes, thereby greatly increasing their output. Recognizing these possibilities of usefulness, the U. S. Bureau of Mines has established a gas mask department at its Pittsburgh Experiment Station, where masks will be developed for industrial purposes.

Placing Bridge Girders without False-Work

Mr. S. W. Connor, in the *Canadian Engr.*, (Jan. 8) describes an interesting method of placing bridge girders across a deep ravine, without falsework. The girders were of the latticed type, 108-foot span. The entire span of two girders with lateral members, was assembled and riveted on the bank. A pair of triangular trusses, 60 feet long with cross bracing, called a "pilot," was then bolted to the forward ends of the girders proper. The first pair of girders, with pilot attached was then rolled out from the first pier, the pilot reaching the second pier before the center of gravity of the whole had passed the first. Subsequent girders were then rolled along the tops of those already set, and jacked down into place. The reinforced concrete was then placed. The method was apparently entirely successful.

Concrete Blocks for Road Cost

A British engineer states that sheet concrete roads are unsatisfactory because of the length of time required for the concrete to set, and the difficulty of repair. He recommended the use of concrete in the form of blocks (analogous to clay bricks) as the remedy for these difficulties.

Engineer Construction in France

Continued from Page 8

By Lt. Col. J. A. Woodruff, C. E.; Discussion and Comment by Maj. Gen. W. C. Langfitt, Maj. Gen. M. M. Patrick, Brig. Gen. Edgar Jadwin, Col. J. B. Cavanaugh, Col. Ernest Graves, and an Extract from the Final Report of General Pershing.

in the intermediate section, each with 4,000-bed convalescent camps, including road, water, sewerage and lighting facilities, and other features necessary that the projects might function as full grown municipalities. Each of the twenty 1,000-bed units was entirely self-contained and provided for the functioning of a completely equipped hospital, in addition to the buildings for administration and quarters for the operating personnel. In each unit were 20 ward buildings, in addition to kitchens, dining rooms, store rooms, operating buildings, laboratory, morgue, baths and personnel quarters; a total of 58 buildings per unit.

Work on the Mars hospital project was commenced February 23, 1918, and was 60 per cent complete when stopped by the armistice on November 11th. At that time 700 buildings, covering a floor space of 33 acres, had been completed and 14,000 wounded and sick American officers and soldiers were housed in comparative comfort, and provided all the facilities of a great modern hospital. In the specially designed operating rooms the most delicate operations of modern surgery could be undertaken with as much confidence as in the best appointed hospitals in the United States. The provision of these facilities necessitated the construction of a water-supply system, involving a 10-inch pipe-line 5 miles long and a 100,000-gallon reinforced-concrete reservoir; 6 miles of standard-gauge railroad; thousands of feet of concrete sewer pipe, and a 15,000-volt transmission line 11 miles long; maximum labor employed, 4,152 men.

In its scope and general layout, the hospital project at Mesves was practically a duplication of the 20,000-bed base center at Mars. Access to the site was provided by the construction of 3 miles of standard-gauge railroad, and on April 23, 1918, the first train-load of material was unloaded. At the time the armistice was signed, more than 4,000 car-loads of construction material had been delivered and quarters had been provided for over 20,000 patients. An idea of the magnitude of some of the work involved may be obtained by considering the fact that the water-supply system necessitated the laying of 28 miles of pipe, about the same amount also being required in the sewer system. In November, when operations were curtailed, a total of 45 acres of concrete floors for barracks had been laid and no less than 23,000 windows, containing 270,000 panes of glass, in place. The maximum amount of labor was 5,184 men.

The story of the Mesves project is one of continuous struggle against a shortage of material, labor and transportation. In July, many of the United States troops and many of the motor trucks were withdrawn from the work. At this time, materials were arriving in trains, requiring the unloading of 115 cars daily, and wounded were arriving in considerable numbers. The maximum number of patients at Mesves, on November 11, was approximately 18,700.

Ports

At first the main ports for debarkation for American supplies were St. Nazaire, Bordeaux, and La Pallice, using existing berths allotted to the A. E. F. by the French government. Brest was also used, but chiefly for the debarkation of troops. These ports at a later period were supplemented by Marseilles and certain small ports. Supplies coming through England were discharged at Le Havre. French ports of shallow draft, such as Tonnay-Charente and Les Sables d'Olonne, were used for coal. At all French ports it was necessary to alter the railway facilities to American standard, which is explained later under the heading of railroads.

Additional berths needed were constructed by the D. C. & F. Up to November 16, 1918, 67 ship berths had been obtained from the French government, 12 had been constructed, and work had been projected and material and equipment obtained for the construction of a total of 40. The port program as finally adopted contemplated the use of 160 berths by June, 1919, 40 of which were to have been built, the balance secured from the French. At all times there was a sufficient number of berths in advance of the necessity of unloading of materials and troops. For September and October, 1918, the total number of month-berths actually used was 63, and the total number available 77. As against this there was an average of 7 vessels waiting berths in the harbors.

During the early days of the A. E. F. the port program was the subject of much discussion. As a result of this discussion, the only construction authorized during 1917 was the 10-berth dock at American Bassens, with a preponderance of opinion in favor of undertaking the construction of a dock at Montoir. A consolidation of this opinion began to take form in December, 1917, by the appointment of a board of engineers known as the "Bassens Board," primarily to make recommendations on the structural difficulties of the Bassens dock, but resulting in a general discussion of the port program.

Further progress was made in January, 1918, when the Montoir board was appointed to report on the practicability of construction of a dock at Montoir. The action of this board was not only to recommend the construction of a dock at Montoir, but also to recommend further development at Brest and the possibility of using the port of Marseilles, provided the navy could furnish the necessary protection.

In March, 1918, the Chief of Utilities appointed a

Digitized by Google

board to report on all possibilities of port development. This board again recommended the construction of a dock at Montoir, also docks at Talmont and at Brest, and lighterage docks at St. Loubes and Donges, with necessary lighters to serve them.

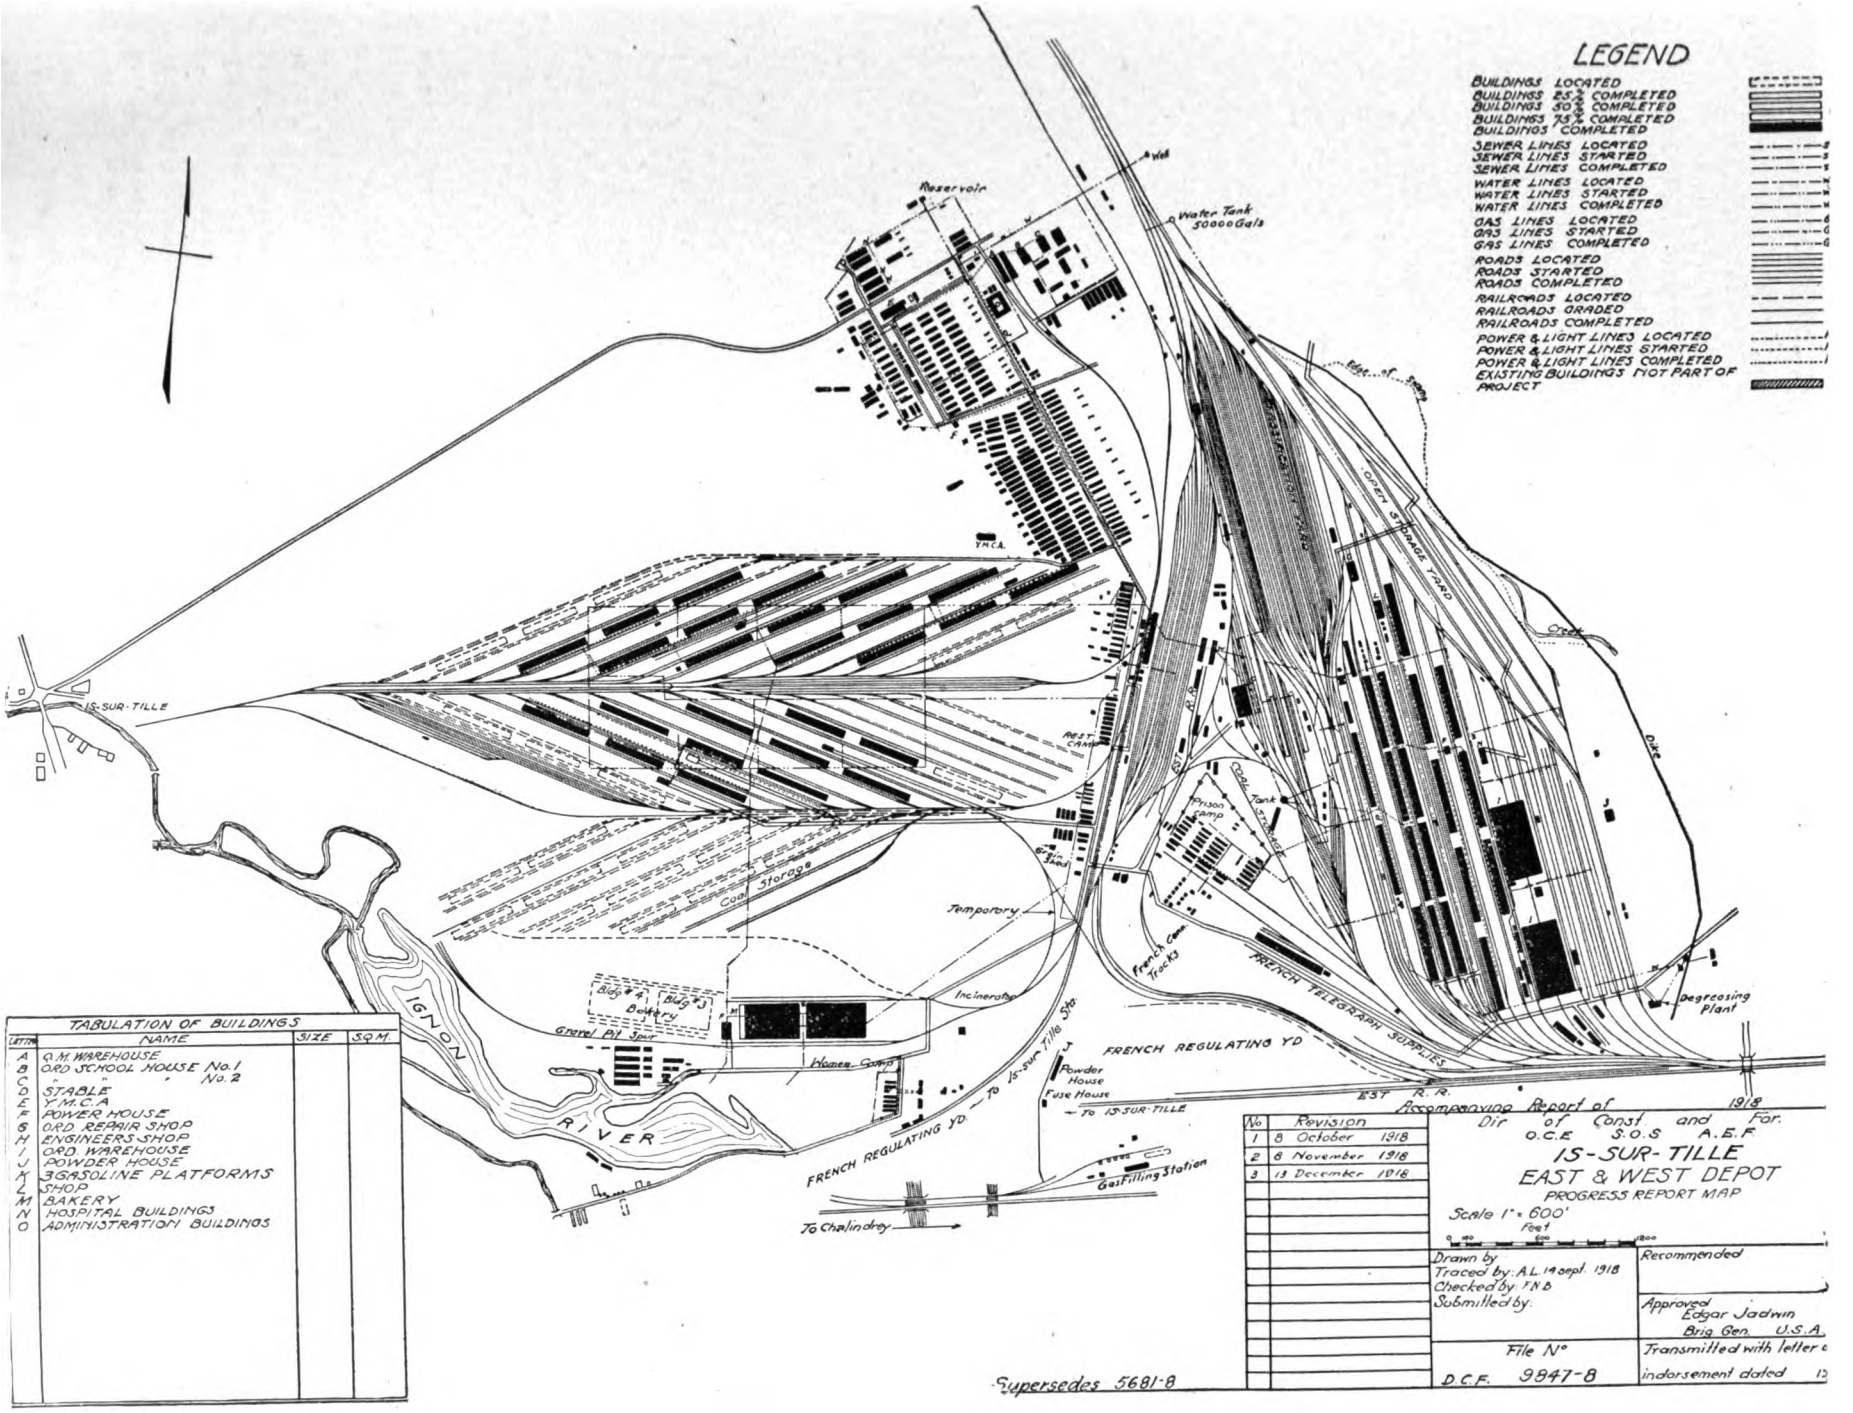
Construction having been started on Montoir, there remained many details yet undecided. In July, 1918, the C. G., S. O. S., appointed Brig. Gen. Edgar Jadwin and Col. W. J. Wilgus as a board to make a definite detailed report and program to be undertaken immediately and carried through to completion by June, 1919. The report of this board not only made recommendations, but also estimates of material and labor needed and transportation by rail required for each project, and was the final and consolidated program for all port development in the A. E. F.

Construction was started on a 10 berth dock at American Bassens in October, 1917, and it was ready for berthing ships by the following March. This dock was 4,100 feet long and 82 feet wide. As originally constructed, it was built of piles and timber mainly obtained from the United States. It had ample switching facilities, including classification and departure yards, and was connected by rail with the 10 berths used by the American Army at French Bassens, the 20 berths being connected by a third track constructed parallel with the P. O. railroad in order that a shuttle service could be operated to the St. Sulpice storage project. In August it was decided to reinforce the dock for installation of American gantry cranes, and 3,200 additional 80-foot piling were driven. This dock, as finally constructed, contained 11,000 piles and timber amounting to 4,500,000 feet b. m. It was equipped with 40 American gantry cranes.

Ward Barracks, Base Hospital—106, Beau Desert

The port program at Brest included the construction of two berths on the Jetée de l'Est and four berths on the Jetée du Sud. The two berths on the Jetée de l'Est were the only ones completed. This dock included warehouses and direct track connection with the Etat railroad. Actual construction was started in July, 1918, and the dock was in use the following September.

Because of the necessity of obtaining accurate soundings and other data, construction on the Montoir dock was not started until July, 1918. The original plan called for double-track trestle approach, 4,000 feet in length, and a dock 3,230 feet long. At the time of the armistice the double-track approach had been completed and 40 per cent of the dock proper. Because of the armistice, it was decided to construct only three berths, and those were completed and in use January, 1919. The outstanding feature of the construction of this dock was that all timbers and most of the piles were obtained in France. Piles 80 to 100 feet in length were found and cut in the Vosges, hauled to the nearest railroad point, and shipped by rail to Montoir.



Preliminary work for the 10-berth dock and storage depot at Talmont was well advanced, equipment and material assembled, and railroad built into the dock site when all work was stopped by the signing of the armistice. This dock would have been completed by June 1, 1919. A labor force of 2,500 men was engaged on this work during October, 1918.

Of the lighterage docks recommended and authorized by the dock program, only one, St. Loubes, on the Dordogne River near Bordeaux, for 8 berths, was completed and in operation at the time of the armistice.

Other docks of similar design were under construction at St. Pardon, on the same river, and at Donges, near Montoir, and material had been delivered and other dock construction was ready to start on the Jetée du Sud at Brest and at two points on the Seine River near Rouen. Fifty-eight 300-ton lighters were constructed from French timber and twenty-six 500-ton lighters from American timber, besides seven derrick barges of from 30 to 100 ton lifting capacity and others in course of construction. A part of this work and a part of the construction of Bassens dock was done under contract by the Phœnix Construction Company and James Stewart & Co.

In addition to the above construction, detailed plans had been provided, equipment assembled and construction started for adapting many French

berths to American standards, notably at Marseilles, Toulon, Cette, Brest, and Le Havre, in accordance with the program mapped out in the Jadwin-Wilgus report dated August 19, 1918. The 17th Engineers handled most of the work near St. Nazaire, and the 18th Engineers that near Bordeaux.

Railroads

The main lines of communication for the A. E. F. utilized existing French double-track railroads, extending from the ports of Brest, St. Nazaire, La Pallice and Bordeaux eastward and converging in the center of France within the quadrangle formed by the cities of Tours, Chateauroux, Bourges, and Orleans, thence radiating easterly to Is-sur-Tille, Chaumont, Neufchateau and St. Dizier, which points were in close proximity to the rear of the American armies. These railroads were the Paris-Orleans Railway, the Paris, Lyons and Marseilles Railway, the Etat and the Est railways. These railways comprised both the first and second lines of communication, and were the lines of railway along which the main American facilities were constructed and upon which American trains with American train crews were operated. The P. L. M. Ry., from Marseilles and Toulon was also used, but with the exception of a few track changes at the ports included no American facilities and was operated by the French.

Starting at the ports and extending the entire length of the lines of communication, all construction work was done in a very densely populated foreign country, with all the consequent difficulties to be met and overcome.

The track layouts at the dock and port facilities were entirely the French standard, where tracks were parallel and all connection was by means of turntables operated by hand, making a very slow and cumbersome operation. In order to get the maximum capacity and use of American railway equipment it was necessary to change from the French standard to the American standard of switching. This change entailed a complete rearrangement of tracks with all the coincident troubles of street crossing, removal of buildings, overhead crossing, and the construction work carried on under traffic. At St. Nazaire, the first port used by the A. E. F., these changes entailed a rearranging and construction to the American standard of switching of a total of 23 miles of track, and at other French ports and docks in like proportion.

There was urgent necessity for getting the supplies away from the ship's side as fast as possible, and in order to do this it was necessary to build direct track connection under American control between the docks and the storage and classification yards. At St. Nazaire, a double-track connection was built, approximately 4 miles in length, involving considerable grading and one double-track bridge across the Etang de Mean. At Bordeaux a third track was built parallel to the P. O. road, a distance of 8 miles, to the storage yard at St. Sulpice.

In order to properly classify and store supplies pending shipment it was necessary to build extensive yards and storehouses as near to the ports as there was available ground. These were built at Montoir for St. Nazaire, at St. Luce for Nantes, at St. Sulpice for Bordeaux, and similar construction was started at Aigrefeuille for La Pallice, and Miramas for Marseilles.

The storage depot at Montoir was originally designed for a total trackage of 240 miles. The construction work proceeded as the facilities were needed, and at the time of the armistice 128 miles of track had been built and were in operation. These facilities included complete operating facilities, comprising 25 miles of track in receiving and departure yards, 5 miles in classification yards, 5 miles in engine terminal, 6 miles in ordnance storage yard, and the balance of track to serve general storage warehouses and the many connections necessary to serve minor facilities. Construction of the project at Montoir started on September 30, 1917, and was completed December 31, 1918. The maximum number of men engaged in the construction work was 3,083. The project at St. Sulpice was practically identical with that at Montoir.

The two large intermediate storage projects were located at Gièvres, and Montierchaume, near the city of Chateauroux. These projects were intended to accommodate the reserve supplies for the operation of the American Army.

At the storage project at Gièvres, supplies were received from all ports and held in storage until needed in the advance depots or elsewhere. This project as originally designed contemplated a total trackage of 280 miles, and at the time of the armistice there was laid and in operation 143 miles of track, which comprised the 36 miles in the receiving and departure yard, 9 miles in the classification yards, 7 miles in engine terminal, 13 miles in engineer depot for open storage, and the balance, 69 miles, to serve the 165 warehouses, refrigerating plant and other lesser facilities; Gièvres was the largest of the storage facilities. It covered an area 6 miles in length and 2 in depth. There were 30,000 men stationed in camps within the project, 20,000 for construction and 10,000 for operation purposes. Construction work was started at Gièvres by the 15th Engineers (Railway) in September, 1917, and the depot started functioning in November of the same year. The maximum number of men employed on construction was 5,877.

The intermediate storage yards at Montierchaume were designed on approximately the same plan and size as Gièvres. Construction work was started on

Digitized by Google

a small scale in April, 1918, and was accelerated in June, and at the time of the armistice a total amount of 50 miles of track had been laid, including receiving, classification and departure yards, engine terminal and storage tracks.

Ammunition storage depots were constructed at Jonchery, Mehun, Issoudun and St. Loubes.

Advance storage and regulating stations were built at Is-sur-Tille and Liffol-le-Grand, and the French regulating station at St. Dizier was used. At Is-sur-Tille, 10 miles north of Dijon, the largest advance storage and regulating station was built, comprising a total of 95 miles of track. This was divided into receiving, classification and departure yards, storage and miscellaneous tracks, and included engine terminal facilities. Construction on this project commenced October, 1917, by the 16th Engineers, and the station began functioning in December of the same year, and was practically completed in June, 1918. The construction of this yard involved heavy grading, a large part of which was in solid rock. The maximum number of men engaged on this work during the course of construction was 3,984.

Liffol-le-Grand, near Neufchateau, was in reality a regulating station, with comparatively small amount of storage. It consisted of 26 miles of track in receiving, departure and classification yards, 7 miles of track in engine terminal facilities, 12 miles for storage purposes. Construction was started in April, 1918, but for military reasons the work was not rushed until the following July. The maximum number of men engaged on work was 2,576. The work was practically complete, and the yard functioning in October, 1918.

It was found that the engine terminal facilities along the French railways would not be of sufficient capacity to handle the heavy traffic necessary to adequately supply the A. E. F., and as these engine terminals were in congested centers, it was decided to build new ones solely for American operations. Under this program engine terminals were built at Montoir, Saumur, Gièvres, Cercy-la-Tour, Is-sur-Tille, Liffol-le-Grand, and along the line out of Bordeaux, at Nexon, Perigueux, and Montierchaume. All these engine terminals were constructed and in operation. Studies were made and in some cases construction was started on other engine terminals in order to further increase the American traffic, but these were suspended by the armistice.

The engine terminals were practically of the same design, including receiving and departure yards, engine house and repair shop and other necessary facilities. The trackage involved varied from 8 to 14 miles. The water supply along the French railroads used by the A. E. F. was improved and augmented in numerous places.

In addition to the railroad work as set forth above, it was necessary to construct sidings and spur lines at the various hospitals, aviation centers, camps, ordnance storage projects, oil and gasoline stations, and to the many forestry operations. A total of 1,055 miles of railroad was constructed. If this were laid in a continuous line it would reach from the Atlantic Ocean at St. Nazaire across France and Germany and to the Russian frontier.

Comprehensive plans were prepared by the transportation service for all track facilities, but the shortage of materials and labor and the rapid increase of the program of troop arrivals called for wise discrimination as to what was needed and what was not, in order to meet the actual situation. It was necessary to make decisions almost from day to day as to what tracks should be put down on the various projects extending from the ports to the front, in order to provide facilities urgently and immediately needed, as there were neither labor nor materials to construct all facilities shown on plans. The comprehensive plans contemplated four tracks along each line of storehouses and open storage space, two on each side of the storehouse. It was found in practice that at the intermediate depots all the traffic could be handled on one track on one side of each line of storehouses without unreasonable delay in loading and unloading of cars. Later, the same type of arrangement was also being used at the large base depots.

Experience and observation of the tracks which were used most and those that were not largely used led to the conclusion that on this class of work, under war conditions, to avoid loss of man-power and material without adequate return, considering the rapidly changing conditions, it was advisable to put in little more than the number of tracks that were needed to start operations, leaving space to add others as their necessity develops.

Storage Depots

The covered storage as estimated by the various services was originally 21 square feet per man in the A. E. F., but it was found by experience that for a 90-day reserve, 10 square feet per man was sufficient for supplies actually requiring cover, inclusive of ammunition. This was later reduced to 5 square feet when a reserve of 45 days was decided upon. These requirements were met as follows:

	Square feet	
Gièvres	3,850,000	
St. Sulpice	2,652,000	
Montoir	3,456,000	
Montierchaume	1,222,000	
Is-sur-Tille	1,380,000	
Other depots	3,608,000	
		Square feet
Total depot storage		16,168,000
Dock storage		3,213,000
Miscellaneous storage		3,858,000
Grand total		23,239,000

Digitized by Google

Original warehouses were constructed of lumber with ruberoid roofing. Owing to the difficulty in obtaining lumber, a type was developed with wood frame and corrugated-iron roofing and sides, using round poles for posts. The warehouse was 50 by 490 feet, and 12 feet high at the eaves and required only 20,800 feet board-measure of lumber and 44,000 square feet of corrugated iron, and could be easily and quickly erected. At Gièvres, on one occasion, a warehouse of 50 by 294 feet was erected by 60 men in 8½ hours, only the roof and ends being covered—with corrugated iron.

It was found necessary to omit floors except in buildings where supplies subject to injury by moisture, such as sugar, salt, and flour, were stored. In these cases a floor was built, or the supplies were placed on loose dunnage.

Considerable attention was also given to the question of placing in open storage supplies that would not be damaged in the length of time that they would have to remain in the open. Experience has demonstrated that the following main classes of supplies can be placed in the open with paulin covers without material damage: hay, canned goods, small arms ammunition and projectiles.

The principal motor transport project was the main base plant and repair shop at Verneuil, near Nevers. It was designed to serve as the base repair center for the motor transport corps. The total number of vehicles repaired in this plant up to March 1, 1919, amounted to: light and heavy trucks, 4,592; automobiles, 1,700; ambulances, 324; motorcycles, 3,230, and bicycles, 1,724. Repair parts, amounting to 485,724, have been manufactured from raw material, and 6,635 broken and salvaged motor vehicle parts have been returned to service. In addition, repair and salvage work was done on horse-drawn vehicles and other miscellaneous equipment and material.

The project consisted of the main base plant, which included 14,400 square feet of office space, 120,000 square feet of stock storage, and 361,000 square feet of shops; the camp for personnel, amounting to a total floor space of 302,430 square feet; and the prisoner-of-war enclosures.

The principal air service project was the air service production center, No. 2, at Romorantin, near Gièvres. This project was designed to be the main assembly and salvage depot for the air service in France and was to receive and assemble all airplanes from the United States, to salvage a large part of the planes from the front, to repair and rebuild planes, to repair and maintain all motor transportation for the air service, and to serve as a depot for air service supplies. Later, a complete balloon depot and repair station and 1,000-bed base hospital were added. The location was chosen principally because it was accessible to the converging main lines of communication from the ports, and at the same time within easy flying distance of the distributing points near the front, while still near the extreme bombing radius for enemy planes.

The supply depot and airplane spare parts depot handled all air service supplies and all airplane and engine parts. An average of 30 cars per day were used in handling these supplies.

The original project was authorized December 27, 1917. A small detachment of Engineers started work on the railroad on January 21, 1918. The first air service personnel arrived January 19, and began erecting barracks January 21. The maximum number of men employed at one time was 2,684. When construction was stopped on November 15, 1918, 85 per cent of the entire authorized work had been completed. The construction consisted of 1,297,200 square feet of shops, 765,200 square feet of storehouses and hangars, 616,000 square feet of barracks, and 126,000 square feet of hospital space.

The plant as completed was capable of assembling about 30 planes per day and would have soon been able to handle double that number. The number of planes assembled was 1,177; liberty and foreign engines repaired, 1,670; salvaged, 212; planes repaired (all types), 776; planes of all types salvaged, 308.

Remount Depots and Veterinary Hospitals

In addition to the work of providing shelter for troops there was the problem of providing necessary shelters for animals required for the A. E. F.

This construction was initiated in August, 1917, when a request was made for the immediate erection of temporary shelters for the mounts of a cavalry regiment expected to arrive at an early date. As a result of this request arrangements were made with the French government to supply 500 demountable wooden stables, each with a capacity of 50 horses, and to use many small existing remount stations to which additional capacity was added when possible.

During May, 1918, a program of remount and veterinary hospital construction was instituted. A board selected sites in the base, intermediate and advance sections and visited the British area to study construction of buildings and accompanying facilities which had been developed during the four years of the war.

Remount depots with veterinary hospitals in close proximity were established at the principal base ports to care for animals arriving from the states or other overseas sources, until they could be forwarded to the intermediate or advance depots. Large depots with veterinary hospitals adjoining were established at Gièvres, Selles-sur-Cher, and Sougy, in the intermediate section. In the advance section a large depot and veterinary hospital was built at Lux, near Is-sur-Tille, and many smaller remount depots

Digitized by Google

and hospitals between that point and the front lines.

The total facilities authorized by the staff comprise remount depots for 61,200 animals and veterinary hospitals for 39,100 animals. Of these, there was actually available on February 1, 1919, the following space for animals:

In remount depots constructed by the engineers.	27,700	
In remount depots obtained from the French...	12,000	
		39,700
In veterinary hospitals constructed by engineers.	16,500	
In veterinary hospitals obtained from the French	11,100	
		27,600
Total space in remount depots and veterinary hospitals		67,300

These facilities involved the construction of 2,210,000 square feet of stabling, provision for quarters for 650 officers and 17,000 enlisted men, and the various facilities required for the functioning of these projects.

At each separate remount depot and veterinary hospital there were required dressing rooms, operating rooms, dipping vats, sulphurizing chambers, forges, and blacksmiths' shops, and storehouses for equipment and forage.

Each large project required a standard-gauge railroad siding and spur with facilities for rapidly unloading animals, an ample water supply and good roads and drainage.

The type of horse shelter adopted for remount depots and veterinary hospitals after a study of the best French and British practice was a stable, 216 by 23 feet, with a space for 100 animals. Supports were of 6-inch round poles with a framework of 2 by 4's and covered with corrugated iron if available, otherwise with 1-inch sheeting and tar paper.

For shelter alone each animal required from 80 to 140 feet board-measure of lumber, depending whether or not corrugated iron was used for covering. The stables actually constructed consumed over five million feet board-measure of lumber.

In general, remount depots were built for 2,000 to 5,000 animals with a veterinary hospital near at hand for from 1,000 to 2,000 animals. The project at Sougy has a capacity for 5,000 animals in the remount depot and 2,000 in the veterinary hospital. It has quarters for 100 officers, 2,500 enlisted men, with necessary mess halls, bath houses, and includes a recreation building.

Water Supply and Sewerage.

In connection with the classes of work described above, much water supply and sewerage work was required. A large amount of labor was required in the listing of supplies to be purchased in American and European markets and in the preparation of priority schedules to permit this material to be ordered and shipped so as to be available in time for use.

A system of water analysis laboratories was established and the water supply in the S. O. S. placed under the same kind of care from bacteriological and sanitary point of view as is customary in the cities and states of the United States. Arrangements were made for the chlorination of various water supplies in the S. O. S. and the storage and forwarding of chlorinating apparatus for the armies. Arrangements were entered into with the cities of Tours, Vendome, St. Nazaire, Le Mans and Dijon for the chlorination of the whole city supply.

The water supply for the city of St. Nazaire and vicinity constituted the biggest single problem of the D. C. & F. The ordinary French uses amounted to about 1,000,000 gallons per day and was obtained from reservoirs of a capacity of 160,000,000 gallons which were filled during the rainy season. During unusually dry seasons it was necessary to resort to tank boats in order to furnish the city. The combined French and American uses were estimated at about 3,000,000 gallons per day and, as the country does not yield deep well water, it being underlaid with solid granite rock, and as the nearest surface free from salinity was at a distance of about 15 miles, it was decided to be more feasible to provide additional storage reservoirs of a capacity of 400 million gallons. It was necessary to construct one rapid sand filter of 3,000,000 gallons daily capacity and another of 1,000,000 gallons daily capacity in order to provide satisfactory water. To fill the reservoirs in the rainy season and to elevate the water to the various levels of the project, 15 pumps with a total capacity of 30 million gallons per day had to be installed; 48,000 feet of 24-inch to 12-inch pipe, 60,000 feet of 8-inch to 4-inch pipe, and elevated tanks of 200,000 gallons capacity were used in the supply and main distribution systems alone, not to mention miles of smaller pipe used for distribution as well as for interior plumbing and piping.

The water supply of the docks and camps at Brest and vicinity offered another large problem. The original French systems which supplied Port de Commerce, Foutras Barracks, Bougen Fortress and Pontanezen Barracks, were insufficient and it was necessary to immediately make provision for an additional 900,000 gallons per day. A pumping station on the Penfield River was installed with a daily capacity of 1,300,000 gallons and 28,000 feet of pipeline laid. In order to supply all portions of the projects and to provide adequate pressure, pumps of a total capacity of 2,000,000 gallons per day and elevated tanks of a total capacity of 100,000 gallons, were installed. Due to the increase in the size of the Pontanezen camp and constantly increasing needs at other ports of the project, this original augmentation of the French supply, almost before completed, became inadequate and further provision had to be made. It was estimated that 3,000,000 gallons per

Digitized by Google

day would be necessary and with this to do away to a large extent with the use of the French system, particularly at Port de Commerce. The Penfield River was selected as the source. Two reservoirs, one of 23,000,000 gallons capacity and another of 2,000,000 gallons capacity, were built. Two pumping stations containing 6 pumps and with a total capacity of 4,700,000 gallons daily were constructed. Forty-one thousand feet of 14-inch to 10-inch pipe and 10,000 feet of 6-inch and 4-inch pipe were used on the main supply and distribution system.

While Brest and St. Nazaire presented the largest problems of water supply, practically all the other large projects constructed required water supply installations of considerable magnitude, a few of which may be mentioned as of interest. For the Saveney Hospital water supply, a concrete arch dam 40 feet high and containing over 6,000 cubic yards of concrete to provide a reservoir storage capacity of 10 million gallons was constructed, in addition to 2 filter plants, each of 330,000 gallons daily capacity. Some 25,000 feet of sewer lines and 50,000 feet of water mains were laid and a concrete standpipe of 50,000 gallons capacity was installed. For the Mars Hospital supply a 10-inch force main, 5 miles long, was laid. A reinforced concrete reservoir of 100,000 gallons, on towers 30 feet high, was constructed. Two pumping stations, each of 500,000 gallons daily capacity, were installed, and a filter plant of 500,000 gallons per day was erected. For the Mesves Hospital an installation practically duplicating that of Mars was made. At both Allerey and Beaune hospitals, some 57,000 feet of sewer pipe and 40,000 feet of water mains were laid. At Romorantin air service plant two filters, each of about 200,000 gallons daily capacity, were placed. A slow sand-filter was installed at both Langres and Chateauroux hospitals. The installations at the Montierchaume storage depot involved the laying of some 30,000 feet of 4-inch, 6-inch, and 8-inch pipe, the installation of pumping stations of a capacity of 100 horsepower, the drilling of wells of a total depth of 1,700 feet, and the construction of elevated tanks of a total capacity of 150,000 gallons. The general intermediate storage depot at Gièvres called for even a larger installation than that at Montierchaume. At Bassens, 1,500,000 gallons of water per day was obtained by drilling two artesian wells to a depth of 700 feet. A well of 1,520-foot depth was drilled at Beau Desert Hospital, and one of 1,020-foot depth at St. Sulpice.

Refrigeration

In addition to such cold storage space as could be obtained from the French, plants were constructed by the D. C. & F., upon plans prepared by experts engaged by the Q. M. C., for the storage of frozen meats from the United States, with a total refrigerated space for the storage of 14,900 tons, and ice-making facilities for 500 tons per day.

The plants at Gièvres and Bassens are the largest of those constructed, having an ultimate capacity for 7,500 and 6,000 tons frozen beef, respectively. These figures are based upon full utilization of refrigerated space with consequent elimination of alleyways. The original rated capacities of these plants, making liberal allowance for alleyways, were 5,200 and 4,000 tons, respectively. Plans were prepared and equipment obtained from the United States for a duplicate of the Bassens plant to be located in the advance section, as well as for a duplication of the cold storage building at the Gièvres plant; also plans for a 400-ton plant at Marseilles, these three projects being canceled after the armistice. A beef storage plant of 700 tons capacity was authorized at Bendorf, near Coblenz, February 6, 1919. This plant is included in the above capacity figures.

The beef storage building at the Bassens plant is cork insulated throughout, using 100,000 cubic feet cork obtained from a point near Bordeaux. The floor is of reinforced concrete over corkboard on a 4-foot sand fill. The cold storage rooms contain 134,800 linear feet of 2-inch standard pipe. The engine room is modern in every respect; the refrigerating machines are driven by cross-compound condensing Corliss engines. The boiler capacity is 900 horsepower. The reinforced concrete reservoir has capacity for 130,000 gallons water. Due to the use of cork for insulation, and improved design, the amount of lumber used was reduced to 931,000 feet board-measure. This plant was constructed and in operation in 4½ months after commencement of work.

Bakeries

A mechanical bakery at Is-sur-Tille was constructed from plans furnished by the Q. M. C. with a capacity of 800,000 pounds daily. This plant is capable of emergency production of 1,000,000 pounds daily. Mechanical bakeries were constructed from plans furnished by the D. C. & F. at Brest and Bordeaux, with a capacity of 150,000 pounds daily and at St. Nazaire of 120,000 daily. Plans were completed for a mechanical bakery at Liffol-le-Grand with a capacity of 400,000 pounds daily. Plans were furnished for the construction of field bakeries totaling in capacity approximately 600,000 pounds daily. Of this amount, construction capable of producing 500,000 pounds daily was completed.

Two steel truss buildings, 240 by 380 feet, with a corrugated iron roof and sides, were erected for the mechanical bakery at Is-sur-Tille. The floors were concrete throughout. All machinery in the plant was electric-driven, power being furnished from a modern steam turbo-generating plant of 900 K.W.

Digitized by Google

capacity, the power-house being a separate building, 55 by 125 feet. Ovens were built on standard British practice in groups of seven, so arranged as to lessen chance of plant being totally disabled.

Electrical Installation

Steam generating stations involving approximately 3,000 K.W. of power were designated and in process of construction when the armistice was signed. The larger of these were a 200-K.W. plant for the bakery and storage project at Is-sur-Tille; a 1,000-K.W. standby plant for the Bassens project; a 750-K. W. plant for the air service production center at Romorantin.

Three thousand K.W., in rotary convertor substations, were designed and under construction. These were at Neuvy Pailloux to serve the tank factory; at Marseilles, La Pallice and St. Nazaire, to serve the gantry cranes. A 2,500-K.W. substation was constructed at Mehun from plans furnished by the Ordnance Department to serve the ordnance shops. A 2,500-K.W. substation design by the Transportation Department was constructed at Bassens to serve the projects at that point. Of this station 1,500 K.W. was in rotary convertors and the remainder in transformers for miscellaneous light and power.

One hundred and twenty-five miles of transmission line had been constructed or was under way, the plans and specifications for which were furnished by the D. C. & F. Low-tension distribution systems and interior wiring of all hospitals, storage yards, warehouses, docks, shops, schools, and camps in the S.O.S. were installed on the basis of plans and specifications furnished by the D. C. & F.

Oil and Gasoline Storage

The D. C. & F. was charged with the construction of the oil and gasoline seacoast storage stations, intermediate storage station fabrication shops for small tanks at Gièvres, and the construction of the small gasoline distributing stations throughout France. The following seacoast gasoline storage stations have been constructed and placed in operation:

La Pallice, four 25,000-barrel tanks; St. Loubes, one 25,000-barrel tank. Two 25,000-barrel storage tanks were erected at Blaye, but this plant was never placed in operation.

Intermediate storage station, four 10,000-barrel-tanks were constructed and placed in operation at Gièvres.

At the Gièvres shop for the fabrication of small tanks there were constructed and tested 69 300-barrel tanks and 150 150-barrel tanks. Of this number 29 300-barrel tanks and 119 150-barrel tanks were shipped out to small gasoline distributing stations at various field locations. To facilitate the installation of the small gasoline distributing stations, the necessary pipe, valves, fittings, and pumps were assembled and marked for field erection and shipped out at the same time as the small tanks. The construction work on the seacoast and intermediate gasoline storage stations and the 150 and 300 barrel tanks was largely done by contract with the James Stewart Company under the supervision of engineer officers. Thirty-seven complete installations of small gasoline distributing stations were shipped out, 17 of which were placed in operation and other 20 were either canceled or construction suspended. These stations were constructed by engineer troops.

With the storage and distributing stations already erected, sufficient gasoline can be stored to provide for any emergency, and the small distributing stations not yet erected could be relocated without much expenditure of labor, and without any further demand for material.

Roads

The D. C. & F. in the year 1918 had charge of all road work in the S. O. S. except that in the advance section, which was performed under the section engineer officer for the division of light railways and roads. During this period 90 miles of new road were constructed within projects such as the larger hospital units, general storage projects, ordnance and aviation projects. The major part of the road equipment available was needed at the front, and for this reason and for the lack of labor due to priority of other work, the maintenance and repair work was limited to approximately 300 miles. The repair work was performed mainly in congested centers, such as the immediate vicinity of Bordeaux, the docks at Bassens, and the streets of St. Nazaire adjacent to the docks and leading to the camps.

The national highways and other French roads along our line of communications and serving the many camps, training centers, and other activities of the A. E. F. were under extremely heavy traffic during the summer and fall of 1918, and comparatively little repair work was undertaken because no labor was available either from French or American sources. The wet weather in the western and southern part of France and the freezing weather in the eastern and northern parts during the month of December put the roads in bad condition and the C. in C. directed that month that extensive repairs be undertaken along the entire lines of communication, not only in justice to the French in repairing their roads damaged by the American traffic but also to permit continued use of the roads by the American Army. This resulted in the issuing on January 2, 1919, of an order placing all road work in the S. O. S. and Luxemburg under the direction of the D. C. & F. and that in the occupied areas of Germany under the C. G., 3rd Army, giving the D. C. & F. a co-ordinating supervision.

Digitized by Google

The D. C. & F. used his existing organization for this work and through the section engineer officers of the various sections, immediately started the leasing and acquiring of quarries, a system of distribution of stone by rail haul and motor transportation, distributed labor upon roads most requiring repair, put into service all available road equipment and tools, both from French and American sources. The section engineer officers were instructed to adopt the cantonier system, which was a system of constant patrol and of carefully placing well-tamped patches and resurfacing wherever the surface of the road developed weak spots. Special attention was also given to opening up all drains and ditches and the removal of accumulated mud, both from the surface of the road and ditches. The French government cooperated by issuing instructions to their departmental engineers to furnish all stone and equipment available and in a few places stone was furnished by the French, transported in American cars and trucks and placed upon the roads by combined forces of Americans and French. The results obtained from the use of this system were very satisfactory and some roads that were almost impassable in January were put in reasonably good condition. This system reduces the cost of new roads and keeps all roads in better condition by constant patrols and repair.

The maximum force engaged in road work has approximated 110,000 men who were scattered in small working parties over nearly 16,000 kilometers of road and placed about 90,000 tons of stone per week. This stone was obtained from quarries operated by the French government and French contractors; also from quarries opened up and operated by the D. C. & F., any many small local quarries where the rock was taken out and broken up by hand. The quarries operated by American labor were 90 in number; the total number operated by the French, 50. The stone was hauled by rail from the quarries to the nearest station and then distributed by motor truck. From the small quarries the distribution was made by means of motor trucks and horse-drawn wagons direct.

The following table shows the work done from January 1 to June 1, 1919, at which time the road program was practically completed in all sections.

Section	Roads worked—km.	Rock distributed—metric tons	Man-days—8-hour day	Truck-ton days—8-hour day	Road rollers
B. S. No. 1...	500	91,000	261,500	38,900	22
B. S. No. 2...	1,700	154,000	295 450	51,830	27
B. S. No. 5...	75	197,500	156,220	16,330	9
B. S. No. 7...	575	25,200	80,530	12,580	8
Int. Sec. W...	4,200	291,000	658,850	78,510	39
Int. Sec. E...	550	95,000	115,230	24,310	17
Advance	5.400	512,500	2,671,600	171,250	135
Total in France	13,000	1,367,500	4,239,380	393,710	257
Luxembourg ..	350	19,700	17,000	4,000	...
Occupied ter...	2,500	307,500	487,250	80,320	40
Total.....	15,850	1,694,700	4,743,630	478,030	297

In the advance section 650 kilometers of road were reconstructed within the battle areas devastated previous to the arrival of the American Army. There was also constructed 34,000 square yards of stone-paved street and 21,000 square yards of concrete road. In addition to restoring and maintaining the road surfaces more than 500,000 tons of crushed rock were distributed and left along the roads for future repair work by the French authorities.

Forestry

The lack of ocean transport made it necessary to obtain practically all of the lumber and other forest products required by the A. E. F. from the French and other European sources. Shipments of such bulky material from the United States was restricted to a small quantity of piling and dock timbers used chiefly in the Bassens dock. Furthermore, the shortage of forest products in France and the heavy requirements of the French and British armies made it necessary for the A. E. F. to be self-sustaining in the supply of these essential materials, which were called for in enormous and steadily increasing quantities. The current monthly requirements of the army at the time of the armistice totaled 50,000,000 feet board-measure of lumber and timbers, 250,000 railroad ties, 6,500 pieces of piling and cribbing, 1,500,000 poles and entanglement stakes, and something over 100,000 cords of fuel wood.

Limited quantities of lumber were obtained from France, Switzerland and Norway. Approximately 590,000 railroad ties used in the first installations were advanced by the French government and some additional ties were obtained under contracts placed in Spain and Portugal. Fully 75 per cent of the lumber and ties, over 90 per cent of the poles and piling, and a large part of the fuel wood required by the army were produced in France by the forestry section.

Lumber production was begun in December, 1917, by the 10th Engineers (Forestry), which operated two American and four French mills that month and cut 321,000 feet of lumber, 205 piles, 12,000 ties, 20,000 poles, and 1,200 cords of fuel wood. During the winter and spring of 1918, the Forestry troops were augmented by the ten battalions of the 20th Engineers (Forestry), and by three battalions comprising the 41st, 42d, and 43d Engineers. Nine battalions of engineer service troops were also assigned to forestry work. Thirty-four mills were operated in March, 1918, and 59 mills in June. At the time of the armistice, 90 operations, including 81 sawmills, were in progress, employing nearly 12,000 technical engineer troops and 8,500 service troops.

The earliest operations of the forestry section were undertaken (1) in the Landes pineries of base section No. 2, where there was an early demand for piling, warehouse lumber, and railroad ties; (2) in the Loire River valley near the line of communica-

Digitized by Google

tion and the large depots and construction projects in central France, and (3) in the soft wood forests of the Vosges and Jura mountains and the hardwood areas immediately behind the American Sector of the Front. The forest resources of these regions were fully explored and new operations placed as far as possible with reference to the main points of consumption and the varied demands of the army for different classes of forest products. Construction lumber had to be obtained mainly from the soft-wood forests of the south and of the eastern mountains. These regions also furnished the bulk of the piling. The hardwood forests of central and western France were drawn upon heavily for railroad ties, road planks, dock, barge, and bridge timbers, and fuel wood. In the summer of 1918, it was necessary to push out into the southern Jura region and the central plateau of France, in order to obtain the quantities of timber needed.

The forestry operations at the time of the armistice were grouped in the 14 operating districts, each under a battalion commander and organized as far as practicable to function as a self-contained unit. In addition, 8 operating units with portable sawmills were attached to the first and second armies, working near engineer camps and supplying them with the forest products most urgently needed from time to time.

At the completion of its work June 25, 1919, the forestry section had produced approximately 206 million feet of lumber, 3 million standard-gauge ties, 1 million small ties, 39,000 piles and 1,800,000 poles and entanglement stakes, for the A. E. F. In addition to these amounts, approximately 10,000,000 feet of lumber and 440,000 standard ties were cut by two forestry battalions which were loaned to the French and British armies. All told, the forestry section up to the same date supplied 400,000 cords of fuel-wood to the army. In addition, 30 of its officers were loaned to the quartermaster corps to direct the production of large quantities of fuel-wood by quartermaster troops.

To maintain this enormous production, it was necessary to scout practically all of France south of the northern provinces for suitable timber and to negotiate its purchase through French channels. This work was extended into the Pyrenees, the French Alps, and the central plateau, in order not only to keep the forestry troops in France continuously supplied with timber, but also to obtain the large quantities needed for the operations of 24,000 additional troops approved by the War Department for forestry work in September. By the date of the armistice, 630 million feet of timber and 700,000 cords of fuel-wood had been acquired; and half as much had been located and cruised and was in process of acquisition.

On account of the delay in the arrival of American equipment, 8 stationary French saw-mills were leased or requisitioned in the fall and winter of 1917 and 12 portable French mills were acquired. This equipment aided greatly in meeting the acute shortage of lumber. The French plants were largely remodeled by the forestry troops and their production doubled or trebled. Their capacity was still so limited, however, that they were discarded as rapidly as American mills could be obtained.

Three types of American saw-mills were employed:

(1) A heavy-powered, permanent steam plant, rated to cut 20,000 feet board-measure in ten hours.

(2) A moderately powered, portable type of steam saw-mill, rated to cut 10,000 feet board-measure in ten hours.

(3) A very light, portable "bolter mill" run either by steam or by gas tractor, rated to cut 5,000 board-feet in ten hours and especially suited to light products, like railroad ties.

Twenty of the large mills were installed at points where the supply of timber permitted their operation for eight months or longer. The other mills were well adapted to the many small wood-lots in France which it was necessary to utilize. In the face of a critical shortage of lumber, every possible effort was made to speed up production. Practically all saw-mills were operated day and night shifts and some of them three 8-hour shifts. More than double the rated capacity of the plants was obtained currently in most of the forestry operations. Upwards of 150,000 feet of lumber were cut in twenty hours at several of the large mills whose rated capacity for the same period was 40,000 feet. Cuts as high as 66,000 feet of railroad ties were made in 20 hours on the little bolter mills. All of the large and many of the small mills were steamed successfully by means of "dutch" ovens for burning sawdust, designated and installed on the ground by forestry millwrights. An enormous quantity of fuel-wood was saved by this means.

Standard or motor gauge railroad installations, up to 3 miles in length, were necessary at two-thirds of the mills to give them direct rail connections and provide adequate facilities for loading cars. Light railroads of 3-foot, meter, or 60-centimeter gauge, with steam or gas locomotives or horse-drawn trams, were used for logging at many operations. A difficult area in the Vosges Mountains was logged by means of a 4,000-foot meter-gauge incline, with an average grade of 35 per cent, down which carloads of logs were lowered by donkey engine and cable. Much of the logging was done by horses with log wagons, spool carts, or high wheels. The excellent French roads were used extensively for bringing in logs by motor trucks and by tractors drawing a low-speed trailer of log-wagons. One hundred-foot piles were hauled by this means for distances up to 15 kilometers.

One of the noteworthy accomplishments of the forestry section was the cutting and logging of 15,000 piles from 65 to 100 feet in length, under great difficulties, which assured the completion of the major dock

Digitized by Google

projects at the A. E. F. base ports. Approximately 15,000,000 feet of long heavy timbers, requiring special selection and manufacture, were also furnished for dock, barge, and bridge construction. By an active field organization, it was possible to keep the current rail and cargo deliveries of lumber, ties and piling up to 70 per cent of current production in spite of the shortage of transportation facilities in France.

While the changing program and the difficulties incident to the submarine warfare, an insufficient amount of ocean tonnage, cars, man-power and material, were all great, still the division of construction and forestry met all of its essential responsibilities and was equal to the situation in each of the various activities of the A. E. F. dependent on it for their success. This was due on the one hand to the organization, to the character of the men in the service, their splendid loyalty, enormous amount of work which they performed, and their rapid adaptability to the changing conditions, and on the other hand to the backing received from the Chief Engineer, the C. G. S. O. S., and the C. in C.

As an illustration of the work done, if all the railroads constructed were laid in a continuous straight-line track it would reach from the Atlantic Ocean at St. Nazaire, across France and Germany to the Russian frontier. Similarly, if all the building construction were consolidated into one building having the width of our standard barrack and hospitals it would reach from St. Nazaire, across France and to the Elbe River. The Forestry troops produced 75 per cent of the lumber and ties used on this construction, and in addition 375 miles of corded fuelwood, and 144 miles of piling.

An appreciation of the work of the division of construction and forestry is contained in the following letter from the Commander-in-Chief:

28 March, 1919.

Brigadier General EDGAR JADWIN,
Director, Construction and Forestry,
Through Chief Engineer, A. E. F.

My Dear General:

Now that hostilities have ceased it gives me great pleasure to thank you, and through you the officers and soldiers of your organization, for the splendid work you have accomplished.

The Division of Construction and Forestry required the services and unselfish efforts of experts in many lines of skilled endeavor. It is a source of deep pride and satisfaction that numbers of this type of men responded readily, and through their invaluable assistance you attained the highest goal of achievement.

The supply and shelter of troops was one of the most responsible tasks that befell any organization. Although operating in a foreign country, under conditions and circumstances vastly dissimilar to those accustomed to, you met successfully each and every demand.

You, and the officers and men of your organization, labored in almost every department in France, often in isolated detachments, working under arduous conditions of service and making countless sacrifices. Yet they withstood all hardships and difficulties, surmounted all obstacles and kept tenaciously at their important tasks. Such tireless energy, actuated as it was by a high sense of duty, deserves the commendation of all.

The vast projects wisely planned and boldly executed by you and your efficient personnel, the thoroughness and celerity with which you labored, the splendid co-operation maintained throughout, especially among the highly trained men of affairs who gave their best to the common cause, the keen foresight displayed in preparing for emergencies and the many sacrifices made are worthy of the highest American traditions.

In the name of the American Expeditionary Forces, I thank them one and all and send them the appreciation of their comrades and their Commander-in-Chief.

Sincerely yours,

JOHN J. PERSHING.

Discussion and Comment

Maj. Gen. W. C. Langfitt
Chief Engineer, American Expeditionary Forces

Colonel Woodruff's article describes in detail the operations of the Division of Construction and Forestry, one of the main divisions of the Office of the Chief Engineer, A. E. F. There seems but little room for comment by the Chief Engineer, except to express here publicly his very great appreciation of the loyal work of the Division of Construction and Forestry and of the great results achieved.

The organization in its final form was necessarily a growth. General McKinstry, I think, first suggested the idea of districts somewhat along the lines of our river and harbor districts, but did not remain long enough in charge to develop the scheme. General Patrick worked along the same lines and the organization was finally developed and perfected by General Jadwin. It, of course, met with my hearty approval and I know of no other suggestion which could have brought about such satisfactory results.

The types of construction and, in fact, all plans were evolved always keeping in mind two main essential governing features. First, the views of the department for whom the construction or work was being undertaken. Second, to keep ahead, so far as possible, of the demands of the various departments.

The first demanded much diplomatic interchange of ideas with the various supply departments, the Transportation Department and, in design of hospitals, with the Medical Department. The second required simplicity and standardization. Standardized buildings were therefore designed, so as: (1) to be built with a minimum of material: (2), to require minimum preparation for erection work: (3), to consume minimum time in erection, with minimum economical force.

As a result of this foresight and care, the Division of Construction and Forestry met all requirements most satisfactorily. Full recognition was had, at all times that we were building only for the duration of the war, resulting in suitability with the ut-

Digitized by Google

most economy. Permanent work, so to speak, was never undertaken, except where, by the nature of things, temporary cheaper expedients could not be adopted.

That civilian labor was never satisfactory should be emphasized. The lack of technical troops, as indicated by Colonel Woodruff, was most seriously felt. The services of such troops will be needed before those of all others in any campaign in which it is possible to conceive that the United States may become engaged. Wisdom would therefore dictate that these troops should, in time of peace, form a larger proportion of the peace organization and provision for necessary prompt expansion be adopted. All labor in the theatre of operations should be militarized, and it may even be questioned if the same policy should not be adopted for all war workers, wherever employed. Therefore, in all legislation looking to preparedness, provision must be made for obtaining quickly such labor in amounts as circumstances demand.

A few words seem desirable in regard to the road question. In the first organization, roads formed a branch of the Transportation Department. All road work from base ports to the Zone of the Armies was under a Director of Roads, under the Director General of Transportation. Later, roads, together with light railways, were separated from the Transportation Department and combined under the writer, as the Department of Light Railways and Roads. After careful consideration, it appeared to me that, except in the Advance Section, perhaps, the roads in the S. O. S. should be under the Department of Construction and Forestry and, accordingly, the necessary instructions were issued. The only reason the roads of the Advance Section were left with the Department of Light Railways and Roads was that, at the time, it appeared that road work so far to the front and joining up with the road work of the Army Zone should be under an officer or department with headquarters nearer to the front than were those of the Department of Construction and Forestry. I therefore had headquarters of Light Railways and Roads, although one of the large subdivisions of the Office of the Chief Engineer, A. E. F., placed in the Advance Section, in order that the Light Railways, only used at the front, might be under closer supervision, and where emergencies could be more quickly met. The exact line of demarcation between road work under S. O. S. and under Armies was never finally decided; but, in general, I am of the opinion that the S. O. S. should do all road work in rear of that which Army troops must necessarily perform. The line would thus be variable and advance or retreat as exigencies of the campaign dictated.

There are several other questions of like nature which were not definitely answered, but no troubles arose therefrom, as everyone in the A. E. F. was there to do his bit, and it was rarely that questions of precedence, or exact status, were raised. A man, officer or soldier, given a piece of work to do, did it and asked questions afterward, or forgot it.

Our experience in France brought out the fact that all construction in the theatre of operations should be under one head, and that head, beyond question, should be the Engineers—fitted by education and training especially for such work. The previous training of our officers in construction, mainly in river and harbor work and fortifications, was of the utmost value to them in dealing with the large problems arising in France demanding prompt decisions and rapid results. From this previous experience the satisfactory organization of the work was promptly developed, and no time was lost in experiments. That army engineers should be trained in such work is so apparent that to state it seems almost supererogatory. Further, that all construction of the Army, in peace as well as war, should devolve on them as one of their duties seems equally apparent. The present situation, with an engineer construction branch in the quartermaster corps, is anomalous and should be corrected. Aside from the value of such work in time of peace as a training school where young engineers under older and more experienced men can be trained in construction methods, handling contracts, contractors and men, there are other controlling reasons for such assignment of army construction. These may be briefly enumerated as follows:

(*a*) The Engineer Department is already organized for carrying on work of all kinds and magnitude. A separate organization for the purpose is an evident duplication.

(*b*) An economy in overhead charges would evidently follow.

(*c*) Greater economy and efficiency in the actual prosecution of the work should certainly follow. That is what trained engineers are for and the record of the Corps of Engineers bears out their claim to efficiency.

(*d*) Elimination of competition between various branches of the army in purchases of supplies and labor in peace and war, as was conclusively shown to be necessary in France.

This whole subject might be discussed much more extensively, but it is thought that here only an outline of what was definitely shown in France at best can be given.

In conclusion, Colonel Woodruff deserves much credit for his very complete article.

Maj. Gen. M. M. Patrick
Director of Division of Construction and Forestry
American Expeditionary Forces

Colonel Woodruff has set forth very clearly and concisely the immense amount and the varied character of the work done by the Engineers in France.

Digitized by Google

It is a plain, unvarnished tale of unswerving devotion to duty and of magnificent achievement under conditions that were more trying than can be realized by any who were not in the midst of them.

The writer was in charge of this work for about 8 months, from September, 1917, to May, 1918, the commencement of it all, a period when we were little acquainted with French minds and methods and when they knew nothing of us, of our energies, our visions, our capabilities. There was never a time while we were in France that there was not a sad lack of both men and material sufficient to do all of the work which was really necessary, but this lack was more real and more apparent during these first few months. It was then that we had to argue at length with the French, to convince them that they must sacrifice some of their well beloved forests, stake them upon the outcome of the war, for if the war were lost it would make little difference to them whether their forests were standing or not.

It was then that the Chief Surgeon recommended that the Chief Engineer, Lines of Communication, be ordered to supply lumber for flooring tents in order to prevent pneumonia, only to be told that it would be a far easier task for the Chief Surgeon to discover or invent an infallible cure for this disease.

It was during this winter of 1917-18 that the engineer regiments, which Colonel Woodruff rightly calls the backbone of the construction force, the others that were added to them, all in fact, officers and men who were part of the organization, showed their worth by the way in which they worked in snow and rain, in mud and mire, giving every bit of brain and brawn they possessed (which was much) to carrying on the tasks which devolved upon them.

There were further complications due to the fact that there were some who seemed to fail to realize the war conditions under which this work was being carried on. They apparently wanted all construction work done along the lines to which they were accustomed in the United States with unlimited resources and under peace conditions. It had to be hammered into them that this was not a time for striving after perfection, it was a question rather of providing something, no matter how rude, that could be made to answer the purpose, that they were expected to get results, and to get them with the means available.

Colonel Woodruff is slightly in error in stating that all railroad construction work was turned over to the Transportation Department the middle of September, 1917. Construction work of all kinds was under the Chief Engineer, Lines of Communication, until the 31st of October, 1917. On that date there was a division of work, that at the ports and some of the railroad construction work being turned over to the Transportation Department, the rest remaining under the Chief Engineer.

As had been pointed out quite clearly and emphatically before this division of work and responsibility took place, it was an unfortunate arrangement, and one which did not make for economy or efficiency. There was the inevitable duplication of overhead, and, then, with sadly insufficient numbers of men and quantities of material, there was the conflict between the two departments, each probably thinking its work the more important and each consequently striving to get such men and materials as were available in order that its own work might progress, even though the work of the other suffered. There was no possibility of establishing correctly the relative priority of all of the different projects.

It took just about four months for this state of affairs to be realized, and then all construction work was put back where it had been originally. But part of this four months was time lost, just when time was most precious.

One of the outstanding lessons of this experience in war is that all of this engineering work should be under one head. In such a war there will never be men enough nor material enough. They must be shifted from place to place as the needs demand. The priority of the many projects must be established, but with the knowledge this may be changed many times by the changing conditions of the struggle and a concentrated power must exist to make such changes and to utilize the entire resources of the army to the very best advantage. This is utterly impossible when the work is divided, part put under one, part under another organization.

Other striking facts were the efficacy of the methods developed under the Engineer Department of the Army and the value of the training on civil works which our officers had acquired. Essentially simple, the Engineer Department methods were adaptable and the organization was capable of great expansion. Decentralization, making each man in charge of work carry his own burden, but with the certainty of vigorous backing when this was needed, was one of the factors in the successful conduct of this great task.

The fact that engineer officers had been doing civil work was responsible for their having come in contact with men of just the kind with which they had now to work. It had accustomed them to large enterprises and had given them vision.

On the other hand, too much can not be said for the men from civil life, many of whom, at great sacrifice, came forward and gave themselves, their brains, their knowledge, their trained intelligences, to aid in winning this war. They were truly loyal and unsparing of themselves. It was always certain that each one of them would do his best. The great difficulty was to determine each man's capability and to put him at work where he would be most effective. Many times this was not possible, but nevertheless these men,

Digitized by Google

one and all, did earnest and effective work under whatever conditions.

Brig. Gen. Edgar Jadwin

Director of Division of Construction and Forestry American Expeditionary Forces

The work of the Division of Construction and Forestry is ably described by Colonel Woodruff, both as regards the difficulties encountered, the results accomplished and method by which these results were obtained. I can not let the opportunity pass without a word as to whom the credit belongs for these splendid results.

Looking at it in retrospect, my predominant thought is that everbody connected with the work at any time showed a most commendable, patriotic and intelligent devotion to duty. This applies both to officers and men from the regular army and to those in the army only for the war, and applies also whether the organization be regarded chronologically or from top to bottom.

With the changing force which at times was as great as 160,000, it is manifestly impossible to cite all the names, much less to specify fully the specific items for which each man should be commended. I can not, however, let the opportunity pass without including at least the names of the heads of the central office organization and of the construction work in the field, namely,

CENTRAL OFFICE ORGANIZATION DURING MY INCUMBENCY.

Col. J. A. Woodruff	Deputy Director.
Col. E. A. Gibbs	General Construction.
Col. J. H. Graham	Railroads and Docks.
Col. E. H. Marks (later Lt. Col. W. B. Greeley)	Forestry.
Maj. Geo. Sykes (later Maj. H. W. Gregory)	Administration.

The construction work in the field was carried on through the following section Engineer officers:

Base Section No. 1—	
Hq. St. Nazaire	Col. J. S. Sewell.
	Lt. Col. W. G. Atwood.
	Lt. Col F. B. Maltby.
Base Section No. 2—	
Hq. Bordeaux	Col. J. B. Cavanaugh.
	Col. Hugh L. Cooper.
	Col. Ernest Graves.
	Col. J. R. Holman.
Base Section No. 3—	
Hq. London	Col. R. G. Powell.
Base Section No. 4—	
Hq. Le Havre	Col. W. A. Johnson.
	Maj. Geo. S. Brinkley.
Base Section No. 5—	
Hq. Brest	Lt. Col. E. V. R. Payne.
	Col. Mark Brooke.
Base Section No. 6—	
Hq. Marseilles	Col. R. C. Moore.
	Maj. A. B. Cutter.
Base Section No. 7—	
Hq. La Rochelle	Col. J. R. Holman.
	Lt. Col. J. W. Williams.
	Maj. C. C. Cragin.
Intermediate Section, East—	
Hq. Nevers	Col. E. N. Johnston.
	Col. Harry Burgess.
	Col. Geo. H. Webb.
	Lt. Col. J. L. Buchanan.
Intermediate Section, West—	
Hq. Gièvres	Col. Ernest Graves.
	Col. S. B. Williamson.
	Lt. Col. E. L. Daley.
Advance Section—	
Hq. Neufchateau	Brig. Gen. J. F. McIndoe.
	Col. T. H. Jackson.
	Col. Ernest Graves.

The forestry work in the field was carried on through district commanders, each of whom also commanded a battalion of 20th Engineers (Forestry), with attached service companies which operated from two to eight sawmills.

Most of the mills were in the advance section and base section No. 2.

The districts in the advance section were combined under Lt. Col. C. B. Chapman (later Maj. F. F. Spencer), section forestry officer, and those in base section No. 2 under Lt. Col. Raymond E. Benedict, section forestry officer. These officers acted directly under the central office for production and shipments outside their own section, but filled local requisitions on the orders of the section engineer in whose section they were located.

Col. J. B. Cavanaugh

Engineers

Colonel Woodruff's presentation of the accomplishments in construction in the A. E. F. needs no additions to show clearly the debt which the Expedition and the country owes to the engineering profession, and which General Pershing acknowledges in his letters of appreciation quoted.

While, as indicated by Colonel Woodruff, the most important and ever-present handicap of the construction program was lack of material and personnel certain difficulties and defects of organization were met by practically all officers in charge of construction which, by careful consideration and the application of remedies dictated by experience gained, might be removed in large part so as to make future operations of this character less difficult.

While the construction materials and engineering equipment available were distributed and used to the best possible advantage, I am convinced that the commanders of all engineering organizations first overseas were thoroughly impressed with the importance of having complete equipment accompany the organization, and those commanding officers who in spite of strenuous objections found their organizations

Digitized by Google

separated from their equipment on embarkation from the United States, saw their fears and objections wholly justified by subsequent loss of efficiency through failure to secure the wherewithal to work.

However wise the general policy of equipping organizations from supplies shipped to depots may be, engineer organizations sent in advance to prepare the way for large movements should not be forced to depend for their equipment upon the shipment of supplies to depots which have not yet been established.

As to the character of equipment and supplies provided for the A. E. F., a study of the supplies in engineer depots in France leads to the conclusion that the items of equipment furnished for construction work and the classes of construction materials were more varied and extensive than were actually needed, and that the primary importance of the saw and hammer of the jack-leg carpenter was underestimated.

While at least the original equipment of engineer organizations may be simplified to include only an ample supply of instruments and tools for rough work, this equipment should be kept with the organization as long as the infantry keeps its rifle.

The greatest lack in equipment experienced on the work with which I was directly connected, aside from the part of the regimental equipment left behind at New York, was of the simple tools necessary to keep labor troops and combat troops, assigned for work, usefully employed.

With construction materials the greatest difficulty aside from their scarcity was lack of immediate availability due to failure to pack all the nails, bolts and other items necessary for erection so thoroughly tied to the shipments that any important part would be complete in itself. Rails should be accompanied by bolts and spikes; roofing and other building materials by nails, special cements, and other materials for erection, and structures in every shipment should be complete, since classification and assembly in the field is far more difficult than at the shipping point.

A consideration of the engineering and construction personnel drawn from civil life, which actually did the work, and to which the success of the construction program is so largely due, leads to the conclusion that the qualifications found most useful were adaptability and enthusiasm coupled with recent experience in handling men or upon actual construction.

The real engineering problems were few, while the amount of work to be actually accomplished was immense. Therefore, workers rather than advisers were necessary, and the field for consulting engineers of the highest grade was small. The axiom that in war the vast majority of men are employed below their full capabilities was well illustrated by the duties of engineers in France.

While in general the spirit shown by engineers of training and experience was of the finest, many of them felt that they were called upon to perform duties not in accord with their training and capabilities, and not all of them were able to recognize that this was inevitable since positions calling for the exercise of their highest qualifications did not exist, or required not only a knowledge of engineering but also familiarity with military and government procedure.

Faulty assignment of officers with respect to special qualifications was one of the inevitable results of lack of preparedness, but this fact was generally recognized and due to the great adaptability of the engineering profession; as a whole, the amount of dissatisfaction and discontent resulting was surprisingly small.

Many of the service battalions and labor organizations were officered by men entirely competent to take charge of large independent works, where the only practical use of their organizations due to the character of enlisted personnel or to the military situation was to utilize them practically as labor forces under the supervision of others at times no more competent than themselves.

Where independent work was not available, the best results were secured with those organizations of labor troops and service battalions where the officers were qualified more for handling men on construction work than as enginers accustomed to the supervision of construction work in direct charge of others. For labor troops construction superintendents and foremen make the most desirable officers.

Criticism, unless constructive, is unwarranted, and in view of the splendid accomplishment in construction in the A. E. F. is offered with reluctance. It is my opinion that the plans, particularly for transportation facilities, tended too much towards the desirable or ideal and could have been simplified with reduction in labor and material far outweighing the resulting loss of efficiency. This opinion is supported by satisfactory functioning of incomplete facilities and the small use of some of those provided, and further by the fact that the later tendency in all plans was towards greater simplicity.

Broadly speaking, the organization and administration of construction work in the A. E. F. was that used in the United States by the Engineer Department in the execution of public works, a competent engineer officer experienced on construction work in general charge, with other trained engineer officers in local charge of the different localities, and a decentralization of authority to the widest extent practicable under the military conditions existing in France.

The most responsible positions in original organization were filled largely by engineer officers of the regular army, but as the organization was expanded and tried out and engineer officers from civil life acquired the necessary military experience they replaced to a large and increasing extent the regular officers, thus not only securing well-earned recognition but

Digitized by Google

also releasing the regular officers who were urgently needed for other duty more strictly military in character.

It is thought that my own personal experience in charge of construction work was not different from that of other engineer officers similarly placed, and this experience brought home the realization that the training secured on public works in time of peace was the most valuable part of my equipment for construction work in time of war.

Experience in handling contracts, in supervising the work of large organizations, in dealing with local authorities of the United States, all found its use in connection with the problems in France.

The important elements for the most successful conduct of engineer operations in time of war, as indicated by experience in the A. E. F., may therefore be summarized as follows:

(*a*) Training and broad experience in construction work for military engineers, such as that now obtained on public works in time of peace.

(*b*) Such a listing and classification of engineers in civil life as will permit assignment in line with special qualification and provision for training in military matters to fit them for the discharge of all the duties of an engineer in time of war.

(*c*) Control of engineering equipment and supplies by the department responsible for engineering and construction work in the field.

(*d*) Simplification of engineering supplies and equipment and special adaptation of both to field requirements.

(*e*) Simplification of type plans and a determination of minimum requirements which shall take into consideration not only what is desirable but what is reasonably practicable of accomplishment.

Col. Ernest Graves
Engineers

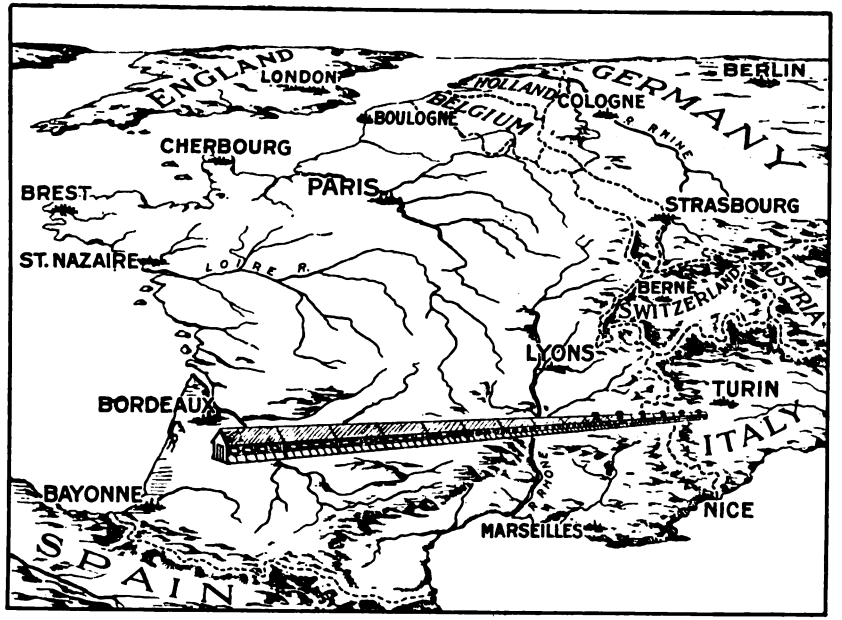
Colonel Woodruff has given us a complete, unimpassioned and accurate account of the engineer construction done by the American Army in Europe. The figures are so enormous that it is difficult to get a birds-eye view of the magnitude of the greatest engineering feat of all time.

The pictorial maps herewith show that the barracks constructed, if placed in line end to end, would reach from Bordeaux, France, to Turin, Italy. Wood cut and corded in line would extend from Bayonne to Nice, thence to Strasbourg and thence to Brest. Enough standard-gauge railroad was laid to make a double-track line from Bayonne to Berne, Switzerland.

During the early, formative days of the A. E. F. there was much uncertainty and embarrassment in fixing the responsibility for the execution of the many and varied construction projects involved in our participation in the mighty struggle. Every branch of the service had construction projects to be promptly executed and all faced the same difficulties of lack of personnel and material. These various services were not equipped and especially they were not trained to do this work. All had other functions. There was a need for a single department with a single head to execute these vast projects. All the other departments turned hopefully to the Engineers. And this was right and proper, for the engineers alone of all branches of the service, civil or military, were trained and able to do the job. Their record in peace and war entitled them to the confidence of the other services, nor did they fail them in this trying time.

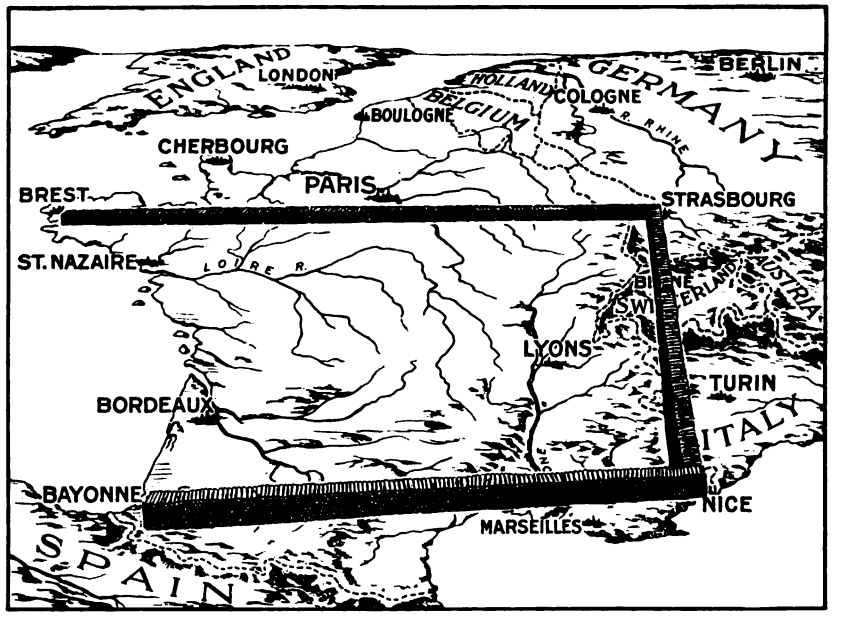
But in the beginning the engineers, like everybody else, had neither personnel nor material to work with. They had only their enthusiasm and confidence in themselves, based upon years of success in overcoming all kinds of difficulties.

On the first boat which carried Americans to France were some quartermasters having blueprints of type camps. These they turnd over in joyful confidence, not misplaced, to the engineers. When the quartermaster in France received from the States the plans for a large ice plant these likewise were handed to us. A firm of civilian contractors undertook to erect shops and warehouses for the Ordnance Department in France. After contemplating the apparently insurmountable difficulties for a time, they placed the responsibility upon the broad, though over-burdened, shoulders of the Engineer Department.



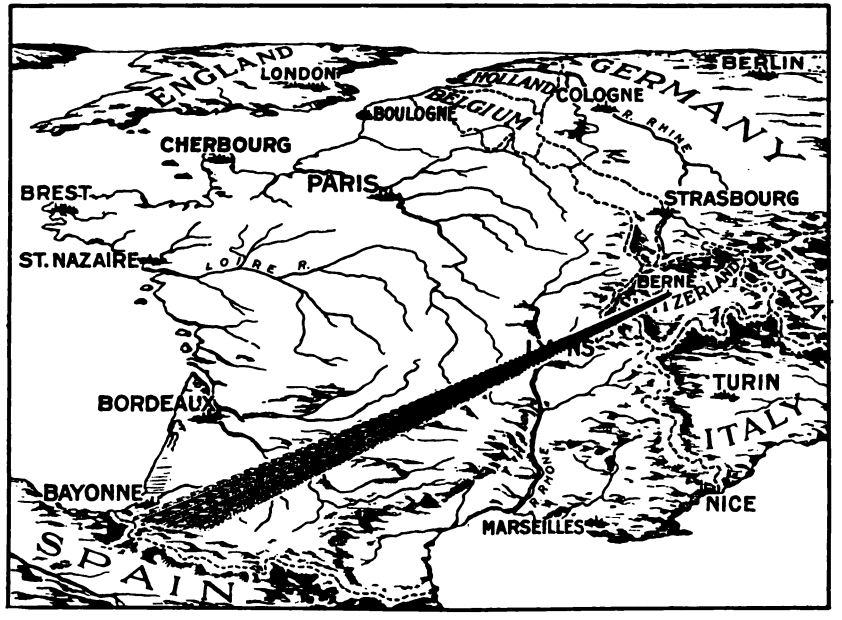
The Air Service, in like confidence, turned over their construction projects. And eventually all such tasks found their way to the department where they properly belonged and where they should have been, and should always be, from the beginning.

Construction of whatever nature and under whatever conditions (the worse the conditions the greater the stimulus) is the natural function of the engineers. We are organized and trained for such work, we ask only "lead us to it." That the army and the nation should look to the Corps for results in this line is natural, proper and just. The confidence of the other branches of the service that the engineers will do the impossible in their own line, a confidence which we have earned and repeatedly justified, is our special pride. It is the reason for our existence as a corps, the justification for our maintenance by the government. We wish the other services to rely upon us. We have not failed and we shall not fail them.

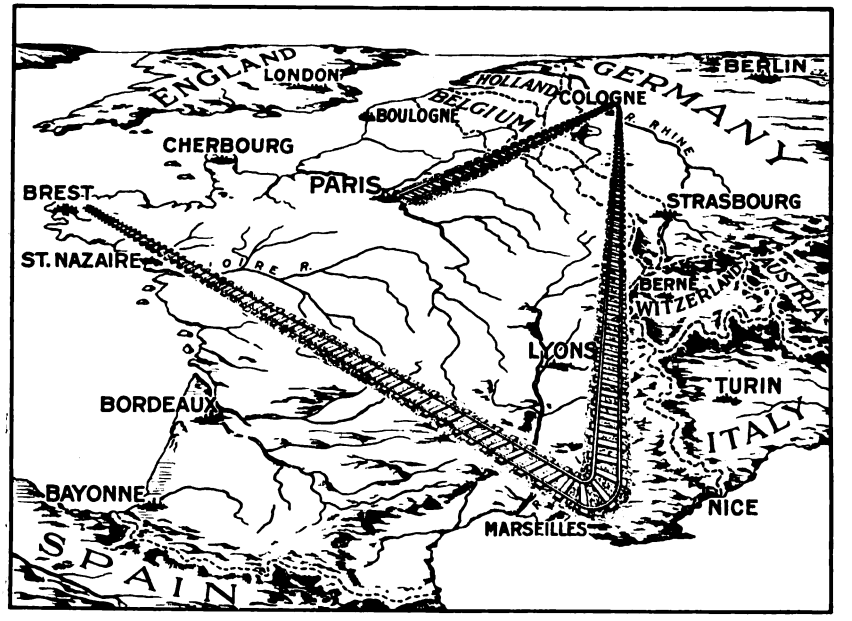


The methods of the engineers, developed by long experience, in handling men, funds, supplies, materials, machinery, property, etc., make it possible for them to perform large tasks under difficult conditions with the minimum of delay and lost effort. At every place where I was stationed in France, and that was all over the country, I was constantly being asked by officers of all branches to do little things which they could not get anybody else to do. Every engineer officer who has been on construction has had similar experiences.

For example, at Bordeaux I regularly furnished



Digitized by Google

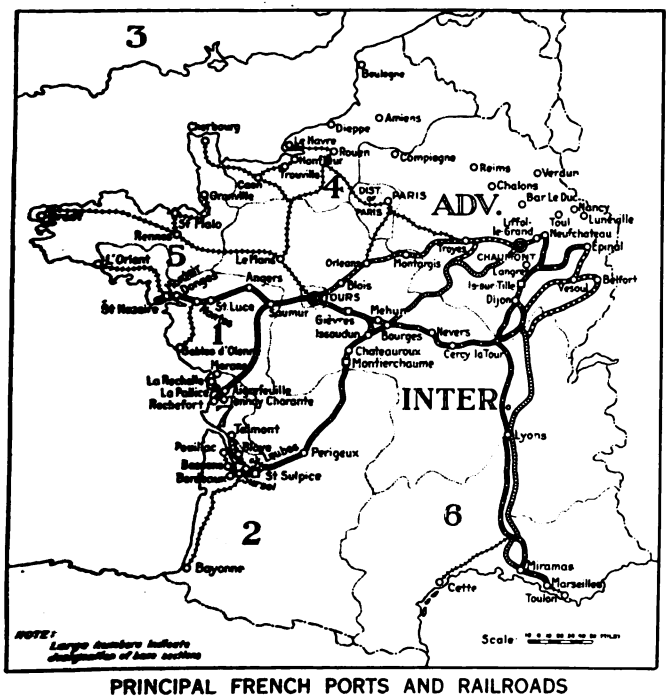


Barracks and Hospitals. The A. E. F. built 258 miles of barracks and 146 miles of hospital wards—enough to make a single building from Bordeaux to Turin

Fuel Wood. The A. E. F. produced 1,332 miles of fuel wood, corded 1 meter high by 1 meter wide—enough to reach from Brest to Strasbourg, to Nice, to Bayonne

Standard Gauge Railway. The A. E. F. laid 967 miles of standard gauge railway track—enough to construct a double-track line from Bayonne to Berne

Light Railways. On November 11, 1918, the A. E. F. was operating 1,400 miles of light railway lines—enough to make a single-track line from Brest to Marseilles, thence to Cologne to Paris



Digitized by Google

the Navy with small supplies which, as they said, they could not otherwise obtain for months because of "red tape" in their own department. At the same place I bought paper for an ordnance officer which he could not get from his department. Apparently, the fundamental facts that we were at war and that the United States furnished and paid for everything necessary to defeat the enemy, were not always successful in overcoming the "red tape" methods of peace.

A comparison, based on the number of men engaged, the amounts of materials consumed and money spent, and the results accomplished in a given time, would show that the construction of the Panama Canal, that "greatest feat of man," is overtopped and dwarfed by the work of the engineers in France during the great war.

A similar comparison between the work done under relatively far more favorable conditions in the United States and that done in France, would show that the storage space constructed abroad was almost equal to that provided at home, and that the hospital capacity furnished in France was twice that in the United States. The fact that expenditures at home were many times those in France has been explained by the statements that prices were high in the United States and that many of the supplies used in France were purchased and charged at home.

It is my opinion that the conspicuous success of the division of construction and forestry was due in large measure to the wise policies of Generals Patrick and Jadwin, in fitting their organization to that of the army and in working for and with all local army authorities for the attainment of the common end. And in even greater measure it was due to the spirit and enthusiasm of the Corps of Engineers and the American engineering profession.

PRINCIPAL FRENCH PORTS AND RAILROADS USED BY AMERICAN EXPEDITIONARY FORCES

○ SECONDARY PORTS AND IMPORTANT TOWNS □ LARGE DEPOTS
MAIN LINES SECOND LINES THIRD LINES OTHER LINES

IV.

[Extract from the final report of Gen. John J. Pershing, Commander-in-Chief, American Expeditionary Forces.]

. . . . . .

Among the most notable achievements of the American Expeditionary Forces was the large program of construction carried out by our Engineer troops in the Services of Supply and elsewhere. The chief projects were port facilities including docks, railroads, warehouses, hospitals, barracks, and stables. These were planned to provide ultimately for an army of 4,000,000 men, the construction being carried on coincident with the growth of the American Expeditionary Forces.

The port plans contemplated 160 new berths, including the necessary facilities for discharge of cargo, approximately one-half of which were completed at the time of the armistice. Construction of new standard-gauge railroad track amounted to 1,002 miles, consisting mainly of cut-offs, double-tracking at congested points, and yards at ports and depots. Road construction and repair continued until our troops were withdrawn from the several areas, employing at times upward of 10,000 men, and often using 90,000 tons of stone per week.

Storage requirements necessitated large supply depots at the ports and in the intermediate and advance sections. Over 2,000,000 square feet of covered storage was secured from the French, but it was necessary to construct approximately 20,000,000 square feet additional. The base hospital centers at Mars and Mesves, each with 4,000-bed convalescent camps, are typical of the large scale upon which hospital accommodations were provided. The hospital city at Mars, of 700 buildings, covered a ground space of 33 acres and included the usual road, water, sewerage, and lighting facilities of a municipality.

Advantages of economy and increased mobility caused the adoption of the system of billeting troops. Billeting areas were chosen near the base ports, along the line of communications, and in the advanced zone, as strategical requirements dictated. The system was not altogether satisfactory, but with the number of troops to be accommodated no other plan was practicable. Demountable barracks were used for shelter to supplement lack of billets, 16,000 barracks of this type being erected, particularly at base ports where large camps were necessary. Stables at remount stations were built for 43,000 animals. Other construction included refrigerating plants, such as the one at Giévres with a capacity of 6,500 tons of meat and 500 tons of ice per day; and mechanical bakeries like that at Is-sur-Tille with capacity of 800,000 pounds of bread per day. If the buildings constructed were consolidated, with the width of a standard barrack, they would reach from St. Nazaire across France to the Elbe River in Germany, a distance of 730 miles.

In connection with construction work, the Engineer Corps engaged in extensive forestry operations, producing 200,000,000 feet of lumber, 4,000,000 railroad ties, 300,000 cords of fuel wood, 35,000 pieces of piling, and large quantities of miscellaneous products.

"The scientists said it couldn't be done, but the damfool engineer didn't know that—so he just went ahead and DID IT!"

Engineer Duties in the Field in War

By

Col. R. R. Ralston

Engineers, U. S. A., Corps Engineer 4th Corps, A. E. F.

Continued from Page 24

work of general construction and road repair and maintenance. Details from the corps engineer regiment of first one and, later, two companies were also furnished the chief engineer, 3rd Army, for work in Coblenz and vicinity, and these companies handled a large amount of general construction work and also provided a depot detail for the army engineer depot at Coblenz. A detail from the regiment also took over and supervised the operation of a steam laundry and power plant connected with one of the 3rd Army hospitials when the surgeons were unable to get the necessary action out of the German operators. About 100 surrendered German trucks were turned over to the 4th Corps by the M. T. O., 3rd Army, for use in maintenance and repair of roads in the corps area. These were received by the corps regiment and issued to the division engineers as required; trucks turned in as unserviceable being repaired as far as practicable and re-issued.

With the establishment of the educational system in the A. E. F. in the spring of 1919, the station of the corps regiment became the site of the vocational schools for the 4th Corps troops; barracks and mess halls were erected and a number of classes started under the direction of the regimental commander; the park of German trucks referred to above, providing good material for the class in motor operation and repair.

The foregoing gives in a general way the engineer duties of the corps engineer troops of the 4th Corps while in the A. E. F., and is given in somewhat greater length than might otherwise be necessary, as it is desired to show that, so far as this regiment is concerned, its duties were practically the same as those of divisional engineers, and hence no special organization of engineers for duty as corps engineer troops appears to me to be either desirable or necessary.

The corps engineer regiment should be organized and trained the same as divisional engineers, and their equipment should be similar, except that some road building equipment might be made available for a corps regiment, in view of the heavier road work which will usually devolve upon them.

I do not regard the pioneer infantry regiment as a suitable organization for assisting in corps engineer operations, mainly for the reason that such a unit would serve a better purpose as a combat regiment. In the 4th Corps the personnel of the pioneer regiment of infantry, both commissioned and enlisted, was very good; but the officers, with few exceptions, had had very little experience in construction work, and hence the organization could not make an efficient working force for general engineer work. The work on which they were engaged could have been handled equally well by a corresponding strength of service or labor troops, and the personnel of the pioneer regiment would then have been available for combat duty.

It is my opinion that the most satisfactory auxiliary to the engineer troops is the service battalion, officered by engineer officers, with white non-commissioned officers, the remainder of the organization being colored troops.

The corps engineer, under tables of organization, was supposed to have the dual function of a corps staff officer and commanding officer of the corps engineer troops—a status similar to that of the division engineer. This arrangement, while generally satisfactory in the divisions, did not work satisfactorily in the corps, due to the fact that regimental headquarters was generally a long distance from corps headquarters; and during active operations it is more important that the corps engineer maintain a closer contact with corps headquarters than with the corps engineer regiment, if he is to be of the maximum service.

The regiment should be commanded by the lieutenant colonel, and if he is not qualified for that duty, the remedy can generally be found in a new lieutenant colonel. The operation of the corps regiment remains under the direction of the corps engineer, and can be directed by him just as well, if not better, if he is not in active command. The corps engineer was furnished by tables of organization, for his office at corps headquarters, with 3 commissioned assistants—1 major and 2 captains—and also a detachment of 9 engineer enlisted men, besides a certain allowance of chauffeurs and orderlies. It was my experience that 2 commissioned assistants and 8 enlisted men were sufficient; 1 officer and 3 men on purely office work, 1 officer and 2 men on the supply of engineer equipment and supplies, while the remaining men were utilized in engineer supervision of jobs at corps headquarters or elsewhere as needed.

The corps engineer's duties in general consist of the direction of the engineer operations by corps troops, the co-ordination of engineer work throughout the whole corps, and the supply of engineer equipment and supplies to corps troops and to division engineers. He is usually called on to prepare the engineer plan included in any field orders, and to advise relative to engineer operations. In his relations with divisions, his actual direction of engineer operations by divisional engineers is neither necessary nor desirable, except in the unusual case where a concentration of all the engineer personnel of the corps is essential to the accomplishment of a definite task, and to

Digitized by Google

insure co-ordination of the divisional engineer operations with the general plan. The corps engineer is frequently able to secure from G-2 of the corps information relative to conditions in advance of our front lines that are of importance in indicating the engineering problems that are likely to be met with in case of an advance. In the 4th Corps such information was compiled and furnished by the corps engineer to division engineers in the form of an engineer bulletin. It was continued on the march into Germany in order to disseminate such information as was available relative to conditions of roads and bridges over which the corps was to advance.

In the 4th Corps sector prior to the armistice there were two corps dumps or parks and an army dump or depot, from which engineer equipment and supplies could be issued to division engineers or corps troops on requisition approved by the corps engineer. The approval of G-1 of the corps on engineer requisitions was waived, except in case of doubt as to the advisability of issue. When the 2nd Army was first organized, instructions were given prohibiting the issue of any materials from the army engineer depots without the prior approval of G-4, 2nd Army, which was in accordance with the provisions of general orders in the A. E. F. on matters of supply. The requirements of these orders had been waived, however, while the 4th Corps was in the 1st Army, and when enforced under the 2nd Army entailed a good deal of difficulty in getting engineer supplies, as the supply officer after getting his requisition approved at corps headquarters had to go in to army headquarters at Toul for the necessary approval there. After a week or two of this procedure, and some strong representations as to the unnecessary work and delay in this method of securing supplies, authority was again granted for the issue of engineer supplies, etc., from the army depot on approval of the corps engineer.

Corps dumps or parks were handled by 2nd Army engineer personnel, and thus constituted practically advance army depots, which were at the disposition of the corps engineer. In addition to these sources of general engineer supply, a small dump of camouflage material was maintained by the corps camouflage officer and issued as required. After the St. Mihiel offensive, due to the changed front, a great deal of new shelter became necessary for the troops in the 4th Corps sector. The corps engineer accordingly prepared plans for typical shelters both for men and animals, based on utilizing materials then available, and distributed them to the division engineers, requesting them to submit the requisitions necessary for sheltering their divisions. Delivery of this material was under way at the time of the armistice.

Requisitions were frequently received for articles not available in the corps or army dumps, and in such cases, when the circumstances warranted, it was necessary to send by truck to a depot of the service of supply or to a depot of the 1st Army, in order to receive them, and, if available, they were usually obtained without difficulty.

A card-index system was maintained in the corps engineer's office, showing what engineer materials, etc., were available in corps and army dumps, which enabled action to be taken on requisitions promptly.

The corps camouflage officer in the 4th Corps sector had under him a small detachment of enlisted men from the camouflage regment, and also several commissioned assistants from the infantry and field artillery, who acted as division camouflage inspectors, devoting their attention to correction of defects in camouflage, particularly in the artillery. This camouflage detachment rendered very satisfactory service.

The sound and flash ranging sections on the 4th Corps front also rendered excellent service, but it is believed that this is a service which should pertain to the artillery, rather than to the engineers, and it is understood that it is to be so assigned in the future.

My experience with the special army engineer services in the A. E. F. was quite limited, but all of the special organizations with which I came in contact gave evidence of a high class personnel and excellent performance of the duties for which they were intended. Whether or not such a variety of special units was necessary in the A. E. F. is a matter on which I do not feel qualified to express an opinion, but I believe it to be better practice to hold the number of special organizations to the minimum and rely principally on an all-around engineer organizations, like a pioneer regiment supplemented by special technical supervision by qualified engineer staff officers when considerable technical skill is required.

One company of the 37th Engineers, electrical and mechanical regiment, accompanied the 4th Corps on the march to Germany as part of the 3rd Army engineer troops, and was afterwards stationed at Trier. While some cases came up where the special qualifications of this unit were necessary, it was also engaged while in Trier on work of general construction for which a sapper company should have been used; but the high command will not and can hardly be expected to assign engineer work to organizations according to their specialty, particularly if a special engineer organization is the most available. This condition will always be present, and as the bulk of the engineer work, particularly in the zone of the advance, will be of the "pioneer" variety, I believe the bulk of the troops for duty as army engineer troops should not be special units ,but rather all-around engineer organizations like the divisional engineers.

Discussion

Maj. Gen. Joseph E. Kuhn
U. S. Army (Engrs.), Formerly Commanding General, 79th Division

As a member of the Board on Engineer troops, whose studies were mainly responsible for the organization, equipment and training of our engineer troops as applied in the war with Germany, I was naturally much interested in observing their practical results.

Digitized by Google

So far as my own experience is concerned I am satisfied that our divisional engineer regiments rendered uniformly excellent service and that their organization, training and equipment leaves little to be desired. Certainly the 304th engineer regiment, which I had the honor of commanding, demonstrated a high degree of efficiency, was always prepared to undertake any job and never failed me, whether in battle, on the march or in camp.

Colonel Ralston points out that with conditions obtaining in France, map reproduction by lithographic processes was outside the sphere of the divisional regiment. I agree with him and future equipment of divisional regiments should omit all lithographic equipment. The hectograph and blue or brown print processes will ordinarily enable the divisional regiments to supply all plans and diagrams required within the division. I also agree with Colonel Ralston's view as to the engineer train being made a part of the engineer regiment instead of a unit of the divisional train.

The present strength of the engineer regiment is, in my opinion, adequate, either for the divisional organization prescribed in the National Defense Act or for the organization used in the war with Germany. With a three brigade organization, one will habitually be in reserve so that the necessity of a 3rd battalion with the engineer regiment is not apparent. True, occasions arise when one could momentarily make use of a much larger number of engineers and instead of a 6 per cent allowance make ready use of a 50 or 100 per cent allowance. When the 79th Division went over the top at Montfaucon on September 26, it was assigned an axial road which ran obliquely across No Man's Land for a distance of 2 kilometers. This road was vital to the advance, and the entire engineer regiment, less one company with the tanks, was assigned to its repair. Instead of being a question of road *repair* it turned out to be a question of road *construction* over an area of overlapping shell holes, requiring 30 hours of the most strenuous work to make passable for animal drawn vehicles. It was an occasion when I would have readily voted for a 50 per cent allowance of divisional engineers. Organization should however, be based on average conditions, which the war showed were well met by a regiment of six companies in two battalions.

Searchlights played an unimportant role in the field operations of the American army, mainly because it engaged in open or semi-open warfare for which portable electric searchlights are not adapted. In position warfare such searchlights still have their place and engineer troops should at least be trained in their use. The experience of this war has shown that they need not form a standard part of the engineer regimental equipment. Their place is in the reserve engineer depots. Small portable electric lighting plants are simply indispensable for lighting division headquarters and the regimental equipment must provide for them in the future.

The assignment of construction work to the engineers was wise and logical. It certainly worked well within the divisional areas. The experience in field fortifications, demolitions and road work did not present any features different from those anticipated. I agree with Colonel Ralston that traffic control over roads under construction and repair in forward areas should be placed under the engineers until finished. Camouflage should form part of the training of divisional engineer regiments so as to be immediately available when required. I would, however, retain a special camouflage organization for the army, to handle exceptional cases such as arose during the war.

My experience with corps engineer troops was so limited that I do not feel myself qualified to speak. I was not favorably impressed, however, by the numerous engineer units to take care of special duties, such as forestry, quarrying, road construction, flash and sound ranging devices, electrical and mechanical, railroad construction, railroad operation, etc. While some specialization is unquestionably desirable, it seems to me this is carrying it too far. Instead of economizing man power we are actually squandering it. I concur with Colonel Ralston in the general view that corps and army engineer units should be organized and trained essentially the same as divisional regiments, that is, the men disciplined as soldiers, trained in the use of the rifle and in general military engineering. Their equipment should also be essentially the same as that of the divisional regiments. When so organized and trained corps and army engineer units will be prepared for almost any class of work and can be pooled or split up as required. Special equipment such as road-building and quarry machinery should be issued as occasion demands from the engineer depots and not assigned permanently to units. The name "pioneer infantry regiment" is a misnomer so far as the observed work of these regiments is concerned. They should be eliminated from future army organization and their functions performed by engineer service battalions.

Maj. Gen. H. E. Ely

U. S. Army (Inf.), formerly Commanding General Fifth Division, A. E. F.

I believe that the argument that the engineer train should be a part of the engineer regiment is sound, and tends toward desired decentralization. In regard to the divisional engineers, I think an increase in strength would not be justified. These units are already, relatively, much stronger than those of any other nation, and, in the present war, filled all requirements—even as to a reserve in combat.

Digitized by Google

While engineers will be called upon to do topographic work, they will be largely relieved by aeroplane photography. The lithographic equipment will not, in my opinion, hereafter be needed with an engineer regiment. On the other hand, I would prefer to have searchlights retained by the engineers, and I concur in the suggestions regarding field fortifications and camouflage, in their relationship to the division engineers.

In regard to the authority suggested to be given engineers when constructing and repairing roads, to act as military police, I would suggest that the military police be required to report to the engineer officer in charge of such work and be under his orders which, perhaps, it would be advisable to have approved by the G-1 in the divisional area. The traffic control would then remain under a single head and responsibility would be definitely fixed.

The present ponton equipment is antiquated and inefficient, but, for the sake of economy, it might be continued until replaced with an up-to-date efficient equipment.

One or more caterpillar tractors for removing ditched trucks or other traffic obstructions, and for helping transportation on steep, slippery hills, should be a part of the engineer train.

I agree, emphatically, with the comment and suggestions relating to "Infantry Duties" of engineer troops. One reason why I approve of the present large percentage of divisional engineers is that in emergencies they can be used as fighting troops, as they were employed to good purpose in both the First and Second Divisions or more than one occasion.

Col. George Grunert
Infantry, U. S. A., G-1 1st Corps and Deputy Chief of Staff 3rd Army, A. E. F.

The historical data requires no comment. In the discussion under "division engineers," I concur, especially, in the suggestion that the engineer train be made an actual part of the engineer regiment, and, further, suggest that the regiment be maintained at the "emergency" strength. Division commanders should not be encouraged to consider such a regiment as a reserve, for the tendency is always to draw on the reserve, thereby neglecting the engineering work.

Under "Duties," I agree in the main with the discussion set forth. I should maintain in the regiment well trained personnel for topographical work, to be employed when and where most needed. I agree, though, that lithographic equipment should not be retained. Searchlights should be retained. The latter properly pertain to the electrical group, should be handled by a technical service, and used where needed. I agree with the suggestions relative to the electric lighting plants, field fortifications and camouflage.

I think the division engineer regiment should especially provide for the rapid movement forward of the two regiments of "seventy-fives." The construction of temporary bridges should be made as strong as time and materials permit, and these bridges should be made sufficiently wide so that the corps engineers will not be under the necessity of rebuilding the whole structure.

Each division should have control over the roads within its sector. This control, and the Division A. P. M., is now under the supervision of G-1 of the division, who regulates the traffic. A close co-operation between G-1, the A. P. M., and the division engineer should, therefore, result in satisfaction to all concerned. Without such co-ordination, I would strongly oppose the handling of traffic by the engineers.

The discussion on ponton equipage and heavy fixed bridges is technical, but the future will certainly require tractor drawn vehicles to handle heavy cargoes of all sorts incidental to modern war. The engineer regiment should furnish and operate any tractors serving as "helpers" on steep grades or required in removing ditched trucks, but their use should be under the control of the A. P. M. who is charged with "traffic control." I agree with the discussion on general demolition and general construction work, but the comment following is technical, and I have nothing to add.

Under "Infantry Duties", I think the engineers should be given both engineer and infantry training. It has been my experience that division commanders are prone to use engineers as combat troops, when there is no real emergency, therby neglecting the engineering work. In this they are aided and abetted by the engineers themselves, who want to get into the scrap. This tendency grew to such an extent in the 1st Corps that several of our field orders strictly forbade the use of the division engineers in the firing line.

In the discussion of the various duties of the corps engineers, I might add that it has been my experience that the engineer troops assigned to a corps were inadequate to carry on the work when advances were being made over a devastated area. The building of roads, light railways, dumps, etc., besides the work on defensive positions and on construction, requires an immense amount of labor. The pioneer infantry regiments are not always available as they are needed for other work, such as burying the dead (men and horses), salvaging, etc. When the advance is rapid, the problem becomes more difficult, and the army troops can not come up rapidly enough to take over the work from the corps troops.

Following the detailed account of the operations of the 4th Corps engineer troops Colonel Ralston discusses the equipment of a corps engineer regiment. It is my opinion that the corps engineers should not be encumbered with heavy equipment, as these troops

Digitized by Google

must be mobile. Let the army keep such equipment, subject to call from the corps when it is needed.

In reference to "pioneer infantry", I think the term was a misnomer, at least in so far as the pioneer infantry regiments with the 1st Corps were concerned. They were strictly "labor troops", and as such assisted the engineers and furnished labor for other purposes, acting mainly as "burial detachments" and as "salvage detachments." If the so-called pioneer infantry is eliminated, then in their stead "labor detachments" should be furnished.

I agree with the statement concerning the "service battalion." But it should be remembered that there is other labor to be performed in a corps, aside from that connected with the engineers. The labor for "burials" should be under the supervision of the sanitary corps, and that for the "salvage" under the salvage service, both operating under G-1.

Regarding the dual functions of the corps engineer, I think there should be a corps engineer officer, in addition to the commanding officer of the corps engineer unit. I concur in the recommendation concerning the officer personnel of the corps engineer regiment, and also in the remarks following, provided the corps engineer works in close harmony with the corps G-1. Close liaison between the corps engineer and the army engineer, and the resulting proper stocking of advance army depots should make the approval of the corps G-1 and the army G-4 unnecessary on requisitions; they could then go direct to depots. Army G-4 can issue instructions (through army engineer) to depots to prevent one corps depleting the stock so as to endanger other corps.

The suggestions relative to the sound and flash ranging sections and the electrical and mechanical regiments meet with my approval. G-2 of a corps requires certain draftsmen, printers, etc. These should not be assigned permanently to the corps, because at times they are not needed by the corps, and should, therefore, be available, where neded, for assignment.

Col. John J. Kingman
Engineers, U. S. A., Chief of Staff, 90th Division
A. E. F.

I am convinced that the regimental organization for division engineers is thoroughly sound for war and will prove of great advantage in time of peace, in that it will afford opportunity for older officers of the Corps of Engineers to serve with troops. This is no argument for giving up the civil work of the corps, for without this work we would be deprived of our principal means of getting practical experience in engineer construction. We would tend to become engineers in name only. Those who feel that river and harbor work is of no value to the military engineer can have given but little consideration to the duties that fell to the engineer corps in France, particularly in the service of supply.

In the 90th Division, from August, 1917, to June, 1919, the engineer train was in fact a part of the engineer regiment from its first organization at Camp Travis, where quarters for the train were built adjacent to those of the regiment, and from that time on the training, administration and work of the train were supervised and controlled by the regimental commander. This plan worked very satisfactorily. Colonel Ralston's conclusion that the train should form part of the regiment is undoubtedly correct.

The experience of the 90th Division fully supports Colonel Ralston's views relative to the duties of divisional engineers in connection with map making and reproduction, handling of searchlights and the providing of electric lighting plants for division headquarters and for other purposes.

In our battle experience we found that the infantry looked to the engineers for advice and assistance in the location of defensive lines and depended upon them to lay the wire entanglements during the period of organizing a new position. The construction or improvement of the division post of command also falls to the engineers and at times they may be called upon to provide for the brigade posts of command.

I agree with the view that camouflage work should be supervised by a detachment of the division engineer regiment. When we were preparing for the St. Mihiel drive a camouflage officer was attached to the division and began at once to acquaint himself with conditions at the infantry positions and artillery emplacements. Rumors of German spies in American uniform were rife at that time, and our camouflage officer narrowly escaped being locked up by G-2. It often occurred to me that the so-called camouflage painting of field guns and motor trucks was worse than useless. I think the result tended to draw ridicule upon the whole idea of camouflage, an art which intelligently practiced has an important military value.

While the engineers have many duties, there is one which, for the divisional engineers, overshadows all others in importance, namely, the construction, repair and maintenance of roads and bridges. Success in this work during offensive operations must be assured whatever else is neglected. Unless the artillery and transport can get forward promptly the attack will soon come to a standstill. Too much emphasis cannot be placed upon the importance of putting through the roads. When a division attacks on a broad front with both brigades in line, it will be generally advisable to assign a battalion of engineers (less 1 company) to work in each brigade sector, the battalion commander to keep in close liaison with the brigade commander, but the battalion to remain under control of the division engineer. When a deep penetration is intended and the division attacks on a narrow front with the

Digitized by Google

brigades in column, it is then best to employ practically the entire engineer regiment on the axial road.

Where a river crossing is involved, ponton equipage and heavy bridge timbers must be brought up from the rear in ample time. This raises the interesting question as to whether our standard ponton equipage should be modified to carry the heavy trucks, tractors and mobile guns that now accompany an army. In my opinion the 5th Division's crossing of the Meuse River at Dun-sur-Meuse may be considered typical of such operations. In this case most of the infantry crossed on small canvas ponton foot bridges, next a standard ponton bridge was laid, and on this the machine gun units, 75's and regimental trains crossed. Meanwhile the destroyed permanent bridge was replaced by a timber trestle structure which was strong enough to carry the heaviest vehicles, namely, the 155 howitzers, 10-ton tractors, trucks of the supply train weighing 15,000 pounds loaded, and the heavy army artillery. This trestle bridge was completed in ample time to cross the 155 howitzers before the infantry had progressed so far that they could no longer be supported by these guns from the west bank of the river. Under these conditions it is generally practicable to supply the forward units by the regimental trains hauling from a dump near the river crossing.

If this may be taken as the normal method of forcing a river crossing, and I believe it may be, then there is not sufficient advantage to be gained from increasing the load capacity of the ponton bridge to offset the expense, decreased mobility and greater difficulty of construction. I do believe, however, that a metal boat similar to the German ponton is superior to our wooden type.

As stated by Colonel Ralston, it is often advisable to authorize engineers engaged on road work to control traffic on roads undergoing repair. We also found it advisable to charge the engineers with the duty of providing and operating one or more motor trucks with suitable tackle and equipment for the purpose of hauling trucks out of ditches. Travel at night over slippery roads without lights always left the ditches full of trucks in the morning.

The mention of the use of high explosives for wire cutting reminds me of the anxiety with which we studied this problem in preparing for the St. Mihiel offensive. In our sector there were oceans of wire to be crossed. During the hot fighting in the Bois le Prêtre in 1915, the opposing front line trenches were but a few feet apart, but later, as each side despaired of making any advance at that place, they both withdrew somewhat, building new trenches and adding band after band of wire. We had no tanks assigned to the division and the brief four hours of artillery preparation at night precluded any effective wire cutting by that means. Consequently we gave serious thought to the possibilities of bangalore torpedoes, and also the use of chicken wire or matting to be carried forward and unrolled over the entanglements. We found, however, the available amounts of torpedoes and wire were not a drop in the bucket, and even had sufficient quantities been available the large number of men necessary to handle them would have made the plan impracticable. Consequently we placed our reliance upon wire cutters and fortunately were able to secure an adequate supply of large, two-handed cutters, which were issued liberally to the infantry. In each platoon a few men were assigned the job of cutting a lane through the wire. Somehow they got through or over the wire, to the amazement of the French officers attached to the division. However, I recall very distinctly that just following that attack it was necessary to issue new breeches and new puttees to practically every infantryman in the Division.

I do not feel particularly qualified to comment upon Colonel Ralston's views regarding the composition and training of corps engineer regiments, but his conclusion that they should be, in general, similar to the divisional regiment with possibly some added bridge equipment, appears to be sound.

There will often be times when the amount of engineer work in the division will call for more troops than can be furnished by the engineer regiment, and details must be made from other troops. We found this to be the case in Germany, where it was necessary to construct a large number of mess halls, kitchens, stables, etc. The materials, and a certain amount of supervision and assistance were furnished by the engineers. When the spring thaw came, a similar situation arose in connection with repair of roads. The engineer regiment and available civilian labor proved inadequate, and it was necessary for several weeks to call heavily upon the infantry, artillery and machine gun units. This recourse should be avoided, however, when practicable for it always causes a slump in discipline, appearance and morale. Of course, the same objection exists in the case of the engineers, but such work is their legitimate function and it is really surprising how quickly they recover in discipline and appearance as soon as they are concentrated for training and given a few inspections by the division commander in competition with the infantry. The engineers like to believe that they can out-drill the infantry, and sometimes they do. When the personnel of the engineer regimnts is as well selected and qualified as it was during the late war, their training should aim at the highest standard of infantry training, discipline and morale. If this be attained a very moderate amount of time devoted to purely engineer training will be sufficient to assure the successful performance of engineer duties.

Col. John C. Lee
Engineers, Chief of Staff
89th Division, A. E. F.

This article is so sensible and sound that one hesitates to offer any comment other than endorsement, and, if one many, commendation. Without doubt the Board of Engineer Troops builded well. The regimental organization and general equipment were fully justified. It is felt that the engineers "delivered," and delivered in a manner creditable to the splendid traditions of the Corps. The author clearly points out certain defects in the organization, equipment, and handling of engineers. He has mentioned practically all that I have noticed.

My limited experience with engineer "specialist" organizations, as such, leads me to vote against them. I believe that the specialization needs can be met by selected officers and certain technical N. C. O.s—master engineers and sergeants 1st class—while the rank and file are just the run of hardy, well trained pioneers. Practically every result-getting engineer I talked to in France was opposed to specialist companies, battalions and regiments as such. It is believed that a few really capable specialists—by that I mean practical men of specialist training, not just theorists or extremists—can soon put a good pioneer organization into a special service job with assured success.

One of the great faults in our recent system—quite beyond engineer power to remedy, no doubt—was the curse of robbing organizations of their skilled men. I know of one engineer regiment particularly, and dare say the same conditions held for all others. This regiment was just built up of men from the river counties, mountain counties, mining counties and the two largest cities of Missouri in order to get pontoniers, woodsmen, miners and artisans. Since its division was drawn from agricultural states, it was felt that the engineer regiment should be given this special opportunity to get its personnel. A splendid lot of men were gotten together—a well rounded class of healthy young farmers, rivermen, lumbermen, miners, mechanics, surveyors, enginemen and construction men. All being from Msisouri, there was a basis for *esprit*. The colonel and his officers got a fine start on the rest of the division and gave promise of having the best regiment by long odds. Then came the black hand of fate in the cold night and snatched away the best of the men to go—no one knew where. Company organization, regimental esprit, friendship and mutual confidence among these lads went for naught. They had come in together and had grown keen to see it through in the regiment. Jim was ordered out one night as a specialist (secret destination); Jake was left behind. And so it happened again and again. The regiment was robbed and re-robbed of its best material. The men who were left, felt they were the scum—the goats—the day-labor class—cannon fodder. Morale and esprit were almost impossible. Thus a fine regiment, with full promise of a glorious future was shot to pieces before it left its first cantonment.

Now this happened all through the line. I think it was even worse in the infantry. Instead of fostering the feeling in the foot-soldier's heart that he was the man to win the war, that he was the select of the selected; instead of raising his morale and his *esprit de corps* to the highest—well, it seemed that everything was done to secure an opposite result.

The cure is simple enough. When men are called to the colors and assigned to a regiment, there they must serve unless removed for lack of ability—physical, technical or moral. If skilled artisans are needed to make war-winning airplanes, we can draft older men—not bleed our front line regiments of their splendid young material. For replacements, we must have replacement units—and preferably by division if not by regiment. We had a fine start for territorial esprit in this war and then announced that it was scrapped. 'Twas bad enough not to produce on that sound plan. But why *announce* such a false policy? It only hurt morale.

I feel that this is a vital point. For if we meet it squarely we will have well rounded pioneer units, and under our sound system of organization and training, we wont need specialist organizations. A few practical officers and higher N. C. O.s (Regulars who have specialized but principally reserve men whose qualifications should be well known)—these will know the specialty and apply it to war conditions. They can always find numerous assistants and apprentices in a good unmolested pioneer regiment. And the rest of the men can do the attendant routine and labor, and do it on any job.

As the author says, our training system was sound. It's a good thing to dust off Part I of the Engineer Training Manual now, and re-read (or read) it in the light of the recent experience.

It is felt however that the author goes a little too far in his desire to train and equip engineers for infantry fighting. Perhaps he is leaning intentionally against a predicted wave of opposition. Happily, however, it is felt that the need of such a margin in this respect is unnecessary. The old reactionaries who used to talk about arming the pioneer with pick and shovel, really had their deserved rebuke when certain high staff people agreed and proposed for such troops the duty of policing the battlefield and burying the dead. Was it not a case of Greek burying Greek?

Practically every one now admits the pioneer is a fighting man and must be so trained and equipped—not for the prime purpose of fighting—but of being allowed to help the fighting man to the full measure

Digitized by Google

of his ability. In an emergency he must fight and fight well. But his first and normal function is to do engineering during fighting, alongside the fighting units.

The automatic rifle is heavy. Infantrymen frequently throw it away, when they get tired, and pick up a rifle. Their officers select the biggest men who are good shots to carry it—and a detail of ammunition carriers is necessary for each auto rifle. Each infantryman goes into action carrying all he can of his special weapons—grenades, extra rifle ammunition, and always some specialist arm or equipment—unless he is a scout and must be left specially mobile.

The engineer goes along carrying bangalore torpedoes, or heavy wire cutters, or Daly's wire escalier, or parts of a light foot-bridge perhaps. He can't be expected to pack a lot of extra infantry equipment too. He must carry his rifle and bayonet and ordinary ammunition. He must be able to take care of himself. But he is there primarily to work.

The use of the automatic rifle as well as the machine gun can profitably, and easily, be taught to the best shots of an engineer organization. In the past we have given special instruction to expert riflemen in the use of the telescopic sighted rifle. This time might well be spent on the automatic rifle, and the instruction extended to sharpshooters. It is believed moreover that sufficient interest could be aroused for these men to take instruction in automatic weapons outside of regular training hours. If possible, instruction should be given in the operation of enemy automatic weapons.

When the occasion arises where engineer troops are thrown into action to replace infantry, the men who have been trained in the use of automatic weapons will quickly pick up many of these arms from the infantry they have relieved or from the wounded and dead. Particularly this could be done in case of an attack. In case of a stubborn defense there is little advantage in the use of the automatic weapon over the efficient use of a full number of good rifles. Engineer troops have always shot well, far better than average infantry—and they should do so. In minor attack problems, reduction of machine gun nests, etc., our fire superiority must be gained by a group of riflemen, less vulnerable than the single auto rifleman, while the flankers work around to the desired point of vantage. In action, if the best shots have picked up automatic rifles, this training will prove all the more effective.

I firmly believe in infantry training for pioneers—both offensive and defensive—but I feel it would be a mistake to weigh down our troops normally with the heavier automatic rifles or other infantry weapons. All pioneers should know how to throw grenades—but should not have to carry them as regular equipment.

Regarding ponton equipage, it is believed that we should still maintain two classes—light and heavy. The light equipage should accompany cavalry divisions and be only strong enough to sustain cavalry divisional loads. In war of maneuver, these trains will accompany the advanced cavalry. In war of position, following a break through, these light trains might be pushed forward for use by the attacking battalions and their supporting guns, so long as the bridges might be subjected to observed fire. The heavier type of bridge, consisting of boats much larger than those now in use, could be of steel construction, tractor drawn, and designed to support all loads of an army corps.

It should be borne in mind however that a balance must be struck between the constantly increasing loads of military vehicles, particularly artillery and tanks, and the capacity of bridges and durability of roads. It is believed that the heavier loads should be broken up or spread out over a wider base, so as to permit workable size bridge equipment to be used, and a practicable system of road maintenance sustained.

Regarding the control of traffic by engineers in the front areas during an advance, such can be only very local control. The general priority and systems of traffic movement should be decided by the commander himself after careful consideration of the probable tactical situation, supply situation, evacuation situation on one side, and the probable condition of the roads on the other. Here he needs the advice of a good engineer, well informed as to the probable work ahead.

If such priority was determined in the St. Mihiel drive, certainly it was not enforced back of Flirey. I understand that D day in the Argonne and the days immediately following were quite as bad around Avocourt. On the last drive however, Nov. 1, 1918, we applied what we had learned—planned a real system of road repair and maintenance, made a real priority list and enforced it. Transportation not on the list for D day was kept back of a dead line—well to the rear. The engineers up front did control traffic over short sections requiring constant maintenance and repair—but it was strictly local. If a corps is attacking, this proirity is a crops matter, and must be enforced mainly by corps and division military police.

The author makes no comment on the training of mounted engineers. When that long looked for real crossing of the border finally comes, our pioneer squadrons must ride with the best, ready and able at all times to do hard and rapid work. We wonder if they are fit.

Digitized by Google

Major R. R. Ralston
Corps of Engineers, U. S. Army

It is possible that the suggestion for an additional battalion in the engineer regiment requires a little more explanation, as it was not the intention to increase the total number of engineers in a division.

The strength of the division, with its three infantry brigades, one artillery brigade, and other troops, as authorized by the national defense act of May, 1917, is practically the same as that of the division as organized during the war; but the six engineer companies, each consisting of 4 officers and 164 men, would total only 24 officers and 984 men, as against a strength of 36 officers and 1,500 men in the emergency organization, which is generally conceded to be adequate. Should, therefore, the organization of tables of organization of May, 1917, be substantially retained, nine companies of 4 officers and 164 men should be provided, which would furnish a total of 36 officers and 1,476 men.

Referring to the subject of military mapping by aeroplane photography, the idea which it was intended to express was that aeroplane photography would largely take the place of the numerous topographical reconnaissances, which, in an advance through a poorly mapped territory, are essential to the preparation of a suitable march map. Such reconnaissances are placed together with little or no control, and, in my opinion, much better results can be secured from aeroplane photographs in the preparation of this preliminary map. Later, when instrumental control becomes practicable, the photographs can still be useful in filling in many of the topographic details of the finished map.

The reference by Colonel Kingman to the crossing of the 5th Division at Dun-sur-Meuse as "typical" is correct, and is another illustration of the principle learned by us at Fredericksburg, in the Civil War, that before substantial bridges can be built the infantry must first secure control of the opposite bank, crossing by any practicable means. I do not think, however, that because a fixed bridge was constructed there, we should conclude that a ponton equipage adequate for heavy army loads is not necessary; for many conditions can be conceived of where the construction of such a fixed bridge would not be practicable in a reasonable time. With a suitable system of sectional—and hence metal—pontons, bridges adequate for the passage of lighter transport can be constructed with one or more sections, and afterwards by the use of additional ponton sections strengthened to pass the heavier transport and artillery.

While on this subject, it seems desirable to invite attention to the desirability of closer co-operation between the engineers who are charged with the preparation and maintenance of roads and bridges, and those services responsible for the design of heavy vehicles for supply and artillery purposes, as it is believed that impedimenta intended for transport overland should have certain limitations as to weight, so as to reduce damage to roads and excessive strength in highway bridges. One instance is recalled of a motor repair shop unit traveling overland to Coblenz in the spring of 1919, when the roads were badly damaged by some of the heavy trailers, one of which weighed 27,000 pounds. It is believed that a unit of this kind could have served its purpose equally well if the machinery it carried had been installed on railway cars instead of on trucks and trailers. Our future military operations are likely to be largely in countries where roads are conspicuous by their absence, or where they are of poor quality, and it is unsafe to base our ideas of overland transport on our European experiences, where we had the advantage of the best highway system in the world.

This article and the discussion thereon serve to establish a consensus of opinion on several important matters, by officers whose natural aptitudes and experiences qualify them to pass wise judgment. These opinions will be of great value in guiding our future policy as to the organization, equipment and methods of training of engineer troops for field service. It is also gratifying to find that in most instances the experiences of the late war confirm in a general way, our pre-conceived ideas on these matters. The following are worthy of special note.

Discipline and the soldierly spirit are the most important items of the field engineers' equipment. The most skilled artisans are almost useless in battle unless they are thoroughly disciplined. There never has been and never can be room for any difference of opinion on this point.

Prior to the great war most engineer officers entertained the view that combatant engineer troops should not be highly specialized. It was generally believed that specialization should be within the regiment and not by regiment. The war has thoroughly established the soundness of this opinion. An engineer regiment with the active army will be called upon to perform all kinds of pioneer duties and should be organized, disciplined and trained accordingly. All our colonels commanding divisional and corps regiments took a jealous pride in developing such organizations. They could and did perform with credit every task that was laid upon them. This demands a well balanced regiment, including civil, mechanical and electrical engineers amongst its officers, and a few practical artisans representing each of the common trades. Such an "outfit," when thoroughly disciplined, can "swing in" and make short work of any task. Specialized units may be usefully employed in the service of supply. Here discipline is of less vital importance

Construction of Lock D, Cumberland River

By

Rufus W. Pafford

Junior Engineer

Continued from Page 20

miter wall and opening into the pit below the upper gates. The ones used for emptying the pit are located just above the recesses for the lower gates and the two in each wall discharge into the same culvert, which remains within the wall until it gets below the gates, then each discharges from its respective wall opposite the other.

The erection of these valves presented no special difficulty. The form for the opening in the concrete leading from the valve straight down to the culvert is circular also. The valve seat was removed from the rest of the valve and placed over this circular form and bolted to same after being set with an instrument, level and to the proper elevation. The concrete was finished flush with the floor of the valve recess, and after this had properly set the remainder of the valve was bolted to the seat, and forms for the recess for the valve rod were placed as the work on this section of the wall progressed.

The lock was placed in operation December 21, 1916. During the two months that it has been worked, the valves have given no trouble. All of the eight valves are protected from drift by heavy iron screens. These valves are connected by rods to machines located in recesses in the top of the walls. One man can easily operate a machine.

The backfilling which the contractors did is behind the upper and lower guide walls and the land wall of the lock. This was made from waste from the excavation for the foundation of the walls, and a considerable part of it was gotten from the bed of the river with the dredge, unloaded with the regular unloading derrick and brought over the same tracks as the material for the concrete. This material was not screened but deposited just as it was taken from the bed of the river. It was necessary to dispose of practically all of the excavation from the pit before the land lock wall was built, so that the material for doing the backfilling had to be borrowed, and besides the specifications would not allow the use of rock behind the lock wall. The contractors considered this pumping plan to be the cheapest way of obtaining backfill and were allowed to use this natural mixture of sand and gravel and were required to compact it by pumping water on the pile as it was being dumped from the cars. This work was completed in August, 1914, except for the part back of the lower guide wall, which was done in the fall of 1916 with sediment from the lock pit.

Work on this contract has been completed, except about 300 cubic yards of earth excavation in the lower approach cofferdam and about 3,200 cubic yards of rock excavation at the same place. Parts of both cofferdams yet remain to be removed.

The contract was let to the Foster-Creighton-Gould Company, and they did the major portion of the work covered by the contract; but they have been succeeded by Foster and Creighton Company. Practically all of the work has been done under the supervision of Mr. W. F. Creighton as superintendent and his assistant, Mr. J. S. Dunbar, Jr. Major H. Burgess, Corps of Engineers, was in charge of the river work in this U. S. Engineer District until July 22, 1916, when he was relieved by Captain Jarvis J. Bain, Corps of Engineers; Captain Bain in turn having been relieved September 26, 1916, by Major Lytle Brown, Corps of Engineers. Mr. Jno. S. Butler, Assistant Engineer, had supervision of the Cumberland River. The writer was resident engineer.

Discussion

Lt. Col. Lytle Brown

Corps of Engineers

The construction of this lock, taken as a whole, was an excellent piece of work. The contracting firm, though not backed by great resources, was directed by men of sterling character, and sound judgment. Their local representative, a young graduate civil engineer, was exceptionally energetic and zealous, and worked for his firm with perfect loyalty. These are the principal facts which led to the successful completion of the work.

A point which may be criticised is the coffer of the lower approach. It was inadequate to keep out water. Experience shows that a failure to appreciate the importance of solid and adequate cofferdam protection is the source of most loss and trouble in lock and dam construction.

While this article treats of the construction of the lock only, an incident in the construction of the dam illustrated the lack of appreciation on the part of the contractors for the dam, other parties than for the lock, of the power of the stream.

The abutment lay against an alluvial bank; half of the dam, a rock-filled crib structure, rested on gravel as a foundation; this was the half next to the abutment. The half of the dam adjacent to the lock rested on solid rock as a foundation. Had there been any failure of the dam it would have been in that half next to the abutment. With such a failure, the other half remaining intact, the river would have opened a considerable channel around the abutment by attack from down stream. At least this is most probable, though

Digitized by Google

good rip-rap was placed on the bank below the abutment.

To insure protection to that part of the dam resting on gravel, a very heavy rip-rap apron of derrick stone was provided in the plans. The placing of this apron was slow and heavy work, and in rushing the work on the dam the contractors pushed the structure up to full height before they placed the rip-rap apron. High water caught them before they could place the apron, and they could not then approach the dam, either from above or below with their plant in order to complete the apron. A season of high water was before them, and the weak end of the dam, without adequate protection, was exposed for the entire high water season.

A cableway was borrowed from the Louisville District and strung across the stream below the dam so that derrick stone could be taken from barges in the lock and dropped into the apron area below the dam.

This was a simple piece of work without any striking features, but is typical of its class.

The author has well presented a number of features of economic importance which will be of interest to those engaged in construction in streams subject to flood. Amongst these the following are noted:

1. Accurate predictions as to the number of available working days or when they will occur, depending on the stage of water, are very difficult in river work. It appears to be a wise rule, when operating in flashy streams, to make the utmost use of periods of low water to concentrate on work which can not be done when the water is high.

2. The most important feature of work of this class is the proper design and construction of the coffer-dams. Colonel Brown points out that inadequate coffers are the chief cause of loss, delay and failure in lock and dam construction. In this case the author considers that an inadequate coffer was responsible for two years of delay in the completion of the work. Considerable latitude was apparently allowed the contractor in the construction of the coffer-dams. Whether or not this is wise depends on the contractor. It invites taking chances. Generally speaking, the government representatives, who are familiar with conditions on the river, are best qualified to determine what coffer-dams are necessary and to prepare the designs for same. Alternative designs submitted by the contractor should, of course, be given consideration. But the loss due to inadequate coffers does not fall alone upon the contractor. A few failures due to this cause give river work an undeservedly bad reputation amongst contractors, resulting in difficulty in obtaining bids and unnecessarily high prices to the government. Skill and good judgment in working under flood conditions have enabled some contractors to make good profits and bad judgment has meant failure and ruin.

3. Difficulties of channeling in hard rock. It may be better to excavate farther back from the face desired, by other methods.

4. Cyclopean or rubble concrete was advantageously employed in this case. The disadvantage of cyclopean concrete is that if constructed with sufficient care to insure ample strength the excess cost of labor may outrun the saving in material.

5. It does not pay to break rock too fine, as this usually increases the cost of subsequent handling. In this case larger pieces were handled more economically. This, of course, would not be true when the rock was removed by a steam shovel loading into cars or wagons.

6. The long boom derrick seems generally to best meet the situation in handling material on lock and dam construction. It is, however, a matter to be decided locally in each case, but before a cableway is installed it should be quite plain that the conditions call for its use. Derricks are used on nearly all construction jobs and are never "white elephants" on a contractor's hands, which a cableway is very apt to be.

7. Superior speed of erection of panel forms. Time is of the essence in river work, as it is in war. Better structural results are probably obtained with continuous forms.

8. A chute would appear to be the best way to place concrete on such a job as this. Specifications should not limit a contractor in this respect, since chutes are now successfully used in high grade column, beam and slab construction.—Ed.

Protection of Piles with Gunite

"Gunite," or dense mortar applied with a cement gun, is being employed to incase the piles of wharves and railroad trestles as a protection against marine borers, the teredo and limnoria. A single "gun" can cover about 75 square feet of surface to a depth of 2 inches in an hour, according to the statements of the manufacturers. The thickness of the coating of gunite varies from a thin scale up to 8 inches, depending on the condition of the pile. The latter thickness, of course, amounts to a re-building of a damaged pile. The treatment is applied only to that portion of the pile subject to the attack of the marine borers. It is claimed that after a seven-day set it was difficult to fracture even the thinnest scale with a hammer. When a coating of some thickness is applied better results are obtained by using a chicken-wire or expanded metal reinforcement. Piles which have been slightly damaged retain the coating better than new ones, as the mortar is forced into the holes, thus forming an anchorage for the casing, and killing any worms in the pile.

There is not as yet sufficient data to prove the durability of piles thus treated, but it seems a conservative estimate that in teredo-infested waters the life of piles may be increased from five to ten times or even more.—*Stone and Webster Journal.*

Engineer Duties in the Field in War

Continued from Page 76

and such units may be organized after the outbreak of war.

The organization of the pioneer regiments is regarded as satisfactory and the proportion of engineers as about correct. The engineer train should, however, be a part of the regiment, probably included in a supply company.

Road and bridge work constitute by far the most important duties of engineers with the active army.

Mapping and map reproduction on a large scale are proper functions of special troops. But a certain amount of such work will be required of all combatant engineer units who should therefore be provided with a simple equipment and the necessary personnel for this purpose. Lithography in the field will seldom be required of combatant units and a field lithographic equipment is hence regarded as unnecessary.

Aeroplane photography will to a great extent obviate the necessity for "filling in" topography by ground methods. It is as yet a moot question to what extent ground forms may be portrayed by this method.

Small electric lighting plants for divisional headquarters and other uses will be required. The divisional engineer units should be able to operate them.

Searchlights find little application in open warfare except for anti-aircraft defense. They should be procurable if needed, and the engineers should know how to operate them.

The impedimenta of the modern army demand heavier bridges than were necessary in the past. At the same time there is as great a need as ever for a light, portable equipment, including foot bridges. The solution would appear to be a floating equipment capable of being readily reinforced to carry at least all the divisional artillery with its tractors and heavy trucks, and probably even the 6-inch corps artillery. This should be supplemented by standardized trestle bridges of wood, or wood and steel, capable of carrying the heaviest loads. It seems doubtful whether a single type of floating bridge (in addition to foot-bridges) will meet all requirements, but this might be accomplished by the use of sectional pontons. The Lampert type bridge, which is a miniature canvas ponton, seems admirably adapted as a foot-bridge, and is the lightest, most portable and most quickly installed of any outfit that has been devised.

Divisional engineer regiments should be provided with a few tractors for hauling heavy materials and helping out stalled vehicles. If these were regarded as desirable in France they are certainly apt to be much more so in any other locality where the American army might operate.

The term "pioneer infantry" is regarded as unsatisfactory. The labor auxiliaries of the engineers should be "engineer service battalions," whose officers are engineers.

The corps engineer should not be the immediate commander of the corps engineer regiment.

There is no unanimity of opinion as to the extent to which engineers should be intrusted with traffic control. The solution is apparently a degree of control on roads actually under improvement by the engineers, and a close liaison between the engineers, G-1 and the A. P. M.

There is the usual sharp difference of opinion as to the extent to which engineers should be employed as infantry. A reasonable compromise between these divergent views is perhaps this. The engineers, being trained and equipped as infantry, form a reserve available as infantry in case of grave emergency. They should not *habitually* be so employed, nor to an extent which would unduly interfere with the performance of their proper functions. Engineers can be and will be used as infantry on occasions. They should have thorough training in infantry duties, and will be better engineers if so trained and in fact will not be good engineers *unless* so trained. This idea is well expressed in the last paragraph of the discussion by Colonel Kingman.

The practice of robbing engineer organizations of their skilled personnel, referred to by Colonel Lee, was undoubtedly carried to excess, and in many cases was most injurious to the working capacity, and still more to the morale of these organizations. It is, however, an inevitable procedure in the case of a nation plunged suddenly into a great war without previous preparation. It is one of the many evils resulting from our policy of leaving the national defense to chance.

There was, accordingly, some justification for the practice during the late war. Each commander and soldier should remember that, as Kipling says, it ain't the engineers, nor yet the infantry that win the battle, but "the bloomin' 'ole." If it can be shown that a certain man will be more useful elsewhere, and sufficiently so to justify the damage done to the organization from which he is transferred, then the transfer is proper, and in the interests of "the bloomin' 'ole." If the transfer of a few men will raise the efficiency of the machine as a whole, even if it temporarily lowers that of a certain organization, it is justifiable. We are all very prone to jealousy of our own personnel and equipment, and to feeling that the entire burden rests on us, instead of upon the whole army and the nation. Of course the way in which each commander can best help is to make his own "outfit" as good as possible. But he may do this and still not disregard the general efficiency. It is a fact that some of the engineer regiments that went to France were too "rich," that is they contained too large a propor-

Digitized by Google

tion of highly skilled mechanics who had often to be used as common labor. It is not a few good organizations that we need, but a high average, with all close to the average. A company composed entirely of marksmen is better than one containing a few experts and a corresponding proportion of "unclassified." It may not make as good a showing in a team competition, but it will be more dangerous in battle. An organization all of whose members were skilled mechanics would have a fine esprit, but it would not be an economical organization. The British learned this to their cost at the beginning of the war.

Local pride, resulting from all the members of the organization being from one locality, is a splendid thing and should not be wantonly destroyed. But there is a higher and more stimulating pride based upon *what we have done*, as many an engineer and infantry "outfit" in France has proven.

The robbing of organizations is most hurtful if carried to excess. This was well expressed by a captain in the writer's old regiment, who was protesting against the transfer of some of his best men. He said: "If a house is held up by 14 props don't knock them all out at once, or the house will collapse. If you must have props for other houses we will give them to you. But take a few at a time, and give us a chance to put in new ones before you take any more."

The only way in which this evil can be avoided is by creating a properly balanced organization in the first place, so that violent disarrangements will not be necessary. This requires a military policy such as the United States have never possessed.—ED.

Largest Bascule Bridge

The new bascule bridge across the Chicago River, installed by the railroads, is the largest of its type, being 260 feet between bearings of the movable arm. It is of the Strauss heel trunnion type. The two concrete counterweights weigh 885 tons each.—*Eng. World.*

Canal Across New Jersey

The state of New Jersey has surveyed a route for a canal from Bordentown on the Delaware River to Raritan Bay, and has appropriated $1,000,000 for right-of-way, contingent on the construction of the canal by the Federal Government.—*Eng. World.*

Extension of Our Highway System

The Federal Goverment has undertaken the construction of some 65,000 miles of paved highways throughout the United States. The various states of the union will construct and improve some 250,000 miles. Counties and municipalities will construct and improve 300,000 miles. This will make a total of over 600,000 miles of metalled road, the approximate cost of which will be 14 billions of dollars, divided as follows:

To the federal government, 2 billions.
To state governments, 6 billions.
To counties and municipalities, 6 billions.

All of this will be paved or metalled road. In addition to these figures 3 billions will be expended for earth roads. The approximate average costs per mile according to the above figures are

National highways	$30,000
State highways	24,000
County and municipal highways	20,000
General average	23,000

During the year 1918 some 250 millions were expended for roads, and during 1919 some 500 millions. It is expected that the rate of construction will be greatly increased in coming years.

Upon the completion of this work the United States will have, for the first time in their history, a nation-wide system of good roads, but there will still remain nearly 2 million miles of unimproved earth roads.

Engineers and National Defense

At a meeting of the American Society of Civil Engineers on October 15, 1919, in New York City, the subject of the "Relations of the engineer to the future military activities of the United States" was discussed by a number of prominent engineers from the army and civil life, and a resolution was passed referring the matter to Engineering Council for action. Maj. Gen. W. M. Black, Chief of Engineers, and Maj. Gen. W. C. Langfitt, former Chief Engineer of the A. E. F. were present.

Engineering Council has appointed a committee, designated as "Military affairs committee," which consists of the following:

Wm. Barclay Parsons,
Harold W. Buck,
Roger D. Black,
George Gibbs,
Fred J. Miller,
F. A. Snyder,
G. D. Snyder,
Leonard Waldo,
Paul G. Brown,
Lincoln Bush,
W. A. Starrett,
H. S. Crocker,
G. P. Solomon.

Wm. Barclay Parsons, 60 Wall Street, New York City, was designated as chairman, and George D. Snyder, 30 Church Street, New York City, as secretary.

The committee wishes to make a broad and comprehensive study of the problem of utilizing the technical resources of the country, in both men and material, in the event of war, desires the co-operation of the technical men of the country, and will welcome suggestions and information.

The recommendations of the Society, when formulated, will be presented to Congress.

The program for road construction in France involves the expenditure of about two billion francs which is expected to produce a road system even better than that existing before the War.

Building Cost in 1919

It is estimated that building projects in the U. S. in 1919 cost $2,600,000,000 which is nearly a billion dollars above the previous high record of 1918.—Eng. World.

When Are River and Harbor Improvements Worthy

of Being Undertaken by the Federal Government?

By

Maj. J. R. Slattery
Corps of Engineers

THIS is a question that recurs frequently in every river and harbor district. Most district officers have probably felt the lack of rules for their guidance. Congress has stipulated only that decisions are to be based on the commerce to be benefited. Hard and fast rules could not advantageously be laid down, on account of the numerous phases the problem presents, but it is proposed to submit certain rules, which, it is believed, do offer a conservative and more or less rational guide for most cases.

In considering this subject, improvements will be grouped in two classes. Under the head of rivers will be included channel improvements, such as those of the Ohio, and Mississippi above New Orleans—in other words, channels intended to provide for the continuous movement of freight. Under the head of harbors will be considered harbors proper, and such river improvements as are undertaken principally to serve as part of a port; for example, the Mississippi below New Orleans, the Delaware below Philadelphia and the Columbia below Portland. The former class corresponds to that portion of a railroad system between termini; the latter class corresponds to that portion of a railroad system at a terminus.

River Improvements

Persons investing money in the construction of a railroad, expect that within the reasonably near future there will be such a movement of freight and passengers as to produce a revenue sufficient to pay operating costs (including maintenance), a fair return on the capital invested, and allow the accumulation of some surplus. It is believed that the Federal Government can properly adopt a much more liberal policy in undertaking improvements than a private corporation would be justified in following, but on the other hand it is certainly wrong for the Government to embark on improvements that are economically unsound, or to continue improvements which, though economically sound in the beginning, have become unsound through changes in conditions. For example, before railroads are built in some part of a country, undeveloped, but capable of development, it might be sound policy to undertake the improvement of waterways capable of serving that country, with a view to assisting in its development. As the country develops, however, and railroads are built, there may come a time when so little use is made of waterways that their further improvement becomes economically unsound. The Erie Canal is, perhaps, a case in point. Before such improvements are altogether abandoned, however, consideration should be given to their possible use in the future, when further development overtaxes the railways, and it may become necessary to utilize all possible methods of transportation in order to care for the needs of the territory.

Consider first the case of undeveloped territory in which there are neither railroads nor improved river channels. This is the most difficult case for which to suggest a reasonably convincing rule, and any rule must be more or less arbitrary. Manifestly, development will not occur more rapidly than the produce of the country can be placed on the market, and sold at market prices, with profit to the producers. The real question to decide would seem to be to what extent the Federal Government is warranted in undertaking river improvement in order to offset the excess cost of profitably placing the produce of this undeveloped country on the markets, over that of produce actually coming to markets from other sections of the country.

If it were known, that unless certain territory were developed, the market price of such produce as could be obtained from that territory would increase by an amount which would represent at least 4 per cent interest, plus all fixed charges, on the capital that would be necessary to develop that territory and start its produce moving in such quantities as to prevent the market price rising, it would certainly be to the advantage of all for the Government to invest

Digitized by Google

that amount of capital in the development of the country. It would seldom be possible to determine just when such conditions would be fulfilled. If the market prices of what this undeveloped territory might produce were such that, if transportation facilities were provided, this produce would move in quantities, and at freight rates such that the revenue produced would at least equal cost of operation, maintenance, renewals and improvements, and 4 per cent interest on the first cost of such facilities, then, too, investment by the Government of the capital necessary to aid such facilities would be to the advantage of the country as a whole, provided the revenue from such facilities accrued to the Government.

It has not been the usual policy of the Government to construct and operate either railroads or boat lines, and it would not seem reasonable to base Government investment on earnings that do not accrue to it. Would there not, however, be reason in basing Government investment on *saving* in cost of transportation that might result from its investment, provided the amount of saving was commensurate with the amount invested, and provided, further, this saving was based on the difference in cost between more or less economical methods of transportation? If the amount that the Government was warranted in expending in the improvement of a river were measured by the difference in cost between hauling freight by wagon and by water, very large expenditures would appear to be warranted, and the Government might be assisting the locality, at considerable expense to, and therefore to the disadvantage of, the people as a whole. The locality might, however, be able to produce such great quantities of certain things, of which there was such a great scarcity on the market, so affecting their market price, to the country as a whole, as to fully warrant investment based on such great differences of cost. But it is probable that, generally long before such conditions existed, the possibilities of the country would have become so attractive to private capital as to have brought about the construction of railroads. Would not the difference in cost between hauling freight by rail, and by moderately improved river channels, seem to offer a fair measure for the saving to be considered? This difference may be taken as 4 mills per ton mile as a general average, although it would not be safe to assume that this was true in every instance.

If it should appear probable that, as a result of improving a river channel, the products of the territory served by such channel would move in such quantities, that if charged channel dues of 4 mills per ton-mile, the revenue produced would amount, annually, for an indefinitely long period of years, to the annual cost of maintenance plus 4 per cent of the first cost of the improvement; or would amount, in total, during a limited period of years to the total expenditures that would be necessary during that period for new work and maintenance; then it is believed such expenditures would be economically sound and fully warranted.

When railroads are built by private capital, this capital provides both the roadbed and the rolling stock. When the Government improves a river channel, private capital provides only the boats. In order that the Government investment in the river channel should be economically sound, there should be a saving in the cost of transportation such that it would represent a reasonable return on the amount of public money invested. It is believed that a reasonable return would be an annual saving, probable for an indefinite future period, at least equal to the cost of maintenance and other fixed charges and 4 per cent on the first cost of the improvement; or a total saving probable, during a limited period of years, at least equal to what it would be necessary to expend during this period for both new work and maintenance.

It would not be sound economics to double-track or better a railroad unless as a result of this work the earnings of the road could be increased, either through reduced cost of handling, or increased tonnage that could be carried, by an amount sufficient to pay a fair return on the sums that would have to be expended. Similarly, when a waterway has been or is improved to the extent of providing a usable channel, its further improvement is warranted only where as a result of the improvement there will be such a reduction in the cost of handling freight, or such an increased amount of freight handled, that the increased savings effected will at least equal the increased cost of maintenance plus 4 per cent interest on the additional cost of the new work.

When, therefore, it is a question of undertaking the initial improvement of a river in the interest of navigation, it is submitted that in order to warrant the Federal Government in doing so, one or more of the following conditions should be fulfilled—

(1) If there are no railroads serving the tributary country, it should be reasonably probable that such an amount of commerce will move over the stream that, if it paid channel dues of 4 mills per ton-mile (or whatever the figure might be) there would be produced (*a*) during a long and unlimited future period an annual revenue at least equal to the cost of maintenance, and 4 per cent interest on the first cost of the improvement; or (*b*) during a limited period, a total revenue at least equal to what would have to be spent during such period for both new work and maintenance.

(2) If there *are* railroads serving the tributary country, it should be reasonably probable that commerce will move over the stream, in amounts, and at costs such that the saving over what it would cost to move this commerce by rail at the established rates,

Digitized by Google

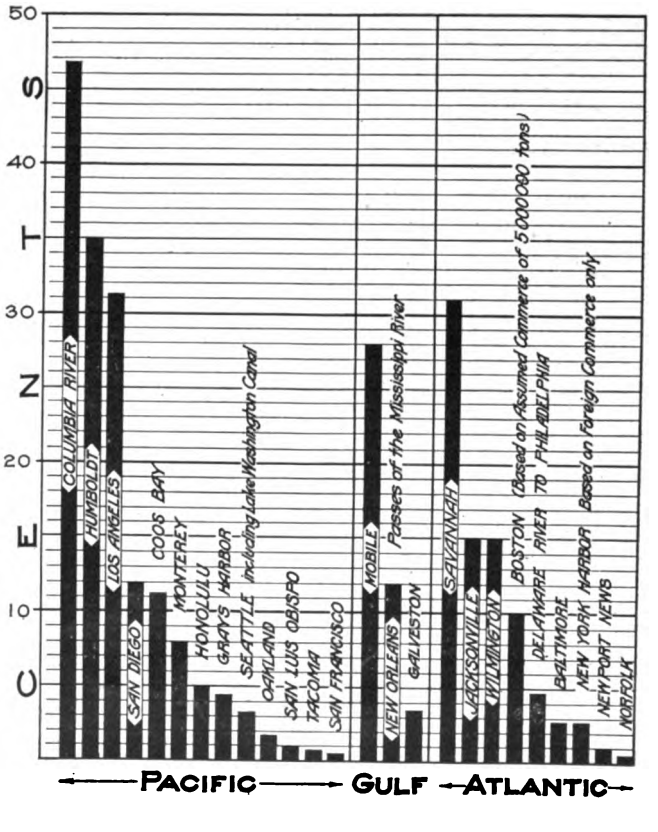
would at least equal (*a*) annually for an unlimited number of years, the cost of maintenance, and 4 per cent interest on the first cost, of the improvement; or (*b*) in all, for a limited period of years, the total amount that would have to be expended, during that period, for both new work and maintenance.

When it is a question of the future improvement in the interest of navigation, of a channel already improved, so as to be usable, it is submitted that in order to warrant the Federal Government in doing so, at least one of the following conditions should be fulfilled.

(1) There should be probable such a *reduction* in cost of transportation or such an increase in tonnage as to effect (*a*) an increased annual saving, for an unlimited period of years equal to the annual cost of maintenance plus 4 per cent of first cost of the later improvement, or (*b*) an increased total saving during a limited period of years equal to the total increased expenditures that would be necessary for new work and maintenance during that period.

(2) There should be probable, as a result of the new work, such a reduction in the cost of maintenance, including maintenance of the new work, as to at least equal 4 per cent on its first cost.

Harbor Improvements



The ton-mileage cost of handling freight at a railroad terminal or in a port can rarely be determined, and even if it could be determined would probably serve no useful purpose. The efficiency of a port or railroad terminal is measured rather by the cost per ton of handling freight through it. In each case this cost might be divided into two parts—in the case of a railroad terminal, into the cost of getting the freight in cars from the running tracks through the yards to the teaming tracks or freight houses, and the cost of handling through the freight houses, and in the case of harbors, into the cost of getting the freight in ships from the open sea up to the wharves, and the cost of handling it across the wharves. In many foreign ports where improvements were carried out by private or municipal capital, as distinguished from state appropriations it was, and in many cases still is, the practice to charge channel or harbor dues. In fixing these dues the aim was to secure an adequate return on the capital invested in the improvement. In the United States the cost of port channel improvements has been borne principally by the Federal Government and no dues have been collected with a view to securing a return on the sums so spent. If, however, it is determined what would have had to be charged per ton of freight handled at the various ports of this country in order to produce a revenue equal to the annual cost of maintenance and other fixed charges, plus 4 per cent of the first cost of the improved channels, the results will indicate to some degree how well these improvements have been warranted. This calculation has been made in the case of a number of ports, the dues determined in each case representing what would have had to be charged the average annual tonnage of commerce during the period 1914-1918, or 1914-1917, in order to produce a revenue equal to the annual cost of maintaining the harbor plus 4 per cent interest on what has been expended on both the present and previous projects where the present project has been completed, or, otherwise on what will have been expended on both present and previous projects when the present project will have been completed. The results are shown in illustration herewith. When channel dues are not collected, it means that whoever pays the cost of the channel improvements, pays a certain amount on every ton of freight that is handled through the port. The chart may therefore be considered as representing what the improvements now completed or under way, at the ports considered, would cost the Federal Government per ton, should the average movements be only equal to the average for the last four or five years.

It s therefore submitted:

(1) That the Federal Government is warranted in undertaking the improvement of a commercial harbor in the first instance, only

(*a*) When there will probably be handled through the port such an amount of freight that, if required to pay *reasonable* harbor dues, the revenue produced would at least equal the cost of maintenance of the

Cost of Federal harbor improvements per ton of commerce

Digitized by Google

harbor plus 4 per cent interest on the first cost of its improvement; or

(*b*) When, as a result of the improvement, there would be probable such a reduction in the cost of transporting freight to and from the hinterland of the port, that the amount saved would equal the revenue specified under (*a*).

(2) That the Federal Government is warranted in undertaking the further improvement of a harbor in which usable channel depths and widths have been provided, as compared with other successful ports, only

(*a*) When it is probable that there will result in the reasonably near future such an increased tonnage that if it were required to pay reasonable channel dues the increased revenue would at least cover the increased cost of maintenance, and 4 per cent on the first cost of the additional work; or

(*b*) When it is probable that there will result such a further reduction in the cost of transportation to and from the hinterland of the port, that the amount saved will at least equal the revenue specified under (*a*); or

(*c*) When it is probable that there will result such a reduction in cost of maintaining the harbor that the amount saved will at least equal 4 per cent of the cost of the new work involved, plus the annual cost of maintaining it.

What could be regarded as reasonable channel dues must be determined independently in every case. Dues that, as a general rule, might be properly regarded as prohibitory, might in special cases be entirely reasonable. It is thought that data, such as can be obtained from the preparation of such charts, will afford a starting point in the study of this question, and a possible index of what would constitute warrantable expenditures on a port, the probable commerce being considered, where it is impossible to determine with at least some degree of accuracy the probable effect of a proposed improvement on the cost of transportation. For example, referring to the chart, it is seen that the cost, to the Federal Government, of the commerce of the Columbia River, during the past four years, has been very high, if it is assumed, as would seem reasonable, that this cost is equal to the cost of maintaining the improvement plus 4 per cent interest on its first cost. The thought immediately occurs that possibly the Government has expended a good deal more on this improvement than is warranted, and with such data before him, one would hesitate long about recommending a harbor improvement, when the probable cost per ton of commerce handled would be so high to the Federal Government, unless more or less conclusive evidence could be adduced, that the benefits to be derived from the improvement would be fully commensurate with such costs.

A detailed study of the commerce of the Columbia indicates that the most important items are fuel oil, inbound, and lumber, outbound, and that for at least some years to come about 700,000 tons of each of these articles will probably be handled on the river.

The fuel oil is brought in tank steamers from points in California to points on the Columbia and distributed thence to inland points. The cost of bringing the oil by steamer from California to points on the Columbia is calculated to amount to $1.48 per ton. The railroad freight rate for the same deliveries would be $6.50 per ton. If it were not possible for the oil to be brought to Columbia River points by steamer, these ports and the inland points which they now supply would probably find the next most economical distribution centers from which they could secure oil to be the Puget Sound ports. The rail freight rate on oil from these points to Columbia River points is $1.00 per ton. About 25 per cent of the oil (175,000 tons) is consumed in the immediate vicinity of Columbia River ports, and on this amount it is estimated that a saving of $1.00 per ton is effected as a result of these ports being able to obtain it directly from ships instead of by rail from Puget Sound ports. It is more difficult to determine the probable saving on the 75 per cent (525,000 tons) that is sent into the hinterland. The most reasonable assumption would seem to be—

(*a*) That on that part of it which moved to points more remote from Puget Sound than Portland is, the same saving would be effected as at Portland, namely, $1 per ton;

(*b*) That on that part of it which moved to points nearer Puget Sound than Portland is, the saving would vary from zero to $1 per ton and would average about 50 cents per ton; and

(*c*) That the average saving on the 525,000 tons now distributed from Columbia River ports would be 75 cents per ton. Under these assumptions the saving on oil attributable to the improvement of the Columbia River would be as follows:

175,000 tons, at $1.00	$175,000
525,000 tons, at .75	393,750
Total	$578,750

The lumber that is exported from the Columbia is manufactured principally at mills on the lower Columbia and Willamette Rivers. The logs are brought by logging roads to these rivers or their tributaries, and are then towed in rafts to the mills. It is doubtful if these mills would have been built on the Columbia and Willamette Rivers, if the deep-water improvement had not been carried out. Without the improvement the lumber certainly could not have been shipped from the Columbia, and it seems probable that it would have moved through Puget Sound ports and would have possibly also been manufactured there. The lumber freight rate by rail between Columbia River and Puget Sound points,

Digitized by Google

varies from $2.60 to $2.80 per ton. The charges for towing rafts of logs from points on tributaries of the Columbia to mills on the Columbia vary from 50 cents to $1.10 per thousand feet board measure, which is approximately equivalent to from 25 cents to 55 cents per ton, or say, an average rate of 40 cents per ton. It is assumed that the lumber would have been manufactured at mills on the Columbia River, even though the river had not been improved, and would have been shipped thence by rail to Puget Sound for export, then there would have been an additional transportation cost in laying down this lumber ready for export, equal to the freight rate between Columbia River and Puget Sound points—namely $2.60 to $2.80 per ton. It seems more probable, however, that the greater part of the logs would have come to the Columbia River for manufacture into lumber, but would have been shipped to Puget Sound for manufacture there. If it is assumed that the average cost of shipping these logs to Puget Sound would have amounted to $1.35 per ton, then the improving of the Columbia may be estimated to have effected a saving in the cost of laying down lumber at the sea-board equal to the difference between the rail rate of $1.35 per ton and the towing rate of 40 cents per ton—namely 95 cents per ton. The total saving thereon the lumber usually exported from the Columbia would amount to:

700,000 tons lumber, at $0.95..... $665,000

The combined saving on lumber and oil then becomes $1,243,750 per year, which is more than the cost of maintaining the improvement and 4 per cent interest on its first cost. There is therefore a sufficient saving being effected by the improvement in the cost of handling these two items alone to fully justify all that has been done. It would rarely be possible to satisfactorily prove in advance that the saving in cost of transportation would be as great as it appears to have been in this case, and it would therefore seldom be conservative to recommend improvements when the ton cost of commerce to the Federal Government would seem likely to run as high as on the Columbia.

The following table shows the channel or port, dues or tolls, per net registered ton, collected at some European Ports.

Manchester	$0.04 -	$0.15	; according to distance travelled.
London	.02 -	.13	
Southampton		.03	
Kaiser Wilhelm Canal		.144	; on the first 400 net registered tons.
Do.....		.10	; on each ton above 400 up to 600.
Do.....		.075	; on each ton above 600 up to 800.
Do..... ...		.05	; on each ton above 800.
Hamburg		.081	
Bremerhaven		.043	
Antwerp		.095	
Rotterdam	.02 -	.06	
Amsterdam	.02 -	.054	
Brest	.05 -	.095	
Marseilles		.08	
Le Havre.....	.052-	08	; apparently also covers quay dues.
Bordeaux		.12	
Stockholm		.065	; per net registered ton or $0.104 per metric cargo ton—whichever produces the greater sum.

The ratio of net registered tonnage to dead weight tonnage capacity of freight steamers is about 1 to 2, and if a chart such as that herewith were prepared, based on net registered tonnage of ships, the costs would be probably at least 50 per cent higher. Statistics of the net registered tonnage of vessels using a port could be obtained with much greater accuracy than statistics of short tons of freight, and would, it is believed, as a general rule, form a better guide as to the extent to which improvements under way are being justified. Statistics, however, of freight actually carried are also of great importance, as improvements that would appear entirely unwarranted, from consideration of the former alone, would sometimes be found to be thoroughly warranted by consideration of the latter.

Harbor improvements that represent an expenditure by the Federal Government of not to exceed 7 cents per short ton of commerce or 10 cents per net registered ton of vessels, are believed to be, generally speaking, reasonably conservative and warranted. Improvements that promise to cost much in excess of this are believed to be warranted only in special cases, when it can be clearly demonstrated that transportation costs will be so reduced as to warrant the greater expenditures. These figures may seem high when compared with the port dues actually charged, as given in the table preceding, but inasmuch as the dues actually collected rarely afford more than a nominal return on the cost of the improvement, and frequently not even that, expenditures higher than consideration of the table alone would indicate as warranted, may still be conservative.

Topographic Map of United States.

On July 1, 1919, the Geological Survey had mapped 42.6 per cent of the United States (exclusive of Alaska). About one-fifth of this area requires resurvey, leaving but 35 per cent of the country properly mapped.

Of the states, Connecticut, Delaware, District Columbia, Maryland, Massachusetts, New Jersey, Ohio, Rhode Island, West Virginia, are completed. The following states are at the bottom of the list: Mississippi, 4 per cent; Florida, 7 per cent; Minnesota, 9 per cent.

It is estimated that about 40 millions of dollars will be required to complete the work, and that if appropriations are forthcoming as needed this can be accomplished by 1932.—*Eng. and Cont.*

Surges in Gaillard Cut from Lockages at Pedro Miguel, Panama Canal

By

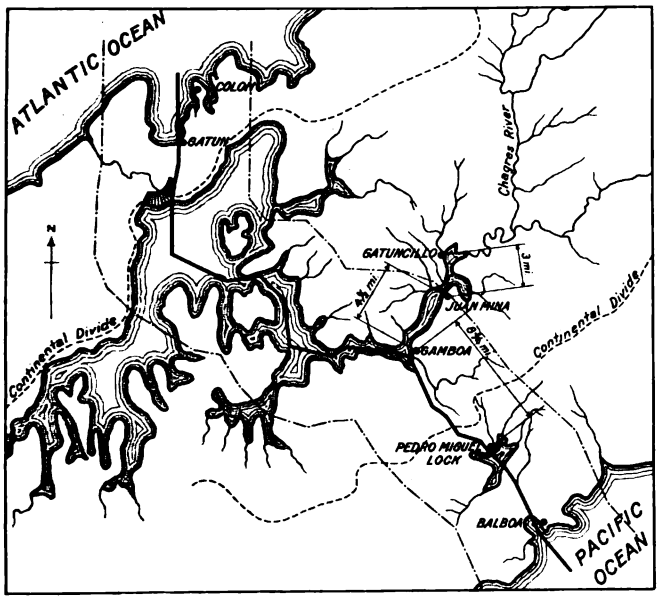
Maj. R. Z. Kirkpatrick
Engineer Reserve Corps, Chief Hydrographer
and
H. G. Cornthwaite
Assistant Chief Hydrographer, Panama Canal

AN interesting phase of the operation of the Pedro Miguel Lock is the surges set up in parts of Gatun Lake by the drawing of water for lockages. In some respects the surges resemble tidal seiches that occur in enclosed bays or gulfs or at the heads of inlets along the seacoast. The surges are recorded on the hydrographs at Pedro Miguel, Gamboa, Juan Mina and Gatuncillo, and have been noticed as far as 6 miles west of Gamboa. The water-stage register stations mentioned are 8¾, 4½ and 3 miles apart, respectively, as shown on the map herewith. In the experiment shown in the accompanying hydrographs, the surge traveled from Gamboa up the Chagres River arm of Gatun Lake in direct opposition to 1260 c. f. s. of inflow. It has been found, however, that a considerable freshet here wipes out the tendency to surge at the two upper stations.

Conditions attending the surges. Pedro Miguel Lock is at the west end of the 8¾-mile long Gaillard Cut. The immersed portion of the Cut prism is theoretically 300 feet wide by 45 feet deep at lake elevation 85 feet, a cross-sectional area of 14,500 square feet. Due to removal of slides, there are many places which have a greater cross-sectional area than this. To cut down current velocity in the neighborhood of the lock the Canal was excavated 600 feet wide, tapering to 300 feet at a point 4,300 feet from the Lock.

A complete filling of a chamber with Lakes Miraflores and Gatun, at elevations of 54 feet and 85 feet, respectively, requires about 3,800,000 cubic feet of water in a lockage. The wall culverts have minimum clear openings of 255 square feet. If both a side and center wall culvert are opened, a lock is filled in 7½ minutes. If a side culvert only is used, 13½ minutes are necessary. Thus there are about 8,440 and 4,690 c. f. s., respectively, being drawn, according to whether two or one culvert is drawing water. If both chambers are receiving water simultaneously, with all three culverts open, there are 7½ minutes in which water will be drawn at the rate of 13,130 c. f. s. This is the maximum case; and while such operation does not often occur, it would theoretically give a uniform velocity of about 1 f. s. or nearly .6 knot an hour in the Cut during a draft of water. A glance at the hydrograph at Pedro Miguel shows that this flow is *not* uniform.

Surges from lockages. When the valves are opened the canal basin above the locks rapidly falls in elevation (sometimes as much as 1.5 foot, according to the number of valves open); that is, the inertia of rest of the canal water plus the friction from the sides and bottom of the canal, prevents an immediate response to the tendency for a flow of water to set up toward the lock.



When the valves are closed and the effect of the difference in elevations overcomes the tendency for a retardation of flow in the Cut, an acceleration sets up, which results in a surge or overtravel, the crest of which, is as much above the original lake level as the depression was below. Equalization of levels is finally reached after a series of wave amplitudes, with decreasing intensities, unless their movement is complicated by another lockage.

It is probable that harmonic action may increase or decrease the currents and amplitudes; that is, if a new draft of water should make a depression in phase with a returning depression or trough of a surge from a previous lockage, the resulting oscillations would be unusually large. It is fortunate that the theory of probabilities decrees that these coinciding phases do not often occur but are either partly or totally antagonistic to each other, thereby cutting down the heights of oscillations.

A study of the accompanying hydrographs shows that from crest to trough the oscillations at *all* stations are about 45 minutes apart. Examination of many such hydrographs have shown this definite period occurs daily. During the six lockages of August 3, 1919, the *average* period of time between the same phase of the surges at each station was as follows:

(*a*) Effect of opening valves at Pedro Miguel Lock

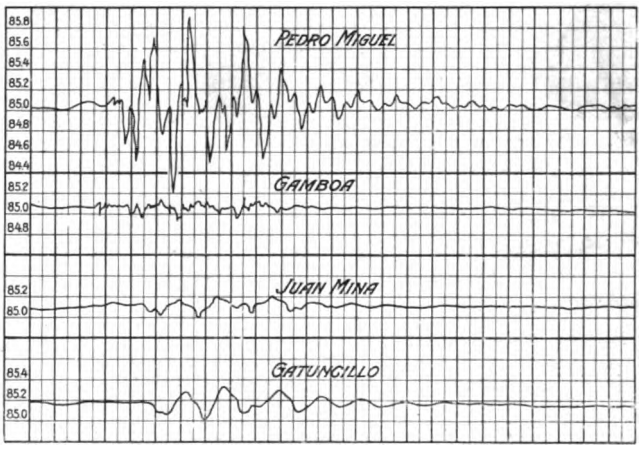
Digitized by Google

The Panama Canal. Sketch map showing station hydrographs affected by Pedro Miguel lockages

appears on the Gamboa hydrograph in 18 minutes; at Juan Mina in 60 minutes; at Gatuncillo in 78 minutes.

(*b*) Effect of closing valves at Pedro Miguel Lock appears at Gamboa in 19 minutes; at Juan Mina in 60 minutes; at Gatuncillo in 82 minutes.

(*c*) The peak of the return surge after the closing of the valves is observed at Gamboa 25 minutes after it appears at Pedro Miguel; at Juan Mina in 65 minutes; and 87 minutes afterward at Gatuncillo.



When the crest of a wave is at Pedro Miguel a trough phase is approximately at Juan Mina, and vice versa. The relative heights of successive waves at the various stations vary somewhat, but the wave at Gamboa averages about one-eighth the height of the wave at Pedro Miguel. Wave heights at Juan Mina are about the same as those at Gamboa, while at Gatuncillo, at the head of the Chagres River arm of Gatun Lake, the wave heights are approximately 50 per cent greater than at Gamboa or Juan Mina.

Effects on Navigation

(1) *From currents.* The currents that accompany these surges are generally too feeble to seriously hinder navigation. The currents toward Pedro Miguel are much stronger than the return currents toward Gamboa. Only the former need be considered as constituting a possible danger to navigation. Vessels are required to navigate the Gaillard Cut section of the Canal at slow speed (not over 6 knots). With the precautionary measures that are taken and moderate currents experienced, no serious accidents to navigation have occurred in Gaillard Cut, and but few minor accidents.

In the case of a restriction of a cross-section, as, for instance, by a wrecked hull or a slide, the current and wave effects would assume values that would make rapid filling of Pedro Miguel Lock unsafe for navigation in the Cut. That is, either no water should be drawn during the passage of ships in the Cut, or the culvert valves should be only partly opened so as to draw water slowly.

(2) *From changes in lake level.* These surges have a maximum range in height from trough to crest of nearly 3 feet; that is, the highest crest levels are nearly 1.5 feet above mean lake level and the lowest troughs are about the same distance below the average level of the lake. These changes in the surface level of the lake due to surges, may affect navigation when the lake is down to its minimum operating level by reducing the navigable depth of water in the canal approximately 1.5 feet at the trough phase of the surge. When the lake stands at or near its maximum operating level there would be a tendency for the water to spill over the lock gates into the lock chambers and machinery pits at the crest phase of the surge. This tendency is not important as the gates and masonry walls at the upper end of Pedro Miguel locks were built higher than the maximum operating level to prevent spilling over.

Hydrographs at various stations, showing effects of lockages at Pedro Miguel

Remarks

It is believed designing engineers may find points of value from a study of these surges. Surges may be expected where heavy intermittent drafts of water occur through a long channel. Somewhat similar surges are said to occur in the Soo Canal. The magnitude, period and character of the surges will depend upon the quantity of water drawn per unit of time, the frequency of operations, the size and shape of reservoir drawn upon, and the mean hydraulic radius and length of canal through which the water is drawn.

A designer of a ship canal subject to intermittent draft by lockages, should carefully consider the points above with respect to

(1) Disturbing currents,
(2) Reduction of navigable draft of water at trough phase of canal and
(3) Height of lock masonry and gates with reference to the crest phase of the surges.

CURRENT NEWS

Note.—This department will include news items of professional or personal interest concerning individuals and organizations in the Army, National Guard, Reserve Corps, Reserve Officers' Training Corps, the Service Schools, the U. S. Engineer Department, other departments or bureaus of the Government, and other related activities, both civil and military.

In the PROFESSIONAL NOTES section will appear news items, short articles and digests on matters relating to current developments in engineering and allied sciences and the art of war—of special interest to the military engineer.

Contributions to these columns, whether from original sources or from other periodicals, are solicited from all our readers. Such contributions should be submitted in time to reach our office not later than the 15th of the month preceding each issue of THE MILITARY ENGINEER

News of the Services

Engineer Districts

Charleston District: Maj. G. R. Lukesh

Two contracts have just been entered into for dredging in Cooper River near Charleston, S. C. The work is part of a project for a channel 40 feet deep at mean low tide and 1,000 feet wide and 22 miles long, estimated to cost $7,500,000. The channel is designed to afford access from the Atlantic Ocean to a projected 1,000-foot dry-dock at the Charleston navy yard for the largest vessels of the Navy.

While the channel is intended to serve the Navy Department, it will be a decided asset to the commercial interests of southeastern United States passing, as it will, the wharves of Charleston. It will furnish a commodious deep-water channel of very short length and easy navigation from the ocean to wharves where facilities for interchange of freight between boat and rail are already to some extent in existence and where they will doubtless be established to greater extent as commerce demands them.

The unit prices of the two contracts are 33½ and 34 cents per cubic yard; the contract consideration in each case is, in round numbers, $300,000. The material to be dredged is sand, broken shell and some clay and mud. The dredging will be by pipe-line, and a convenient and suitable dumping ground is found near by on the marsh forming part of the naval reservation. The specifications were so drawn as to require dumping on this land and regulating its distribution, so that the material dredged will form valuable land for Navy Department uses.

New Orleans District: Lieut. Col. H. Deakyne

Mississippi River

A contract was entered into September 27, 1919, with L. F. Alexander for the construction of 10,600 feet of bulkhead placed between the jetties at the Southwest Pass, Mississippi River. These bulkheads will consist of double rows of close-spaced piles. The purpose of these bulkheads is to contract the channel between the jetties to a uniform width of 2,400 feet.

The work of constructing submerged deflecting dikes and spur dikes at the Head of Passes, Mississippi River, in connection with the maintenance of channels through South and Southwest Passes, is practically completed. The submerged dike, located on the left bank of the river immediately above the head of Pass a l'Outre, consists of a fascine mattress, 200 feet wide and 1 foot thick, extending at right angles from the left bank of the river for a distance of about 2,000 feet, and thence turning downstream and connecting 2,200 feet below the headland between South Pass and Pass a l'Outre. This dike is supplemented by a system of pile dikes along the left bank of the river immediately above the head of Pass a l'Outre. The object of the dikes is to control the flow through the Passes and to destroy the shoals that form periodically in the wide channel at Head of Passes.

Intracoastal Waterway

All bids for the Mermenau-Colcasieu Section of the Intracoastal Waterway were rejected and the work will be readvertised with slight changes of specification. The work includes 37.5 miles of channel, through marsh land and existing waterways, to have a least cross-section of 5 by 40 feet.

Mobile District: Maj. R. S. Thomas

Survey of Mulberry Fork, Black Warrior River

By authority of Congress, a survey has been made of Mulberry Fork (including Sypsey Fork) to 7 miles above Sanders Shoals. The purpose of the survey is to locate sites for locks and dams to extend slackwater navigation of the Black Warrior and Tombigbee system into the great coal fields of Alabama, known as the Black Creek Group, estimated to contain 200,000,000 tons of coal of high grade. The survey was made between June and December, 1919, at an approximate cost of $30,000.

Galveston District: Lieut. Col. Spencer Cosby

The tropical storm of September 13, 1919, caused considerable damage to jetties and dykes in the vicinity of Port Aransas, Texas. The center of the storm passed inland from the Gulf near Corpus Christi, Texas, (about 20 miles from Port Aransas). All the bridges over the intracoastal canal from Galveston to Corpus Christi were carried away. The storm also caused some damage to construction work on the Galveston seawall extension, due to scour around the completed portion of the work. Construction work on the seawall extension was again begun after an interval of six weeks which were devoted to repair of storm damage. The dredging fleet in the Galveston district was not severely damaged, but some portions of it were scattered by the storm.

The U. S. 12-inch pipe-line dredge *Guadalupe* was completely destroyed by fire November 27, 1919, near Freeport, Texas. The cause of the fire is unknown, but it was probably due to waste oil catching fire. No lives were lost. The

Solve the Problem with an Insley Derrick

Correct engineering principles, strict attention to the positive efficiency of all details, and honest construction make Insley Derricks able to withstand the continued strain of hard usage with a minimum operating and maintenance expense. Their superiority, demonstrated in actual use in varied industrial enterprises, is making Insley Derricks the answer to the derrick problem.

Let our staff of engineers consult with you on your requirements in Derricks, Industrial Cars, or Concrete Placing Equipment.

Insley Manufacturing Co.
Indianapolis, Indiana

INSLEY

dredge was employed on light-draft projects in the Galveston district.

Major Raphael C. Smead (Engineer Reserve Corps), principal assistant engineer in Dallas and Galveston Districts, and engineer in charge of the Galveston District during the War, died suddenly in his office November 28, 1919. Major Smead had been in charge of much of the construction work on the Washington Aqueduct and on the dam across the Potomac River at Great Falls, Va. He had been in the Engineer Department continuously since 1885.

Maj. C. L. Hall, Corps of Engineers, has reported for duty under the orders of the District Engineer at Galveston.

Rock Island District: Lieut. Col. Harry Burgess

With a view to equalizing the work in the Rock Island and St. Paul districts, that portion of the 6-foot channel improvement of the upper Mississippi River from St. Paul to the Wisconsin River was transferred December 1, 1919, from the Rock Island district to the St. Paul district, taking from the former 212 miles of river. Included in the transfer were the sub-offices and personnel at St. Paul and La Crosse, in charge of assistant engineers J. D. DuShane and W. A. Thompson, respectively.

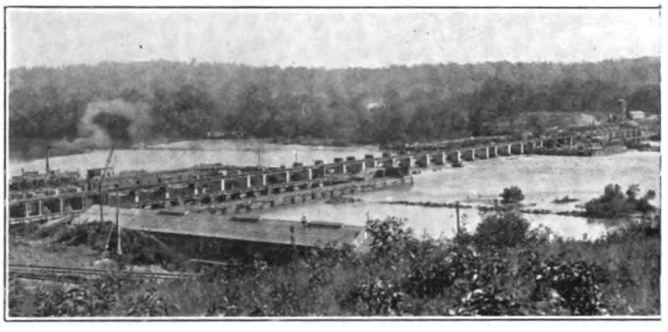
Jr. Engr. Robert Iakisch was on October 31, promoted to assistant engineer. Mr. Iakisch was for several years on duty under Asst. Engr. Edwards, on the Mississippi River between the Wisconsin and Le Claire, and has now for two years been in charge of the section between Hamburg and the Missouri River.

Kansas City District: Maj. R. T. Ward

Missouri River Improvement

The work of providing a 6-foot depth of channel from Kansas City to the mouth of the river, by regulating works, is about 32 per cent completed. The work includes revetment on concave bends and pile-dikes on convex bends. The revetment consists of a continuous willow mattress paved with concrete on both edges. The cost of this mattress is about $14.00 per linear foot and of the pile dikes about $20.00 per linear foot.

No systematic improvement of the river above Kansas City has ever been undertaken. Present operations are confined to snagging.



Maj. Wm. M. Hoge was relieved from duty as assistant to the district engineer on November 5, and ordered to the Virginia Military Institute as instructor.

Florence, Ala., District: Lt. Col. Lytle Brown

As the result of a recent transfer, the entire Tennessee River is now included in the Florence District.

Progress on Wilson Dam, Tennessee River

The Wilson Dam at Muscle Shoals (Dam No. 2), will be 96 feet high from bedrock to pool level, and over 4,000 feet long. With its volume of masonry, nearly a million cubic yards, this dam will be one of the largest ever constructed. The fifteen turbines, each of 30,000 H. P., at the south end of the dam are designed to develop a yearly output of

between 300,000 and 375,000 H. P., net—only four of these will comprise the initial installation. Of the 100,000 net H. P. thus first generated, the bulk of the power will be supplied to nitrate plant No. 2, close by. A flight of two locks, each 60 feet wide and 300 feet available length, at the north end of the dam, connects the lower and upper pools. Thus, with the later completion of Dams 1 and 3, below and above, the Muscle Shoals, which has always constituted the most serious obstacle to navigation on the Tennessee, will be completely eliminated.

Construction work on the dam is in the preparatory stage. About 10 miles of railroad have been built. The first of six cofferdams was unwatered in August, 1919, and the rock has been largely removed from the excavation for the cut-off wall along the heel of the dam. A construction bridge, with concrete piers, and track level above ordinary flood heights, is being built upon the apron of the dam. About two-thirds of the total mass of 10,000 cubic yards of concrete in the piers has been placed. This bridge will carry four standard-gauge tracks and will handle all supplies and material going to the dam. On a fifth wider track will be mounted seven 10-ton travelling tower derricks, with 90-foot booms, which will lift the concrete in skips from the cars and place it in the dam. With these derricks in operation by next spring, it is planned to place 2,000 yards of concrete per day.

In order to provide the aggregate for the concrete, a dredging fleet is being assembled at Buck Island, 9 miles below Florence. Two powerful suction dredges will work at a bar of excellent sand and gravel, which will be screened and washed, and then towed upstream in barges. The last 2 or 3 miles' haul will be by rail to the three mixing plants. The largest plant, located on Jacksons Island in midstream, is equipped with two 4-yard mixers; the other two each have 2-yard mixers.

Work on the south side of the river at the power-house site has just fairly commenced. A railroad connecting the nitrate plant with the abutment is nearly completed. Three additional traveling tower derricks will handle the concrete for this section of the dam.

The work is being prosecuted with hired labor, and the growing pay-roll now numbers 4,000 men. A construction camp, with facilities to house and mess about half this number, has been completed on the north bank, 3 miles from Florence, while housing facilities at nitrate plant No. 2 are available on the other side.

The construction is under the immediate direction of the District Engineer, Lt. Col. Lytle Brown. Of his assistants, Maj. S. C. Godfrey is in charge of Administration and Supplies, Assistant Engineer D. A. Watt of the Engineering Division, and Assistant Engineers Joseph Wright and J. S. Butler of Construction Divisions 1 and 2 (north side and south side).

Lackawanna Steel Sheet Piling Cofferdam

For Building U.S. Government Dry Dock No. 4

Norfolk, Virginia

The cofferdam, in which the outer or gate section of this dry dock was constructed by George Leary Construction Co., consisted of 14-inch by ⅜-inch Lackawanna Arched-Web Sheet Piling in 40-foot and 65-foot lengths.

The original boring indicated materials to be sand, shell, clay, and muck, very unstable and apt to be very porous.

The preliminary excavation was completed, temporary timber forms set, and the steel sheet piling assembled around these forms complete. The closure was then made and the walls were driven to refusal. The 65-foot steel sheet piling lengths were cut off at the dock floor level and the bottom ends left in position as a permanent protection wall for the outer end of the dry dock.

DOUBLE-LOCK LACKAWANNA INTERLOCK

The picture shows the uniformity to which even very long lengths of LACKAWANNA STEEL SHEET PILING can be driven and also that complete assembling around temporary forms before starting to drive is a great help in securing this uniformity.

If you have any cofferdam problem where our advice would be helpful, you have but to state the requirements and our engineers are at your service.

Ask for our book, "Lackawanna Steel Sheet Piling."

PITTSBURGH DISTRICT
Lt. Col. H. B. Ferguson

Contracts for the Emsworth locks and dams on the Ohio River, 6 miles below Pittsburgh, Pa., were let to the Dravo Contracting Company of Pittsburgh, Pa., July 22, 1919. The work consists of building two locks, 110 feet by 600 feet, and 56 feet by 360 feet; one main channel fixed concrete dam and one abutment; and one back channel fixed concrete dam and two abutments. These structures will replace locks and dams Nos. 1 and 2, and will furnish pool water to the first dams on the Allegheny and Monongahela rivers. The total amount of the contracts is approximately $2 298,600.00. To date the following work has has been accomplished: upper guide wall, 50 per cent; back channel fixed dam, 50 per cent; abutment No. 2, 70 per cent; and abutment No. 3, 30 per cent. Two wooden cofferdams, generally known on the Ohio River as the box type, have been built and unwatered, inclosing parts of the upper and lower guide walls. Earth cofferdams are being used for the back channel dam and abutments, a heavy pile trestle supporting the movable derricks, which were used to excavate sand and gravel, bank the coffer and handle piles, crib timber, stone, forms and concrete.

On the Monongahela River, a large amount of construction and miscellaneous repair work has been done by hired labor. The Betwa wickets on dams 1 and 5, and the Chittenden drums on dams 2 and 3, are being replaced by fixed concrete tops, and the downstream slopes reduced to 1 on 3. The total concrete required for the four dams amounts to 20,000 cubic yards on 2,900 linear feet of dam crest. This work is 43 per cent complete and was much hindered during October and November by unusual rises in the river. Wooden miter gates were erected at lock No. 2, replacing the steel ones which were badly eaten by acids in the water; the upper guard wall at lock No. 6 was extended 100 feet, and the upper miter sills in the outer chambers of locks Nos. 3 and 5 were raised, 1,800 cubic yards of concrete being used.

Plans and specifications for lock and dam No. 4, Allegheny River, about 24 miles above Pittsburgh, have been approved by the Chief of Engineers. Plans and specifications for lock No. 5, 30.5 miles above Pittsburgh, have been completed. It is expected to ask for bids for these two structures during the month of January.

LOUISVILLE DISTRICT
Lt. Col. G. M. Hoffman

The construction of lock and dam No. 44, Ohio River, at Leavenworth, Ind., was begun November 20, 1919, with the sinking of the first section of the lock cofferdam. This work will be done with Government plant by hired labor. This is the third dam to be started below Louisville in the 9-foot channel project for the Ohio River.

Lock and abutment No. 45, Ohio River, at Addison, Ky., twice advertised for construction by contract during 1919, will be again advertised in the spring of 1920, no bids having been received as a result of the previous advertising.

Assistant Engineer Malcolm Elliott, in charge of the construction of lock and dam No. 43, Ohio River (Louisville District) has been transferred to the Florence, Ala., District.

DULUTH DISTRICT
Maj. F. A. Pope

Enlargement of Superior Harbor Basin

The project dredging for enlarging the Superior harbor basin (160.2 acres to 20-foot depth, L. W. D.), was carried on the past season with two large dipper and one hydraulic dredge. Project consists in the removal of 3,000,000 cubic yards of sand and soft material; the present contract covers 2,083,000 cubic yards. Work closed November 14 on account of ice, to be resumed early in 1920. An average of more than 150,000 cubic yards per month were removed. Contract now about 69 per cent completed.

A large amount of pier repairs and dredging for maintenance was carried on during the season at Grand Marais, Michigan, Keweenaw Waterway, Michigan, Ontonagon, Michigan, and Grand Marais, Minnesota. Heavy storms during November did considerable damage to construction work at Grand Marais, Minnesota, Ontonagon and Keweenaw Waterway, Michigan, all of which will have to wait until spring for repair. The storm of November 11 wrecked several large ore and grain carriers near Grand Marais, Michigan, with loss of the steamer *John Owen* and crew of 25. From the steamer *Runnels* the life savers removed the crew of 17 but the boat was a complete wreck. On the 23d the steamer *Myron* (lumber laden) was wrecked near Whitefish Point, with a loss of 17 lives. lives.

River and harbor improvements at Warroad, Zippel Bay and Baudette, including operations on Lake of the Woods boundary waters. were transferred from the St. Paul district to the Duluth district July 31, 1919.

Plans are being prepared for the construction of a steel derrick scow of about 800 tons carrying and 25 tons lifting capacity for general use in this district.

Work in Prospect

The Superior harbor basin will be completed as early as possible.

Removal of shoal at East Gate Basin will be done by U. S. dredge *Gaillard*. The usual maintenance work will be carried on at all points in the district. Work on the cut-off channel three-fourths of a mile long, 200 feet wide and 20 feet deep, at Princess Point, Keneenaw, will be started as soon as the necessary land can be purchased, negotiations for which are now in progress.

E. J. Dugan, Assistant Engineer was transferred from St. Paul to the Duluth district, September 1, 1919.

MILWAUKEE DISTRICT
Lt. Col. Edw. H. Schulz

Harbor of Milwaukee

In furtherance of the outer harbor at Milwaukee, Wis., the city has awarded a contract to the Great Lakes Dredge & Dock Co., for the construction of 1,375 linear feet of timber revetment on the inner side of Jones Island, along a new bulkhead line, approved by the Department, Nov. 19, 1919.

The amount of the contract is $99,487, or about $72.35 per linear foot. This does not include the dredging to be done in front of the revetment, which will be carried out later.

It is proposed to use the dredged material in filling behind the revetment, and along the lake shore of Jones Island. The wharfage to be created by this revetment will probably be used as a public wharf for miscellaneous freight.

Manistee (Mich.), Breakwater

Work on the construction of 1,200 linear feet of shore arm extension of the south breakwater, Manistee, Mich., was suspended Nov. 8th for the season.

The work, originally begun under contract, was carried on the past season by hired labor and use of available government plant. The shore arm consists of a substructure of round and sheet piles surmounted by a concrete superstructure. The substructure is entirely completed. About one-half was done during the past season, the other half having been previously built under contract. About 54 per cent of the concrete superstructure is completed, all of which was done during the past season.

It is expected to complete the work by June 30, 1920. The completion of the substructure has produced a marked stilling effect in the harbor entrance.

Sturgeon Bay—Turning Basin

Dredging for the formation of a turning basin near the easterly end of Sturgeon Bay Canal, was completed in October, 1919. The work was done during the past season by the Government dredge *Kewaunee*.

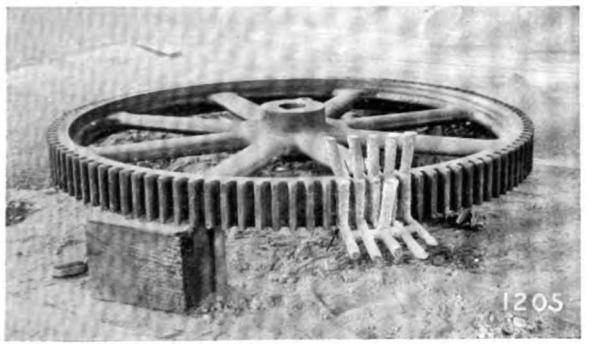
The basin is 500 feet by 1.600 feet, with a depth of 19 feet. It is to be used for turning vessels which have run in from Lake Michigan for shelter in the canal.

Wreck of Steamer "Muskegon"

Early on the morning of October 26th, while attempting to enter Muskegon Harbor, Mich., during a severe westerly gale, the Crosby Line Steamer *"Muskegon"* was totally wrecked, with the loss of 27 lives.

The *"Muskegon,"* formerly the *"Holland,"* was an iron hull, side wheel passenger steamer, built in 1881. The vessel was lifted and thrown against the outer end of the south pier, the starboard paddle wheel becoming firmly lodged in one of the pockets of the pier. The entire wooden upper works were carried away in about fifteen minutes after the vessel struck. The wreck was abandoned by owners and underwriters.

As it partly blocks the harbor entrance and in heavy weather would be a dangerous obstruction to navigation, a contract for its removal was awarded November 15th to Thomas L. Durocher, of Detroit, Mich., in the sum of $35,000, including all salvage of vessel or cargo. It is expected that the wreck will be removed during December.



BUFFALO DISTRICT
Lt. Col. C. S. Smith

Buffalo Harbor

Redredging the Buffalo river entrance channel, including the removal of two small bed rock shoals, which was begun July 8, 1919, is now practically completed. The Empire Engineering Company is the contractor for the work, the estimated cost of which is $72,760. The company's drill boat *E. C. C. No. 1*, and dipper dredges *Peconic* and *Pocantico* were used on the work.

Other dredging is the removal of an area at the junction of the Buffalo River and Black Rock Canal, and deepening of two areas in the outer harbor, for which the Great Lakes Dredge & Dock Company holds the contract (estimated cost $178,868). The company's dipper dredge No.8 was employed on the work, which was suspended for the winter, November 6, 1919.

THERMIT WELDS ON LARGE GEAR WHEEL

THERMIT

is the only reliable process for Welding Heavy Steel Sections

SUCH AS BROKEN

Crankshafts, Locomotive Frames, Steel Plant Equipment, Sternframes of Ships and Many other Heavy Steel Sections.

The steel required to make a Thermit Weld is produced in bulk at a temperature of 5000° F. instead of drop by drop, as in other welding methods. It therefore makes a perfect amalgamation with the adjacent metal and secures a Homogeneous Weld free from shrinkage strains, unattainable in any other way.

Oswego Harbor

In anticipation of the completion of the enlarged Welland Canal by the Dominion of Canada, dredging the eastern part of the outer harbor, to a depth of 2 feet at low water datum, is now in progress, operations having been begun October 27, 1919. The United States dipper dredge *Sodus* and attending plant is being used. The estimated cost of the work is $50,000.

LOS ANGELES DISTRICT
Maj. F. B. Downing

The Los Angeles County Flood Control District, in accordance with legal agreements, provided for the United States the right-of-way for the silt diversion works for the protection of Los Angeles and Long Beach Harbors, California, on October 21st; and on October 25th a contract for the construction of the works was let by the U. S. District Engineer, Los Angeles, to the United Dredging Company. The contractor began preliminary work at once, and on November 17th commenced dredging in the lower section of the channel with two hydraulic dredges. The contract calls for the completion of the work by December 31, 1920. The Federal appropriation is one million and eighty thousand dollars.

The purpose of the project is to prevent the deposit of silt in Los Angeles and Long Beach Harbors by restraining the Los Angeles River in a leveed channel, and preventing it from entering the harbors. The project comprises the construction of a channel about six and one-half miles long from the upper end of a diverting dam along the river to the ocean. The channel will be built on the flood plain of the river. It will be 530 feet wide on the bottom, and for a mile and a quarter of its lower reaches will be in excavation; the upper portion will be formed by earthen levees averaging 30 feet wide on top. The channel will enter the ocean between stone jetties, and its banks on the water side will be strongly protected with stone revetments.

FIRST DISTRICT, PORTLAND, ORE.
Lt. Col. J. B. Cavanaugh

Coos Bay Bar

During a season exceptionally unfavorable on account of bad weather the dredge *Col. P. S. Michie* removed 767,000 cubic yards of sand from Coos Bay bar, between April 1 and November 21, 1919. The result was a deepening of the channel through the bar from 19 to 29 feet.

PORTO RICO DISTRICT
Col. J. C. Sanford

San Juan Harbor, P. R.

It is expected that, under favorable conditions, the work of improvement of the harbor at San Juan, Porto Rico, will be started at an early date. The improvement proposed embraces the dredging of an area of approximately 230 acres in the harbor to a depth of 30 feet and depositing the dredged material on adjacent swamp lands for their reclamation. The project was adopted by the river and harbor act of August 8, 1917, but because of the excessive bids received in response to advertisements of the work, its prosecution has not yet been begun. A dredge has been recently purchased by the United States for use on this improvment, however, and it will be towed to San Juan from New Orleans as soon as arrangements for the purpose can be completed, thus permitting an early beginning of operations. The law adopting this improvement required the Government of Porto Rico to reimburse the United States to the extent of $600,000 of the cost of this project, at the rate of $50,000 annually, but in view of the increased cost of executing the work, the legislature of Porto Rico has obligated itself to reimburse 70 per cent of any sum the United States may expend on the work to a limit of $1,200,000. A full report of the project is contained in House Document No. 865, 63d Congress, 2d session.

FOURTH MISSISSIPPI RIVER DISTRICT
Maj. H. S. Hetrick

Levee Building

Eight levee building machines and two mattress placing plants are being operated by hired labor. Twenty contracts for levee building, involving 6 million yards of earthwork, are in force.

PUBLIC BUILDINGS AND GROUNDS, DISTRICT OF COLUMBIA
Col. C. S. Ridley

The office of Public Buildings and Grounds, Washington, D. C., has entered into contract for the excavation of a reflecting pool in West Potomac Park. Work on this project will be commenced at once. This pool will be located between the Lincoln Memorial and the Washington Monument, the main axis being the line through the two aforesaid memorials and the National Capitol. The project contemplates the construction of a main pool or basin 2,018 feet long on the main axis, by 160 feet wide, and a secondary transverse pool 160 feet on the main axis and 300 feet long on the normal axis, together with the necessary drainage, water supply, conduit. pump, control house, etc. Surrounding and outlining the pool, there will be a rather massive granite coping with concrete base. The bottom of the pool will be paved.

Engineer Troops

2ND ENGINEERS, CAMP TRAVIS, TEXAS
Col. G. E. Edgerton, Commanding

The training program for the 2nd Engineers and the 2nd Engineer Train inaugurated November 1, includes general service training and disciplinary exercises, one and one-fourth hours daily, and special engineering training of 3 hours daily. About three and one-half hours daily are devoted to vocational schools and fatigue. At present the special engineering training covers the following subjects only: carpentry, drafting, mining, demolitions and explosives, and hippology. The regimental school system is employed, with officers as instructors. All available enlisted men are enrolled in one of these schools, each man being assigned to a subject in which he has not already attained a considerable degree of proficiency, but otherwise individual preferences and adaptability have been the governing considerations in making assignments to classes. Other schools in special engineer subjects are to be opened as equipment becomes available and desirable students are secured. As almost all of the enlisted personnel have had several years service in the engineers, no general engineer training is planned except for recruits.

The 1st Battalion under the command of Captain W. A. Snow, is temporarily at Ft. Riley, Kansas, engaged in the reconstruction of a highway bridge across the Kansas River. The original structure, which was partly burned, was built in 1906-7 by the old 3rd Battalion, under command of Colonel (then Major) Thos. H. Rees, Corps of Engineers.

Lt. Col. L. E. Oliver was relieved by Col. G. E. Edgerton as commanding officer of the 2nd Engineers, on October 20, 1919. Colonel Oliver left for duty in the office of the Chief of Engineers on October 23rd.

Capt. Wm. C. Atwater was relieved from duty October 30 and ordered to Camp Humphreys.

2nd Lieut. D. A. Newcomer reported for duty on October 15th.

Capt. James M. Farrin was relieved from duty Nov. 16 and has been assigned as Assistant Professor of Military Science at the University of Illinois, Urbana, Illinois.

5TH ENGINEERS, CAMP HUMPHREYS, VA.
Col. Richard Park, Commanding

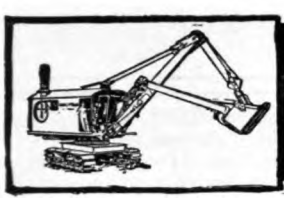
Though but recently organized this regiment has had a strenuous and interesting existence. On May 21, 1917 the regiment was officially born at Headquarters of the 2nd Engineers, then stationed at Camp Newton D. Baker, El Paso, Texas. On June 24th the first battalion and headquarters went to Camp Scurry, Corpus Christi, for training and recruiting to full strength, while the second battalion was assigned to Fort Brown, Brownsville, Texas. Colonel Barden was the first regimental commander.

On November 20, 1917, the second battalion joined the first at Corpus Christi. Training proceeded until June 13, 1918, on which date orders were received to proceed to Camp Merritt, N. J., under command of Colonel J. C. Oakes, in order to join the 7th Division. After the usual inspections and drawing of equipment the regiment sailed on the U. S. S. *Mallory* on July 31, 1918.

After disembarking at Brest the regiment was speedily moved into the 15th Training Area, Yonne Department. September 27th orders were received to move to Minourlle. Final training occupied the regiment until Oct. 8th, when it went into the line with the 7th Division in the Puvenelle Sector. After a month in the Puvenelle Sector the regiment participated in the offensive of the Second Army on November 10th and 11th.

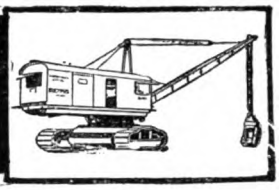
On February 2, 1919, we started for the United States. Soon after its arrival the regiment, with exception of "A" and "C" companies, which went to Washington Barracks, took up general camp and garrison duties at Camp Humphreys. Since that time it has rendered varied service in the activities around Washington, such as the Victory Loan Drive, the race riots, reception of the Prince of Wales (the regiment is very versatile) and also on several recruiting trips to eastern cities, duty with the transcontinental motor convoy, etc.

The month of November saw little change in the strength of the regiment. A few men were furloughed to the reserve but their loss was offset by recruits.



The band of the 5th Engineers played during the presentation of medals on November 13th by H. R. H. the Prince of Wales, at the Belmont House in Washington. With reference to this ceremony the following letter was received from the British attaché:

November 20, 1919.



"His Royal Highness, the Prince of Wales, asked me to express his thanks to the Officer Commanding the 5th Regiment Engineers for the very good selections of music played by their band at the presentation of medals yesterday."

A regimental field meet was held on November 19th, and included the following

BUCYRUS

The Power that Moves the Earth

"The 8 (Bucyrus) Caterpillar Draglines are Making Especially Gratifying Records"

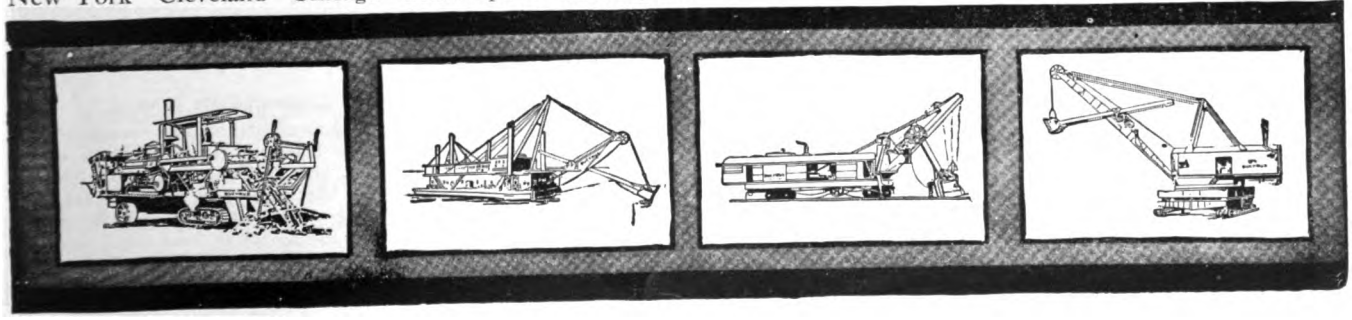
This is the report of the U. S. Reclamation Service Engineers on the Rio Grande Project, involving over 15,000,000 cu. yds. of excavation. Eight Bucyrus Class 9½ dragline excavators, mounted on caterpillars were used. These draglines were equipped with internal combustion engines, using distillate as fuel, due to the poor quality of water and to no electricity.

These draglines averaged 12.4 cu. yds. per gal. of distillate at a cost of 0.0123 per cu. yd. One of these machines excavated 80,210 cu. yds. in a month, working 3 8-hour shifts, averaging 1055 cu. yds. per 8-hour shift. Another dug 76,464 cu. yds. in a month, averaging 946 cu. yds. per 8-hour shift. These are just a few of the many high records of output these machines have made.

The U. S. Government has purchased more than 20 Class 9½ draglines for use by the U. S. Reclamation Service, the Mississippi River Commission and the Alaska Railroad Commission. This is in itself a proof of the efficiency of this machine. It will pay you to investigate. Write for bulletin G-91-H.

Let our representative confer with you.

Bucyrus Dragline Exavators are built in the following sizes:



Class 7	1 yard bucket	Class 20-2½	yard bucket
Class 9½-1½	yard bucket	Class 24-3½	yard bucket
Class 14-2	yard bucket	Class 175-4	yard bucket

Send for Bulletin GH

events: Bayonet fighting, wall scaling contest, tug of war, dry land bridge building contest and a football game.

As a result of the firing on the rifle range during the previous month six expert riflemen, sixteen sharpshooters, and fifty-eight marksmen qualified from the regiment.

6TH ENGINEERS, CAMP PIKE, ARK.
Col. C. L. Sturdevant, Commanding

Sixth Engineers' Colors are Decorated

The colors of the 6th Engineers were decorated with the Croix de Guerre with palm on Thursday morning, November 20th, by Col. E. G. Peyton, acting Commander of the Third Division, Camp Pike, Arkansas.

The award was conferred upon the regiment by Marshal Pétain of France, the citation being forwarded to division Headquarters through the War Department.

The decoration was awarded in recognition of the work of the Sixth Engineers in constructing ponton bridges across the Marne in the middle of July, 1918, under heavy bombardment from the enemy, and later throwing down their tools and helping the infantry push the enemy across the Vesle River.

The translation of the order follows:

With the approval of the General, Commander in Chief of the American Expeditionary Forces in France, the Marshal of France, commander in chief of the French army of the East, cites in army orders the Sixth Regiment, American Engineers.

In the most difficult situations, it has given demonstration of the highest qualities of perseverence and faithfulness, proving at all times its ability to surmount every obstacle. It particularly distinguished itself in the organization of positions on the south bank of the Marne, 15th July, 1918, and thus largely contributed to the breaking up of the German attack. In spite of violent bombardment it constructed ponton bridges over the Marne and, taking a direct part in the combat, aided the infantry in driving back the enemy across the Vesle.

Signed:—The Marshal of France, Commander in Chief of the French Armies of the East.

PETAIN.

318TH ENGINEERS, CAMP GRANT, ILL.
Col. J. J. Bain, Commanding

The regiment have been unusually fortunate in the amount of construction work they have been able to handle, which insures that both officers and men benefit materially in gaining a large amount of experience.

The demand for skilled workmen has been so great that practically every man of the organization is on construction work a large share of the time.

Among the more important works that have been accomplished since Colonel Bain assumed command in October, are the construction of the building for the Automotive School, including the installation of steam-heating, and plumbing and electric lighting, the erection of a 10-ton stiff-leg derrick for use of the camp at the railroad yards, the operation of a one-half yard caterpillar steam shovel. At present the regiment is occupied altering certain buildings in camp for school purposes and also have a detail engaged in the alteration of the hostess house.

The regiment furnished a platoon for the provisional regiment organized for duty during the coal strike.

The personnel of the regiment has not been greatly increased, for although a large number of new men have reported, many men have been furloughed to the reserve. Special efforts are being made to increase the number of recruits and to that end two non-commissioned officers, Master Engr. Bentley and Corp. Kenaugh, have been sent out on recruiting service with a set of sixty slides depicting the activities of the engineers, which they will exhibit at various towns in the middle west and in conjunction with the exhibition a talk will be given.

The enlisted personnel now numbers one hundred and forty-six men as compared with one hundred and fifteen men on November 15th.

Col. Jarvis J. Bain assumed command of the regiment on October 15, 1919, relieving Major J. W. Fraser. Colonel Bain commanded the 309th Engineers and the 315th Engineers and was Corps Engineer, 7th Corps, and before coming to Camp Grant was secretary of the Mississippi River Commission with station at St. Louis, Mo.

Major J. W. Fraser, 319th Engineers, (1915 U. S. M. A.) resigned on November 5, 1919, and now resides in St. Louis.

Lieutenants Henry Berbert and George Consoer have been relieved from duty and ordered to Camp Humphreys for instruction at the Engineer School.

Lieutenants Don G. Shingler and Sidney W. Gould (1921 U. S. M. A.) have been assigned to the regiment, upon their return from temporary duty in Europe.

Service Schools

ENGINEER SCHOOL, CAMP HUMPHREYS VA.

History of Belvoir on the Potomac

The historical significance of the ground now occupied by Camp A. A. Humphreys at Belvoir on the Potomac River in Virginia, was certainly not considered when the site was selected. It seems a far cry from the Camp Humphreys of 1919 back to the time of the earliest settlers on this beautiful Potomac peninsula where the camp is situated, yet the connection between these widely separated periods of our national history is not as remote as might at first be supposed.

That the engineer school and training camp should be even temporarily located on this ground is extremely appropriate when its genealogical history is considered and that it is the place where Washington, the first Engineer of the U. S. Army, received his engineer training from his aristocratic preceptor, Lord Fairfax. It was Washington who at one time managed this property for the lord of the manor, and who surveyed for him the boundaries of the original grant, consisting of something like five million acres and comprising twenty-one of the present counties of Virginia.

When Thomas Fairfax built here for himself the most pretentious residence of its time, in the new country, he little dreamed that two hundred years later the site of his old Belvoir dock from which the ocean greyhounds of his day departed directly for the old country laden with tobacco, would be the site of our first engineer training camp, that his "beautiful primeval forest" would be spotted with barracks to accommodate thirty thousand soldiers, or that his fertile tobacco plantation, the source of his wealth, would be the drill field for the training of troops to fight at the side of his country's troops in a foreign land, a great war for civilization.

Yet such is the history of Belvoir peninsula, the location of the engineer school and training camp, Camp A. A. Humphreys.

School Courses

Since the return of the instructors and students of the engineer school from their overseas trip, the work has settled down to serious business, reports show excellent progress with the courses completed and those being carried on at present, also an ambitious program for future courses for the education of engineer officers in all engineering subjects and allied branches.

The engineer school consists of three sections all under the direct command of Major General C. A. F. Flagler who is also the commanding general of Camp A. A. Humphreys. The school staff consists of Lt. Col. R. W. Putnam, Secretary; Captain Hastie, Supply Officer and the heads of the three sections of the school. These are the post graduate school, the undergraduate school and the vocational training school.

The post graduate school commanded by Colonel Warren T. Hannum, includes engineer officers who have completed the full course at West Point before graduation. There are seven instructors and thirty-three students, six of whom serve as assistant instructors.

The courses at present in progress and those proposed for the post graduate school are:

Department of Military Art

Interior guard duty,
Rules of land warfare,
Training methods and principles,
Army organization,
Troop leading: Infantry squad, platoon and company,
Machine guns,
Duties of engineers,
War games and map problems involving not more than a company,
Bayonet fighting and physical exercise,
Gases and chemical warfare,
Tanks,
Hand to hand fighting and boxing,
Artillery,
Grenades,
Liaison,
Mass games and athletics,
The defensive,
The offensive,
Lessons from the World War,
Night movements.

Department of Military Engineering

Map reading and use of compass,
Military sketching,
Field fortification,
Light railways,
Military roads,
Mining and demolition,
Camouflage,
Military bridges and hasty stream crossings,
Surveying and field astronomy,
Photography and map reproduction,
Practical engineering problems.

Department of Military Administration and History

Military courtesy,
Customs of the service,
Administration, company and regiment,
Military hygiene and first aid,
Military law,
Hippology,
Military history.

Undergraduate School

The undergraduate school, commanded by Col. V. L. Peterson, has three heads of departments, sixteen instructors and eighty-six students. The students in this class are those who on account of the war were graduated before the full course at West Point was completed.

The three heads of departments are: Colonel Earl North, director of structural engineering; Colonel A. K. B. Lyman, director of sanitary engineering; and Lt. Colonel C. F. Williams, director of electrical and mechanical engineering.

The courses in progress and the proposed work for this class in the order of their sequence are:

Army organization,
Guard duty,
Rules of land warfare,
Training methods and principles,
War games, map problems (small units),
Troop leading, squad, platoon and company,
Duties of engineers,
Physical exercises,
Bayonet fighting,
Boxing,
Athletics and mass games,
Artillery,
Tanks,
Grenades,
Rifle and pistol,
The defensive,
The offensive,
Night operations,
Lessons from the World War.
Structural engineering, including:
- Roads and pavements,
- Foundations,
- Wharves and piers,
- Masonry structures,
- Reinforced concrete,
- Materials of construction,
- Roofs and bridges and building construction.

Sanitary engineering, including:
- Hydraulics,
- Water supply,
- Sewerage,
- Sewage disposal.

Electrical and mechanical engineering will include the usual engineering school course in this subject with the necessary preparatory work for the undergraduate classes, and heating and ventilation.

The subjects of law, ordnance, astronomy, field service rgulations, army organization and civil war campaigns will also be taught.

Vocational Training

The vocational school in charge of Captain B. C. Dunn, is the third section of the engineering school. Schools in both educational and vocational training were established during the summer months but were not actually attended in force until the return of the 5th Engineers from target practice on October 31st.

It is contemplated to establish the vocational school in the 'F' section of the camp and shortly to have a large percentage of men in camp learning one of the later vocations which will make them better soldiers and better civilians. All enlisted men in camp have the privilege of electing one or more school courses; i. e. one vocational and one educational.

Schools are now being conducted in English, automotives, electricity, sheet metal work, surveying and topography.

Funds and equipment are available and men are anxious to apply themselves. It is hoped that the enlisted strength of the command will soon be increased so that more men may profit by the special facilities and equipment offered for training.

It is well known that Camp Humphreys is particularly well adapted to vocational training, due to the quantities of war equipment of a mechanical nature amassed during the world war for the instruction of engineer specialists.

Library

The former A. L. A. Librarian, Mr. Langdon, has been placed in charge of the local branch of the school library which contains some 1,800 volumes from the Washington Barracks Library. More books of an engineering nature are being secured daily which will soon make the library complete for all technical engineering reference. There is also to be added a map library to be used in connection with the school work and composed of all procurable engineering maps of the United States and its dependencies.

The first floor of one of the barrack buildings in the engineer school section has been transformed into a day room for the school detachments. Everything for the comfort of the men has been installed including billiard table, writing tables and reading space with comfortable seats and excellent light.

Engineer Museum

In the engineer museum at Camp Humphreys, there is now being placed on exhibition all of the museum formerly displayed at Washington Barracks, and in addition, all the "World war exhibit material" of an engineering nature carefully selected and brought back by the A. E. F.

In general the Washington Barracks equipment includes various models and pictures of work pertaining to seacoast fortification, sea power, pioneer operations, ordnance and gunnery, and rivers and harbors.

"War exhibit material" comprises the technical, electrical, mechanical, pioneer, water supply, railway, ponton, ordnance and miscellaneous equipment of an engineering nature used by all the great nations (allied and hostile) in the world war.

All exhibits are plainly marked, giving any items of information which may be deemed of interest, and an up-to-date filing system will be used in which will be placed copies of all available information of interest from a military, engineering, and historical standpoint.

Officers' Quarters

There has been a great shortage of quarters for married officers at Camp Humphreys. Originally, six sets were built of portable barrack material, each including living room, dining room, three bed-rooms and bath, kitchen and servants' quarters, with bath. When the school was moved from Washington Barracks to Camp Humphreys, the need for more quarters became pressing. Thirty-two additional bungalows, similar to the original six, were started, and twenty-one were completed when work was stopped by War Department order.

Appropriations were asked for a total of 68 officers' sets, which would accommodate nearly all the married officers. The amount granted, however, provides only for the completion of those already started, with heating plants for each. This work is nearing completion. Quarters in the old training camp have been altered for use of married officers. Bachelor officers are quartered in Harris Hall, or near their organizations. There is an excellent officers' club and mess, and a resident mess in Harris Hall.

An old log cabin has been altered to serve as a "country club," bath houses along the Potomac are built, and a garage for officers' cars is to be built in the bungalow section.

Athletics

The baseball and foot ball teams have had successful seasons, and four "mounted" athletic meets were held.

The Camp Humphreys Athletic Association has been organized, and there will be teams representing the camp in every branch of sport.

Examining Boards

A board consisting of Colonels George B. Pillsbury, Warren T. Hannum, and Lewis H. Watkins, Corps of Engineers, was recently appointed to meet at Camp Humphreys, to examine the following provisional officers in order to determine their fitness for permanent commission:

Maj. L. R. Lohr
Capt. T. M. Curry
Capt F. C. Albert
Capt. I. Medine,
Capt. A. H. Bond
Capt. H. W. Collins
Capt. R. A. Love
Capt. R. D. Ingalls
Capt. W. A. Lyon
Capt. F. S. H. Smith
Capt. F. B. Hastie
Capt. E. F. Gaebler
Capt. P. S. Cristal

Officers who are due for promotion will appear before the board appointed by par. 47, S. O. 281-0, W. D., 1919. The board consists of Cols. Sanford, Hannum and Adams, Engineers, and two medical officers. The board will begin sessions at Camp Humphreys at an early date.

A permanent board has been appointed for the examination of officers applying for promotion to a higher rank in the Reserve Corps and consists of Colonel Harrington, Lt. Col. Larkin, and Major Kelton, Corps of Engineers.

Company "B" of the 1st Engineers, Captain J. E. Brown, Commanding, is now at Camp Humphreys preparing to go overseas about December 16th as a railroad unit.

ARMY SERVICE SCHOOLS, FORT LEAVENWORTH, KANS.

Engineer Instruction at Fort Leavenworth.

1. All instruction at the Army Service Schools at Fort Leavenworth is now comprised under the one subject of Military Art. The former departments of engineering, law, and modern languages have been abolished, and there is no instruction in modern languages and in law in the present course. The instruction in engineering which was formerly part of the course in engineering is now the general instruction in Military Art.

2. The engineering instruction consists of the following:

(a) Map reading. Five periods in the Line Class and 3 periods in the Staff Class.

(b) Fortification sketching. Fourteen periods in the Line Class and 11 periods in the Staff Class.

(c) Field fortification. Fifteen periods in the Line Class and 19 in the Staff Class.

(d) Four general terrain exercises in the Line Class and 3 map problems in the Staff Class, in addition to the regular terrain exercises in map reading, fortification sketching and field fortification.

(e) Nine lectures in the Line Class on map reading, fortification sketching, combat engineers (3), corps and army engineers, S. O. S. engineers, engineer staff officers, and map reproduction; 12 lectures in the Staff Class on map reading, fortification sketching, combat engineers (3), corps and army engineers, S. O. S. engineers, engineer staff officers, sieges, seacoast defense, mapping large areas, and map reproduction.

3. The engineer instructors are Major W. A. Mitchell, Major J. W. N. Schulz and

Digitized by Google

Capt. X. H Price. Major Schulz in addition to his duties as engineer instructor, also is in charge of the instruction in Chemical Warfare comprising several lectures and map problems. Capt. Price, in addition to his duties as engineer instructor, is in charge of the personnel of the schools, and is superintendent of the drafting department, lithographing department and printing establishment. He also gives lectures on the British Army, troop movements by railroad and certain operation orders.

OFFICERS' RESERVE CORPS

Information Relative to Appointment in the Officers' Reserve Corps

The present policy governing the selection and appointment of members of the Officers' Reserve Corps, contemplates the establishment of a competent Reserve Commissioned Personnel, the individual members of which will be qualified to perform fully duties of their respective grades when ordered into active service in case of emergency. All officers who have demonstrated their fitness and who so desire, are being appointed if their service has been satisfactory and if they are properly recommended. Appointments are limited to discharged officers, to men of demonstrated fitness and gallantry in action, and to training camp and Reserve Officers' Training Corps graduates, with the exception of a small number who had been found qualified for special services and whose appointments as temporary officers were stopped by the Armistice.

In general, discharged emergency officers are appointed in the Reserve Corps in the grade held at time of discharge. An advance of not to exceed one grade, and in no case above the grade of Colonel, may be made on account of special fitness, long and distinguished service or because of recommendation for a promotion not received, due to the termination of hostilities. Promotion received after November 11, 1918, is considered to have been given under such special conditions that increase over grade held at time of discharge, in general, will not be given. Appointees should accept the original commissions tendered them and await such subsequent action as may be determined upon with reference to promotions.

Approximately 7,500 applications for recommission in the Officers' Reserve Corps have been received from officers who have been discharged from the service since the signing of the armistice. Of this number about 4,000 have been recommissioned and if the present rate of progress can be maintained all applications will have had final action taken on them within two months.

At the present time there are commissioned in the Corps about 30 Colonels, and 85 Lieutenant Colonels. The total strength of the Corps, by grade, will be noted in our next, and subsequent, issues.

RESERVE OFFICERS' TRAINING CORPS

History and Purpose of the R. O. T. C.

Among its many provisions the National Defense Act, approved June 3, 1916, authorized the establishment and maintenance in civil educational institutions of a Reserve Officers Training Corps, to consist of a senior and a junior division. Units of the senior division may be organized at universities and colleges requiring four years collegiate study for a degree, including institutions benefited by the land grant act, and those essentially military schools which, though they do not confer an academic degree, are deemed to be specially qualified Units of the junior division may be organized at all other public or private educational institutions.

Under the terms of the act those institutions desiring units must agree to establish and maintain a two years course of military training, and the work done therein must be credited to the student in the requirements for graduation. No unit may be established or maintained until an officer of the army has been detailed as professor of military science and tactics, and at least one hundred physically fit students must be under military instruction. An average of three hours per week per academic term must be devoted to the work under courses or schedules to be prescribed by the Secretary of War. The military instruction given during the academic year is to be supplemented by training camps of not over six weeks duration in any one year. Students will receive transportation to and from the camps and subsistence while on duty as well as while in the travel status. Provision is also made under certain circumstances for commutation of subsistence at the expense of the United States for students who have completed two academic years of service in the senior division and who have been especially selected for advanced work of a military nature.

The primary object of the Reserve Officers Training Corps is to provide systematic military training at civil institutions for the purpose of qualifying selected students of such institutions as reserve officers in the military forces of the United States. It is intended to attain this object during the time the students are pursuing their general or professional studies, with the least practicable interference with their civil careers, by employing methods designed to fit men physically, mentally, and morally for pursuits of peace as well as pursuits of war.

The World War awakened the patriotic spirit of our people and brought out in clear relief the democratic privilege and obligation of every citizen to take a direct and personal part in the defense of his country. The educational institutions of the land very early realized their responsibilities to the young manhood of the nation and took their proper place in the vanguard of this great movement. It should be and, in a gratifyingly large measure, it is the aim of all educational institutions to assume a definite place and responsibility in our country's system of training military leaders, and to maintain one or more units of the R. O. T. C. In time of national emergency the country will have instantly available through this means a large number of educated men, physically efficient, versed in the fundamentals of military science and fitted to lead intelligently the units of the armies upon which the safety of the country will depend. The extent to which this object is accomplished will be the measure of success of the Reserve Officers Training Corps.

Aside from this constitutional purpose of "providing for the common defense," it is not to be denied that military training will aid greatly in the development of better citizens and thus "promote the general welfare" of the nation.

The Reserve Officers Training Corps will enrich the educational resources of schools and colleges by contributing new problems, applications, and equipment. This will not only vitalize the course of study but give to the student a training which will be as valuable to him in his industrial or professional career as it would be should the country call upon him to act as a leader of its defensive forces. In carrying out the provisions of the policy adopted by the War Department, it is intended to give all students of the Reserve Officers Training Corps a thorough physical training, to inculcate in them a respect for lawful authority, to teach leadership, and special knowledge required to enable them to serve efficiently in the various branches of the military service.

Progress to Date

Under the provisions oof the act, the War Department has recently organized in selected civil educational institutions a number of R. O. T. C. units, and has thus established a system of training which will tend toward making better citizens, and which will furnish a means whereby the graduates of these schools may function promptly and advantageously to the best interests of the nation in time of military necessity.

Recent reports show an enrollment in the various units of the Senior Division as follows:

Infantry	46,424
Field Artillery	5,389
Coast Artillery	3,142
Cavalry	741
Engineers	2,055
Motor Transport	524
Signal Corps	799
Total	59,074

As a matter of special interest to the readers of THE MILITARY ENGINEER the following list shows the institutions at which engineer units have been established with the names of the engineer officers in charge.

Alabama Polytechnic Institute, Auburn, Ala., Capt. Wm. Michener.
Alabama, University of, University, Ala., Major E. W. Cochran.
Carnegie Institute of Technology, Pittsburgh, Pa., Major Paul Reisenger.
Cincinnati, University of, Cincinnati, Ohio, Lt. Col. C. H. Rankin.
Colorado School of Mines, Golden, Colo., Major G. C. Dobson.
Illinois, University of, Urbana, Ill., Captain J. M. Farrin.
Iowa State College, A. & M. A. Ames, Iowa, Captain J. H. Jones.
Kansas, University of, Lawrence, Kans.
Massachusetts Institute of Technology, Boston, Mass., Maj. H. F. Clark.
Missouri School of Mines, Rolla, Mo., Major H. J. Wild.
Northwestern University, Evanston, Ill.
Oregon Agricultural College, Corvallis, Ore., Captain W. Y. Stamper.
Rose Polytechnic Institute, Terre Haute, Ind., Captain W. D. Weidlein.
Tennessee, University of, Knoxville, Tenn., Captain C. A. Rothwell.
Throop College of Technology, Pasadena, Calif., Captain A. M. Engle.
Virginia Military Institute, Lexington, Va., Major W. M. Hoge, Jr.
Virginia Polytechnic Institute, Blacksburg, Va., 1st Lieut. E. P. Ketchum.
West Virginia, University of, Morgantown, W. Va., Captain H. Swenholt.
Yale University, New Haven, Conn., Major E. B. Murray.

Changes in Special Regulations No. 44, War Department, governing this work, are under consideration by the General Staff, with a view to greater flexibility in adapting the military instruction to local conditions and requirements at the various institutions.

Digitized by Google

It may be that legislation for the re-organization of the army now under consideration in Congress, will affect this work but, if any statutory changes are made, it is quite safe to assume that they will be in the direction of greater liberality and will tend to harmonize the military instruction with the fundamental educational aims of the various colleges and universities. The outlook is very favorable for greater interest, larger enrollment, and higher efficiency in this work with the beginning of the next college year. The work for the current year, in many cases, was slow in starting, with the result that the colleges were obliged to make up their plans without a detailed knowledge of the military courses, and students had likewise disposed of their time. The work now in progress is therefore, in a large measure, preparatory for the work of next year, by which time many questions now at issue will have been solved and the situation will have crystallized to an extent which will permit of a definite program.

Personals

Losses of Officer Personnel

During the quarter ending December 31, 1919, the Corps of Engineers suffered 26 losses by retirements and resignations, as follows:

Maj. Gen. William M. Black, retired; Col. John M. Wright, resigned; Col. Earl G. Paules, resigned; Col. Lindsay C. Herkness, resigned; Col. Albert H. Acher, resigned; Maj. Francis L. Palmer, rtired (disability); Maj. John W. Fraser, resigned; Maj. Joseph H. Earle, retired (disability); Capt. Roland Stenzel, resigned; Capt. Geo. Sherrerd, Jr., resigned; Capt. R. W. Parkhurst, resigned; Capt. Thos. K. Meloy, resigned; Capt. W. L. Mackenzie, resigned; Capt. S. J. Leonard, resigned; Capt. W. A. Clark, resigned; Capt. B. G. Chynoweth, resigned; Capt. F. C. Albert, resigned; Capt. W. H. Smith, resigned; Capt. N. K. Sheppard, resigned; Capt. A. S. Niles, resigned; Capt. C. O. Isaakson, resigned; Capt. H. P. Hart, resigned; Lieut. P. V. Hauf, resigned; Lieut. J. J. Gromprie, resigned; Lieut. B. S. Goodman, resigned; Lieut. Carl E. David, resigned; Lieut. Geo. O. Consoer, resigned.

Between the signing of the armistice and December 31, 1919, 96 officers of the regular corps have resigned from the service, as follows: majors, 5; captains, 25; 1st lieutenants, 63; 2d lieutenants, 3. The colonels listed above were all in temporary rank.

Engineer Post of American Legion

The engineers in Chicago and vicinity who took part in the World War have formed a local branch of the American Legion, to be known as the Castle Post. The membership embraces engineers of all schools, civil, chemical, electrical, mechanical, and others who served, whether in the Engineer Department, Chemical Warfare Service, Motor Transport Corps, Construction Division or any other staff department, or in the combatant branches. Its purpose is to get the technical engineers under one roof irrespective of the insignia which they happened to wear on their collars when in uniform; its policy is one of preparedness and looks to the development and organization of army engineer reserve units of every sort.

Such an organiation with such an objective, had it been in existence prior to our entry into the World War, could have rendered service of incalculable value in facilitating the organization of special technical troops.

Lt. Col. R. W. Stovel, formerly chief of the terminal facilities division in the Army Transport Service in France, has accepted a position as consulting engineer to Westinghouse, Church, Kerr & Co.

Maj. Harry D. Williar, Engineers, recently discharged, who served in France with the 1st Division, A. E. F., has been placed in charge of the Washington District of the Asphalt Assn., this district including the states of Maryland, Pennsylvania, Delaware, Virginia, and West Virginia.

Maj. H. S. Hetrick, Corps of Engineers (U. S. M. A., 1906), was shot by an unidentified assailant in his home in New Orleans, January 1, and died January 3. Major Hetrick was commissioned Colonel of Engineers during the war, and prior to his death was District Engineer Officer at New Orleans.

Lieut. Col. Claude H. Birdseye, who served as topographic officer on the staff of the Chief of Artillery of the First Army, A. E. F., has been appointed Chief Geologician of the United States Geological Survey, succeeding R. B. Marshall, who resigned to go into private business. Colonel Birdseye has been connected with the Geogical Survey since 1901, and was in direct charge of work in Hawaii and in the Rocky Mountain Division. At the outbreak of the War he was commissioned in the Engineer Officers' Reserve Corps. He was assigned to duty in France in the early fall of 1917, and continued on duty until June of 1919, when he was "demobilized" and returned to service with the Geological Survey.

Col. Walter Fry, formerly sanitary officer at Camp Funston, has accepted a position as health officer at Lincoln, Nebr.

Col. Theodore H. Dillon (U. S. M. A., 1904), who organized the 37th (Electrical-Mechanical) Engineers for service in France, is now Professor of Electrical Engineering at the Massachusetts Institute of Technology. His attention is devoted principally to electrical railway work, electrification of steam railways, and power transmission. Prior to leaving the military service, Colonel Dillon was engaged for a time on the Dalles-Cellilo lock and dam work in the Columbia River and later he served on the Panama Canal as superintendent of the Gatun locks. His service in France included duty as executive assistant to the Chief Engineer, First Army, during the St. Mihiel and Meuse-Argonne operations. After the armistice he served in similar capacity under Gen. C. H. McKinstry, Chairman of the Board for the evaluation of damages due to enemy operations in the allied countries.

Col. Henry W. Hodge, an officer of the Engineer Service during the World War, died in New York on December 21, of heart disease at 54 years of age. He was noted as a designer and builder of bridges and was also engineer for the construction of the Singer, Woolworth, and other large buildings in New York City. He had practiced extensively also in Mexico and South America. Before the war, Colonel Hodge was a public service commissioner of New York City. He served in France as chief of the department of roads in the Division of Light Railways and Roads, which was one of the four major administrative divisions of the Engineering Service of the A. E. F.

Col. E. G. Paules, Corps of Engineers (U. S. M. A., 1912), has resigned from the service to accept a position as employment manager with Crompton & Knowles, Worcester, Mass. Colonel Paules commanded an engineer regiment in France during the war. His last assignment with the Corps of Engineers was as Editor of PROFESSIONAL MEMOIRS.

Gen. E. J. Spencer, formerly Colonel commanding the 32nd Engineers in France, is now manager of the newly organized Electrical Board of Trade of St. Louis, Mo. Col. Spencer is a graduate of the U. S. Military Academy, class of 1882, and served in the regular army until 1892, when he resigned to go into private business. In 1898, he reentered the Service as Lieutenant Colonel of the 3rd U. S. Volunteer Engineers in the Spanish-American War, returning to civil life at the close of the war. In 1917 he was made Colonel of Engineers in the National Army. He organized three regiments of Engineers in succession and personally conducted the last (32nd Engineers) to France, where he served for a time as Chief of Staff of Base Section No. 2 of the Services of Supply, headquarters at Bordeaux, and later as Section Engineer. General Spencer's career as an engineer has been in the electrical field, conducting research work for the Thomson-Houston Electric Company and various light and power companies in the Mississippi and Missouri valleys. For many years he was connected with the Missouri National Guard, appointed a Brigadier General in 1913.

Capt. N. P. Lee, Engrs., recently discharged, has accepted a position with Clarkson & Gains, Fort Worth, Tex., as engineer in charge of their Amarillo office.

Col. Francis F. Longley, Engrs. (U. S. M. A., 1902), formerly commanding the 26th (Water Supply) Engineers in France and principal assistant to the Chief Engineer, A. E. F., on water supply, is now associate director of the Division of Sanitation in the Bureau of Hygiene and Public Health of the League of Red Cross Societies, with headheadquarters at Geneva, Switzerland.

Col. Edgar Jadwin, Corps of Engrs., who returned from overseas about Dec. 1, 1919, has been assigned to duty as District Engineer, Second Cincinnati District.

Col. Thomas H. Jackson, Engrs., has returned from overseas and has been assigned to duty in the office of the Chief of Engineers.

Lt. Col. John C. Gotwals, Engrs., who returned recently from duty overseas, has been assigned to duty as Department Engineer, Eastern Department, with station at New York City.

Lt. Col. Howard S. Bennion, Engrs., recently returned from overseas, is now on duty in the office of the Chief of Engineers.

Col. Ulysses S. Grant, 3d, Engrs., formerly Secretary, American Section, Supreme War Council, at Paris, is now on duty in the office of the Chief of Staff.

Col. DeWitt C. Jones, Engrs., who has just returned from France, has been assigned to duty in the Office of the Chief of Engineers.

The American Bridge Co., through its Chief Engr., Mr. F. W. Dencer, states that discharged engineer officers may obtain positions at the Gary Plant, Engr. Dept., as draftsmen and engineers at salaries from $125 to $250 per month, depending on men's experience and ability.

EMERSON
STEAM PUMPS

Emerson Standard
Made in Eight Sizes

Emerson Foot Valve and Quick-Cleaning Strainer

The EMERSON is a steam vacuum pump designed and built to handle air, sand, mud and grit in percentages with the water impossible by any other kind or make of pump.

It is invaluable for all work in cofferdams, caissons, and for keeping excavations dry—continuously.

EMERSON PUMPS are in daily use by U. S. Engineers in River and Harbor Work, Reclamation, and on the Panama Canal, where 64 EMERSONS have been in service

The Improved Type EMERSON is built of steel pipe instead of cast iron, is increased in capacity 10 per cent, with a decrease of 35 per cent in weight, less parts and steam consumption.

PROFESSIONAL NOTES

OF MILITARY AND ENGINEERING INTEREST

Federal Public Works for Fiscal Year 1921

The estimates of the Secretary of the Treasury for public works in the fiscal year 1921 total $283,921,810, as against $93,872,092, for the previous year. The principal items of this estimate are:

Rivers and harbors	$ 53,659,265*
Lighthouses and aids to navigation	6,759,900
Reclamation service	20,134,000
Naval bases, yards, depots, training stations, etc.	29,795,000
Panama Canal	18,245,931
Military posts	14,225,251
Fortifications	117,793,300
Arsenals and powder depots	7,278,259
Public buildings	6,735,396

—*Eng. World.*

* Cut to $12,000,000 by House of Representatives.

German Floating Foot Bridges

At Louppy, France, on November 9th, 1918, a large German dump was taken over by the 7th Engineers and two types of floating foot bridges were discovered among other equipment.

One type of bridge consisted of rectangular sections, twelve feet six inches long by three feet four inches wide, and seven inches deep; the sides being one solid piece and the bottom being constructed of one-inch by two-inch slats, running longitudinally. The deck was designed with a twelve-inch center, running board, on each side of which were two longitudinal strips or slats, the remaining width being covered with solid planking. Each section was divided into four equal compartments and in each of which were placed pillows made of eight ounce duck stuffed with kapok and varnished.

Each section was provided with two perforated hinged straps on one end, and two locking pins on the other end. It was therefore necessary in launching and constructing these bridges that correct ends be butted together, and right side up.

Three handles on each side were provided for carrying the sections, which could be easily done by six men for a distance not exceeding two hundred yards.

Near the center and on each side of every section were attached steel rods with their upper ends bent to form a ring, through which were passed the hand ropes. These rods when not in use were secured to the sides of the sections by clip springs, and raised to a vertical position by hand when needed.

Between the end handles and the section locking device were secured U-shaped straps between which a small wooden roller was fastened. This no doubt, was used for securing L-iron pickets, driven into the bed of a shallow but swift stream in order to prevent the bridge from arching down stream.

The second type of bridge, similar in general design to the first, varied to the extent that in lieu of four compartments and pillows, it had only one full length compartment and pillow.

The deck of this bridge was composed of two planks, laid longitudinally, and the sides of two pieces of 4 by 4, spaced three inches vertically and forming a side rail approximately one inch above both top and bottom. There being no difference in the construction of the top and bottom, either could be used as the deck, which is a decided advantage.

Both types were well constructed and showed careful workmanship, the second being somewhat more expensive. As to buoyancy, a bridge of either type would easily support men in single file as close as they could walk, while one section of either type would safely serve as a dry raft for four men.

A few changes would be advisable, as follows: a longer, narrower, thinner and lighter section with a deck or running board on both sides, and a simple universal section latch that would permit easy fastening, no matter in what shape the sections were launched.

While somewhat bulkier than the present type of ponton in use in our army, this disadvantage might be offset by handling and shipping "knocked down," with the floats or mattresses baled. One distinct advantage is the fact that the above type is much less subject to damage by enemy fire, and once damaged is more quickly and easily repaired.

A large number of sections of a foot-bridge of this type could be kept in readiness in ponton parks and in an emergency could be easily carried and placed by infantry under adverse conditions, and without the use of skilled labor. Stream crossings could therefore be started simultaneously from a number of points, the distinct advantage of such an operation having been seen in the recent crossing of the Meuse River between Dun-sur-Meuse and Brieulles.

Automatic Weapons For Divisional Engineer Regiments

The question of how the divisional engineer regiments should be armed was debated and investigated many times during the late war.

Major W. T. Snow who commanded a battalion of engineers which fought alongside of the marines at Belleau Woods, gives certain reasons why automatic weapons should be issued to combat engineer regiments. He says.

"The engineers are intended *primarily* for engineering work and *secondarily* for emergency fighting, although this is not as well understood as it should be. In an advance the engineers are less apt to be used as infantry than in defense or retreat, although several regiments were so used in some of the offensives of the past year. Although automatic weapons are sometimes needed by the engineers when engaged on engineering work, the great need for the weapons comes when they are being used as infantry. It seems that the chief engineers of the divisions, corps and army are divided in their views on this subject, but by investigating the work of their respective units it is found that the ones who favor having automatic weapons are those who fought on the defensive while those opposed had been engaged in the advances only."

Tanks in Warfare

There is no doubt of the great value of tanks in warfare. They are an answer to the machine gun. As in other automotive design the questions which arise in formulating specifications for tanks relate to overall size, amount of internal space, power, capacity and running speed. There are, of course, numerous other matters involved, by virtue of the characteristics of tank operation, such as balance and ground pressure. The power plant is obviously a vital feature of the tank. The tank now has one-man operation as a feature, whereas several men were required to drive the first European models. Generally speaking, it is to be expected that tanks and tractors

Digitized by Google

will not only be equipped with various types of accessories developed and to be developed, but be lighter, faster and less noisy. One interesting phase of tank construction is the feasible life of the machine under strenuous conditions so far as the power plant is concerned. The task of an engine in a large tank is a very severe one. Our army had, however, a goodly number of tanks in operation for a considerable time during the war and these were at the front when the armistice was signed. The tanks are not an independent arm of the service, in that they require infantry support. One of their particular functions is to clear the way for the infantry, especially with regard to enemy machine guns. There is no doubt that the tanks are a decidedly effective humane element in the saving of men in war.—*Society of Automotive Engineers, 1919.*

Invisible Light in Warfare

When a source of light is placed at the principal focus of a converging lens the emergent beam consists of parallel rays and has a constant cross-section. Often the narrowness of such a beam prevents its being observed. Greater accuracy was obtained by using a filter which permitted only the extreme red rays to issue. These would be invisible to an observer unless he protected his eyes from daylight by a similar screen. Through such a screen only the red light could penetrate and the eyes of the observer would be in a sensitive state owing to the exclusion of ordinary light. By such an arrangement secret signals can be transmitted. A variation of method was the use of a screen transmitting only ultra-violet light, which was received on a fluorescent screen. The range of signalling was about six miles.

The following arrangement proved of great value in maintaining communication between ships of the same convoy at night. The light was sent out not as a parallel beam, but diverging in all directions. A Cooper-Hewitt mercury arc was the light source. It was surrounded by a glass chimney through which only ultra-violet light could pass. This caused parts of the eye and natural teeth to fluoresce, while false teeth were black. The receiving apparatus is a barium-platino-cyanide screen placed in the principal focus of a converging lens. The range was about four miles.—R. W. Wood in *Proceedings of the Physical Society of London.*

French Railways, Highways and Canals After the Invasion by the Huns

In a report made to the President of France, March 21, 1919, it is stated that the following losses were inflicted upon the railroads of France during the war: 5,600 km. of single track line, 1,510 bridges, 12 tunnels and 590 buildings. To render the tracks useless the huns employed a crude but effective plow of rails dragged along the road-bed by a locomotive. Some hundreds of mines calculated to explode after a long interval, were left in place. The seriousness of the situation was shown by the fact that of the seven lines formerly connecting Paris to Alsace-Lorraine only one was left in operating condition. Fifty thousand freight cars were lost by France in August, 1914. At the beginning of the present year great numbers of locomotives, freight cars and passenger cars were awaiting repair. Highways:—One hundred and five thousand kilometers of roads were in need of more or less considerable repair. Canals:—The work of destruction embraced 450 bridges, 115 locks and 1,075 km. of canals or canalized rivers.

The later number of *Génie Civil* gives due credit to the assistance of the British and the American troops and presents an encouraging report of the state of the repair work. In the railroad systems of the north by September 1, 1919, all of the single-track lines and all but 6 km. of the double-track lines have been restored. Only four of the destroyed stations

remain to be cleared away, one viaduct has been put anew in service and others were nearing completion. In the system of the east more remained to be done.

The canal system has been restored to a surprising extent. Paris is again connected to the coal fields of the north by internal water-ways, and also with the east. Electric traction to transport the coal from the Sarre basin is to be installed on the Marne-Rhine canal.

Out of a total of 228 miles of canals or rivers rendered unnavigable prior to the date of the Armistice, only 62 miles remained unserviceable on November 1, 1919, and on a considerable part of these navigation is possible with light-draft vessels. It was expected that the greater part of this remainder would be ready for service by the first of the present year.

Much work has been done in road repair. Bridges amounting in length to a total of 4 km. have been put in position. Seven thousand kilometres of roads have been restored, but much repairing awaits the future.—*Génie Civil, April 5, September 27.*

Water Power of France

In the Alpine region drained by the Rhone and its tributaries 6,000,000-horsepower can be developed at average water flow. Elsewhere in France 3,000,000-horsepower additional may be obtained from streams. These numbers should be divided by two for the output for low-water flow. At the close of 1915, 738,000 horsepower was obtainable from installations in the Alps. This amount has been much increased since that time.

The execution of the project for canalizing the River Rhone will cost upwards of half a billion dollars and will require fifteen years for its completion. It is computed that it will produce hydraulic power equivalent to five million tons of coal per annum and will materially improve the navigation now practically impossible on account of the extremely rapid current. The canal section is designed to accommodate boats of twelve hundred tons capacity. The project will also permit of the irrigation of large tracts of land.

Extermination of Squirrels by Gassing

Squirrels and other rodent pests which injure embankments by burrowing have been destroyed by gassing them in true war time fashion with engine distillate which is forced into their burrows by a vapor machine.—*Eng. and Cont.*

Hauling Heavy Loads on Highways

The two fundamental rules to be observed in hauling heavy loads on highways are:

1. To apply the motive power as close as possible to the load.
2. To have tires broad enough to avoid cutting the road.

Land Values Increased by Drainage

Mr. Isham Randolph, of Chicago, cites a number of cases in which land values have been increased from $10 to $20 an acre to $75 to $300 per acre by drainage.

Captain André Tardieu is authority for the statement that the losses of the French Army during the World War were 26 per cent of the total number of men mobilized, and that of men under 31 years of age serving with the colors 57 per cent were killed.

Suez Canal During the War Period

Although international agreements under which the Suez Canal is operated prohibit its blockade the war influenced materially the traffic through it, particularly in view of the activity of the submarines of the Central Powers. As the German-Austrian surface navy was practically swept from the seas in the early days of war, it is probable that if submarine activity had not occurred but little difference would have been found in the canal traffic. The data for 1918 in comparison with those for 1912, for instance, show a falling off of over 50 per cent, in number of ships, and somewhat less than the same percentage in total tonnage. Notwithstanding the concentration of submarines on the English commerce, the canal traffic under the English flag was, during 1918, over 79 per cent of the total. Throughout the years, England has led by a large margin, Germany being second. German tonnage, of course, disappeared, and that of Holland which was third in 1912 fell to a single ship of less than 5,000 tons. The falling off of the Dutch tonnage is probably due to the diversion of the East India traffic to the Cape of Good Hope route for safety. Italy and Japan have increased somewhat their canal tonnage. The United States tonnage is, as might be expected, quite small; for some recent years less than half a dozen ships a year, with a total tonnage of less than 10,000. Comparative statistics show that the average tonnage per vessel has been, as a rule, increasing.—*Jour. Franklin Inst.*

Journal of the United States Artillery

Founded 1892

The Technical Journal of the Coast Artillery Corps

Published monthly at Fort Monroe, Virginia, under supervision of the Commanding General, Coast Artillery Training Center, by direction of the Chief of Coast Artillery. Issued on the 15th of each month.

The primary purpose of this publication is the dissemination of Artillery information. In addition it is the medium for presentation and discussion of new and original ideas pertaining to the tactical, technical and administrative problems of the Coast Artillery Corps.

An especial effort is being made to include articles and data of particular interest to Reserve Corps Officers, who desire to keep abreast of advances in Coast Artillery methods.

Subscription Rates:

Army Reorganization

The Senate Army Reorganization Bill (S. 3688), introduced January 9, contains the following provisions of special interest:

The following are classified as "combat arms": Infantry, Cavalry, Field Artillery, Coast Artillery Corps, Corps of Engineers, Air Corps, Signal Corps. The Tank Corps is merged with the Infantry.

The following officers are provided for the regular army:

General (during tenure of Gen. Pershing only)	1
Major generals	20
Brigadier generals	50
Colonels	611
Lieutenant colonels	688
Majors	2,292
Captains	4,584
1st lieutenants	4,355
2nd lieutenants	2,752
Total officer personnel	15,353

This personnel is to be decreased 10 per cent during a period of 5 years after the establishment of universal training.

Officers may be assigned to arms, or transferred between different arms at the will of the President, any arm being thus increased or decreased not more than 20 per cent.

A chief for each of the above combat arms, with the rank of major general, is provided.

The enlisted strength of the combat arms is as follows:

Infantry, 94,000; cavalry, 14,000; field artillery, 39,000; coast artillery corps, 28,000; air corps, 21,000; corps of engineers, 16,000; signal corps, 5,000.

The General staff will be filled by appointment of officers specially qualified for such service.

An "Undersecretary" of War is provided.

The old "Departments" are designated as "Services."

Temporary officers who served during the war are to fill out not less than half the total number of vacancies created by the act, but their distribution as to grades is not prescribed.

One of the most important features of the bill, from the army's point of view, is promotion from a single list, which, if enacted, would forever remove the inequalities of rank between different arms. The "single list" as used in the bill means a list in which all officers are arranged according to total commissioned service, regardless of present relative rank. A peculiar provision of the bill is that former army officers who may return to the service, shall be placed on the list according to their total active commissioned service, which debars them in many cases from high rank, but a civilian who had no service prior to the war may be appointed to the grade of colonel.

Officers will be classified into three classes, A, B, C. Class A officers are those qualified for promotion; Class B those not qualified; Class C those to be discharged or retired. Promotions to include the grade of colonel shall be made by seniority from Class A officers of the next lower grade. Promotion of general officers is to be by selection, but the selection is limited to Class A officers of the next lower grade. Class C officers, retired, shall be placed on the unlimited list.

The bill provides Universal Training for all male citizens of the continental United States between the ages of 18 and 21 years. The period prescribed is 4 months plus time necessary for mobilization and demobilization. The provision becomes effective Jan. 1, 1921. Any alien who secured exemption on the ground of being an alien shall be forever after debarred from citizenship in the United States. The instruction is to include vocational training. Persons liable for training who do not speak the English language may be required to undergo not more than two months of preparatory education.

Men liable for Federal military training may obtain exemption therefrom by joining the National Guard for a 5-year enlistment, provided that not more than 200 men for each Senator or Representative shall be permitted such exemption in any one year.

Reservists (men who have completed their training as above) shall be assigned to the National Guard or to reserve territorial units for 5 years, after which they pass to the unorganized reserve. While in the organized reserve they shall be subject to mobilization and additional training for two periods not to exceed two weeks. Those who desire to qualify as non-commissioned officers will be given additional training and may be retained in the organized reserve for 10 years.

Except as above, reservists shall not, without their consent, be subject to military service except in case of war.

Any person who served honorably as an officer in the war may, upon application be commissioned in the Reserve Corps at the rank held at the time of his discharge. If recommended for promotion prior to discharge he may be commissioned in a higher grade.

Men who served honorably as enlisted men during the war, or who have completed the prescribed military training, or who are specially qualified for service in some branch are eligible to commission in the Reserve Corps.

Commission in all grades, including general officer, is provided for. Commissions in grades above that of Colonel must have the approval of the Senate.

Promotion in the Reserve Corps shall be according to merit, but so far as practicable shall follow the general principles applicable to the regular army.

Reserve officers may be assigned to any duty by the President.

The National Guard shall have a strength of approximately 800 officers and men for each Senator or Representative in Congress.

A National Guard Division of the War Department whose chief will be a reserve officer, replaces the present Bureau of Militia Affairs.

War Department Conferences

With War Department staff officers, the commanders of six departments and seven regular army divisions in attendance, the first of a series of conferences, unique in the history of the Department, was held Jan. 12, at Washington. These conferences are for the purpose of familiarizing the various department and division commanders with the policies and activities of the War Department.

General March opened the conference, outlining its purpose, speaking of the value of education and recreation as applied to the new army and the necessity for universal training in time of peace.

Secretary Baker followed, and said in part that there were two important purposes of the series of conferences: The first, to bring together the officers in the field and those in the War Department to promote co-operation and understanding between them; the second to explain the Department's views in the matter of training soldiers, and maintaining the army at the highest point of efficiency, based on the lessons of the war.

He eulogized the American soldier and spoke of the splendid record he had made for himself in the war. He outlined the three principal ways of obtaining men for the army in time of peace: First, to offer such pay as to compete with private employers. Mr. Baker said this would make soldiering merely a "job" and would remove the inspiration which should go with the profession of arms: Second, by compulsory service: Third, by making the army so attractive by means of education, recreation, etc., that the nation will be glad to see their sons in the army.

Major General Willliam G. Haan, formerly in command of the 32d (Red Arrow) Division overseas, now Assistant Chief of Staff, and in charge of the War Plans Division, addressed the conference at some length. He explained the functions and activities of the War Plans Division of the General Staff, and spoke of the relations between staff officers and those on duty with troops. The new and important work of educational and recreational activity as applied to the army is under General Haan, and he laid great stress on the importance of this work, which is to make the army in time of peace a vast university in khaki.

At the 2d conference, Jan. 13, Gen. Haan, presiding, outlined the War Department's scheme for training camps for candidates for reserve officers in each territorial division. Under this policy the camps would be controlled by Department Commanders, each of whom would thus have at his disposal a trained reserve of officers of all branches, line and staff, in case of a national emergency. As yet no appropriations for these camps are available.

The use in time of peace of the Sam Browne belt, divisional insignia and blue uniform, was also discussed.

At the third session, Jan. 14, took place a discussion of publicity for the army and the program for educational work.

A motion for the adoption of the Sam Browne belt as part of the uniform was made and unanimously carried. The sentiment of the meeting was also in favor of permitting officers to wear civilian clothes when off duty. Sentiment in favor of the blue uniform was not general.

Much discussion took place with reference to living conditions for officers at cantonments, as affecting the morale of the service and the number of resignations. Many officers are now compelled to keep their families in nearby towns and the motor transport corps is not permitted to furnish them transportation to and from their places of duty.

Maj. Gen. Henry Jervey, Assistant Chief of Staff, gave an account of the activities of the Operations Section of the General Staff (G-3).

The decisions of the Conference as to regulations and policies will be forwarded to the Secretary of War for review and action.

Among those attending the conferences were Lieut. Generals Hunter Liggett and Robert L. Bullard; Major Generals Leonard Wood, Clarence R. Edwards, Henry G. Sharpe, John L. Hines, Edward M. Lewis, Charles P. Summerall, James G. Harbord; and Brigadier Generals Douglas MacArthur and W. P. Richardson; also officers of the General Staff and heads of the various War Department bureaus, together with many staff officers from the field.

Strength of Engineers Before and During the War

Prior to our entering into the war the engineer forces of the U. S. Army consisted of some 360 officers and 2,000 men. At the date of the armistice they included some 11,0000 officers and 285,000 men.

A Substitute for Jute Burlap for Sandbags Used in Military Work

Preliminary laboratory tests have been completed in the investigation of substitutes for the jute burlap ordinarily used for sand bags by the Army. It has been shown that while paper does not equal burlap in tensile or bursting strength, it may, nevertheless, be made up into bags which will be of value for this purpose. Further tests are to be made on four types of paper, as well as on burlap and cotton fabrics and all these materials will be subjected to weathering tests to determine their deterioration under service conditions.—*Technical News Bulletin, Bureau of Standards.*

Slag as an Aggregate for Concrete

The results of the investigation made during the past two years on this subject have been summarized in a report called "Crushed Slag as Aggregate in Concrete." The products of three companies, the National Slag Company, the Birmingham Slag Company and the New England Slag Company, were used in the investigation. The conclusions of the report are as follows:

According to the tests reported, crushed slag as a coarse aggregate produced concrete of as high or higher strength than gravel. The tests have not been extensive enough to determine the durability of slag, but so far as they have gone, no signs of disintegration have been observed due to sulphide sulphur. Slag sand, because of its lack of fine material, does not produce easily workable concrete when used as fine aggregate. If it must be used, its working qualities can probably be improved by the addition of small amounts of fine sea-sand and hydrated lime, or other similar material. In all probability, a larger amount of fine aggregate to replace some of the coarse aggregate would aid workability. Provisions in specifications for slag aggregates calling for a maximum sulphide sulphur content of 1½ per cent and a minimum weight per cubic foot of 70 pounds have been tentatively recommended.—*Technical News Bulletin—Bureau of Standards.*

Cost of Concrete Pipe

The cost of standard concrete pipe made for the Modesto Irrigation Project (Cal.) was as follows, per foot: 8 in., 12½ cts.; 16 in., 36 cts.; 24 in., 68 cts.; 36 in., $1.50.

The pipe was in 2-foot lengths, bell and spigot ends, thickness from 1¼ ins. (for 8 in.) to 3 ins. (for 36 in.). The mix was 1 cement to 3½ sand. The force consisted of 10 to 12 men at $4.00 per day. Cement cost $3.25 a bbl. and sand $1.50 per ton.—*Eng. and Cont.*

Lining Irrigation Canal with Reinforced Concrete

An old canal of the Naches-Selah Irrigation Project was relined with reinforced concrete. The lining is 1: 2: 4 concrete, 3 ins. thick, reinforced with 12 by 12 in. wire mesh. It was laid in 5-foot strips and screeds were placed at intervals to regulate cracks due to contraction.

The mesh was rolled out along the sides and bottom and blocked up with large gravel just ahead of the concrete laying.

Concrete was placed with shovels, roughed into place and finished off with trowels. The cost was $23 per cubic yard, including wire mesh.—*Eng. and Cont.*

Placing Steel Pipe Under Water

The town of Queensborough, Tasmania, has laid 700 feet of 30-inch steel pipe in a maximum depth of 26½ feet of water.

A row of guide piles was driven at 100 feet intervals and a stone foundation dumped and graded alongside. The pipe,, in 48-foot lengths with ends closed, was floated to position, lined up on the guide piles, sunk by opening the ends, and adjacent sections bolted together by divers The pipe was then covered with a rock fill.—*Eng. and Cont.*

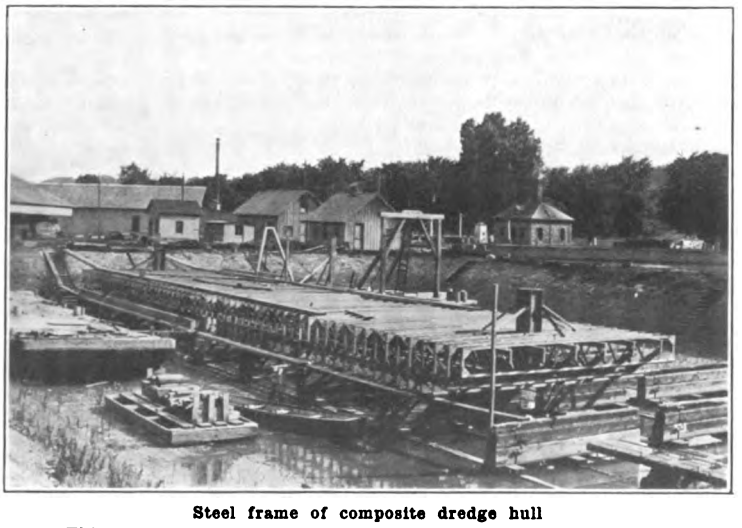
What Risks Should Cities Take in Installing Untried Processes?

In a late issue of *Eng. News-Record* a number of prominent engineers express their views on this subject.

They favor a conservative procedure in spending the money of tax-payers. Recoging that progress is often impossible without experiments on a large scale, they believe that large municipalities may often be justified in spending money not for "experiments" but for "experimental study." Small municipalities are advised to stick to current standard practice. In every case the advice of a competent, disinterested engineer should be obtained.

Value of Irrigation

During 17 years past 2,000,000 acres of arid land have been reclaimed by irrigation. The increase in land values amounts to $356,000; the value of the crops produced is $70,000,000 annually, and 400,000 people have established homes on the land reclaimed.—*Reclamation Record.*



Comparative Durability of Steel and Pressure Creosoted Wooden Dredge Hulls.

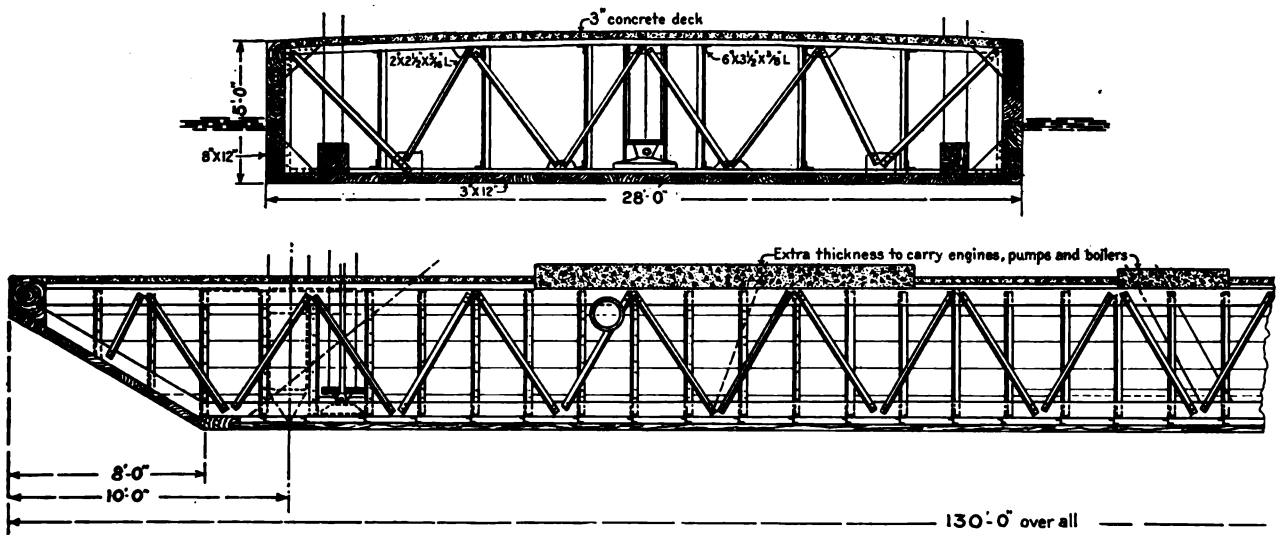
Mr. C. W. Durham, Principal Assistant Engineer, Rock Island district, has furnished some interesting information on this subject. He states that three 18-inch hydraulic pipeline dredges built by hired labor at the United States dry dock at Keokuk in 1912 with steel frame trusses, untreated timber bottoms, creosoted timber sides, reinforced concrete decks, showed in December, 1918, no evidence of rot, rust, or distortion, and no hull repairs have been necessary. These dredges have had seven seasons of moderate use, usually with double crews working 16 hours a day. In comparison, three dipper dredges of steel construction, while in excellent condition, have required scraping and repainting at considerable cost.

In 1908 and 1909 there were built at the various yards in the Rock Island district 79 standard barges of Douglas fir, creosoted by the open-tank or dipping process. After 10 years' service, 40 of these were reported good, 37 fair, and 3 bad. Most of the barges classed as "fair" showed some decay. The principal deterioration, however, was the abrasion and wear of the decks.

In 1911 and 1912 there were built 90 standard barges of Douglas fir, treated with coal-tar creosote by the pressure process, 10 pounds to the cubic foot. Of these, 80 were reported to be in good condition December 31, 1918, showing no evidence of decay; 10 were reported fair, and none bad. All barges can be placed in the "good" class at small cost for repairs.

The experience in the Rock Island district does not show that creosoted lumber is weakened by the pressure process, although it may become less resilient. Mr. Durham believes that creosoted lumber will not decay to the depth of the creosoted penetration, but that when the abrasion goes deeper than that decay is invited. (See figure, next page.)

Steel frame of composite dredge hull
This frame was erected by 1 blacksmith and 5 laborers in 5 days



Building Roads With a Hydraulic Dredge

Hydraulic dredges were used to construct a 250,000-yard embankment for a road connecting Atlantic City, N. J., with the state highway system. The fill, mostly sand, was pumped from Absecon Bay. It was 5 to 6 feet high in places and was retained by side walls built of meadow sod, raised as the fill progressed. The longest discharge was about one mile. A 12-inch and a 16-inch hydraulic dredge were employed, but these were regarded as too small to be economical on a task of this size. The unit cost was 30 cents a yard.—*Eng. News-Record.*

Cast Iron Solid Car Wheels

Fifty plants for the manufacture of cast iron freight car wheels in the United States and Canada have an output of 20,000 wheels per day or some 6 millions per annum. These wheels are guaranteed for a life of 5 years; but usually exceed that period.

Military Railways and the Corps of Engineers

The following decisions of the Secretary of War have been announced:

SUPPLY OF RAILWAY MATERIAL.

(*a*) The Corps of Engineers will procure and develop all railroad equipment.

(*b*) In order that army reserves be set aside, surpluses determined and current needs of all branches of the army met, the transportation services will maintain an inventory of all railroad equipment in use or in storage. The Corps of Engineers will procure and issue to the army, or will issue from stocks on hand, railroad equipment on requisitions approved by the chief of the transportation service.

(*c*) In order that railroad transportation for military service may be placed in such status with respect to appropriations that it can be freely assigned and utilized on any activity under the War Department without necessity for transfer of funds in each case, the transportation service will submit estimates for all railroad construction, operation and maintenance, for the military service at large. Such of these funds as are stated by the chief of engineers as being necessary for construction, maintenance and operation of railroads under his control will be set aside under the estimate for that purpose.

CONSTRUCTION, OPERATION, AND MAINTENANCE OF RAILWAYS.

(*a*) The extension of railway lines into the theater of hostile operations devolves upon the Corps of Engineers.

(*b*) The Chief of Engineers in conformity with the basic supply plan furnished by the purchase, storage, and traffic division of the general staff, will make working plans and preliminary preparations necessary to carry out the construction, maintenance, and initial operation of railroads of all gauges in contemplated theaters of operations. In order to avoid the possibility of duplication of effort, or of construction of unnecessary lines, and in order to insure necessary liaison between existing lines under civil control or under control of the chief of transportation, basic supply plans should receive consideration by the chief of transportation before lines to be constructed by the chief of engineers are determined.

(*c*) The extensions above referred to will be absorbed by transportation service into the railway system of the line of communication when, by decision of the commanding general of the expeditionary forces, the engineering features have ceased to be predominant and the operating features have become reasonably secure from hostile interference. The chief

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you **to investigate our equipment.** Catalog on request.

of transportation service will plan to extend his service accordingly.

(*d*) The Corps of Engineers will procure, organize and train all military personnel for construction, operation and maintenance of railroads. The Corps of Engineers will furnish to the transportation service such troops as the transportation service may requisition for operation and maintenance of railroads assigned to that service.

(*e*) Standard gauge railroad facilities at posts, camps and other establishments are not considered to be military railroads as the term is used in paragraph 1493, Army Regulations. They are either terminal facilities or part of specific projects, constructed and operated as such. As a rule, their construction is an incident in the construction of the plant to which they pertain and can not be separated therefrom. Their operation, under supervision of a transportation officer responsible to local commander for the proper administration of all maintenance matters, is in accord with the past practice of the War Department. No change in this respect is contemplated. The installation of light railway systems at camps and cantonments by the Corps of Engineers or the assignment of engineer troops to the operation of such roads for the purpose of instruction, are matters for special authorization in each case.

The Society of American Military Engineers

It is with pleasure that we are able to announce that the Society of American Military Engineers is now an accomplished fact. Many prominent engineers are already numbered amongst its members, and the list is growing daily.

Since the first draft of the constitution of the Society was promulgated a number of minor changes therein have been found advisable. The constitution and by-laws of the Society, as amended, are printed elsewhere in this issue. Pamphlet copies of these, and application blanks for membership, may be obtained from the Secretary of the Society, at Washington Barracks, D. C.

There has been some misunderstanding and confusion, largely due to changes in the tentative plans, with reference to charter membership in the society. All persons who are eligible to membership are at present eligible to *charter* membership. It has been decided by the temporary Board of Directors that applications for charter membership will be received until the permanent organization is effected, after which it will scarcely be practicable to admit applicants as *charter* members. A former tentative plan provided that all former subscribers to PROFESSIONAL MEMOIRS, who were eligible to membership in the Society would be *automatically* admitted to *charter* membership upon payment of amount necessary to carry their dues and subscriptions to December 31, 1920 at the new rate ($4.50 per annum). Thus in the case of a subscriber paid at the old rate of $3.00 per annum to include No. 65, September-October, 1920, an additional payment of $2.00 would be required (No. 60 at 50 cents, Nos 61 to 66, $4.50, total $5.00, less $3.00 paid, balance due, $2.00). However, as all subscribers do not necessarily desire to become charter members, it has now been decided that all be given an opportunity to express their wishes in the matter and to take a positive action in the premises. Accordingly all persons eligible, who desire to become charter members, should so inform the Secretary, at their earliest convenience, when they will be so admitted, and confirmed upon payment of any amount or additional amount due to December 31, 1920. To save correspondence it is requested that the necessary remittance accompany the application for charter membership.

It is not practicable at this time to fix a final date for closure of the list of charter members, but it is anticipated that under the provisions of the constitution and by-laws a permanent organization of the society may be effected on or before July 1, 1920.

The Secretary
Society of American Military Engineers
Washington Barracks, D. C.

Sir:

I desire to apply for membership in the Society of American Military Engineers.

Please furnish me with formal application blank.

Duties of a Corps Engineer

By

De Witt C. Jones

Colonel, Engineers; formerly Corps Engineer, 1st Corps, A. E. F.

At the time the United States entered the war against Germany, the corps was not a unit of the United States Army. The duties of the chief engineer of any unit were known in a general way or could be deduced from the general duties assigned to the Corps of Engineers by Army and Field Service Regulations, but the specific office of Corps Engineer did not exist. We had been thinking in terms of regiments and divisions. The "Division Engineer" was a familiar character, at least upon paper, but the "Corps Engineer" or the "Field Army Engineer" had not reached even a satisfactory paper stage in his development.

With the revival of the corps as a unit of our service, the questions of duties, office organization, and Corps Engineer troops became important and received consideration, but even after the publication of an organization table allowing him an office force of three officers and a small enlisted detachment, the Corps Engineer of the First Corps had great difficulty in securing this personnel. Even the corps staff did not recognize the importance of promptly organizing the corps engineer's office.

It was intended to provide a special regiment of engineer troops for each corps, but this plan was not carried to completion, and, at the signing of the armistice, the troops assigned to the various corps consisted of such divisional engineer regiments, parts of corps regiments, pioneer infantry regiments, labor and service battalions as had become available for such assignment.

In the absence of definitely prescribed duties, each corps engineer performed the duties which the conditions of service in his particular corps rendered necessary and which were possible with the troops at his disposal. Our corps engineer who served with the British troops worked under conditions quite different from those in the American sectors.

Relations between Division, Corps and Army Engineers

The Corps Engineer supervises the work of his Division Engineers. He should in no sense command the division engineer troops. His supervision is exercised by keeping in touch with the situation throughout the corps, providing and distributing engineer materials and supplies to best serve the common cause, distributing corps engineer troops so that their work shall supplement that of the division engineers, and advising division engineers as to the general engineering situation in the corps, the object to be accomplished and the part each division engineer must take to complete the task.

Corps engineers should be especially careful not to give the division engineers any orders which will infringe upon the province of a division commander. The Division Commander rightly considers his engineer regiment as an integral part of the division and as absolutely within his own control. He is responsible for everything within his division and should be permitted to exercise entire control of his engineers. He has a right to expect assistance from the corps engineer but will resent undue interference.

If the division engineer is competent and keen to foresee coming events, his division commander will allow him great latitude in doing his work. He will in general find it possible to work towards the ends desired by the corps engineer and at the same time meet all requirements in the division.

Should a division commander work his engineers at cross purposes to the general engineer plan the matter can usually be adjusted by a personal conference between the corps engineer and the division chief of staff.

To sum up, the division engineer should look to the corps engineer for information as to the general engineer plan, the part he is to play, and what he can expect in materials and help from corps troops. Combining this knowledge with the known plans of the division commander, he should arrange his work so as to meet both requirements. He must do all this *in advance,* and must inform his division staff of his proposed actions in order to forestall the issue of division orders which will run counter to the corps engineer's plans.

The relations between the Army Engineer and the Corps Engineers are somewhat different. The corps engineer can usually count upon having the corps

Digitized by Google

engineer troops absolutely at his disposal for engineer work. The corps commander will seldom think of the corps engineer troops as a part of his fighting force. On the contrary, the division commander always has in mind the fighting value of his engineer regiment, and when he wants to throw it into the fight he seldom if ever asks the opinion of the corps engineer. It follows that arrangements made between army and corps engineers are less apt to be disturbed by tactical situations and commanders than are those between corps and division engineers.

The army engineer supervises the work of the corps engineers by fixing upon each the responsibility for executing certain works and himself assuming responsibility for the remaining work. He then assigns materials and troops to the various Engineers and to the Chiefs of Section in his own office. In general the corps engineer's work lies completely within the corps area, still there is no definite geographical line which separates the corps and army engineers' activities. As an example, the corps engineer may be maintaining a certain highway in his corps area while the army engineer is constructing a railway and operating quarries alongside the highway in question. This relationship was a development of the St. Mihiel and Meuse-Argonne operations. It is an emergency product, and is thought by some corps engineers to be wrong in principle. These officers hold that the corps engineer should be held responsible for all work in his corps area and should be given troops and equipment to accomplish this work. A corps engineer who had experience with British methods has stated that the corps engineer should be able to furnish all connecting facilities between the divisions at the front and the Service of Supply in the rear, thus eliminating the army engineer as a commander of large numbers of troops.

Under the system as developed in the First Army, at the signing of the armistice, the chief engineer of the army was exercising direct command over more than 50,000 army troops while the corps engineers each commanded about 5,000 corps troops.

Strength and Organization of Corps Engineer Troops

In training areas and under stabilized conditions, the divisions are in direct contact with the railheads and other installations of the services of supply. Railway, water supply, and general construction projects can be handled by the services of supply, and each division can handle its own road problems.

Under these circumstances there is no urgent need for corps or army engineer troops except for minor utilities work around headquarters which can as well be done by detachments of divisional troops. The services of supply will have need for every available engineer.

It is not to be expected that corps and army troops will be assigned and held idle while they are urgently needed for emergency work in the services of supply.

We must assume that in future, as well as in the recent operations, corps and army troops will not be actually concentrated in their respective areas until immediately prior to an operation.

Recognizing these conditions, what can be done to render the work of the corps and army troops effective immediately upon their arrival in the forward areas? The obvious answer is that we must know what work these troops will have to do, and must have ready an office organization competent to direct the efforts of the troops when they arrive.

This means that the offices of the corps and army engineers must be organized as an integral part of their respective headquarters and must not be allowed simply to grow up as the troops arrive. The latter course brings inevitable inefficiency in the early stages of the operation and cripples the arriving units which will be robbed of some of their best officers to provide personnel for the headquarters offices.

As to the numbers and classes of troops which should be assigned to the corps and army engineers, it must not be assumed that our recent experience carries very much weight. On November 11, 1918, the Chief Engineer of the 1st Army commanded over 50,000 men and each of his corps engineers commanded, say, 5,000; but if hostilities had ceased a month earlier or a month later the figures would have been very different.

As the divisions move forward in an offensive, they open a gap between themselves and the organized establishments in the rear areas which must be bridged by greatly expanded engineer activities. The three spans in the bridge are the corps engineers, the army engineers, and the advance section of the services of supply. At least one of these organizations must be capable of great and rapid expansion. Logically, the greatest expansion should fall upon the services of supply, although in the recent operations it fell upon the army engineers. At any rate, it may be assumed that the corps engineer will control from two to four regiments including engineer and labor troops, which assumption may serve as a basis upon which to organize the corps engineer's office.

The corps engineer should properly be stationed with his corps headquarters, while the several corps regiments will as a rule be working miles away. The provision requiring that the corps engineer shall be the colonel or commander of the corps engineer regiment is wrong, and has the practical effect of depriving the regiment in question of its colonel.

Work to be Done

Our service included stationary operations, a number of advances and the conditions in training areas. Since we took no part in a retreat, we can only specu-

Digitized by Google

late as to what duties would have fallen to the Corps Engineers in a retreat.

Engineer supply and road work (including fixed and floating bridges) constitute the great bulk of the corps engineer's work. The office organization must therefore be built around a road section and a supply section. In stationary warfare or in a retreat, defensive lines and military demolitions may become very important. Mining and counter-mining are not pressing matters, and can be developed when the necessity actually arises. Motor and animal drawn transportation are ever present problems of the greatest importance, not only on account of the large quantities of materials which must be moved but also to make possible the intensive engineer reconnaissance and the rapid communication which are vital to the success of engineer operations.

Standard and light railway construction and operation, general construction, water supply installations, electrical and mechanical work, lumbering and forestry operations, camouflage, drafting, photography, administration and records are of importance to higher engineer officers, but touch the corps engineer only lightly or incidentally. The burden of his thought turns upon road work, supply and transportation.

Neither the road work nor the supply problems can be successfully handled without an efficient system of engineer reconnaissance and communication. This system must give the corps engineer early and accurate information as to the capacity and condition of roads and bridges, damage done by the enemy, materials required for repairs, location of fords, character of banks of streams, location and capacity of quarries, location of timber and other engineer materials, estimates of labor and transportation, location and contents of captured dumps, and information as to what the Division Engineers are doing and propose to do. Combining this information with the known plans of the corps commander, the corps engineer can assign his available supplies and troops to the best advantage.

Nor should the corps engineer fail to make systematic reports to the corps staff as to road and bridge conditions. The staff is responsible for traffic routing and regulation, and if it acts in ignorance of true road conditions disaster to the general operation and in particular to the corps engineer's program will be the sure result.

While traffic control is the duty of the military police, acting under the staff, still the fact remains that the engineers are the ones who will be found in force at the critical points where trouble is most likely to occur. The corps engineer should therefore arrange with the staff to have all road officers and non-commissioned officers vested with the power of military police in the matter of clearing up traffic jams. He should also see that these powers are recognized throughout the corps.

The question of camp utilities is, in itself, a small matter, but is apt to cause trouble. In time of war the Corps of Engineers handles all construction and maintenance work in the theatre of operations. The corps engineer officer will, especially in periods of inaction, be called upon to do a great variety of small jobs around headquarters, such as running lighting plants and pumps, erecting bath houses and latrines, making board walks and delousers, etc. The headquarters troop is supposed to handle this utilities work, but as a matter of experience it has neither the necessary men nor material. If the corps engineer resists these demands he is branded as an obstructionist. It is therefore best to recognize that these things must be done and to organize a small utilities section to handle them in a businesslike way. It is even well to take the initiative in doing small jobs which will contribute to the general comfort around headquarters.

Training

The corps engineer is responsible for the training and efficiency of the engineer troops of the corps. He should coördinate training in the divisional regiments by inspections and suggestions but must not attempt to prescribe specific schedules for these regiments. To do this would surely cause trouble with division commanders and would relieve division engineers of responsibility for the efficiency of their regiments.

Uniformity in the training and use of divisional engineers is desirable but hard to attain. Division commanders, seeing the emergencies in the fighting line, are prone to throw in their engineers regardless of conditions in rear. Higher commanders and staff officers, seeing the emergency conditions in rear, are impressed with the necessity of conserving the engineers to meet these conditions. They therefore in their training instructions, at maneuvers, etc., stress the view that engineers should be thrown into the line only in real emergencies. The more tractable division commanders heed this advice while the headstrong disregard it. Uniformity can come only with the authoritative enunciation of proper doctrine and as a result of uniform education of our higher commanders and staff officers.

As a member of the corps staff, the corps engineer will constantly be called upon to act as umpire at division maneuvers. To perform this duty well, he must be familiar and in sympathy with the methods of conducting these maneuvers and the manner of thought of his associates in the work. In other words, he should have the same tactical training as our higher staff officers. He should be a graduate of and maintain familiarity with the methods of the General Service and Staff Schools of the Army. These

Digitized by Google

methods are used in our training and consequently in our operations.

Relations with the Corps Staff

As at present organized, the corps has a Chief of Staff with three principal assistants, known respectively as G-1 (Administrative), G-2 (Intelligence), and G-3 (Operations).

The corps engineer is associated with G-3 in matters of training and military operations, with G-2 in matters of military intelligence, but especially with G-1, who is charged with the duty of coördinating the work of all staff and supply services of the corps. The maintaining of proper relations with G-1 is an important consideration for the corps engineer. The officer selected to be G-1 of a corps will probably be a strong man more inclined by disposition and training to command than to merely coördinate. If he in fact assumes command of the technical auxiliary services, his action may be countenanced or even encouraged by the chief of staff and the corps commander. Under these conditions the corps engineer finds himself seriously handicapped by receiving orders from G-1, issued in the name of the corps commander and often arising in a misapprehension on the part of G-1 of the true engineering situation or requirements and in ignorance of the capacities and limitations of available troops and supplies. Theoretically, with a general staff properly trained and administered such situations will not exist, but in fact many corps engineers have in the past received orders to perform absurd, unnecessary, impossible tasks.

In the interest of efficiency, the corps engineer must do his utmost to maintain proper relations with G-1. He must keep him informed at all times of the engineering situation and of engineer plans. He must, insofar as practicable, make himself personally agreeable to G-1, avoiding especially all written controversies. He must be in actual command of the engineering situation by knowing engineering conditions better and earlier than any other man in the corps. He must formulate and propose good plans before poor ones are thrust upon him. G-1 will generally approve any reasonable engineer plan, provided it is presented before he has been forced to formulate a plan of his own. When G-1 finds that the corps engineer is beforehand with his work and his plans, he will refrain from interference in the details of the engineer work, and his notes to the corps engineer upon unforeseen problems will come in the form of requests for recommendations or proper action rather than as arbitrary orders.

As an example, the corps and army have many staff officers who ride over the area and report to headquarters upon any and all subjects. Suppose a report comes in that a road is bad at a certain point. G-1 may remember that the corps engineer has spoken to him about that bad place and has said that it would be repaired at once or perhaps that it could not be handled at present. He therefore throws away the report. But suppose he knows nothing of the matter. He then checks the report to the corps engineer for his information or for proper action. Suppose now that the corps engineer knows this matter to be of no immediate importance. It is then wise for him to so inform G-1, otherwise in a few days he will probably get a second report directing that the road be repaired within twenty-four hours and report made upon completion. Such occurrences are most annoying and may delay important work. They can be avoided if the corps engineer takes the initiative in reaching a working understanding with G-1.

As another example, take the lumber situation. The demand is always greater than the supply. Division commanders and other services requisition for lumber upon the corps, and G-1 in the absence of knowledge of the situation may issue orders to the detriment of more important work. However, if the corps engineer has talked over the lumber situation with G-1, explaining the shortage, and what is being done to remedy it, or if he has made an agreement with G-1 that the two shall resist all calls for lumber except for certain urgent uses, then the lumber situation remains within the corps engineer's control.

By means similar to the above, any but the most refractory G-1, should be brought to see the advantage of coöperating with the corps engineer rather than commanding him.

In important cases where the views of G-1 and the corps engineer can not be reconciled, the question should be taken to the chief of staff.

To sum up, the corps engineer must not only do his work promptly and well, but must also keep the staff informed as to what he is doing and proposes to do.

In this brief article, no attempt has been made to describe engineering methods or the details of execution. These are questions which relate more particularly to the duties of officers in immediate command of engineer troops and in actual charge of work.

For the corps engineer the questions of office organization, relations with staff and other services, general military information, foresight, and a well developed sense of proportion are of far more importance than personal skill in the actual execution of engineering work.

Discussion

Brig. Gen. Campbell King
Formerly Chief of Staff, 1st Division and 3d Corps A. E. F.

Relations between Division, Corps and Army Engineer

The principles set forth in Colonel Jones' article in regard to the relations between division, corps and army engineers are concurred in so far as my experience as a division and corps chief of staff is concerned. My observation was

Digitized by Google

that in active operations the engineer of the higher unit seldom encroached upon the domain of the lower unit, but the latter, owing to the exigency of the case, was often required to extend its activities back into the area normally assigned to the next higher unit.

Organization and Strength of Corps Engineer Troops

While there is a certain advantage in the matter of giving orders, in having the corps engineer directly in command of the engineer regiment, as a matter of fact in my experience, he rarely has actually commanded the regiment, but only nominally occupied this position as his duties usually required him to be detached from the regiment. The actual regimental commander is really the senior engineer officer on duty with the regiment and I believe for this reason that the principle set forth by Colonel Jones, in regard to the direct command of the regiment not being in the corps engineer, is correct.

Work to be Done

While there are many other duties that fall to the corps engineer, engineer supplies and road work certainly constitute the main burden of engineer work. It is believed that the suggestion that powers of military police be conferred upon engineer road officers and non-commissioned officers on road work at critical points is very useful. This practice was followed in the First Division when I was its Chief of Staff.

The further suggestion as to a utility section of engineers around corps headquarters is believed to be sound and conforms to my experience in this matter.

Training

The training of engineers in the divisions should be coordinated as is all other training, under the general supervision of the G-3 of the corps upon consultation with and acting through the agency of the corps engineer. It is believed that the consequent uniformity in training can thus be secured without trespassing upon the responsibility of the divisions and without any friction resulting therefrom.

The remarks as to the tendency of division commanders to use engineer troops too frequently as combat units is very true according to my experience and must be carefully restricted to urgent emergencies.

Relations with the Corps Staff

The relations of the corps engineer to G-1, G-2 and G-3 as set forth by Colonel Jones are thoroughly concurred in by me. Under certain conditions the duties of the engineer assume such a great importance in their relation to the general work of the division that I found it expedient in the First Division to have him attend the daily conferences held by the Chief of Staff with the heads of the General Staff sections. Ordinarily this was not necessary. However, neither in the first division nor in the third corps were the difficulties suggested by Colonel Jones encountered in the relationship between the engineer officers and the G-1's. It is believed that the reasoning which assumes an inefficient, incompetent G-1 as an objection to the principles governing the relations established between the engineer officer and G-1 is hardly correct because such an assumption would make any relation with any general staff officer unsatisfactory. No such difficulties ever occurred either in the first division or the third corps.

The remarks about the division or corps engineer officer being beforehand with his work and looking well towards the future cannot be emphasized too strongly as a prime factor in making for the efficiency of the engineer service and the general betterment of the staff work.

Line of conduct set forth in Col. Jones' paper to govern the relationship between staff officers is a good exposition of the principles which should control in all staff work, and is essential to that team work which is necessary to produce high efficiency.

In conclusion, I would say that I consider Col. Jones' paper a particularly clear and lucid statement of the duties of a corps engineer and those which, based on my experience as a chief of staff, I believe to be logical and correct.

Brig. Gen. Wilson B. Burtt

Formerly Chief of Staff, 5th Corps, A. E. F.

Corps Areas

The point should be borne in mind that the difficulties of the engineer increase as the forces move forward. It happened in our own experience that the corps area was much lengthened by the advances made. The army and service of supply troops were not available or their forces were not so mobile as to immediately take over the back areas of the corps and permit the corps engineer to give most of his supervision to the areas nearest the divisions.

Reconnaissances

The reconnaissances of roads, etc., are of vital importance to the commander, staff and engineer. They should be made by the engineer on his own initiative. These reconnaissances should extend to the front line and as far beyond as conditions permit. They must be kept up to date as the army moves forward. It seems almost unnecessary to say so, but the material must be on hand, the assignment of labor made, and everything put in order so that repair and construction can begin at zero hour. In no other way can we be assured of even slight progress. All advances will come to an end finally, through the wearing down and "petering out" of the fighting forces. This should not be hastened by failure to provide all the necessary labor and material for the repair and construction of arteries of supply.

Command of Engineer Troops

I do not agree with the idea that the commander of the engineer troops should *not* be the corps engineer. He should be the commander of the troops. His subordinates should handle the regiments or units. The question of rank does not enter. The man in charge of the work should have control of the labor which does the work.

Relations with the Corps Staff

It cannot be emphasized too strongly, that if the corps engineer is thoroughly posted in his duties, has had ample outdoor work with troops, and thoroughly understands his responsibilities, and his relation to the commander and staff, no friction between the corps engineer and the assistants to the chief of staff can arise which are not easily disposed of. They will welcome a strong resourceful man in any capacity, and it can be confidently predicted that they will be glad to accept his forehanded recommendations. "He must formulate and propose good plans" and no others will be "thrust upon him."

Digitized by Google

Brig. Gen. Stuart Heintzelman

Formerly Chief of Staff, 2d Army, A. E. F.

I have read Colonel Jones' paper with great interest, and my own opinion is in general accord therewith, especially as to "Relations with the Corps Staff." There are three points of difference of opinion probably more apparent than real.

First. In the summing up of the paragraph headed "Relations between division, corps and army engineers" the phrases "To meet both requirements," "To forestall the issue of division orders which will run counter to the corps engineer's plans," and, later, "Arrangements made between army and corps engineers, etc.," give an impression that there are two wills involved. On the contrary, there is only one. The corps commander orders, upon the advice of his engineer officer through G-1, what the division is to do in the way of engineer work. Except as thus prescribed or limited, the division commander's will is supreme. The corps engineer officer can urge his interpretation of these orders on the division engineer, but he cannot give any orders except to his own corps engineer troops.

If the division staff refuse to accept the corps engineer's interpretation of the corps commander's orders, he, as a staff officer of the corps commander, reports the whole matter to him through G-1, who issues the necessary orders to the *division commander.* Any other conception of this relationship will cause increasing friction and divided responsibility.

Second. With reference to bridging the gap opened between the troops and the rear areas by an advance, the greatest necessity for rapid expansion will always fall on the army engineers rather than on the advanced section, S. O. S., since the army is vitally interested and its success or failure depends on bridging this gap. Hence, all available engineer troops should be given the army and the army have an undivided responsibility. It will be only too glad to turn over the bridge as built, once flow of supplies is assured, but until thus assured the army must control.

Third. The corps engineers must assist in clearing up traffic jams. But it must be clearly kept in mind that the engineer building the road cannot control traffic. For here are two conflicting interests; moving supplies and road building. A third party must decide priority at any given time or place. Frequently these decisions will be so important and so difficult to make that they will require an officer in close touch with the condition of the troops and the plans of the commander.

The most important thing to keep in mind is that all good staff management depends on personnel. Good staff officers will make any system work, or at least amend it so that it is workable. On the other hand, the best system will not operate satisfactorily under the direction of inefficient officers.

Col. Hj. Erickson

Formerly Commanding 1st Brigade, and Chief of Staff 8th Corps, A. E. F.

With reference to Colonel Jones' article on "Duties of a corps engineer" the following remarks are submitted:

It is intimated that under certain circumstances a corps engineer may deal directly with the chief of staff of a division. In practice, when the engineer work of a division does not co-ordinate with the scheme of work for the entire corps, the corps engineer would take the matter up with the corps chief of staff who, in the name of the corps commander, would cause orders to be issued which would remedy the matter.

Colonel Jones believes that the division engineer should try to mold the divisional orders so as to coincide with his own pre-determined plans whereas in practice he would be informed by G-1 what would be required from him, and his plans would be made to meet those demands. The part of the G-1 annex to the divisional orders referring to "Works" would of course be in accord with the will of the corps commander.

In a rapid forward movement it seems that the work of both the division and corps engineers would be of a temporary character and only just sufficient to aid the advance of their organizations. As the army would be interested in the advance as a whole, it is believed that the main permanent work, such as railroad, tunnels, complete bridges, etc., would be carried out by the army engineers and that consequently, for a short period, corps and army engineers would be working side by side at their respective jobs. However, this would be only for a very short time. If the advance continues, the temporary work of the division and corps engineers would be elaborated by the army engineers. In other words, there will be a constant forward flow of work following the advancing divisions, the rear limits of the division and corps zones of work will be more or less overlapping until the movement stabilizes. It seems therefore that the strength of the army engineers, whose work is of a more permanent character and whose scheme of work is broader, will exceed that of the corps engineers.

It is never advisable to divide responsibility for work in a campaign, and for that reason if no other, and there were others, traffic control should be strictly under the military police. It is true that in a number of instances during the campaign of 1918, engineers assisted in traffic control in the American zone of advance. However, this was a makeshift to assist an organization new to the American military establishment and will not be called for in our future campaigns. The engineers have their well defined and important work to perform and their efforts should not be reduced by performing police duty. They assist, of course, indirectly in reducing traffic jams by repairing bridges, constructing "run arounds" when necessary, etc.

Col. Wm. J. Barden

Engineers; formerly Corps Engineer, 6th Corps A. E. F.

Colonel Jones' article is interesting and instructive. It is, of course, based on experience with the American Expeditionary Forces in France in the greatest war, not only in which our country has ever been engaged but the most stupendous one in history. Lessons derived from our experience therein should therefore be the best guide for our future organization and policy, but in considering these lessons it seems that sight should not be lost of two important factors: first that our next war may be fought under entirely different conditions and second that our participation in this war was too short as compared with that of the other nations engaged to justify us in accepting without very thorough examination the conclusions apparently to be drawn from our experience. While the 1st Corps was organized to take effect January 20, 1918, the 1st Army was not organized until August 10th so that there were only four months before the armistice in which the army corps functioned during active operations in their normal relation to divisions and armies.

I do not recall having seen any statement of the reasons for reintroducing the corps organization into our system—possibly it was to harmonize our organizations with that of the French. The corps had been definitely and appar-

Digitized by Google

ently advisedly abandoned in our regulations which prescribed the organization of divisions into "field armies' and the latter into "armies." This may be considered as practically the same as the "corps" and "army" as organ ized in the A. E. F., except that a field army or army involves the idea of a more complete and complex organization than that of a corps. The corps is primarily an organization for training and fighting a number of divisions and is only incidentally concerned with supply and administrative details. The original plans apparently contemplated the definite assignment of six divisions permanently to a corps—four combat, one replacement and school, and one base and training (G. O. 9 Jan. 15, 1918, G. H. Q.—A. E. F., and corps tables of organization) but in practice, divisions were changed from corps to corps so frequently that the smaller organizations of a division often did not know to what corps they belonged. In combat therefore practically the sole purpose of the corps organization was tactical; to fight most effectively the divisions temporarily assigned it. Nevertheless, the corps staffs were elaborately organized, heavily officered units. One corps at one time had as many as 140 officers at headquarters and even as late as April 30, 1919, when it was about to be broken up, the 9th corps had some 60 officers on duty in the staff These officers were largely from the line and competent troop commanders, many of them regular officers whose services with troops were certainly greatly to be desired in view of the serious shortage of trained troop leaders. It seems that serious consideration might be given to the possibility of omitting the corps organization and reducing somewhat the size of the field army. If this could be done it would considerably reduce the number of officers required for over-head.

If the corps is to remain as a part of our system the question of the assignment to it of engineer troops should be more definitely determined. In my opinion, the corps engineer regiment should be a pioneer regiment similar in all respects to the divisional regiment except as regards the train. The latter should be more complete especially as to the bridging equipment. Its transportation could probably all be motorized and should include tractors and dump wagons or dump trucks for road work, and a portable pile driver and light derrick for heavy bridge work. If streams of such size as to require ponton bridges are likely to be encountered one or more divisions of bridge equipage should be assigned it. An ample amount of the canvas type, portable foot bridge should form a part of its permanent equipment. Colonel Jones is right in his statement that this regiment should have its own colonel. The corps engineer in active operation will have his hands too full of other work to exercise actual command of the regiment. It is also of course essential, as he points out, that the office of the corps engineer should be promptly organized with its full complement of authorized commissioned personnel and such enlisted personnel as is likely to be needed, but I cannot agree with his assertion that it will probably be necessary to wait the actual entrance into hostilities to secure the corps engineer regiment. That should be promptly and permanently assigned and join the corps, or the corps engineer will be likely to find it missing when combat begins. In training areas it will probably need some training itself, and in any event either there or under other stabilized conditions there will be no difficulty in finding useful employment for it. If necessary it can do work for the army or services of supply but should never be withdrawn from the active control of the corps engineer.

If the pioneer infantry regiments are to be retained, one of them should also be permanently assigned to the corps: otherwise, and probably preferably, one or two labor battalions. Additional engineer organizations may be assigned from the army temporarily, as may be required.

The duties and relations of army, corps and divisional engineer officers and troops were prescribed in G. O. 98, G. H. Q. A. E. F. June 18, 1918, and in G. H. Q. pamphlet approved by the Commander in Chief, August 30, 1918, and republished in Engineer Field Notes No. 44. The most important of the engineer functions is unquestionably that of providing the means of communication sufficient to secure the passage and supply of all troops and material. This of course includes roads and bridges, railways and light railways. All kinds of engineer troops, divisional, corps, army and S. O. S. will be engaged on this work and it is not always nor even generally practicable to make definite division of areas within which each will work. They will necessarily overlap. The corps troops may have to assist the division engineers on road and bridge work in the division areas, and the army road troops will almost always be working in corps areas. The army railway and light railway troops will work as far forward as possible, the former almost to the front lines. I do not believe it to be practicable to hold the corps engineer responsible for all work on his corps area nor to give him troops and equipment sufficient to accomplish this work. It is of too great variety and requires too many kinds of engineer troops to make it feasible to allot to each corps troops of all classes needed. The number of different kinds of engineer regiments or organizations should be reduced to the lowest possible limits:—for example, water supply, electrical and mechanical and shop and supply regiments should be combined into one class, and possibly other reductions can be profitably made—but even so these special troops should belong to the army rather than to the corps. It may be necessary occasionally to temporarily assign portions of them to the corps. But in general they can be better supplied and cared for and more constantly usefully employed by leaving them under the army engineer, and in the 2nd Army satisfactory results were obtained by instructions to them from him to do such work as was requested by the corps engineer so far as this did not conflict with his general orders.

Colonel Jones' discussion of the relations of the engineer to the general staff section of the corps staff will be of particular interest to officers of our corps who served as division or corps engineers. He seems, however, to have rather dodged the issue as to whether G-1 had been given proper authority by orders and regulations to assume command of the technical auxiliary service and to issue orders in the name of the commanding general. The average G-1 certainly considered that he had such authority and I think an analysis of G. O. 31, G. H. Q. A. E. F., Feb. 15, 1918, will show that this was correct. Hardly any one can now be found who will question the necessity of a general staff, nor will any troop commander or technical staff officer object to receiving orders from the chief of staff in the name of the commanding general. The delegation of such power to the assistants to the chief of staff, however, and its exercise by them, undoubtedly caused occasional irritation both to line commanders and to the technical staff. In the case of the latter the matter was further aggravated by a tendency on the part of G-1 to do more than "co-ordinate" the work of the different technical services. The verb "co-ordinate" is defined in the dictionary as "to regulate and combine so as to produce harmonious action: to harmonize." This would seem to be the proper function of the general staff as regards the technical services and if its activities were limited thereto, even if exercised by G-1, there could be little ground for complaint.

Col. George B. Pillsbury

Engineers; formerly Corps Engineer, 2d Corps A. E. F.

I am in complete accordance with views expressed by Colonel Jones in his article, and desire merely to correct a misunderstanding, for which I fear that I may be myself responsible, concerning the functions and duties of the corps engineer of our corps which served in the British 4th Army.

The British organization, as I understand it, made no provision for corps engineer troops. As a result of their war experience, however, they arrived at an organization that I believe we were rapidly approaching in the American Army, under which the army engineer troops were assigned to duty under the corps.

Each corps had a definite sector, and within this sector the corps engineer was responsible for:

(*a*) All roads in advance of a line known as the D. G. T. line. An organization analogous to our Advance Section of the Services of Supply took over the roads behind this line. The line is so drawn that the emergency work, required for the immediate prosecution of military operations, falls to the corps engineer; the systematic repair of the roads behind the area of congested traffic to roads.

(*b*) Bridges in the corps area, including those in rear of the D. G. T. line. I presume that the reason for this lies in the desirability that the control of all available bridge material be exercised by those responsible for front line operations.

(*c*) Water supply in the corps area.

(*d*) Engineer supplies for the corps.

All work on light and standard gauge railroads was wholly outside of the province of the corps engineers. Army railroad troops would accordingly be working alongside troops under the corps engineers; and, when necessity therefor arose, troops would be diverted from the corps to report to the army railroad engineer.

The chief engineer of the field army did not have control of the roads in rear of the D. G. T. line, nor of light or standard gauge railroad construction, these being under the quartermaster branch. Outside of maintaining water supply points, bridges, training grounds, etc., in the army area, which lay behind the corps area, he controlled the supply of material and troops to the corps engineers, kept them supplied with engineer information concerning the territory over which the advance would take place, and maintained a general supervision over their work.

This was the system in the British 4th Army. In some other British field armies the troops directly under the army engineer took over water supply and bridging work well up into the corps areas. Such practice, from my limited observation, did not lead to the efficient execution of the duties observable in the 4th Army.

It will be seen, therefore, that the British practice, as concerns the functions of the corps engineer, was not substantially different from the American practice as described in this article. The difference lay in the fact that in the British service, the duties and sphere of action were very definitely defined, and a well ordered procedure established for the execution of these duties. Thus, on taking over the sector, the new corps engineer was furnished with a complete "turn-over report," giving the precise status of the work in hand; the corps engineer troops were transferred with the corps area, and continued their operations, which, however, were thereafter conducted in immediate and complete accord with the plans of the corps commander, being directed by a member of his staff, the corps engineer.

I believe that the American practice of placing the construction of light and standard gauge railroads under the engineers, instead of under the supply branch of the staff, is the preferable one, as it permits of a better utilization of all construction agencies.

As for extending the scope of activity of the corps engineer to include light and standard railroad construction, it is of course evident that these lines must follow a comprehensive plan for the supply of the army as a whole, or even for the army group as a whole. Responsible control by the corps is therefore impossible. On the other hand, there should be close co-operation between the rail construction forces and the corps engineer forces in such matters as water supply, unloading points, labor, etc. If the corps engineer was notified of all rail construction operations in his territory, and if the officer in charge of such construction was instructed to confer with him, this co-operation should be assured.

Another point may be emphasized. The corps engineer executes his work by means of organized troops. Efficiency and good organization require that the commanders of these units be in responsible subordinate charge of the work which these units are performing. The corps engineer's road officer should be the senior officer on duty with the troops on road work; his water supply officer the commander of the troops who are engaged on water supply work, etc. The corps engineer's office staff, as such, should be limited to an executive officer, a supply, and a junior officer who is charged with looking out for the facilities necessary and desirable at corps headquarters.

Inefficiency will inevitably result if a junior officer on the corps engineer's staff has charge of work which is being executed by troops whose commander is a senior officer. If the commander of the troops is not qualified to execute the work, he should be replaced.

Col. J. R. Slattery

Engineers; formerly Corps Engineer, 7th Corps A. E. F.

Colonel Jones outlines clearly the relation that exists between the corps and division engineers. At times considerable difficulty in securing the best engineering results are likely to arise from this relation. The writer found the division engineers of his corps at all times eager to co-operate with him in making the engineer plan for the corps just as complete and well co-ordinated as if it were laid down in detail by the corps commander himself, and there were no division commanders to be considered. This would probably be the usual case.

As an example of the difficulties that may arise, the following experience may be of interest. In one of the divisions the division engineer did not have the entire confidence of the chief of staff of the division. This chief of staff forbade his division engineer to give any orders to the German road-masters in regard to road work under way, insisting that all such orders be given by the officer in charge of civil affairs. There resulted a situation which seriously interfered with the progress of the road work and greatly annoyed the German road officials through whom the work was being carried out. The corps engineer immediately took the matter up with the chief of staff of that division, pointing out the methods in use in the corps and other divisions, but was unable to persuade this chief of staff to change his decision and was compelled to bring the matter to the attention of the chief of staff of the corps.

Multiple Production of Relief Maps

By

Louis M. Manheimer
Captain, Engineers
and

Frank T. Fuller
Lieutenant, Engineers

At the very beginning of the World War it was recognized that with an army composed so largely of officers drawn from civil life, it would be of great importance to have maps which would enable officers with little or no training in map reading to visualize the terrain. It is well known that this faculty is a rare one, and that map reading is, by many, mastered only after years of training.

The following is quoted from a service manual:

So important is the influence of the *lay of the land* upon *military operations* that every officer must thoroughly acquaint himself at the earliest practical moment with the topography of the area within which his responsibilities lie.

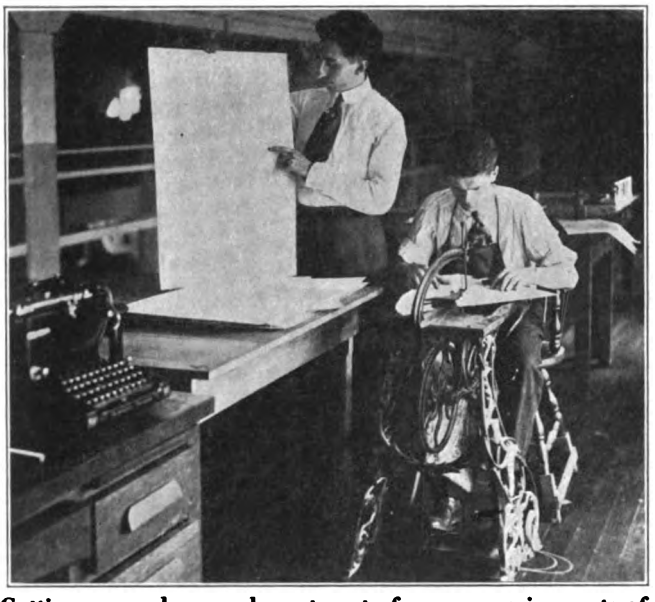
A mere knowledge of the main roads, of the direction and distances to nearby towns is by no means sufficient. He must know where the plains are, where the hills rise, how the streams run. *He must have a mental picture, a birls-eye view,* impressed on his brain, of the main *physical and military features of his territory.*

It was to meet this need and supply a miniature of the battlefield, true to scale, in such form as to be available for the use of officers down to the company commander, that the experiments in relief mapping were undertaken.

In addition to this use it is common knowledge that relief maps played an important rôle in the World War as media through which were obtained technical data in connection with visibility, fields of fire, defilade, masks, location of gun emplacements, and the like.

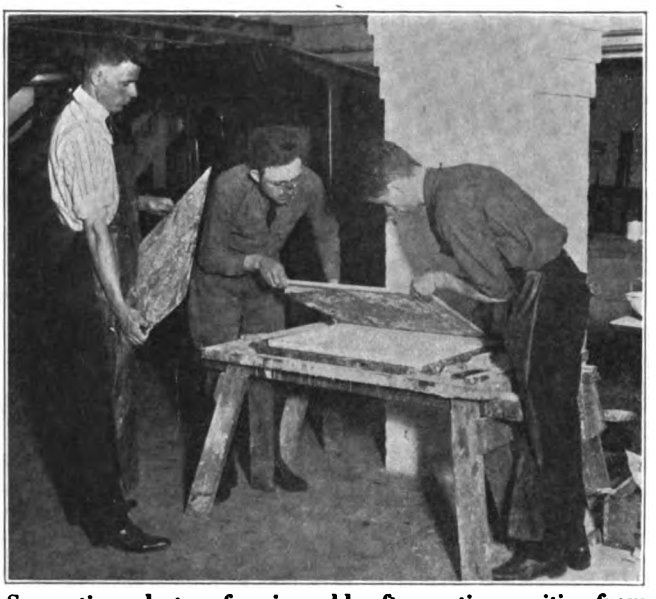
A study was made and experiments undertaken in an attempt to devise a method whereby a large number of durable and portable reproductions in relief of each map could be made in a short period of time and at reasonable cost. At the time this was begun there was no known method for making such maps except in single copies by painting, drawing or pasting the details upon a cast of plaster of Paris or some such material. Although maps of that kind are cumbersome, fragile, and often inaccurate, they have a great advantage over flat maps for certain purposes.

The work of the Corps of Engineers upon this problem can hardly be said to have passed out of the experimental stage, but as a result of extended study a process has been evolved whereby are made relief maps, formed solely of paper, which are true representations of the terrain and which can be produced in quantity by such talent as may usually be found in an engineer organization, at reasonable expenditure of time and money.



Briefly, this is accomplished by forming up a model of wax and cardboard from which a metal die and counter-die (male and female) are cast. Paper which has been softened is then embossed between the two dies under pressure and at a temperature of approximately 200° F. Upon this blank paper relief map the topographic and military features are projected photographically or drawn by pantograph. This original relief map is then softened and flattened out again, and a flat distorted map thus obtained which is reproduced in quantity in the proper colors, by lithography or other methods. The printed maps are then formed up between the same dies, at the same register as the original map, making accurate reproductions of the terrain in relief.

The above brief description outlines the general principles upon which the process is based, but the actual construction of the maps is quite complex and has required a great deal of study to perfect. The process is more completely described as follows:



(*a*) A cardboard wax model is formed from the ordinary topographic contoured map. The model is made by lithographing, and printing, or drawing the contours of the map which is to be copied in relief, upon cardboard whose thickness represents a contour interval at the determined vertical scale, which is, of course, exaggerated relative to the horizontal. From the original map each contour is cut out with a scroll or jig saw.

Starting with a sheet of cardboard the size of the printed map, the irregular curve representing the lowest contour is sawed out and pasted into the position indicated upon the base map. Then the contour above the lowest

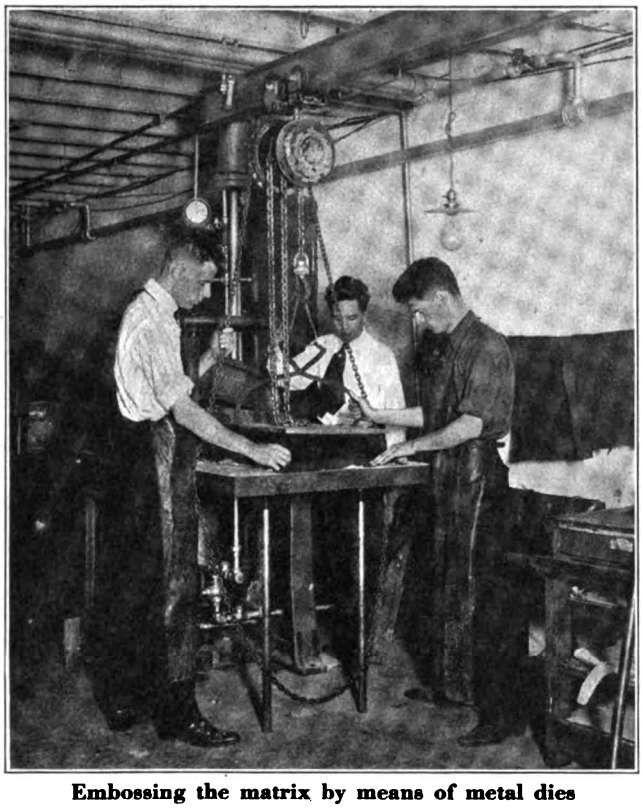
Digitized by Google

Cutting maps along each contour to form successive parts of original model

Separating plaster-of-paris molds after casting positive from negative

is pasted upon the first, its position being easily seen as it is printed or drawn upon the map from which the lower contour was taken. In this manner each layer is built up on the one below until the highest full contour elevation has been reached.

We now have a solid mass of cardboard of the correct height for the relief map and true to scale. The contour intervals are like a flight of steps, the top edges of which are in theoretically correct position vertically and horizontally. It remains to slope off the portion of the map between the tops of these contours so as to create the natural ground forms in place of the steps. To do this,



Finishing model by scraping away surplus wax

Digitized by Google

wax is mixed with balsam of fir or Canada balsam, which is heated slightly until it is a creamy liquid. It is painted on to the paper model with a brush to such thickness as to fill in all the steps and to round off the tops of the hills and ridges above the upper layer of cardboard. The wax is allowed to cool and harden. The surplus is then cut away with dull tools. The result is a wax and paper model which is a reproduction of the ground as shown by the flat contour map, with an exaggerated vertical scale.

(*b*) From the original model thus produced a mold of plaster of Paris is cast by pouring a wet mixture on to the wax relief model, from which a counter-mold is in turn cast in like manner.

(*c*) When each plaster mold becomes dry it is placed in a metal molding or casting box which has previously been heated. Molten linotype metal, at a temperature of approximately 800° F. is now poured into the mold against the plaster model and a metal die and counter-die are thus cast.

Embossing the matrix by means of metal dies

(*d*) The next step is to form up the paper matrix. To do this several sheets of paper are first pasted together with a cold mixed dextrine paste and these, while still wet with the paste, are placed on the concave die. Two woolen blankets are laid over the matrix to absorb the moisture and then the convex die is inserted. This combination is formed on the apron of an ordinary stereotyper's matrix press and when complete is slid into the press which previously has been heated. The hand screw of the matrix press is now promptly turned down upon the dies, bringing them firmly together. The matrix is left in the press about 6 minutes, during which time it becomes baked into a hard substance

(*e*) The surface of the paper is next sized and an emulsion, which is a very rapid bromide-silver solution, is sprayed upon the surface in an even layer by means of an air brush or atomizer.

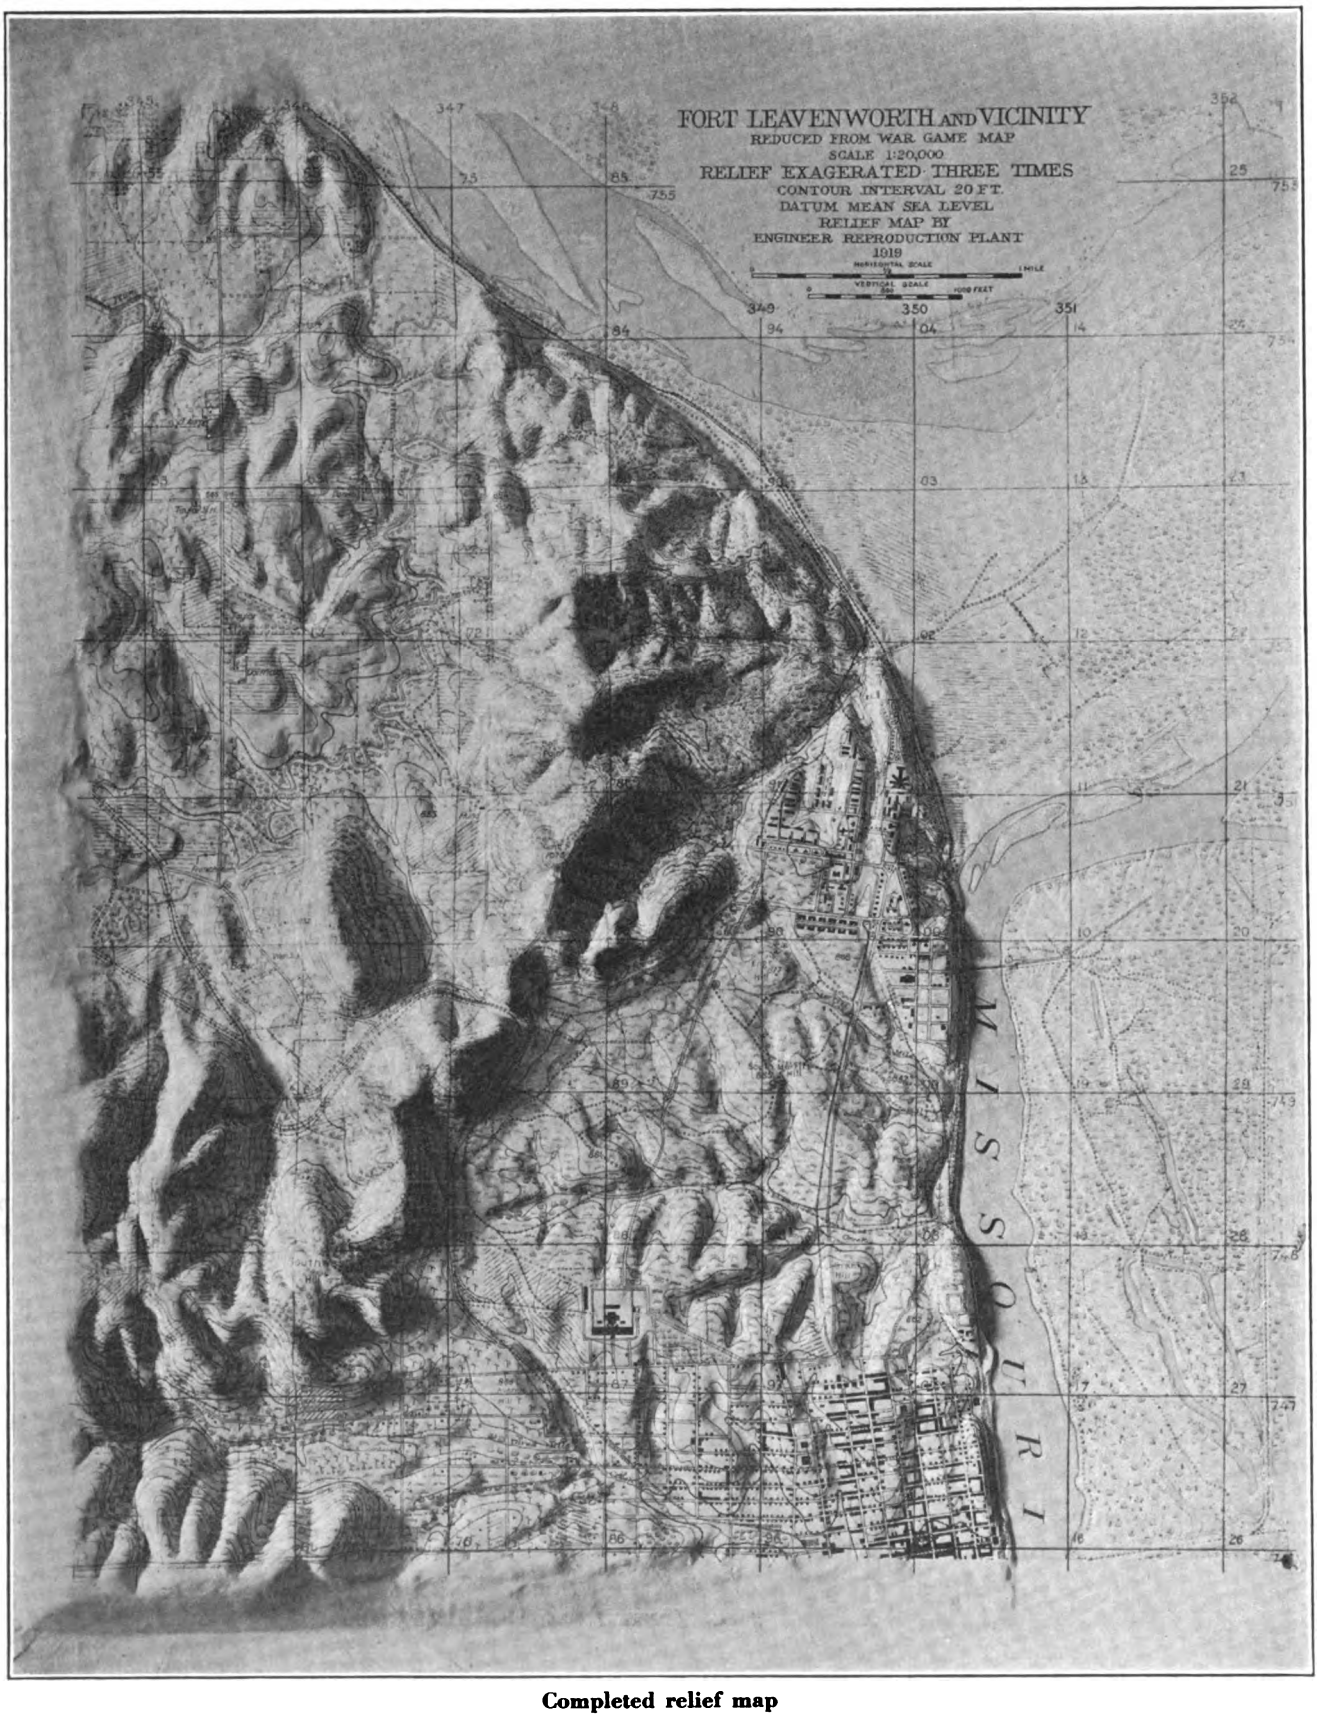
(*f*) The original flat map is photographed in a copying camera in the usual manner. The negative thus obtained is placed in a projecting machine or enlarging camera and the sensitized matrix is hung on the easel. The negative and matrix are adjusted by turning appropriate screws until exact register and focus are obtained. The light is projected through a piece of orange celluloid which protects the sensitized matrix from exposure until the adjustments are made.

(*g*) This master map thus made by projection, is next placed in a bath of water and softened. When quite soft it is flattened out upon a piece of stiff cardboard, placed in a cold press and allowed to dry under pressure. In flattening the map, care is taken to avoid wrinkles.

The embossing of the map is accomplished by two separate processes in treating the paper. First is the permanent stretch in which the fibers are actually separated one from another; and the other is the temporary deformation in which the paper moves or slides into appropriate position. This is best understood by thinking of a high, rounded, lone hill; to accomplish a conformation to this the fibers shift along one another and the paper becomes thinner. Whereas in accommodating the paper to a high embankment such as would occur along the right-of-way of a railroad tangent, there is a slipping of the paper into the ravine which does not cause any deformation of the paper. So that when the matrix is flattened out the paper is larger than the model, the amount of the sliding of the paper, and is puffed up with the permanent stretch. In order to flatten out the permanent stretch, a paper is used which is composed of especially long fibers and which can be softened almost to the consistency of pulp. The fibers are virtually shifted back into their original position and with them the lines on the map.

(*h*) When the flattened map has become dry, separate tracings of each color are made. These tracings collectively show the entire map. The tracings are then printed directly to metal by a well known lithographic process and maps in the desired colors are run off on the press upon the same quality of paper employed in making the paper matrix (*d*). We now have, it will be seen, a number of distorted flat maps in color

(*i*) The next step is the embossing of the flat, distorted maps. On the four corners of the concave metal die are four dowels or tits which fit into corresponding holes in the convex die. On the corners of the printed maps are corresponding holes which are fitted over the dowels on the die to insure proper register between the ground forms of the die and the corresponding contours representing these forms on the map.



The register may not be perfectly correct at the first trial, that is to say, the contours may not fall in the proper position with reference to the hill and valley forms they represent. The amount and direction of the parallax is determined by inspection and corrected by shifting the register points on the printed map.

The secret of success in this embossing process is in exactly duplicating with the printed maps all that was done with the original blank matrix.

(*j*) The finished matrices are mounted upon beaverboard, but no washing takes place and as no chemical or water reaches the map it is not necessary to apply the paraffin to the edge or to paint with varnish. However, it is deemed expedient to varnish the maps, the better to preserve them.

Maps made by this process have been compared with the relief maps of the western battle front in France, made by the French and by the British, and it is at

Digitized by Google

Completed relief map

Digitized by Google

least conservative to say that our work compares very favorably with theirs, besides having the additional advantage of being lighter in weight and far less fragile and therefore more portable and convenient to use. As far as known a paper relief map, which is a true representation of the terrain and which can be reproduced in quantity, has never before been made. The French and British maps are made by pasting upon a relief foundation flat maps which are printed upon thin India paper. These are not true maps in relief, and are patched and touched up with pen and brush to correct evident inaccuracies.

If the relief map produced by this process be lighted by parallel rays from one side or one corner, so as to produce the shadows of the hill forms, and then photographed, a flat print conveying a very good indication of the ground forms is produced. The appearance of such a map is indicated in the accompanying plate. While inferior to the actual relief map it conveys a far better idea of the topography than an unshaded, flat contour map. Experiments looking to the production of such a map *in color* are now in process. One method under experiment is to print the shadows as photographed from the blank relief map in sepia upon a regular contoured map. If a map of this character can be successfully produced in color it will be most useful, possessing all the advantages of the ordinary flat map as to speed and economy in production, portability, and general utility, while possessing to a considerable degree the advantage of the relief map in visualizing ground forms.

An estimate of cost and time required for reproduction of relief maps by this process, based upon the Camp Humphreys map (size 15 by 18 inches, on a scale of 1:4224), indicates that maps can be made in four colors and in quantities greater than 200, for approximately $1.30 each, the cost greatly decreasing with larger production, as the making of the original models, dies, and lithographic plates, which is a considerable item of the total cost, is the same whether one map or several thousand be produced. The cost and time required for production vary greatly with the nature of the topography, and the estimate given above cannot be regarded as applicable to all cases. It is certain that by a subdivision of the work among a large number of men the time required could be greatly reduced, so that in an emergency maps could be issued in 48 hours. Ordinarily it requires about ten days for the first 100 copies and 100 copies per day can be produced by a single unit thereafter.

It has been recommended that maps be prepared by this process of the training areas and important land defense areas, and that this work be carried on in such manner that engineer troops will be trained to take charge of relief map-making.

This process was conceived and developed for the Corps of Engineers at Washington Barracks, D. C., under direction of the Board on Engineer Equipment of Troops, by Louis B. Manheimer, then Captain of Engineers. The work is at present being carried on as one of the activities of the Engineer Reproduction Plant, under the direction of Major H. R. Richards, Officer in Charge, Engineer Reproduction Plant. The plant is at present engaged in producing relief maps of Fort Leavenworth, Fort Sill, Camp Humphreys, and the island of Oahu, H. I.

Board on Surveys and Maps

The President, on December 30, 1919, issued the following:

In order to co-ordinate the activities of the various map-making agencies of the Executive Departments of the Government, to standardize results, and to avoid unnecessary duplication of work, I hereby constitute a Board of Surveys and Maps, to be composed of one representative of each of the following organizations:

1. Corps of Engineers, U. S. Army.
2. U. S. Coast and Geodetic Survey.
3. U. S. Geological Survey.
4. U. S. General Land Office.
5. Topography Branch, Post Office Department.
6. Bureau of Soils, Department of Agriculture.
7. U. S. Reclamation Service.
8. Bureau of Public Roads.
9. Bureau of Indian Affairs.
10. Mississippi River Commission.
11. U. S. Lake Survey.
12. International (Canadian) Boundary Commission.
13. Forest Service.
14. U. S. Hydrographic Office.

The individual members of this Board shall be appointed by the chiefs of the various organizations named and shall serve without additional compensation.

The Board is directed to make recommendations to the several Departments or to the President for the purpose of co-ordinating all map-making and surveying activities of the Government and to settle all questions at issue between Executive Departments relating to surveys and maps in so far as their decisions do not conflict with existing laws.

This Board shall perfect a permanent organization and shall hold meetings at stated intervals, to which representatives of the map-using public shall be invited for the purpose of conference and advice.

This Board shall establish a central information office in the U. S. Geological Survey for the purpose of collecting, classifying and furnishing to the public information concerning all map and survey data available in the several Government Departments and from other sources.

All Government Departments will make full use of the above Board as an advisory body and will furnish all available information and data called for by the board.

So much of the Executive Order of August 10, 1906, as grants additional advisory powers to the United States Geographic Board is hereby rescinded and these additional powers are transferred to the Board of Surveys and Maps."

The Board has been organized and is now ready to function. O. C. Merrill, Chief Engineer of the Forest Service, was elected chairman of the Board. A committee is now engaged in drawing up a set of by-laws and rules of procedure.

Military Committee of Engineering Council Announces Military Policy and Indorses Universal Training

NOTE: In Dec., 1919, Engineering Council created a Military Affairs Committee to consider the relation of engineers to the future military establishment and activities of the United States. The membership comprises civilians as well as ex-officers of many of the services of the Army and Navy, men of all the important branches of the profession of engineering. Under date of Feb. 26 this committee submitted the following communication to Engineering Council:

1. We believe it of vital national importance that sound military legislation should be enacted during the present session of Congress.

2. Effective provision for national defense with an adequate organized trained Army and Navy, sufficient to discharge our national and international obligations, is essential to security and stability, which must be present if our country is to go forward in constructive activity and achieve its possibilities as a nation.

3. The training of the entire youth of the nation and the establishment of organized reserves are indispensable provisions for national defense. With an adequate organized citizen force, so that a minimum of professional soldiers is required, that maximum protection is afforded with a minimum of expense.

4. The careful selection and training of personnel and their assignment, when reservists, to organized reserved units are vitally important to the efficiency of the technical services of the Army and Navy, and therefore essential to the proper preparedness of the individuals of the engineering and allied professions and trades for the discharge of their constitutional obligations in national military service.

5. The full utilization of specially and technically qualified men and specialized industries has proved impossible where an organization was built up only after war had become imminent or had been declared.

6. The status of the membership of the National Engineering Societies with respect to all military matters, on which to base their plans for individual and collective preparedness, must remain indefinite until a military policy and principles of a military organization shall have been determined.

7. We believe national security and stability can be assured only by application of the foregoing principles, in particular the principal of universal military training and the creation of organized reserves, above all in the technical branches.

We therefore recommend to Engineering Council that the President and Vice-President of the United States, the Secretary of War, the Secretary of the Navy, the Speaker of the House and the Chairman and Members of the Military and Naval Committees of the Senate and the House be urged to incorporate the foregoing principles into any bills passed by either body for army or navy organization, and particularly the principle of universl training.

We also recommend that each member of the Founder Societies (American societies of Civil, Mining, Metallurgical, Mechanical and Electrical engineers) be urged to study carefully the foregoing principles of military policy, and in case, in the light of such study, he endorses said principles to give his active support through letters to his Senators and Congressmen, or otherwise, to their incorporation in pending legislation.

MILITARY AFFAIRS COMMITTEE

Col. Wm. Barclay Parsons, *Chairman,*
Mr. Paul G. Brown, *Vice-Chairman,*
Lt. Col. George D. Snyder, *Secretary,*

Col. Roger D. Black,	Mr. George Gibbs,
Mr. Harold W. Buck,	Maj. Fred J. Miller,
Col. Lincoln Bush,	Mr. Spencer Miller,

The Field Lithograph Equipment

In the very excellent and comprehensible article in "The Military Engineer," Jan.-Feb., 1920, entitled "Engineer Duties in the Field in War," by Colonel Ralston, and in some of the discussions in connection with this paper, it appears that there is a concurrence on the elimination of the lithograph outfit from the equipment of divisional engineers.

In view of the array of opinions by those who were actually in command of engineer troops in the field, the writer hesitates to express ideas contrary to their conclusions. However, he did have the opportunity to study the needs of divisional engineers in the training camps, and was in command of an engineer regiment during its year of training in the United States.

As a result of his observation, it would seem to him inadvisable to take away from divisional engineers their power to furnish local maps for the training of troops, as under ordinary circumstances there will be no other even fairly well-equipped map reproduction service available, and the hectograph and the blue print or brown print processes are not satisfactory for turning out maps promptly and in sufficient number.

I feel that I can state positively that the work of the division with which I was on duty would have been materially interfered with if my regiment had not been equipped to turn out lithographed maps. We did suffer, as probably most regiments did, from the disadvantage of not having trained officers or enlisted personnel familiar with the lithographing process. It is rather an antiquated process, and therefore we were unable to obtain assistance from trained commercial lithographers in the nearby city. If a system of instruction had been instituted, under which men who understood the equipment could have spent a week with each of the regiments giving special instruction, much of the delay with which we had to contend would have been avoided, and we would have been able to supply maps to the division much earlier than we could under existing conditions. It was largely a case of experimentation, but after considerable time and after the modification of one or two of the elements of the equipment, mainly the zinc plates, we were able to turn out very creditable work.

It appears to the undersigned that the decision to eliminate this equipment from the divisional engineer regiment is based largely on the conditions that existed in France, where the forces were fairly well concentrated and where the central mapping plant or the movable mapping units could readily supply all outlying organizations. I feel that this would not be the case in the training camps and would probably not be the case in almost any extended operations with which we might be connected in our own country or in the defense of our borders. I would urge that the elimination of this equipment be made only after a thorough study, and after assurances can be given that local maps can be promptly turned out by some central agency.—F. C. BOGGS, Colonel, General Staff (Engrs.).

Concrete Caissons for Breakwater Construction

Milwaukee, Wis., District

By

J. A. B. Tompkins

Principal Assistant Engineer

WHILE concrete caissons have been used for in foreign countries since 1905, so far as is breakwater and other harbor construction known the first to be used in the United States for such purposes were built in 1908. These caissons were built by the Government, not by contract, at a plant established for that purpose at Kewaunee, Wis., and were used in breakwater construction at Algoma and Manitowoc, Wis. They were 24 feet long, 15 feet wide, and 12 feet 4 inches high, with walls 12 inches thick, and were designed and constructed under the direction of Col. W. V. Judson, Corps of Engineers, U. S. A., in accordance with a patent obtained by him in 1901, and dedicated by him to the United States.

A very complete description of these caissons is given in a paper read by Colonel Judson before the Western Society of Engineers in May, 1909, published in Vol. XIV, No. 4, of the *Journal of the Society*. In this same paper appear many studies, including drawings, of other caissons than those employed at Algoma and Manitowoc, including caissons 54 inches long and rectangular in cross-section, subsequently employed on pile foundations in the South Pier at Milwaukee; and caissons, trapezoidal in cross-section, 40 feet long, 16 feet wide at the top and of various widths from 22 feet to 27 feet at the bottom, for use on rubble foundation in localities of different degrees of exposure. An historical summary of foreign and domestic development of concrete caissons, prepared by Mr. Harrison S. Taft, was published in Vol. VII, PROFESSIONAL MEMOIRS.

Caisson construction has now been carried on in the Milwaukee, Wis., district for twelve years, during which time 144 caissons, exclusive of 15 now under construction for Indiana Harbor, Ind., have been built. The general design, methods of construction, etc., have been greatly modified since building the first caissons in 1908. The design and construction are now fairly well standardized. This paper describes in detail the standard concrete caisson adopted in this district.

Design

Prior to 1916 all caissons were rectangular in cross-section, the width being generally about 3 feet more than the height. Since then a trapezoidal cross-section has been adopted, with uniform top width 10 feet for all heights, the side walls having a slope of 3 vertical to 1 horizontal; the bottom width is therefore two-thirds the height of caisson plus 10 feet. The standard caisson is 54 feet long with vertical interior cross walls, dividing it into four compartments.

This section is more economical, both in materials and cost of forms, than is a rectangular section having equal stability, the quantities of materials being approximately as 1 to 1.3. Caissons vary in height by 3 feet, so that by adding or removing 3-foot sections at the bottom of forms, various heights can be built from a single form. As the cost of forms is considerable, approximately $7,500 at the present time, the advantage of a form adjustable to various heights is very great, especially when, as frequently happens, two or three different heights of caisson are to be used on one job. This cannot be done with the rectangular section, the width of which changes with the height, if necessary stability is to be economically obtained. Four sizes of caissons have been designed, all of which, except the smallest, have been used in breakwater construction. The draft of caissons of the same size will vary slightly, owing to slight variations in thickness of walls and bottom. The sizes and approximate draft and freeboard when floating are as follows:

Height	Bottom width	Draft	Freeboard
21 ft. 3 in.	24 ft.	16 ft. 3 in.	5 ft. 0 in.
18 ft. 3 in.	22 ft.	14 ft. 1 in.	4 ft. 2 in.
15 ft. 3 in.	20 ft.	11 ft. 7 in.	3 ft. 8 in.
12 ft. 3 in.	18 ft.	9 ft. 2 in.	3 ft. 1 in.

The thickness of plank, 3 inches, is added to all heights.

While the resistance of caisson or crib to overturning can be computed, the forces which tend to overturn the structure are unknown as to magnitude, point of application, and direction. The necessary stability of a caisson is determined by comparison with cribs which have successfully withstood the severest storms for many years. Timber cribs, 24 feet wide, 100 feet long, filled with stone and resting on a rubble foundation, the top of which was about 20 feet below the water surface, and which formed part of

Digitized by Google

the Milwaukee breakwater, were carried away. These cribs were replaced by others of the same length and height, but 30 feet wide, which have successfully withstood all storms for at least 25 years. Practically the same horizontally applied force per linear foot is required to overturn a concrete caisson of trapezoidal cross-section, having a bottom width of 24 feet, a top width of 10 feet, and a height of 21 feet 3 inches, as for a timber crib 30 feet wide, 20 feet 6 inches high, the caisson and crib in each case being provided with standard superstructure. Fig. 1 is cross-section of this caisson.

In computing reinforcement, walls are considered as restrained beams, taken in widths of about 2 feet vertically. The bending moment is computed from the formula $\frac{W1^2}{12}$, 1 being the distance between fillets. The generally accepted straight line formula for determining stresses in steel and concrete is used. As caissons are launched when the concrete is about ten days old, the ratio of moduli of elasticity of steel to concrete, is taken at 24, instead of the more usual ratios of 10 or 15. Walls are reinforced equally on both sides, the steel being generally placed 2 inches from the surface. While theoretically this is not an economical distribution of steel, it is found in practice to be more economical than to care for the negative bending moments, which develop at the ends of the walls and near the cross walls, by bending the bars, or using shorter bars; furthermore, as caissons are frequently filled with sand, there will be an outward pressure which, while materially less than hydrostatic pressure, must be cared for.

Steel reinforcing bars are standard deformed sections. For 10-day concrete, bonding stresses of 250 pounds per square inch are allowed, and for 30-day concrete, 375 pounds per square inch. On account of negative bending moment occurring near ends of the restrained beams, a minimum bonding length of 20 inches is taken. Diagonal tension stresses of 50 pounds per square inch for 10-day concrete, and 65 pounds for 30-day concrete, are allowed. High carbon steel, having a minimum elastic limit of 50,000 pounds is used, allowing 20,000 pounds per square inch on 10-day concrete for launching submergence, and 30,000 pounds per square inch on 30-day concrete for complete submergence while towing, increased bonding strength of the older concrete permitting the development of the greater steel stress. Steel is proportioned according to which of these considerations requires the greater reinforcement. To allow for "list," the submergence at launching is taken as 1 foot greater than the floating draft of the caisson.

The foregoing stresses are much higher than those commonly allowed. The steel, however, is not subjected to them after the caisson has been placed and filled, forming part of the completed breakwater. For this reason and as a failure before placing in breakwater would not cause loss of life or personal injury, a low factor of safety is considered permissible. Furthermore, no allowance is made in the computation of stresses for the vertical steel, which serves as a "warp," its size and spacing depending upon the strength needed to support the horizontal steel without appreciable buckling. It actually takes up some of the stress, and materially increases the general factor of safety. During the twelve years in which caisson construction has been carried on, there has been no failure on account of the high stresses allowed.

Construction Plant

Caissons are built by hired labor at the government plant located along the inner side of the breakwater in Milwaukee Bay. It consists of a wharf, launching ways, and necessary equipment of buildings, tools, and machinery. The plant is at a disadvantage in having no rail or highway connection and being accessible only by water. The floating plant used for transporting materials and supplies, mooring and towing caissons, etc., consists of one 36-foot gasoline launch, one 50-foot steam tug, and one 60-foot flat scow of about 100 tons carrying capacity.

The wharf is pile and timber construction, 90 feet wide by 328 feet long, having material sheds, stone and sand bins, and office building. The cement shed has a storage capacity of 1,200 barrels. Cement is usually delivered in the warehouse from lake vessel. A shed 30 feet by 60 feet is used for storage of reinforcing steel and miscellaneous tools and equipment. Stone and sand bins having a capacity of about 315 cubic yards of stone and 155 cubic yards of sand are located along the edge of the wharf where they are accessible to vessels. The bins are built up on posts and blocking so that stone and sand can be delivered to the mixer by gravity, avoiding the use of derrick and skips. A water tank, capacity about 900 gallons, serves the concrete mixer and other purposes. It is filled by a pump under the stone bins.

There are two sets of launching ways, each about 50 feet by 185 feet, built of timber piling and 4 runs stringers. The ways are on a slope of 1 vertical to 8 horizontal, and extend into the water to a depth of 20 feet over the outer ends of the stringers. The upper surfaces of the four stringers in a set of ways should be as nearly in the same plane as possible. The greater part of the ways is under water, and it is practically impossible so to cut the piles and frame the caps and stringers as to secure the necessary plane surface. It is found to be easier to place shims on the stringers, their thickness being determined from levels. By this means a surface can be secured which will be less than ½ inch out of plane. Without shims, variations of 6 inches occurred.

Caisson forms are of wood, lined with No. 24 sheet

Digitized by Google

steel. The outside form is in eight pieces, two end pieces, and three pieces for each side. There are four cores to a form by which the cross walls and compartments are molded. Each core form is in six pieces, the trapezoidal ends being in two pieces separated by a removable wedge which permits the withdrawal of the form from the molded caisson. The form is held together longitudinally and transversely by steel rods

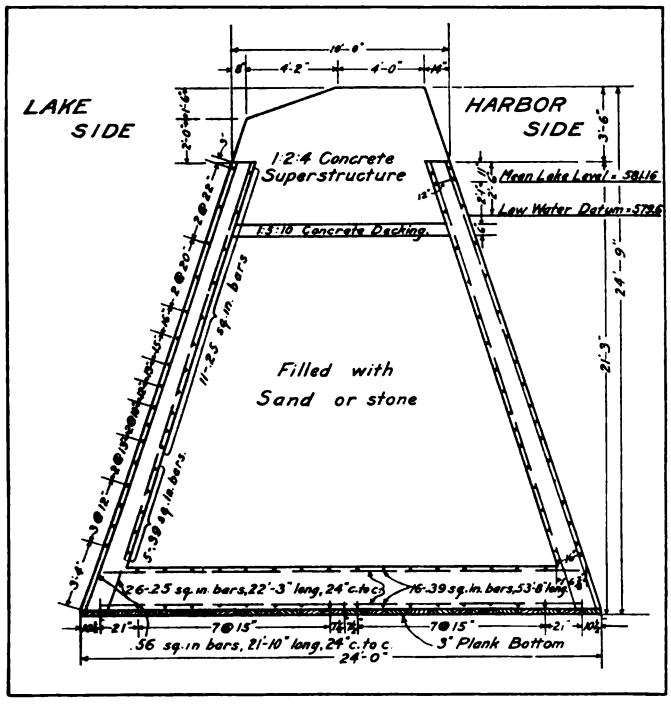

Fig. 1. Standard cross-section

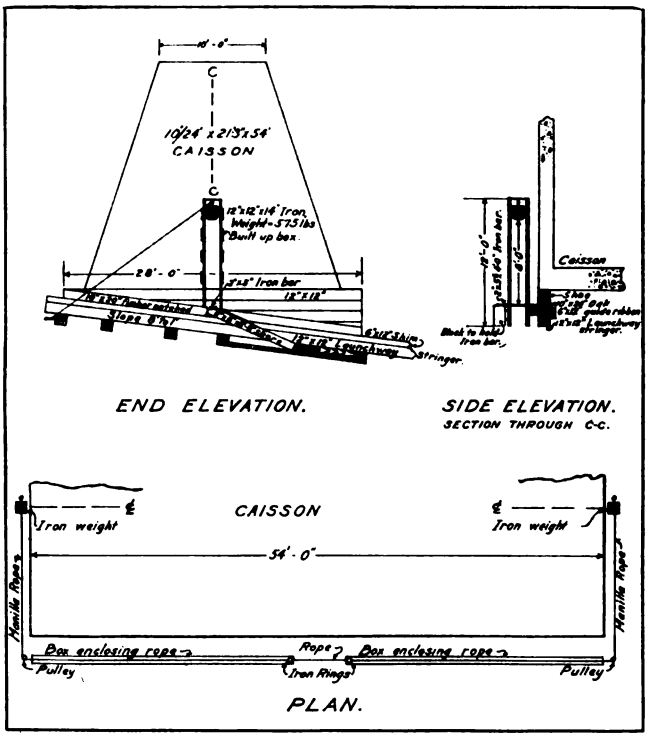

Fig. 2. Release for launching

and cables passing above and below the form and through heavy trussed timber "strong backs." No rods or bolts extend into or through the caisson walls.

Forms are handled, concrete delivered to same, and other heavy lifting work done by a locomotive crane of about 20 tons capacity on a standard-gauge track running longitudinally along the wharf. A concrete mixer, 1 cubic yard capacity, equipped with mechanical side loader, is mounted on a truck and moves on the same track as the crane. A turnout is provided at the outer end of the wharf, so that the relative positions of the crane and mixer can be reversed whenever necessary. Narrow-gauge industrial tracks extend in front of the stone bins and lead from the cement shed. Stone, sand and cement are delivered to the mixer by push cars on these tracks.

Plans are now in preparation for enlarging this plant. It is proposed to lengthen the wharf about 64 feet, to practically double the capacity of the stone bins, and to build an additional set of launching ways. With the enlarged plant, and two shifts working 16 hours per day, it is expected to double the present seasonal output of fifteen caissons.

Construction Methods

The foundation, upon which caissons are built, is at the upper end of the launching ways. It consists of 12 by 12 inch timbers, spaced about 4 feet center to center, and supported by blocking and 2 by 6 inch locomotive jacks. The blocking is placed under the longitudinal edges of the caisson to be molded, the remainder of the foundation being supported entirely by the jacks. Three-inch planks are then laid longitudinally with the caisson on the foundation timbers, thereby forming a level floor on which the caisson bottom is molded. The plank floor is covered with a cheap grade of tar paper so as to make it sufficiently water-tight while depositing the wet concrete thereon. Six-inch wire spikes are then driven at 2-foot intervals along each plank, projecting about 4 inches above the floor, by means of which the plank floor is anchored to the caisson bottom and remains a part of it. The plank floor attached to the caisson affords a means of releasing the completed caisson when launching.

The bottom reinforcing steel is then placed in position followed by the core forms. These latter are supported on 6 by 12 inch timber sills, which in turn rest on steel knees set on the plank flooring. These knees are imbedded in the concrete and remain a part of the caisson. Fig. 2 illustrates the placing of core forms, and shows the method by which the two parts of the trapezoidal end-piece are held together. Note the 6 by 12 inch sills and the steel knees supporting them.

Digitized by Google

Reinforcing steel for the walls of the caisson is assembled in horizontal position on the wharf, and placed in the form in separate units by locomotive crane. A 6 by 6 inch timber provided with bolt grips and eye bolts for hoisting chains, is attached to the steel unit assembled on the wharf, and by means of which the unit is hoisted into place without distortion. Figure 5 shows the steel being assembled and woven into a reinforcing unit for the side wall of a caisson. On the extreme right of the picture, a portion of the stone and sand bins may be seen. The caisson in left foreground has been molded, and the core forms have been removed and placed for the next caisson. The outside form is still in place. Bars, whose deformation is such as will effectively prevent slipping of the wire ties, are especially desirable for the verticals. It is necessary for men to climb the steel units when securing the intersections at the end walls and cross walls; also, concrete falling on the horizontal bars, when dumped into the walls from the tops, will cause slip, unless the bars are firmly secured to the verticals. Spreaders, to hold the two steel webs at proper distance apart, are used in all walls. Figure 6 shows an assembled unit being placed by the locomotive crane. The blocking and 12 by 12 foundation timbers on which the caisson is built may be plainly seen.

When the reinforcing steel has been secured in position, the outside form is erected, after which the entire assembled form is locked by timber strongbacks and tie rods. In setting up or removing forms, each section is handled by the locomotive crane. In continuous operation, the form as removed from the finished caisson is transferred directly to the site of the next caisson to be built and erected. Strongbacks consist of 12-inch by 18-inch timbers, each timber trussed with two 1¼-inch steel rods. For caissons 21 feet 3 inches high, a 4-foot depth of truss is used. These strongbacks are placed in pairs along the two sides of the form, and are fastened together, top and bottom by 1½-inch steel rods, passing above and below the form. Five pairs of strong-backs are used along the sides of the form. The ends of the form are similarly held in position, except that an A-frame strong-back, instead of a single timber, is used. Figure 7 shows a form assembled and locked, ready for pouring concrete. Note the heavy locking of the form, which has been found by experience to be necessary, the wet concrete exerting a very great pressure against the sides and ends. Formerly 12 by 16 timbers, without trussing, were used, but it was found that deflections of as much as 1½ inches occurred when molding caissons of less height than those now built.

The proportions of the concrete are 1:2:4. The coarse aggregate is crushed limestone, ranging in size from ¾ inch to ¼ inch. Crusher screenings which will pass a ¼-inch screen are used as the fine aggregate, except for the upper 5 feet of the caisson, where well-graded sand is used. The use of crusher screenings is not advocated. They are only used on account of the cost and difficulty of getting sand placed in the gravity bins. Crusher screenings are delivered by the same vessel as the crushed stone. This vessel has an elevating device whereby the materials are discharged directly into the bins. The use of crusher screenings is now limited to that portion of the caisson which is at least 3 feet below the water surface when in place, and where there is no danger of the freezing of the water absorbed in the concrete, which is believed to be the chief cause of disintegration. Stone and sand are delivered by gravity from the bins into side dump cars, which in turn dump into the mechanical side charger of the mixer. Cement is dumped into the charger at the same time.

On account of the height and narrowness of the walls a very wet mixture is necessary in order that the concrete may flow around the steel and thoroughly imbed it, as it is impossible to tamp the concrete in the walls in the ordinary manner. The concrete is puddled from the top of the form with special steel spades. Puddling is done only between the two tiers of steel. On account of the slope of the side walls, it is impracticable (from above) to puddle the concrete thoroughly at the bottom of the walls and especially at the corners where they join the vertical end walls. Openings of 2 by 3 feet are left in the outside forms at each corner and at the middle of each compartment of the caisson, about 4 feet above the bottom. The lower part of the walls is puddled through these openings. After the concrete is brought up to the openings, they are closed with shutters. One of these openings with shutters in place can be seen in Fig. 7.

Concrete is mixed in a mechanical batch mixer, capacity one cubic yard. Each batch is given at least twelve turns after the last of the materials are discharged into the mixer. Concrete is delivered by the locomotive crane to the forms, a controllable bottom dump bucket being used. Concrete for the bottom and walls of a caisson is dumped from the top of the form. In dumping in the walls, special care is necessary to prevent concrete from "blowing out" under the sills. Anchor bolts (⅜ by 12 inch), to secure the decking used in towing, are set by template, about 3 feet center to center, in the top of the caisson walls. The tops of all outside walls are troweled off smooth, so as to provide a close joint between the concrete and the decking. After the form is removed, all outside faces are given a waterproofing coat of cement grout, consisting of 1 part cement and 2 parts sand, which is applied with a brush. No difficulty has been experienced in making caissons water-tight, and no precautions, other than those stated, are ordi-

Army Construction and the Corps of Engineers

By

G. A. Youngberg and C. O. Sherrill

Colonels of Engineers

ONE of the most important matters in connection with Army reorganization, now under consideration by Congress, is the question of the responsibility for "army construction" in time of peace. As discussed in this article, this includes all construction of whatever nature required at army posts, camps, cantonments, depots, terminals, schools and hospitals, excepting only fortifications and auxiliary defensive works which, from the foundation of our government, have been the particular province of the Corps of Engineers.

Three proposals have been made for the execution of this army construction as follows:

1st. That it be done by the Quartermaster Corps;
2nd. That it be done by a new Construction Division to be added to the other branches of the peace-time organization of the army, and
3rd. That it be done by the Corps of Engineers.

The Army reorganization bill recently introduced into the Senate by Senator James W. Wadsworth, Jr., Chairman of the Committee on Military Affairs, provides for a new Construction Service, with one brigadier general as chief, 200 officers of all other grades and 6,000 enlisted men. The corresponding bill recently introduced into the House of Representatives by Mr. Julius Kahn, Chairman of the House Committee on Military Affairs, proposes to place this work in the Quartermaster Corps with a suitable provision for the necessary personnel.

The writers of this article are of the opinion that effective national defense, sound organization of the army, and economy in expenditures for military purposes, all combine in demanding that army construction work, in peace as in war, be placed in the charge of the Corps of Engineers.

General Principles Governing Organization of the Army

The United States maintained an army for but one purpose—"the security of the state" against assault by a foe from without or insurrection from within its borders. Military necessity demands that it shall be organized in such a manner as to efficiently fulfill that purpose and economic necessity demands that it shall be organized on the simplest and most inexpensive lines consistent therewith. The United States, though by far the richest nation in the world, can, nevertheless, ill afford to establish and maintain a defensive force consisting of many departments, duplicating duties, increasing costs through useless overhead expense and decreasing efficiency by division of responsibility. It cannot afford to maintain a Corps of Engineers which shall be useful only in time of war within the theatre of operations, and which shall lie idle at home in time of peace, and maintain at the same time another construction force, also composed of engineers, which shall be useful only within the boundaries of the United States and principally in time of peace.

In devising an organization for the army, we must keep in view the situation as it may exist at the front in time of war, and our military machine must be designed to meet that situation. Its peace organization must be such as to admit of ready expansion to a war footing. We must reduce to the lowest minimum the lack of coördination, the possibility of confusion, needless competition and wasteful work at cross purposes between departments, at the outbreak of hostilities. The machine must be such that it can speed up at the outbreak of war without useless friction, without breaking down and without having to be rebuilt in the face of an enemy. In drafting legislation for an army, it is necessary to keep before us at all times the reason for having an army and the conditions under which it must work. At the same time the army must be such as to render to the United States, even in time of peace, a maximum return on the investment.

These conditions, which conflict to a greater or less extent, can be compromised through the simplification of the army organization, by retaining a minimum number of staff bureaus or departments and by assigning to the army such duties in peace as it can fulfill in direct furtherance of its functions in war.

In the industrial world, the greatest economies are

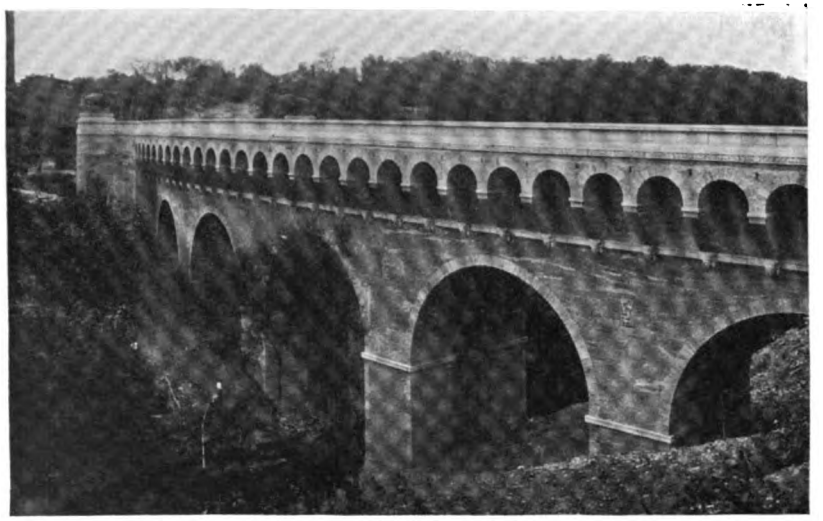
Digitized by Google

effected by utilizing both plant and personnel to their maximum capacity. We do not install factory equipment to run only on Mondays and Tuesdays and duplicate the mechanism for use on Thursdays and Fridays. In our largest ships, as well as in the smallest, the same engines do duty for 24 hours a day throughout the run. We do not engage labor to work on part time with full time pay and overhead costs. We do not elect legislators for service during regular sessions of Congress and other legislators for service during the special sessions of that body. What has been found good practice in civil life will be equally applicable to military procedure.

It is, furthermore, a fundamental principle of good organization that functions or activities of the same general nature should be segregated and administered under a single head. This applies to public and to private undertakings alike, and the army is no exception to the rule.

The Engineer in War

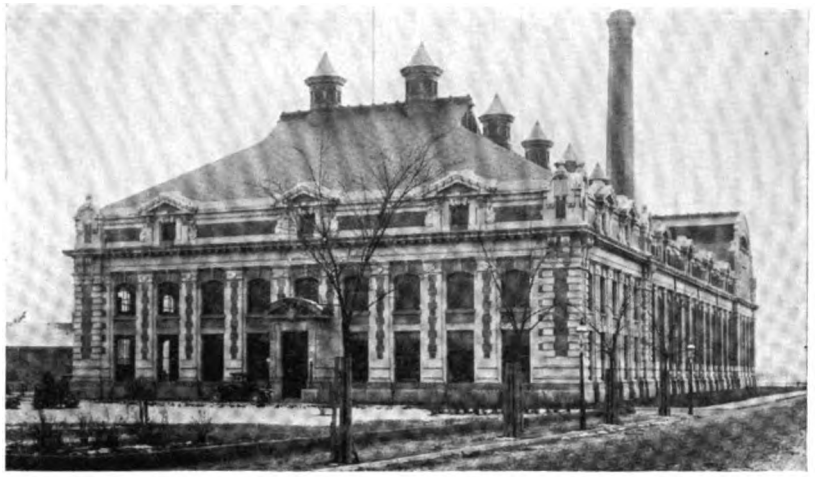
It is true now, as ever, that the foot soldier is the backbone of the army, but it is none the less true that auxiliary troops are necessary to develop his full fighting efficiency. Among these auxiliary troops are the engineers, and from the dawn of recorded history the engineer has played an important part in war. Modern warfare has multiplied his usefulness a hundred fold. There is not an activity at the front, on the lines of communication within the theatre of war, or within the base at home, in which the services of the engineer do not enter in some capacity.



Engineers are as necessary to an army as artillery or medical corps personnel. The United States army has always had its Corps of Engineers and will continue to have such a body until the need for armies shall have passed.

A vast amount of construction is required at the front within the army areas, often under fire of the enemy. This can only be executed by militarized labor, that is, by soldiers subject to all the rules of military discipline who can be supplied and equipped in the same manner and by the same means as the combatant forces. In all the armies of the world, this work is done by the military engineers, and in our service it devolves upon the Corps of Engineers and its various troop units. In general, the structural materials and the troops required for construction work at the front are similar to those required farther back on the lines of communication, or within the area of the services of supply. Moreover, the military situation at the front often requires the immediate shipment of structural material and troops to supplement those on hand, in order to meet some sudden emergency imposed by the action of the enemy, or as required by our own plans of operation against him. Again, during inactive periods at the front, the engineer troops can be safely withdrawn and utilized to advantage in the construction of much needed facilities at the rear. These rapidly fluctuating conditions necessitate the utmost conservation of resources and a flexibility of organization which can be secured only by centralizing the control and responsibility under a single head, that is to say, by pooling the resources in labor and structural materials under a single director, the Chief Engineer of the forces in the field.

It is not possible to carry on any great amount of construction within the theatre of operations by civilian labor, either under contract or working by the day. Civilian administration with its great freedom of action, its powers to give or to withhold, does not harmonize with military operations. Military necessity knows no law other than that of military force and the will of the commander must be at all times supreme. While definite duties may be assigned to definite individuals, decentralization of authority and division of responsibility have no place in military procedure. The assignment of similar duties to separate services within the army necessarily involves such a division and introduces competition for material and for labor, entails a considerable duplication of overhead cost and what is more serious still, a loss of time. It necessitates coördination by the general staff or by the commander-in-chief and distracts them from more important duties. These evil effects can be avoided by segregating such activities under a single bureau, the head of which will then be able to dispose of the total construction resources to the best advantage of the service as a whole. It is the only possible solution of the problems presented by the great shortage of materials and labor and the ever increasing demands occasioned by the tremendous wastage which is the concomitant of modern war.



It was demonstrated in the early days of the American Expeditionary Forces that two or more construction forces cannot exist side by side. The aviation service attempted to construct its own aerodromes and shops, bringing to France for that purpose construction squadrons who were really engineers and builders drawn from civil life. The engineers of the A. E. F. were in the field at the same time constructing barracks, hospitals, warehouses and railroad yards. The ordnance department had made contracts with civilian firms in the United States for the construction of certain ordnance shops, and there were other contracts with civilian firms for the construction of certain port facilities. This situation led to serious competition for structural material, and involved a division of labor which was wasteful of money and even worse, of time. It led to many serious conflicts with the French and British, who were also in the field for labor and material. The experience of all armies was

that only one construction force was possible within their respective theatres of operations, and eventually, even before the consolidation of the tactical command, it became necessary for the allies to pool under a central supervisory control their common resources in labor, lumber and other supplies. The allies as a whole thus duplicated on a larger scale what each had found to be necessary in its own special sector.

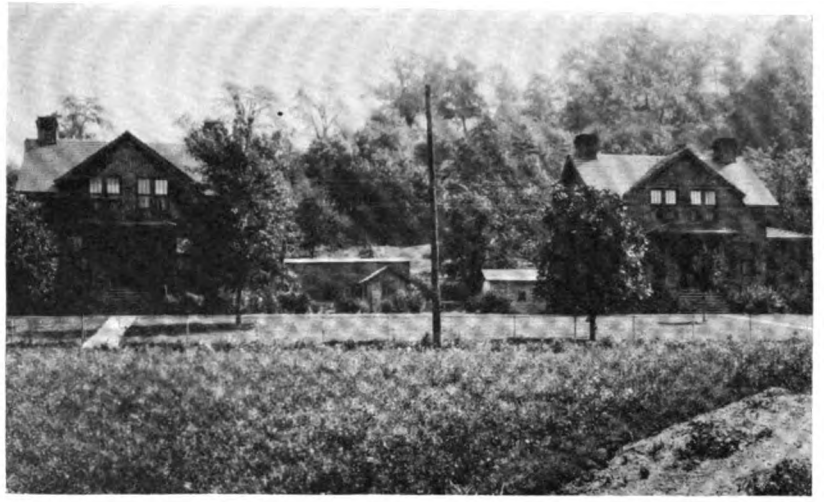
The Military Engineer in Peace

The military engineer should be made an effective instrument for war but he should also be utilized to the limit of his useful capacity in time of peace. There is here no conflict of requirements. On the contrary such duty is, in fact, necessary to his efficiency in war. There is a strong family likeness in all engineering and there are very few engineering activities in war which are not analogous to the activities in peace. There is no reason why the military engineer, whose primary function is war, should not also be utilized on peace-time engineering work during the intervals between wars, and it is necessary to his efficiency for war that he be given this experience in peace.

National economy demands that our military engineers, maintained at government expense, shall be employed whenever available on public works which shall be to the benefit of the country. Construction of public works is applied engineering and requires a knowledge of strains and stresses, of the characteristics of material and its proper utilization, the employment of construction plant and equipment, the management of labor, and experience and judgment of a technical engineering and industrial nature directly in line with the whole training and life-time activities of the officers composing the Corps of Engineers.

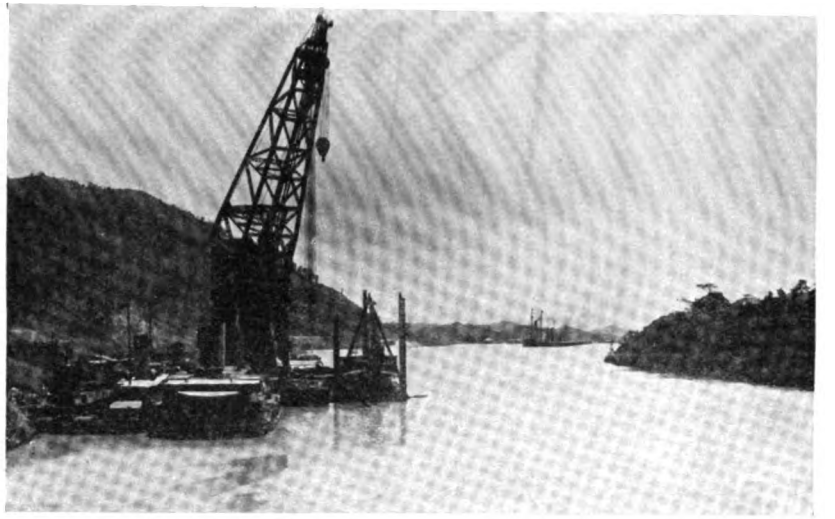
From the foundation of our government this corps has been charged with the construction of fortification and auxiliary works at military posts, erection of public buildings, monuments and other memorials. Their ability is attested by such structures as the State, War and Navy Building, the Congressional Library, the Government Printing Office, the Army War College, the Municipal Building of the District of Columbia, the Million Dollar Bridge on Connecticut Avenue, the Washington Monument, the Lincoln Memorial and the Key Bridge, the two last named being still in course of construction. With the exception of two or three old buildings now standing at Washington Barracks the school buildings, barracks and officers' quarters at that post were built under the supervision of officers of the Corps of Engineers.

Washington Monument



Built, illuminated, and photographed by the Engineers

In addition to the foregoing, the Corps of Engineers is charged by law with the improvement of rivers and harbors throughout the United States. This duty necessitates a knowledge of construction in the building of locks and dams, jetties, levees and other works for the improvement of navigable channels. For the furtherance of these improvements they are required to build storehouses, quarters for lock-keepers, and other structures necessary to the administration of our waterways. The work gives them experience in the principles of construction and trains them in the management of labor in a manner which contributes directly to their usefulness in war, while at the same time it keeps a certain number of them profitably employed on work which must be done.



The Corps of Engineers has executed many of the greatest civil works in the world by contract or day-labor, including the following:

The levees, channels and outlets of the Mississippi River; canalization including all locks and dams in the Ohio River and all its tributaries; the great canal and locks at Sault Ste. Marie, through which passes the greatest commerce in the world (over 100,000,000 tons annually); removal of the great rock shoal at Hell Gate, and construction of the great 40-foot deep entrance channel, New York harbor; all breakwaters, jetties and dredging at all American harbors on the seacoast and Great Lakes; all lighthouses on the seacoast, lakes and rivers, including the famous lighthouses on Minots Ledge (Boston Harbor), Spectacle Reef (Lake Huron), and Tillamook Rock (Oregon); the Hudson and Columbia River improvements; the Panama Canal; and thousands of other works of varying magnitude.

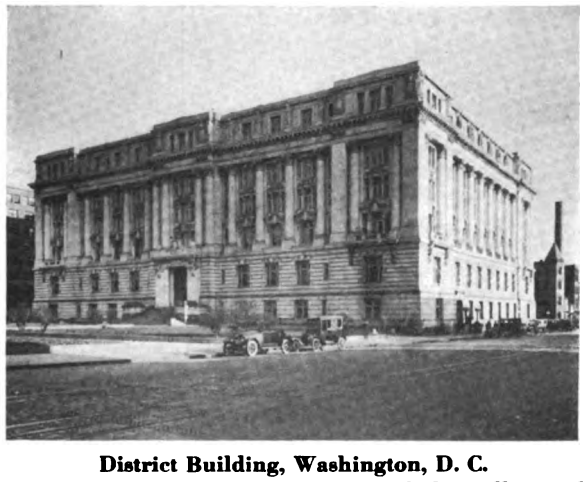
It has sometimes been stated that it is undesirable that military engineers should have charge of river and harbor improvements for the reason that when war comes these engineers will pass to the military service, leaving the work disorganized. Recent experience has proven, however, that these fears are without foundation. During the period of the war requirements for the normal systematic development of waterways are curtailed, and the small amount of work remaining is carried on by the available per-



A Government River Steamer on an Inland Stream. The Engineers use a vast variety of vessels which they design, and often build, to meet their needs

sonnel without dislocation of organization. In war we must expect that the best and most active of the employes already in staff departments will enter the military service and the resources of the nation are mobilized for war with a corresponding reduction in ordinary peace time pursuits.

This varied and important construction and operation of engineering utilities would certainly appear to be convincing as to the ability of the Corps of Engineers to execute any task of civil construction that might be placed upon it by Congress, but there is still other and more conclusive evidence of the ability of the Corps of Engineers to do satisfactorily and rapidly the type of construction work that was required by our forces in the United States during the war. It is found in the work actually done by the Engineers for the American Expeditionary Forces in France.* To any one who had opportunity to view the work done within the area of the Services of Supply in France, or to any one who has read of the vast amount of construction work required for the A. E. F., no argument is necessary to prove that the Corps of Engineers is fully able to do construction work similar to that done in the United States during the war. A comparison of the accomplishments of the Corps of Engineers in France and those of the Construction Division of the Army in the United States is given by Colonel Leonard P. Ayres, a civilian statistician commissioned as an officer on the General Staff for the period of the war. His statement is as follows:

> The conduct of the war in France necessitated a construction program comparable in magnitude and number of projects with that in the United States. Less new building was required for shelter and for the manufacture of munitions, but more for the development of port and railroad facilities and for the repair and operation of the complicated equipment of a modern army.
>
> The storage space constructed in France was more than nine-tenths as large as the amount built at home. Hospital capacity constructed in France was twice the new capacity at home.
>
> All construction work in France was performed by the Corps of Engineers under the Services of Supply. The labor force consisted largely of American soldiers and German prisoners, although French and English civilians and Chinese coolies were used wherever available.

To accomplish this work in France, it was necessary to assemble material from Switzerland, England and the Scandinavian countries, as well as from Holland, Belgium and France. The militarized labor was not sufficient, and it was necessary to import laborers from various countries, even from Asia and Africa. This introduced difficulties of supervision, administration and supply not existing in the United States. Due also to the activities of the enemy and his varying successes, changes in plans were numerous, and not infrequently the construction division of the S.

District Building, Washington, D. C. This handsome structure is seen yearly by millions of visitors to the National Capital

O. S. was more or less completely stripped of its material and labor to meet the situation at the front. A study of detailed statistics will demonstrate that the problem confronting the Division of Construction of the Engineer Department abroad was far more difficult than that of the Construction Division in the United States. No contractors with their organization and facilities were available in France, and the work there had to be done by day labor, necessitating an organization from the ground up and the utilization of whatever material or labor could be found. The

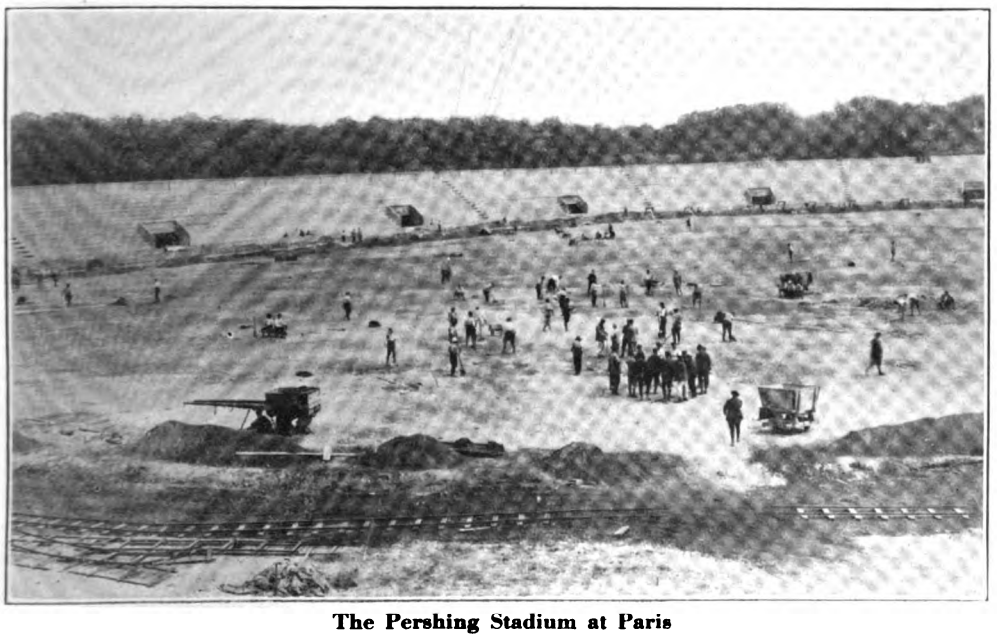
Digitized by Google

work at home was an easy task under exceptionally favorable conditions; that abroad a difficult task under very unfavorable conditions.

The construction done by the Corps of Engineers in France was not only of great magnitude but infinite variety. It included works of every conceivable nature. Amongst the more important items may be mentioned:

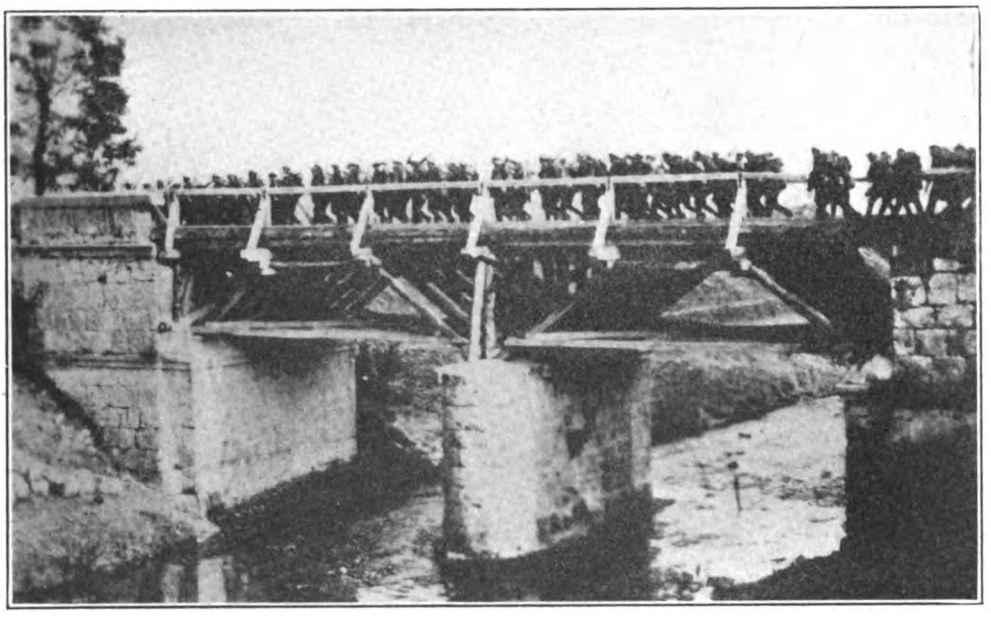
Oil and gasoline storage,
Port and dock construction,
Forestry and lumbering,
Railroads, standard and light,
Railway shops and terminals,
Storage warehouses,
Veterinary hospitals,
Shelter for troops,
Remount depots,
Lighterage,
Hospitalization,
Water supply,
Sewerage,
Refrigeration,
Bakeries,
Power plants,
Roads,
Bridges,
Quarries,
Cement mills.



A temporary office building for war use in Washington, erected by the Corps of Engineers. Some of the construction at home during the war, and all of it abroad, was done by the Engineers

These works are in addition to the work of the Engineer Troops operating with the Armies, which maintained lines of communication, built roads and bridges, fought as infantry, conducted camouflage, searchlight, flash and sound ranging, water supply activities, and many other special functions.

The Corps of Engineers Can Do the Construction Work for the Army without Material Change in its Organization



For over 140 years the Corps of Engineers has discharged with signal success every duty laid upon it in war or in peace. The conduct of river and harbor improvements and the construction of various public buildings and other public works in the United States for many decades proves its competency to handle this class of work in peace. The record made by the Division of Construction and Forestry in France, an organization officered and manned by engineers, demonstrates its ability to handle construction work under difficult conditions in time of war. Further proof of the professional ability of the officers of the Corps of Engineers to take over the construction work of the army is therefore not necessary. The question then is as to the organization of the corps. Can it now take over the construction work for the army? The reply is unhesitatingly in the affirmative. Its organization is, in fact, such as to readily facilitate taking charge of these duties with very small additional cost for overhead expense.

For over a hundred years the Corps of Engineers has maintained an organization covering the United States and its outlying possessions. For the execution of river and harbor works the country is divided into a number of large areas called divisions, each comprising a number of United States Engineer districts. Each district is in charge of a trained officer of the Corps of Engineers of the army, who is assisted by technical specialists according to his needs His work is supervised by a Division Engineer, an officer of greater rank, age, and experience in the Corps of Engineers.

In addition, at departmental headquarters of the army there are officers of the corps serving as Department Engineers through whom the army departmental commander is able to exercise supervision and control over all engineering matters within his jurisdiction.

All of these officers have such engineer assistants and clerical forces as are required in their work and by a slight reorganization and a small increase in the personnel in subordinate positions they can readily take charge of the work of constructing barracks, quarters, and facilities needed for the army, in addition to their present duties. This organization, already existing and in operation, would save large sums to the United States in the way of superintendence and clerical costs. The officers are there and the principal technical and clerical assistants are there. On the other hand, if construction is to be done by any other department it must practically duplicate throughout the United States the existing organization of the Corps of Engineers. It would have to maintain offices with the necessary technical and clerical staff with a corresponding duplication of costs. To take over this work it would be necessary to add to the Corps of Engineers only a small force of administrative officers for duty at the headquarters of the Corps, at the Departmental Headquarters, and possibly at District Headquarters within the larger departments. It is estimated that for this work about 130 officers and 4,000 enlisted men would be required in addition to the personnel provided for other duties assigned to the Corps of Engineers. This force would be suitably organized and might, for administrative purposes, be given a provisional regimental organization, each unit being assigned to a definite geographical district. Such an arrangement would result in a military organization for military purposes. It would harmonize with the organization of the War Department as a whole and, by reason of their military training, its officers and men, would appreciate, in a proper military sense, the requirements of the army as a fighting force, and their relation to it.

The organization of the construction forces into engineer regiments would be similar to that of the Division of Construction and Forestry in France which achieved its results as a branch of the

Engineering Department of the A. E. F. Such an organization will have conspicuous advantages in case of a national calamity, as of fire, flood, storm or earthquake. Organized within the Corps of Engineers, it can, whenever necessary, take over for construction purposes such number of divisional, corps, and army combat engineer regiments or other special engineer troops, as may be available for the purpose. All of these troops will be under the same control, the Chief of Engineers of the Army, working in direct conjunction with other personnel of the Engineer Department in the same territory. They will be co-ordinated by a single agency and will have a mutual understanding of each others' capacities and limitations. There will be no crossing of staff department lines; no preliminary agreements will be necessary. Time and money will both be saved.

Two Separate Construction Forces in the Army neither Necessary nor Desirable

There is neither need nor room for two separate and independent construction services within the army. There is no need for maintaining in the army a Corps of Engineers for certain classes of work and a separate construction division for other work of the same general class. Construction is an engineering specialty and a construction corps in the army outside of the Corps of Engineers cannot be efficiently maintained by the detail of officers from the infantry, cavalry, and artillery branches of the service unless these officers happen also to be trained engineers. This is seldom the case, and furthermore, to maintain their efficiency as engineers, such officers must practice engineering constantly, and not intermittently. They cannot, at the same time be thoroughly competent as officers of the purely fighting branches of the service and also as officers of the staff departments. Therefore, any construction service formed by the detail of officers from non-engineering branches of the service would have to depend, for its technical advice and assistance, on engineers hired from civil life and the officers detailed from the line would become administrative and disbursing officers only. A construction division so maintained would, therefore, draw its technical personnel from the same sources as the Corps of Engineers now recruits its forces. This would be particularly true in an emergency requiring an expansion of the peace-time force to a war-time basis and the situation is inherently one of unnecessary and harmful competition and duplication.

During the war, the Atlantic Ocean separated the A. E. F. from its base in the United States. No competition for labor and material was apparent on the surface, but, in the last analysis, it existed between the Construction Division, charged with the acquisition of structural material for use in the United States, and the Corps of Engineers, charged with the acquisition of similar material for use in France. It must also have existed in the recruitment of labor, since the contractors doing the work for the Construction Division in the United States required carpenters, masons and other artisans, while the Engineer Service in the A. E. F. required similar personnel to be inducted into the service as soldiers.

These conditions incidentally have not been without an aftermath of evil consequences. Under the draft act many a skilled artisan was inducted into the service and transported overseas to work at his trade under all the discomforts of war and without regard to hours at a cash remuneration of $1.10 per diem, while his brother-craftsman, more fortunate perhaps, remained at home in a civilian capacity with short hours of labor and freedom from military obligations, at eight, ten, twelve dollars per day, and even more.

For reasons previously stated, militarized labor,

Digitized by Google

that is to say, engineer troops, must be used within any theatre of operations. Should we ever engage in a war with Mexico or with Canada, or should we by some evil chance suffer invasion and have to fight on our own soil, keen competition would at once arise between a construction force operating within the theatre of operations and another operating within the United States, unless all construction should be administered by a single head. In the beginning, at least, the theatre of operations under the control of the commander of the field forces, would necessarily include some portion of the United States. The boundary between this theatre of operations and the base within the United States would be a mere geographical line, and the two independent construction forces operating within the theatre of operations and in the base areas, respectively, would draw their material and labor from identical sources in the United States. This would introduce much competition and the necessity for much "coördination" by the General Staff or by the Secretary of War. In this case, obvious advantages would accrue from placing control of all construction, including necessary material and labor, under a single head. Since, moreover, the troubles would be most acute at the front in contact with the enemy or in the areas immediately behind the front lines, military necessity requires that the control of structural resources should be vested in that officer or department having charge of construction and military labor at the front, that is to say, the Corps of Engineers. If such action is necessary eventually, and it will be necessary, why not recognize the fact now and organize to meet the situation that will inevitably be encountered?

The provision of a Corps of Engineers for construction service within the theatre of field operations and another construction division for service within the United States is indefensibly illogical and wasteful. It would be just as consistent to maintain a medical department to serve our forces in the theatre of operations in time of war, and require the Public Health Service to serve the army of the United States in time of peace. It would be just as logical to build up and maintain an Ordnance establishment to supply guns and ammunition to the troops abroad and make contracts with private concerns for similar material for the troops at home. It would be just as consistent to provide a navy for naval operations in time of war and to direct that its duties in time of peace should be performed by the U. S. Shipping Board or the Revenue Cutter Service.

Training for the Military Engineer

In common with all other forces, the military engineers must be schooled for their duties in war. The infantry, the artillery, the cavalry can all be trained in peace to a very appreciable degree to fit them for their military work. By means of target practice they are taught to shoot. In the absence of the actualities of war, it is possible to assume certain conditions and through the study of maps and the solution of map problems based on those conditions, officers and men receive instruction for their guidance in war. Through maneuvers, terrain and battle exercises on a suitable topographic field it is possible to gain a measure of training in the movements of war without the heart-breaking costs of tuition exacted by the sterner master—war itself.

The circumstances of daily life with its incidence of disease and its recurrence of accidents, afford the military medical man most helpful experience. For the military engineer the case is quite otherwise. Special measures are necessary for his training, though fortunately, such measures need entail no great extra costs. The daily industrial life of the country provides the means, and all that is necessary is to recognize their existence and to so organize the military engineering service as to take advantage of them.

It must be conceded that the mere study of text books and the reading of engineer literature will not make an engineer. Actual practice is an absolute necessity. Without it an engineer may become a learned man but he will be no more competent to perform his duties than would a surgeon who has studied but has never performed an operation, or a prosecuting attorney graduated from a law school who has never appeared in court. The practice of engineering involves the use of large quantities of material, and the employment of great numbers of laborers. This nation, rich as it is, can not afford to expend public money for material or labor for the mere purpose of training its military engineers. Their work must at all times serve some direct utilitarian purpose. This training can only be obtained in time of peace through the employment of officers on public works; that is, on river and harbor improvements, construction of public buildings, and the civil activities which are similar to those required in war.

This consideration alone, aside from all others, is of sufficient moment to require that all construction work for the army shall be assigned to the military engineers in order that their work in peace may afford the maximum of practice with a maximum of peace-time utility. Such assignment would in no wise preclude the employment to the necessary extent of civilian contractors in the United States in exactly the same manner as was done during the war and for years before the war. In point of fact, the officers of the Corps of Engineers, in connection with their work on fortifications, rivers and harbors, let contracts annually involving millions of dollars, and, in the natural course of their duties, acquire a practical working knowledge of contract law and contracting procedure not exceeded by that of any other branch of the service.

A Construction Section in the Quartermaster Corps is Illogical

Previous to the World War construction now being executed by an independent construction division was executed by a branch of the Quartermaster Corps. This system originated many years ago, when our Army was scattered in small garrisons throughout the country, especially in the west. The number of these garrisons was so great and the amount of construction work at each was so simple and so limited that it was considered impracticable to use the small number of officers in the Corps of Engineers for this work. It was consequently, as a matter of expediency rather than of logical arrangement, placed in the hands of the Quartermaster Corps, which was charged at that time with a great variety of miscellaneous jobs for the military service. At each of these small posts a local quartermaster, usually detailed from the line, was available for supervision of the simple construction required.

Under the detail system provided in 1901, the direction of construction work was frequently placed under officers not trained in engineering or construction work, who were detailed for more or less limited periods in the Quartermaster Department. They retained administrative control of the work but had to depend in large measure upon civilian employees in subordinate positions for the necessary technical supervision. It is obvious that under such an arrangement the officer in administrative control and responsible for work must have operated under a great handicap, due to lack of practical knowledge of the work upon which he was engaged, and he could rarely have secured the most economical results.

When conditions made necessary the change from the small one-company garrisons of the Indian warfare days to the divisional cantonments of the present, the necessity for close and skilful supervision became much more pressing. Notwithstanding the fact that trained engineers and an engineering organization has always been recognized as necessary for the supervision of large building projects, such as that of our cantonments, such is the power of precedent and so great is the inertia of previously existing organization that the old construction section of the Quartermaster Department was perpetuated only to be projected

Digitized by Google

into the present Construction Division, whose status is that of an emergency bureau for the duration of the war.

The very organization of the Construction Division, which it is proposed to officer by detailing from the line officers who may or may not be qualified by engineering training for that duty (usually not), supplemented by engineers from civil life, is strong evidence of the incorrectness of the present policy of having a Construction Division in addition to the Corps of Engineers. To further prove that this kind of work demands engineers for its proper direction, it is only necessary to cite the fact that almost all of the commissioned officers of the Construction Division, during the War, were engineers from civil life; only a very limited number of the officers in administrative control at the top, including the Chief of the Corps, were officers of the regular establishment who had originally been detailed into the Quartermaster Corps.

At present the duties of the Quartermaster Corps consist principally in furnishing subsistence and clothing, forage, camp equipage and miscellaneous supplies. Construction as now practiced is highly specialized and has very little in common with the other duties of the Quartermaster Corps. To function efficiently, a construction section within that Corps would be practically independent of all its other activities and would, in fact, become a separate entity merely acknowledging the Quartermaster General as its titular head. The latter would have to have a special deputy as Chief Constructor who would, in fact, be the real head of the Construction Service. The error inherent in placing construction in the Quartermaster Corps was demonstrated at the outbreak of the war, when it was necessary to completely reorganize this branch and eventually separate it altogether from that Corps. The Corps of Engineers on the other hand, though it had not previously been charged with this class of work for the army, was able to take it up and conducted it with conspicuous success in France.

A Construction Division Outside of the Army

There is on foot a movement to establish a Construction Division, temporarily, as a separate staff department of the Army, with a view to its bodily transfer at no distant date from the War Department to a proposed Department of Public Works. This proposition is predicated on the annihilation of the Department of the Interior and a raid on various other governmental departments to take away from them their duties in connection with construction of public buildings, the making of maps, the administration of the public roads and forests, and the river and harbor improvements.

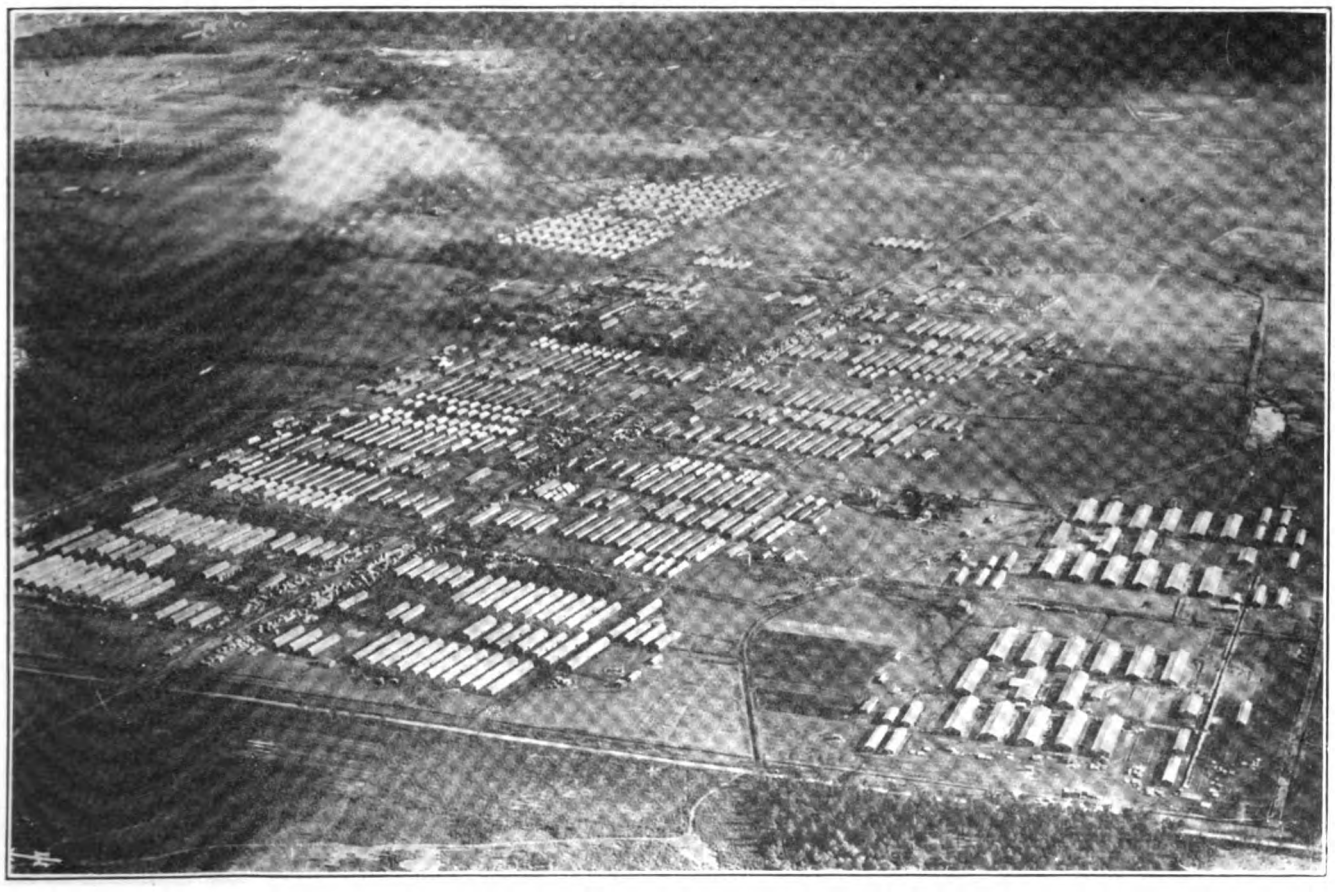
Of all the ideas included in this proposition for a Department of Public Works, that providing for the transfer of the Construction Division of the War Department to another governmental department is perhaps that which would be provocative of the greatest inefficiency and confusion.

It is a very common, and perhaps in some respects a venial, fault of construction engineers, that they emphasize the importance of the means which they provide, and overlook the ends which they serve. In this idea, brought forward in the interest of the engineering profession, it is therefore not strange that such misconception is manifest. Constructional activities of the army are not undertaken with the end of erecting barracks, storehouses, and other structures, but for the shelter and service of the army. No matter how well and efficiently such buildings may be built, they are useless, and the money spent upon them is wasted if they do not meet the needs of the military service at the time being; not, for instance, the needs of a time in the past. Even within the War Department it has been necessary in the past, and undoubtedly will be necessary in the future, to curb the tendency of officers charged with construction toward planning according to their own lights rather than according to the real needs of the users. Such tendency will be many times magnified if the construction is in charge of a different department. A purely civilian construction division could not handle the construction work for the army until its personnel had acquired a considerable degree of military training. Constant friction, lack of coördination, and resulting red-tape, inefficiency and waste of public funds, would be the inevitable consequence of such an organization. In short, it is an obvious principle that, subject to the control of Congress over appropriations, construction should generally be executed by the department which will use the structures that are built.

Expansion to a War Footing

There are other considerations which make it necessary to vest all construction for the army as well as all other allied engineering activities in the Corps of Engineers. As was clearly exemplified by the World War, it is wholly impossible to maintain in time of peace a force of military engineers sufficient to meet the demands of war. On April 6, 1917, when the existence of a state of war with Germany was formally declared, the engineers available for immediate military service consisted of 256 officers and 2,228 soldiers. In November, 1918, nineteen months later, there were in the Engineering Department of the United States service 10,886 engineer officers and 292,300 soldiers, and this takes no account of a large number of professional engineers who for various reasons became identified with other departments of the Army. In the future, then, as in the past, we must look to the engineering profession in civil life for the vast num-

Digitized by Google



bers of officers and construction men required in such an emergency. The Corps of Engineers by reason of its training, and by reason of the work which now devolves upon it, maintains affiliation with the engineering profession as a whole. It constitutes the natural channel of communication between the army and the civilian engineers. It must, therefore, in time of peace, maintain the machinery for assimilating the civilian engineers at the outbreak of war. It must have prepared in advance tabulated lists of all suitable engineers who will accept commissions, and must have tables of assignments ready for use when these civilians are called to the colors. Any other construction section would have to maintain similar contact and again we encounter duplication which would lead to confusion and delay in an emergency.

Through the Reserve Corps authorized by the National Defense Act of June 3, 1916, the Corps of Engineers has already established such machinery and this is further supplemented by its list of officers who served during the war. The same spirit of patriotism which actuated them in offering their services during the late war would impel them to again come forward in time of emergency. To eliminate doubts and uncertainties and to keep these individuals informed and interested in the service, there should be one single body charged with the duty of keeping them in touch with military progress, and the Corps of Engineers with its great variety of duties and its organization covering the entire country is the logical agency for this purpose.

Not a Scheme for Promotion

The proposal to vest all construction work for the army in the Corps of Engineers has naturally met with opposition in certain quarters in the service. It has been stated that it is a scheme fostered by the officers of the Corps of Engineers to increase their rate of promotion. This is entirely contrary to facts. The question of organizing the army as a whole and organizing the Corps of Engineers as a part of that army must be given consideration on its merits, irrespective of any scheme for promotion. If the single list idea is framed in appropriate terms, promotion incident to the expansion of any branch of the army will be distributed throughout the army as a unit and no one branch will profit at the expense of another.

For many years before the war it was the opinion of a great many officers of high rank and acknowledged ability, that army construction is properly a function of the Corps of Engineers. At least one former Secretary of War and one former Chief of Staff seriously contemplated the assignment of this

American Hospital, Beau Desert, France

The American Army Engineer covered France with camps, hospitals, depots, etc.

Digitized by Google

duty to the Corps of Engineers but, on account of the difficulties of obtaining the necessary legislation and the inexpediency of attempting such an assignment without some legislation, their plan was not put into effect. Our experience during the World War has fully confirmed the soundness of their views and, as a result of their observation and experience, disinterested officers throughout the service are now of the belief that placing construction within the Corps of Engineers is the only natural and logical arrangement. It is obvious that to have two engineering organizations in the army doing exactly similar work can only lead to waste of Government money even if both be organized properly to execute this function.

Construction of every kind is the logical function of engineers, and military construction of every kind is the logical function of the Corps of Engineers.

Invents American Shield Tunnel to Carry Vehicular Traffic under Hudson River

The plans for the interstate tunnel under the Hudson River are contained in a report of Mr. C. M. Holland, Chief Engineer of the New York State, and the New Jersey Interstate, Bridge and Tunnel Commissions. The plan adopted was chosen in preference to a number of plans proposed including a double-deck concrete-block tunnel, a precast reinforced concrete tunnel with an outer protection of tremie-placed concrete, and cast-iron tubes of different size from those of the design adopted.

The approved design provides for two circular cast-iron tubes of an external diameter of 19 feet. The mean length of the tubes is 7,345 feet and the mean length of the tunnels, including the open cut approaches, is 9,300 feet. The estimated cost of the project is $28,669,000, which includes $2,500,000 for real estate rights, and engineering administration, and contingencies at 6, 2, and 5 per cent, respectively, of construction and equipment costs. The time required for completion is estimated at 3½ years.

The New York terminals are near the foot of Canal Street and the Jersey City terminals are at 12th and 14th Streets. The southern tunnel is intended for traffic to New York and the northern for traffic in the opposite direction. The alignment of the main portion of the tunnels includes three tangents; the two shore tangents are nearly parallel to each other and approximately at right-angles to the direction of the river. The river tangents make small angles with the shore tangents. Curves and short tangents are necessary in the approaches. The maximum grade in either tube is 3.61 per cent at the New York end of the north tunnel.

Each tube is to be built up of cast-iron segments 2 feet by 6 inches and 6 feet long, flanged and bolted together with 1¾-inch bolts. The weight of the cast-iron tube is 8 tons per linear foot, except in the sections to be laid in silt where it is 8½ tons. The tubes have a concrete lining 19 inches thick. Each tube contains a roadway with a clear width of 20 feet and an overhead clearance of 13 feet 6 inches. A 2-foot walk is provided on one side only. The roadway is intended to provide for two lines of traffic, one fast and one slow, moving in the same direction, and the maximum capacity of each tube is estimated at 1,900 vehicles per hour.

Each tunnel has four ventilating shafts, two 3,800 feet apart near the pier-head lines, the other two between these shafts and the portals. The electrically driven blower and exhaust fans are located in the shafts. Fresh air is carried in the large space under the roadway and admitted just above the curb line. Exhaust air leaves through a similar large duct at the top of the tunnel over the roof of the vehicular space. Drainage is provided for by sumps, at the portals for storm water, and at the low points of the tubes for leakage and flushing water. The latter is carried to the sumps by drains within the lower air duct which prevents the pollution of the fresh air by the drainage water. Electrically driven and automatically controlled pumps remove the water from the sumps.

Traffic tolls proposed are 45 cents for motor and 20 cents for horse-drawn vehicles. It is estimated that at these rates the cost of the tunnel will be amortized and a surplus fund of $67,270,000 produced in twenty years.—*Eng. News-Record.*

Military Organization for the Pennsylvania Railroad

Gen. W. W. Atterbury, late Director of the Railway Transportation Corps, A. E. F., in resuming his duties as vice-president in charge of operation of the Pennsylvania Railway, has adapted to this system the scheme of army organization used in France. The combined lines east and west of Pittsburgh have been divided into four sections, each under a regional vice-president, who will have on his staff a general manager, a superintendent of transportation, a chief engineer of maintenance-of-way, a superintendent of motive power, general superintendents, a traffic manager, a purchasing agent, a real estate agent and an accountant. The duties of the regional vice-presidents are analogous to those of president, insofar as the operation, maintenance and traffic regulations of their territory are concerned.

The relations between the central organization and the regional organizations constitute an entirely new departure, although some features of the scheme were found in the Harriman system of roads as under development at the time of Mr. Harriman's death. It is of interest to note in this connection that Col. C. D. Hine, West Point '92, was Mr. Harriman's adviser in developing this idea.

General Atterbury's duties consist in coordinating the work of the regional vice-presidents in both operation and maintenance. The divisional form of organization which has been the keystone of the Pennsylvania system will be preserved, but coordination will be achieved through a staff in Philadelphia.—*Railway Age.*

The British Ordnance Survey in the War

No branch of the British service was put to a severer test by the war than the Ordnance Survey; certainly none rose better to the emergency, equipped itself more creditably or did work of greater importance. Not only was there a tremendous and ever-increasing demand for trench and other maps for the various fronts, but a great many maps and charts were prepared and printed for the Admiralty and for military use at home, besides the keeping up of a certain amount of the ordinary work of the survey.

The work of the survey may be classified under the following headings:

1. The supply of topographers, observers, draftsmen and printers for the various fronts, of whom about 800 were specially enlisted and drafted abroad in addition to those already in the department.

2. The drawing, printing and supplying of maps, plans and diagrams to the army and navy, of which the total number amounted to 32,872,000, including those supplied by the overseas branch of the survey.

3. The supply of stores, paper, artillery boards and map models. Altogether 12,000 artillery boards and 1,000 map models were supplied.

Duties of a Corps Engineer

Continued from Page 120

The latter agreed entirely with the corps engineer but naturally felt great hesitation about issuing any order regulating the division commander's method of handling the engineer regiment. Eventually the corps commander, at a conference, made clear his own preference for methods being used by the corps engineer and the other division engineer. This, however, required considerable time and during this time work was delayed and the corps engineer was compelled to arrange for work that should have been done by this division to be done by the other regiments of the corps. The result was, of course, delay in the road work throughout the corps area.

This leads naturally to a consideration of engineer relations with the general staff. Up to the present time these have been the resultant of the personalities of the engineer officer and the general staff officers concerned. If the engineer officer is competent to be a division or corps engineer, greater efficiency will be assured in this day, when operations are so dependent on engineer work, if he is given a chance to present his end of it in the preparation of the plan, and not merely left to fit his work as well as he can to a plan prepared by the staff with little or no consideration of what it may involve in the way of engineering work. It is not advantageous to have the relations that exist between chiefs of service and the general staff sections dependent solely upon the personalities of those concerned. In some cases the writer felt that he never succeeded in gaining the confidence of some of the general staff sections despite his utmost eflorts to that end. In some cases he was made to feel that he was an interloper if he sought information vital to the execution of engineering work, before the issuance of an order. In other cases he was made to feel that engineering advice was entirely unnecessary and that he presumed in trying to be of service, the general staff section being all sufficient in itself. With all of the several chiefs of staff with whom he served he found it easy and pleasant to work, but the same was far from being the universal rule when it came to the chief of staff's assistants. Ease of working with the latter was largely proportional to their experience and the experience of those under them.

It may be argued that with experienced staff officers such difficulties will not occur. That is true but it is equally true that in future wars, as in the one just over, there will be many young and inexperienced staff officers, and difficulties such as the majority of chiefs of service experienced will be repeated unless there is a marked change in the method of handling matters from those in vogue during the last months of the great war. Colonel Jones apparently accepts existing arrangements as impracticable to change, and proposes to solve the difficulties that arise as they were solved in the past, by charging the chiefs of service with the duty of making themselves personally agreeable. This is believed a poor method, even though it worked out after a fashion in the recent war. It should be remembered that, in active operations, officers work under severe nervous strain, and at such times it is not safe to allow relations between officers to depend solely upon personality. Psychological considerations cannot be safely omitted in staff organization, to the extent they apparently are at present. It is to be remembered that the chiefs of service, if they are fit to fill their positions, are specialists along their several lines, and that, if they have the force and self confidence necessary to carry out their functions, they will have considerable personal pride and will be quick to resent, even though they may conceal all outward appearance of resentment, any undue interference with the execution of their work. In the organization of the corps staff there was a strong tendency to decentralize beyond all reason, and to provide in the general staff sections men whose duties almost paralleled those of the chiefs of services. For example, the chief of staff was not supposed to concern himself with road matters but turned it over to G-1; G-1 in turn was not to particularly concern himself with such matters but in turn assigned that duty to an assistant for whom there was often little to do that was not also done by the corps engineer, or some other chief of service.

The writer entered a G-2 office one day and thought he had by mistake gotten into some greatly glorified engineer office, from the number of engineer officers on duty therein, many if not all of whom were engaged in duties similar to those carried on by officers in the corps engineer's office or the corps engineer regiment. Some of the results of this were as follows:

1st—An enormous corps staff.

2nd—Much duplication of work: For example, map reproduction both in the G-2 section and the corps engineer regiment; reconnaissances carried out under direction of G-2 or G-3 by officers who, on account of their lack of engineering experience, would not get the information needed by the corps engineer, who therefore had to send engineer officers on the same reconnaissance to get the engineering information required.

3rd—Uncertainty of chiefs of services as to exact ideas of the corps commander because of the long chain through which information reached them.

4th—Lack of those cordial relations so necessary for good staff work. This latter was minimized to a considerable extent by the corps commander under whom the writer had the honor of serving, by the simple expedient of bringing together in the same mess the chief of staff, his assistants, and the chiefs of services. A few days after this arrangement was put in operation one of the general staff sections remarked on the ease with which business was conducted as a result of the personal conferences incidental to association at mess. This probably promoted smooth operation even more than did the daily formal conference.

In the interest of efficiency it is believed *regulations* should provide: 1st—That in the preparation of plans there shall be the most complete understanding between the commanding general and *all* members of his staff. This will be best accomplished by having the chiefs of service as well as members of the general staff section present whenever plans are under consideration. By this arrangement chiefs of service will not only understand more perfectly the exact intention and wishes of the commanding general, but the commanding general and the general staff section will understand more perfectly just what the services can and cannot do. Finally the several services will have a better realization of their mutual relation to the plan as a whole. Until a plan is decided upon, the relation between the chiefs of service and the chief of staff should be identical with those between the chief of staff and his general staff assistants.

2nd—That a plan having been decided upon and the order prepared, the effort of the services should be *coordinated* by the assistants to the chief of staff, but that such officers should scrupulously limit their efforts to coordination, and scrupulously avoid all actions that will savor of technical command, direction or supervision of work. They should realize that they are concerned only

Digitized by Google

with results; that methods are immaterial to them; that even if results are not all that the commanding general desires, its staff is rarely competent to change methods. More will be accomplished by merely pointing out to the chief of service concerned in what respect he is failing to secure results, leaving him to determine what changes in methods are desirable, than by attempting to lay down such methods themselves.

3rd—That assistant chiefs of staff shall personally handle all matters affecting the chiefs of service and not leave such matters to their assistants.

The chiefs of the general staff sections should keep in touch with operations of services by personal conferences and contact with the chiefs of services, rather than through assistants.

In order to avoid a duplication of effort, personnel, and equipment it is believed:

1st—That all drafting, lithography and map reproduction work should be carried out in the offices of the division and corps engineers, and under their supervision, it being of course understood that G-2 is the one whose wishes in all such work are to be met.

2nd—That all road, railroad, river and bridge reconnaissances and surveys be conducted through the corps or division engineers, G-1, G-2 and G-3 having authority to order any they desire.

Strength and Organization of Corps Engineers and Corps

The strength of the corps engineer regiment is considered about correct. It is believed, however, that the engineer train should be organized as a supply company, and should form an integral part of the regiment. Its relation to the regiment is so much closer than that of the trains to the other arms that it cannot be handled in the same manner as other sections of the train without seriously interfering with engineer operations. Its relation to the engineer regiment is very like that of the ammunition caissons to the fighting battery, *i. e.*, it forms an essential part of the unit.

The corps engineer should command all engineer troops of the corps but should not be the regimental commander of the corps regiment. The place of the corps engineer is unquestionably at corps headquarters; otherwise he cannot maintain the proper staff relations. So located he cannot exercise the close supervision over the corps regiment that a regimental commander should exercise.

The pioneer infantry regiments appear to have been regarded by many as unsatisfactory either as infantry or as pioneers. One corps commander made strenuous objection to having a regiment assigned to his corps. It is believed that it would be better to do away with "pioneer infantry" in favor of labor battalions. The writer obtained excellent results from labor battalions during his prolonged stay in training camp. These organizations would best be organized and trained under engineer officers. It is thought that three battalions could be advantageously assigned to a corps in lieu of a pioneer infantry regiment. While it is recommended that these units be trained under engineer officers it is not contemplated that they would be in any sense engineer units. They would probably work more generally under the engineers than any other arm, but should be available also for use under any other service where they might be needed. There would probably be less difficulty as to their effective use if they formed a part of the corps troops and it was clearly understood that they were for use under the engineers only when so assigned by the general staff section.

The writer's experience was that the corps commander is inclined to hold his chief engineer responsible for all utilities, such as electric and water installations, in the corps area, even though organization charts may indicate such matters as within the province of the chief engineer of the army. If anything goes wrong, the corps engineer is invited to remedy it without delay. Such matters should be under the supervision of the engineers, and there is something to be said in favor of handling them, and possibly also light railways, through the corps engineer instead of the army engineer. The writer's experience was too limited to warrant him in expressing any fixed opinion on this matter, but there is reason to believe that better results which would more perfectly fit the needs of the military situation, as they present themselves to the view of the corps and division commanders, would be obtained if all work in corps and division areas was handled by the corps and division engineers, the army engineer limiting his work to co-ordinating the efforts and following up the work of the corps engineers, as the corps engineers co-ordinate and follow up the work of the division engineers.

Engineer officers should be impressed with the fact that they, in common with all other chiefs of service, exist only for the benefit of the troops, and that their correct attitude is to turn their hands to anything they can do to promote the success of military operations and the comforts and welfare of the troops, whether it be advising the commanding general or digging latrines.

Conclusion—There is a marked tendency in our service to make the general staff too much of a class by itself and a privileged class at that, a tendency generally harmless enough so far as older and experienced officers are concerned, but often a dangerous intoxicant to the self esteem of younger and less experienced men. But the question arises, are honor and credit to be obtainable only by service on the general staff? Such service represents but one of the multitudinous phases of duty and there should be room for officers to aspire to other things than service on the general staff. In order, however, that such may be the case there must be honor and credit in service in command of troops or in the technical branches. This is an indisputable fact, the importance of which, however, was forgotten during the war. The writer believes firmly in the necessity for a strong general staff but he is no less firmly convinced that skilled surgeons, skilled signal officers, skilled supply officers, skilled regimental commanders, and skilled engineers are necessary.

Col. W. A. Mitchell

Formerly Division Engineer, 2d Division, Corps Engineer, 8th Corps, A. E. F.

This article covers the ground in an excellent manner, and brings out many points which are worthy of study by engineer staff officers, and by corps and other headquarters staff officers.

However, I differ with the author in his statement that certain work around corps headquarters can under certain circumstances be handled by detachments of divisional engineer troops. I have never seen the time when a divisional engineer regiment should not preferably remain with its division. Naturally there are some times when it will not be occupied with active engineer duties; and these times are always seized upon by some one for the employment of the divisional engineers in some outside work. As a result of this idea, the division engineers have practically no time to drill. It is a curious fact that many infantry, cavalry and artillery officers have an impression that engineers, signal and medical troops should never drill; but when called upon, they should have acquired the art of obtaining the results in some mysterious manner. Now, if the engineers also adopt this idea, the division engineer troops

Digitized by Google

will become very poor indeed. As a matter of fact, I have never seen an engineer regiment that I considered well drilled. In the division with which I was on duty, the division engineer had to drill his regiment at every opportunity, even while the other division regiments were resting. On one occasion, he managed to work in a week's drill while the division was in the front line in active engagement with the enemy; and yet he never considered the regiment as at all well drilled at any time.

It is also believed that the corps engineer should demand daily reports from the division engineer officers. Naturally, he cannot give orders to the division engineer officers, but he can very quickly have orders changed when the division commander is not properly employing his engineers. For example, in the first phase of the Meuse-Argonne offensive, cases were known where the division engineer regiments were split up and actually employed as extra infantry companies when there was no emergency calling for such action. Of course the division commander cannot be perfect; but the corps engineer should have known of this failure to use his engineers properly, and he should have arranged so that the division commander should use them properly. The corps engineer in many cases knew that much engineer work was necessary, yet he allowed division engineers to be wasted by inaction in division reserves which every one knew would not be needed in a great hurry and, what is even worse, allowed them to be thrown away as poor infantry in places where they were of no assistance whatever. He should have so arranged that they were ordered to do engineer work, and to be prepared to enter the fight in a short time if the emergency arose. This was done in at least one division; and the engineers were used in both ways during the battle.

Col. Robert R. Ralston

Engineers; formerly Corps Engineer, 4th Corps, A. E. F.

I concur in general with Colonel Jones in his views as to the duties of a corps engineer; but there are one or two points with which I feel I can hardly agree:

Under the heading, *Strength and Organization of Corps Engineer Troops,* Colonel Jones intimates that in training areas and under stabilized conditions there is little need for corps engineer troops, and that for this reason they should be available to the Service of Supply. I cannot agree to this fullly, for it should be remembered that the corps troops aggregate nearly the strength of a division, and their demands for engineer work should be met without using detachments of divisional engineers, which is always unsatisfactory, particularly to the division engineer.

In the 4th corps, due to press of work on the corps engineer regiment, a company of divisional engineers from a corps reserve division was detailed on the construction of a corps headquarters. This division was soon afterwards transferred from reserve to a front line sector, and the division engineer was considerably handicapped by the absence of this company until corps G-1 could be persuaded to release it.

As a matter of fact, assistance should always be furnished from rear to front; that is, by the higher units to the lower, and the service of supply particularly should provide its own engineer personnel without depending on divisional and corps troops, for the latter can always be profitably engaged in training when demands for engineer work in their divisions and corps are not pressing.

While I agree that it is in general impracticable for the corps engineer actually to command the corps engineer regiment, I do not believe that another officer of the grade of colonel should be assigned to command the regiment. Theoretically, the corps regiment should be organized as such with an officer in command who is by rank suited for duty as corps engineer. If conditions are such that he can act as corps engineer and command the regiment also, well and good; if not, the actual command can generally be handled by the lieutenant colonel satisfactorily, as he will be under the direction of the corps engineer, and can have the benefit of his advice and suggestions, if necessary. Higher engineer authority should not insist (as has been done) that the colonel of an engineer regiment, who is also a division or corps engineer, actually command his divisional or corps regiment, for as a matter of fact this is a question which should be settled by division and corps commanders, and if they prefer that the colonel devote his time to staff duty rather than to the command of the regiment, higher authority should not interfere.

There is no need, according to my experience, for another colonel of engineers in a corps, and with the suggestion mentioned the September-October, 1919, issue of PROFESSIONAL MEMOIRS that the corps engineer is entitled to the rank of general officer, I have no sympathy, as the latter seems to be based on the idea that the corps engineer exercises something akin to command over the divisional engineers, which is not the case.

My experience as to the availability of the members of corps headquarters troops for small jobs around corps headquarters was the same as stated by Colonel Jones, as there were too many demands upon them to count on a continuous detail for any length of time, and such work was usually carried on by details from the corps engineer or pioneer regiments with supervision by a member of the detachment of the corps engineer officer.

I agree with Colonel Jones, that for such tasks the proper course is to go ahead and do them, and I think it should be impressed on every engineer officer and enlisted man that in the field, in time of war, the poorest possible excuse for not doing something requested is that it is "some other person's job." It is not excuses but results only that count.

With reference to the idea that a corps engineer should be responsible for all the work in his corps area and be given the men and equipment to accomplish the same, I do not consider this sound, but regard it as proper that engineer functions of higher units be carried on side by side with those of lower units at times when conditions render it necessary. It is similar to the case where divisional, corps, and army artillery may be emplaced in the same area; but each has its own function and carries it out practically independently of the others.

Col. Harold C. Fiske

Engineers, formerly Division Engineer 32nd Division, and Corps Engineer, 3d Corps, A. E. F.

Colonel Jones very truly states that at the outset of our participation in the World War the division engineer was a familiar character on paper, but that the corps and army engineers had not even reached a definite paper stage. At the time of the armistice we had had sufficient experience in active field service to make the status of the division engineer definite, not only in theory but also in practice. In the case of the corps and army engineers their duties were rapidly taking shape but their status was then much more indefinite than that of the division engineer. In the case of the corps engineer there had been a sufficient accumulation of actual experience to define very clearly his duties, powers and limitations, and had the war continued another year the position of this officer would have been as well fixed as that of the division engineer.

Digitized by Google

With the corps engineer the difficulty arose from a failure to clearly comprehend the difference in the position of a commanding officer and that of a staff officer, and it was felt that the corps engineer had to be given command of a definite unit, the corps engineer troops, in order that he might have the authority to command, which was felt more or less vaguely to be essential. It is well to have such a unit as a regiment of corps engineers to which he may issue orders directly, but this represented a small and comparatively unimportant part of the duties which fell to his lot. In addition to ordering the execution of work by the corps engineers the chief engineer of the corps was responsible for the proper technical solution of all engineer problems arising within the limits of the command of his immediate superior, the corps commander, and this involved direct responsibility for all technical features of the work done not only by the corps engineers but by the division engineers, and also for the competence from a technical viewpoint of all engineer units included in the corps.

Officers are sometimes confused as to just what is meant by technical supervision, or the responsibility for technical details, or the means by which technical supervision is exercised. In the case of the engineers the trouble comes from the fact that practically every officer, irrespective of his branch of service, feels that he is possessed of a certain amount of engineer skill and experience, and staff officers or commanding officers are willing to issue orders involving technical engineer procedure where they would not think of doing so in the case of some of the other technical services. For example, the chief surgeon of a division will receive his patients from the combatant arms of his unit, and the procedure involved in having men sent to his dressing station or hospital must be connected up with the plans for all other branches of service and here staff or commanding officers will express their views. But once a soldier has reported to a medical officer no one other than a medical officer expects to supervise the future treatment of that man as long as he remains within the jurisdiction of the medical department. If he is sent to a hospital no line or staff officer would think of ordering what medicine should be administered, or what operation should be performed, or what instruments should be used in the operation, or at what hospital the operation should take place. In these matters the lieutenants and captains of the medical corps look to their superiors in the medical corps in the division; the division surgeon looks to the chief surgeon of the corps, and the chief surgeon to other medical superiors of higher command. The principle is the same in the engineer service. Engineers are organized and trained presumably to perform certain tasks for which a certain amount of special engineer knowledge, training and skill are essential and these to a higher degree than that found in officers of other branches of the service. Engineers with a division, corps, or army must keep so closely in touch with the co-ordinate branches within their unit that they may be sure that the work which they do will be of maximum benefit to all other branches of the service. Questions pertaining to their engineer training and technique, and to their co-ordination with other engineer organizations in the corps must be supervised by engineer officers and engineer officers only. It is in this special field of technical engineering that the chief engineer of a corps represents the corps commander, and relieves that commander of all anxiety for, or personnal supervision of, technical details. Within this field he must possess the corps commander's confidence to such an extent that he can without question issue in the name of the corps commander any orders to engineers or to division commanders which are necessary to the proper functioning in technical matters of all engineer troops in the corps or its divisions. It must be emphasized that this does not in any sense give him an independent command or diminish the command of any other officer. It simply causes him to act as all staff officers should act. He becomes, if you will, the engineer portion of the corps commander's brain, and he should keep so closely in touch with all other portions of this commander's brain or staff that he will not issue an order within his sphere which is not harmonious with all orders which may be issued in all other spheres.

This may sound complicated and difficult to put into practice but, as a matter of fact, it is simple and easy and is the only way in which the chief engineer or any other staff officer can function efficiently. With this conception of the corps engineer's position in the general scheme of things the details of his duties flow very naturally, and his relation to the various parts of his organization has been well stated in this paper.

In the matter of training of engineer troops, it is believed that the chief engineer of the corps had not yet found his proper place. A corps is a large organization and often covers a considerable territory. The engineer problems in one corps may be different from those in others, and the officer best informed on the training necessary for the engineers in a given corps should always be chief engineer of that corps. In the A. E. F. there were in existence what were called corps schools; but these schools were actually located at points remote from the rest of the corps and were in no way in direct touch with its daily problems and experiences. Corps schools in general, and the corps engineer school in particular, should be so located as to be readily accessible to the corps staff, and the chief engineer of the corps should be so thoroughly in touch with the army and its policies above him, the division and its needs below him, that under his personal supervision this school will give the engineer instruction most needed within his jurisdiction. This school should preferably be as accessible as are the divisional engineer regiments of the corps. The corps engineer should be as familiar with what is going on, and with what is being taught in the schools as he is as to what is being done within the divisions, this school should be under his technical supervision to the same extent as are the divisional engineer regiments, and it should respond as quickly to the changing needs in his front as does any other part of the corps organization.

The chief engineer of our corps which served with the British is quoted as saying that the corps engineer should be able to furnish all connecting facilities between the divisions at the front and the service of supply in the rear, thus eliminating the army engineer as a commander of large numbers of troops. If the thought underlying this statement could have been generally accepted in corps, army and S. O. S. Headquarters, it is believed that the efficiency of the engineer service at the front would have been greatly increased. At the time of the armistice our army headquarters had not yet learned how actually and practically to sub-divide its duties among the corps and to utilize the abilities, the organizations, the knowledge, and the strategic positions of the corps engineers to anything like their full value. As has been pointed out in this article, there were thousands of engineer troops doing work important to the corps and divisions who looked only to the army engineer for orders and direction. At the same time each of the three corps engineers was much closer to the work, in more immediate touch with the work of these troops, with the local needs and resources, and had a more just appreciation of the rapidly varying demands upon the engineer services, yet the corps engineers were operating with a comparatively small number of troops under their command and they had no authority over army engineer troops doing

Digitized by Google

work in their area for which their corps commander held them primarily responsible. They were unable at times to give the prompt assistance to their division engineers which was necessary, and were forced into difficult expedients where had they had more authority and more troops under their immediate orders the necessary results would have been attained without particular difficulty. To a still greater degree was a similar liaison between the army and the S. O. S. lacking. During the last phase of the Meuse-Argonne the engineer troops under the immediate orders of the army commander represented the last available supply. There were plenty of engineer troops in the S. O. S. It is to be presumed that many of them were engaged on work which for the moment was of less importance than was that in the 1st Army upon which the rate of pursuit of the enemy by that army depended, yet there was no definite and sure means by which additional troops could have been brought for the emergency from the S. O. S. to serve in that army.

In the final perfected army the chief engineer of the army will keep in close communication with the S. O. S. His arrangements will be such that in periods of emergency the engineer organization of the S. O. S. will bend all of its energies to furnishing him with supplies and engineer troops to the limit of its ability. Of these the army engineer will retain under his own orders a rather small percentage for service in an area extending from about army headquarters to the vicinity of corps headquarters. The larger part of these resources of men and materials will be divided up among the corps engineers, each of whom will retain a moderate percentage for use in an area extending from wherever the army troops stop working and not far from corps headquarters up to the division engineers and the general neighborhood of division headquarters. These corps engineers will have their corps dumps of engineer material for distribution in their corps area subject to a minimum of restriction from the army, and they will have within reasonable limits a reserve of engineer troops also subject to use in corps areas or at times for re-enforcing the division engineer. Of the supply of men and material received by the corps engineer and by the army engineers a certain amount will be distributed to the division engineers according to their needs.

In general, the division is a unit which moves at short notice if necessary. It therefore keeps its surplus of engineer supplies and the number of its engineer re-enforcements to a minimum. The corps is a slower moving unit and remains in one sector while divisions come and go. The corps engineer then can maintain a reserve of engineer material and re-enforcements, the stocks at hand being proportioned in each case to the probable needs of the immediate future, looking ahead for a week or a month or more depending upon circumstances. The army is still more permanent in location than the corps and has its reserves of engineer material and troops. It furnishes a place to which, if necessary, the corps reserves may be withdrawn when the corps moves and does not take such things with it. Such moves, however, do not occur at very short notice, and in general the bulk of these reserves can be kept distributed among the corps.

The above sketch of the perfect army is not quite as fanciful as it may sound. In the Meuse-Argonne, in the matter of engineer material, for example, there was a large engineer dump in the vicinity of Souhesme, and there were what were called advanced army dumps at Les Islettes, Aubreville, and Dombasle. These three advanced dumps were located one in each of the three corps areas into which this army area was divided and prior to this operation were theoretically stocked with the engineer materials needed in that corps. In other words, we had here the three corps dumps in everything but name and a sufficient degree of authority over them on the part of the corps engineer. Had these been formally turned over, one to each corps engineer, with the necessary personnel to handle them and to replenish them from the army dump at Souhesme the matter of engineer supplies during this campaign would have been handled even better than it was, and it will be noted that the only change needed from the existing to the proposed condition was a change on paper ordering dump commanders to report to the chief engineer of the corps instead of the army. As for the army engineer troops, it needed only an order to assign them to the corps engineers. Had this been done the army engineer would have been relieved from the responsibility for a large and difficult task—the immediate direction of so large a body of troops and the corps engineers would have welcomed their share of this responsibility because of the greater efficiency it would have given both to them and to these troops assigned to them.

Assuming that the corps in the future remains similar in composition to that found in the A. E. F. at the close of the hostilities it will consist of about four divisions in active service, one depot or reserve division, certain corps troops, and a corps school. The engineers in this corps will consist of six or more regiments, one with each of the five divisions and one or more regiments of corps engineer troops, and the engineer section of the corps school. The duties of the chief engineer of the corps will be:

(1) The solution of all engineer problems encountered by the corps.

(2) To see that division engineers solve their engineer problems correctly, each in his own division.

(3) That all work together harmoniously with each other and with all other troops for the carrying out of the whole engineer plan of the corps.

(4) That all these engineer units are properly trained and equipped in technical matters.

(5) That the engineer supplies needed in his corps are in the corps' depot in time to be distributed among the divisions and corps engineers.

(6) That each obtains his share at the proper time and in the proper amount.

(7) That his supply of corps engineer troops is sufficient and their distribution is suitable for the needs of the operation at hand.

(8) That their work ties up properly with the work of the army or S. O. S. engineers in rear and that of the division engineers in his front.

(9) That additional engineer troops are loaned to or withdrawn from divisions in accordance with the best interest of the progress of engineer work.

It would seem that merely to state these duties is sufficient to demonstrate that the chief engineer of the corps cannot be burdened with the duties of the immediate commanding officer of any individual regiment, and further that he needs a permanent staff to help him carry out these duties. It might further be added that the magnitude of his responsibilities and the number of troops over which he exercises either complete or technical command is so great that the rank of a general officer would not be inappropriate.

Col. J. L. Schley
Engineers, formerly Division Engineer, 82d Division, and Corps Engineer 5th Corps, A. E. F.

In commenting on Colonel Jones' paper on the duties of a corps engineer, comments will be arranged under the same headings.

The subject is very clearly and logically treated by Colonel Jones. I feel that the only useful additions that I can make are ideas formed from my own experience and emphasis of certain features.

Relations between Division, Corps, and Army Engineers

Since the practice of most of our senior commanders had not been ripened by experience in command of large units in war and had not been standardized by training in peace, it is natural that methods varied in the several commands. Experience was crystalizing their opinions as the war progressed, but the influence of the several foreign armies with which we served and the widely different conditions under which the units operated failed to develop uniformity of practice.

My own experience was that the corps commander held the corps engineer responsible for all the engineer operations of the corps. This included the engineer operations in the divisions of the corps. In other words, he expected the corps engineer to keep him informed of engineering conditions, to see that engineer material was supplied, and to see that necessary and adequate engineering operations were accomplished. If the corps commander's assistance in authority or troops was needed for their accomplishment, he expected to be called on in time to furnish them. If the jurisdiction of the division commanders was involved, the corps commander expected the corps engineer to consult him or his chief of staff. He expected further to be kept informed of the instructions received by the corps engineer from the army engineer, required that they be complied with unless they interfered or conflicted with his own plans, in which case he required that he or his chief of staff be consulted before action was taken.

This was an entirely satisfactory method of procedure from the point of view of the corps engineer. It placed full responsibility where it belonged, and it gave the corps engineer a definite status and ample authority to perform his duties.

In determining whether or not proposed plans of the corps engineer infringe on the province of a division commander, the corps engineer finds it necessary often to rely on the division engineer. The division engineer should keep himself so thoroughly informed of the division commander's plans that he can inform the corps engineer whether proposed operations will interfere with those plans. If they do, it is a matter of judgment whether the next step should be a conference with the division commander or with the corps commander. The former is preferable when practicable. In a matter of considerable magnitude or great importance, my experience has been that the matter should be taken up by the chief of staff of the corps with the division commander or his chief of staff. This kills many birds with one stone.

Colonel Jones has discussed this subject with special reference to the use of divisional engineer troops as combatant troops, but interference with the plans of the commander of the next lower unit may involve purely engineering plans only.

Strength and Organization of Corps Engineer Troops

While it is true that in most cases under stabilized conditions there is no urgent need for a full complement of corps and army engineer troops, and the service of supply will have great need of such troops, yet it is important that the full complement be located in that part of the service of supply area which is near at hand in order that these troops can be concentrated promptly and made available to their proper commanders.

The problem of determining the proper strength and organization of the corps and army engineer troops is one most difficult of solution. In an offensive under the conditions in France in October and November of 1918, the number of engineer troops needed by all commanders was beyond any reasonable estimate. At the time, I felt that the corps engineer and pioneer troops were either too few or too many. There were available in the case in mind one regiment of sapper engineers and ten companies of pioneer infantry. As the advance progressed, the division engineers reported to the corps engineer each night the rearmost points on the main roads which could be covered by the divisional engineer troops for the following day. Likewise, the corps engineer reported to the army engineer the rearmost points which could be covered by the corps engineer troops. And the parts of the roads to be worked on by the corps engineers were assigned to the companies in conference that night. The rapid advance of the front lines made necessary the daily advance along the roads of the corps engineer troops. This meant that only temporary repair work could be undertaken by any troops except the army troops and those of the service of supply. And it often meant that rapid movements had to be made by the army engineer troops to take up immediately important work which had to be abandoned by the corps troops. This proved difficult to accomplish and resulted in the assignment by the army engineer of additional engineer units to the corps. The armistice prevented a thorough trial of this plan. In the absence of further experience, I should recommend the same organization as we had for service in similar kinds of warfare. The strength can be varied at the time to meet conditions. I should not recommend placing the road work in the corps and army areas under the service of supply. It seems to me to be an unnecessary division of responsibility, in principle at least. I believe that army headquarters should form the contact with the service of supply for all purposes.

Work to be Done

I wish merely to emphasize under this head the very important part which the division engineer and the corps engineer must take in prescribing traffic routing and regulations. So far as I know this was done without exception by G-1. The subject is too intimately connected with the problem of keeping the roads open to allow the decision to be made without taking this problem into consideration. If it comes to a show-down, the Commanding General must be appealed to in order to make certain that the routes selected can be improved and kept open.

Training

If the corps organization is in existence during the training, general instructions concerning the training will naturally be issued by corps headquarters. The corps engineer should see that these instructions contain the essential general requirements for engineer troops, and limited engineer training for infantry.

Relation with Corps Staff

Under present conditions, it is necessary that the chief engineer create a position for himself at headquarters. He knows that proper plans for military operations cannot be made without full consideration of the engineering fea-

Digitized by Google

tures, and he knows that he is in the best position to advise on such features. If plans are made without such consideration, he will most probably be required to do the impossible when the time for execution arrives. He knows that changes in the plan as the operations develop must depend largely on engineering features, and he should be best posted on the development of these features. He must accordingly be consulted and, in my opinion, should be present at the conferences of the general staff officers. He must create this position for himself if it is not done automatically. Since this requires a man of ability, force, and tact, the officers designated as chief engineers of the combatant units should be selected with the greatest care.

In connection with, and as an important element in accomplishing the results described above, I wish to emphasize the advice of Colonel Jones that the chief engineer must be "beforehanded" in his information, his plans, and his work.

Col. Jarvis J. Bain
Engineers, formerly Corps Engineer, 7th Corps, A. E. F.

The writer served as division engineer during the closing days of the Meuse-Argonne offensive and on the march into Germany, and as corps engineer of the 7th Army Corps from February 8, 1919, until May 21, 1919, inclusive. During this time the 7th Corps held the reserve position of the Coblenz bridgehead as a part of the American Army of Occupation, with Corps headquarters in the small city of Wittlich, Germany.

The writer's ideas of the duties of the engineer of a corps during combat and movement have therefore been determined chiefly from the standpoint of the division engineer.

It is believed that Colonel Jones in his article has covered splendidly the general duties of the Engineer of a Corps, and few exceptions can be taken to the statements which he makes. In fact, about the only criticism that occurs to the writer is that, in order to cover the entire field in the short paper, Colonel Jones has made his article entirely too general. In reading the article the idea occurred to the writer that during the time he served as engineer of a corps he had totally failed to appreciate the snap which the fortunes of war had permitted him to enjoy.

The question as to proper distribution of engineer work for an army in the field between the service of supply, army, corps, and division, is a vital one. In a stabilized sector proper co-ordination of engineering activities is much simpler than during field movements either forward or to the rear. There are two possible ways of dividing engineer activities for an army in the field. The first is a territorial division and the second is division based upon the nature of the engineer duties to be performed. It is believed that any system based upon one of these methods to the exclusion of the other would necessarily fail in campaign, and that any successful scheme must be some combination of the two, in other words, based partly on territorial distribution and partly on the nature of the duties to be performed.

The critical point in engineer operations, the same as in the operations of the army as a whole, is the firing line, and all the energy of the engineer organizations from rear to front should be utilized to facilitate the operations of the men on the firing line.

During the Meuse-Argonne advance fully 90 per cent of the work of divisional engineer troops was road and bridge repair and construction. This work was very heavy and in the experience of the writer the division engineers were not able to keep up with the advancing infantry unless they were rapidly relieved from the rear by corps troops. The point where this relief was effected varied according to the exigencies of the moment. As a general rule corps and army troops should at all times take over all engineer construction in rear of division headquarters, and divisional troops should endeavor to perform all engineer duties in advance of their own Division Headquarters, but should not be called upon for any in rear thereof.

The engineer of a corps is in position to be of great assistance to division engineers, and if his co-ordination of engineer work as listed among his duties is carried out with a sincere and energetic desire to co-operate in producing results, there is no excuse for any friction with division commanders. The writer, as division engineer, secured at all times most highly beneficial co-operation and help from the corps engineers under whom he served. It was noticeable, however, that better results could always be obtained by personal interview than by interchange of written or telephonic messages. A division engineer with his troops is working at all times for the good of his division. If he can assure his division commander and members of the division staff that the corps engineer is co-operating with him and rendering all assistance possible, the division commander will not resent the efforts of the corps engineer to co-ordinate engineering activities.

Neither the enlisted nor commissioned strength allowed the corps by table of organization in the A. E. F. were sufficient for conditions as they existed in the 7th Corps in Germany. Upon reporting for duty the writer found an office organization with one of the commissioned assistants in charge of operations, one in charge of administration and office, and the third in charge of supply. This distribution of duties, considering the number of officers available, is considered proper, and was continued until the 7th Corps left Germany en route to the United States. The operations, however, were so varied and so numerous that one officer was not able to handle all of them, even with the direct assistance of the corps engineer, and it was necessary to draft both the administrative and supply officers for some of the duties of the "operations officer." This interfered with the full performance in their own departments of duties which were sufficient to require their entire time, but the sacrifice was accepted as the lesser of two evils. In addition to utilizing these officers it was necessary for the corps engineer to withdraw from the corps engineer regiment officers for supervision and inspection duties under his immediate command when the services of these officers were badly needed on the actual construction work being carried on by the regiment. It was also necessary to secure at all times by detail from the engineer troops enlisted men for administrative and technical duties, which could have been better performed by personnel from the corps engineer detachment if suitable personnel had been available. In addition to the major and two captains allowed as assistants to the corps engineer, there should be four 1st lieutenants.

In the early period of the American occupation of Germany engineer operations were seriously handicapped by two difficulties. The first of these was the inability to secure engineer materials. The second was the disinclination on the part of the engineer personnel, both officers and enlisted men, to perform work energetically. That portion of the Rhineland occupied by the American troops was largely agricultural, and manufactured articles were hard to obtain. One of the early difficulties was that connected

Digitized by Google

with the supply of lumber. It was necessary for the engineer troops to take over the operation of such small saw mills as existed. During the closing days of actual hostilities we captured a large number of engineer dumps plentifully stocked with a well selected assortment of engineer construction material. It was not possible, however, to transport any of this material with the troops on the expedition into Germany, and as engineer priority was lost with the termination of fighting, all available transportation was used for food, clothing, equipment, etc. The American engineer officer and soldier performed his duties before the armistice under almost insurmountable difficulties in a manner that was truly wonderful. He did all manner of jobs with an enthusiasm and tireless energy that secured for him the admiration and praise of all other troops in the combat zone. In many cases where divisions were withdrawn from the lines the engineer troops were left in and continued their operations. Corps engineer troops remained on the line practically continuously. When the armistice went into effect the limit of endurance had almost been reached and the engineer personnel was worn out. With the incentive of fighting removed it was natural that the engineer should to some extent lose interest in his work, and long for an early return to the United States, and this was characteristic of all that part of the American Army of Occupation which was under observation of the writer. Both these adverse conditions, however, were overcome, and by the 1st of March, 1919, supplies were reasonably plentiful and the engineer officer and enlisted men had recovered their morale and were producing results satisfactory to all concerned.

By far the most troublesome work of the Engineer of the 7th Corps and his assistants in Germany, was the road work. The corps occupied an area of more than 2,000 square miles. In this area were almost 700 miles of highway subject to military use and about 350 miles of these roads were actually repaired or reconstructed by the engineers of the 7th Corps and of the 89th and 90th Divisions. The corps engineer with the corps troops assumed charge of road operations on the Wasserbillig-Trier-Wittlich-Alf Road, which traversed the corps area from southwest to northeast and carried all the heavy through traffic of the army. This road was designated as the corps axial road. Each division engineer under his division commander was made responsible for all the roads in his divisional area except the corps axial road. The German roads were a great disappointment structurally, and their upkeep and maintenance was a trying problem during the winter and spring. Apparently the Germans have depended upon their wonderful strategic railway system for heavy through traffic and have built their highways to serve only the local traffic, which consisted principally of a few ox-carts on short hauls to the nearest railway station. Practically every village in the 7th Corps area, no matter how small, was reached by a railroad line. Considering the character of the country, which was purely agricultural, it is not possible that the traffic of these villages could warrant the building of these railroads to them from a commercial standpoint, as we view such matters in the United States. The highways that were metalled were smooth and had been well kept, but the metalling was very thin, consisting usually in a surface coat of from three to six inches, well rolled in place. The heavy service that these highways rendered during the retreat of the German Army and the advance of the American Army practically ruined them. During the spring thaw the lightly metalled roads gave way under heavy truck traffic, and long stretches of road had to be entirely reconstructed. The patch-work methods which were so successful on the heavily metalled limestone roads of France gave only temporary relief in Germany, and in many places even where a thickness of 2 feet of metal was put down with a base of large stone placed on edge, Telford fashion, such work had to be renewed several times within a period of a month. The subgrade of the road, under the constant pounding of army motor trucks, became a sort of a jelly and the road failed in most cases by heaving upward at the middle instead of downward under the wheel tracks. The roads of Germany are very narrow and were properly constructed only for one-way traffic of the kind which an army imposes. The use of these roads as two-way roads increased the difficulties of the engineer to a remarkable extent. As Engineer of the 7th Corps I worked up a circulation system for the corps area. This circulation system, however, was never presented to the corps staff because it would have required co-operation with the corps adjoining the 7th and also with the 2nd Army in our rear. It is believed that in such cases a general circulation system should be prepared by the army and adhered to by the corps and divisions in their own areas, each corps and each division forming its own local circulation and traffic systems within its area based upon those of the army.

In addition to the road work the 7th Corps Engineers were very busily engaged in the supervision of the operation of utilities, principally water supply and lighting plants, in the construction of target ranges, barracks, kitchens, mess halls, and stables for the use of the various organizations in the corps. Considerable work was also done in the preparation of grounds, construction of band stands, grand stands, etc., for various athletic fields, horse shows, etc. Several leave and rest camps were erected and a huge re-mount station, to hold about 20,000 animals, was a rush job which was with difficulty completed in time for the engineer and other troops engaged thereon to return to the United States with their organizations. In the operations carried on by the engineer, 7th Corps, a great handicap was the entire absence of labor troops. It was necessary to use engineer soldiers as common laborers when their services would have been much more valuable as supervisors, mechanics and skilled laborers. It was also necessary to secure details from other troops for practically all construction, and such details were secured only with great difficulty.

The rule of the American Expeditionary Forces which required that the engineer of the corps also command the corps engineer regiment is a mistake, and it is not believed that such rule was followed out in any of the corps of the Army of Occupation. If the corps engineer attempts to command the regiment, then the corps commander is deprived of a necessary staff officer. The engineer regiment should have its commander who is responsible for the discipline and administration of his regiment and also responsible for such construction duties as are assigned by the corps engineer.

The writer believes that such duties as are called camp utilities by Colonel Jones are properly the work of the corps engineer and not of the headquarters troop, as stated by him. These duties should by all means be looked after by the engineers. They are usually small jobs, comparatively speaking, but their performance or nonperformance is noticeable to the commanding general and all members of the staff. An engineer who does these small matters promptly and well will naturally have the confidence of his associates on the corps staff. He who neglects them will perform his other duties with a handicap due to lack of confidence.

The relations with the corps staff are believed to have been well stated by Colonel Jones. In these relations it is probably impossible to entirely avoid the personal ele-

Digitized by Google

ment in either G-1, the engineer, or both. The secret of success is to keep G-1 informed at all times, to talk with him informally and frequently on all engineering subjects, and to make him an office partner in the execution of engineering projects. The engineer who has the confidence of his commanding general, chief of staff, and G-1 will be able to perform his engineering duties without non-technical interference and will be permitted to make recommendations on engineering subjects. The engineer who has not this confidence will receive orders on engineering matters and the orders will be so worded as to limit him in the execution of work from an engineering standpoint. Most of the difficulties encountered by the writer in his relations with the corps staff were not with the chief of staff or G-1, with whom he worked, but with their subordinates. On one occasion he received a direct order to construct a building and was furnished as a part of the order of construction a detailed bill of material and instructions for the organization of the force on the work. This order came from a subordinate of G-1 and was promptly withdrawn when the matter was taken up personally with the officer who had sent it. The writer has also knowledge of one case where a division engineer was ordered to undertake a large construction program, the preliminary operations for which would have required several weeks, for the use of his division, when it was definitely known that the division would vacate its area and the construction therefore be useless within two weeks from the time when the order was issued. It has seemed to the writer that G-1 in the American Expeditionary Forces, both division and corps, had too many assistants. These assistants were bright and energetic young men, but usually not engineering or other technical specialists. In a praise-worthy effort to find something to do they sometimes lost sight of the co-ordinating nature of their duties as prescribed, and attempted to take direct and personal charge of engineering operations. The writer in his service as division and corps engineer had to resist the efforts on the part of subordinates of G-1 to take over his engineer subordinates and perform engineer work, thus eliminating him as the director of such work while he felt that the responsibility still remained with him and particularly so in the event of failure. It is essential to the proper performance of engineering operations that such operations be kept continually under the direct control of the senior engineer officer in the organization involved. It is believed that it would be preferable, instead of having subordinates of G-1 to look after engineering operations, to have a subordinate of the chief engineer or division engineer in the office of the G-1 as liaison officer pure and simple between the engineer and G-1. This liaison officer would be available at all times to report to G-1 the condition of works when the engineer was not available, and could present all engineering matters from an engineering standpoint and in accordance with the engineering desires and intentions of his own superior officer. Many of the unpleasant episodes which occurred in the relations between the corps engineer and other members of the corps staff were due to the fault of the engineer in either failing to require the energetic performance of engineering work or by neglect or failure to present engineering matters in the proper light to G-1 or to the chief of staff.

The most discouraging feature of the engineering activities of the writer in Europe, both as division and corps engineer, had to do with the entirely inadequate transportation facilities which he was able to obtain to perform the work at hand. It is extremely difficult to convince an officer who is not an engineer, or even an engineer officer who is not personally acquainted with the work at hand, that all military engineering jobs require a large amount of transportation. The writer was enabled to secure a fair amount of transportation at times when no one else needed transportation. At other times it often seemed to him that the engineers were discriminated against in the distribution of transportation, even considering such distribution to be made on a numerical or proportional strength basis, while it is certain that the demands of the engineers, if their work is to be properly performed, require much more than their numerical proportion of the available transportation. The work of the engineers is necessarily widely separated and 75 per cent of the successful operation of this work is proper reconnaissance prior to its undertaking, and supervision and inspection by engineer officers and higher non-commissioned officers. Such reconnaissance, supervision and inspection require an amount of transportation which seems excessive to everyone except the engineers involved. It is the fixed opinion of the writer that no system of furnishing transportation to engineers will be satisfactory unless the engineers control their own transportation.

The duties of a corps engineer follow naturally from a consideration of the mission of engineers in a military force. This mission has been most admirably expressed by an engineer officer in somewhat the following words:

The mission of the engineers in any military force is to plan and execute all constructions, to facilitate the operations of the rest of the military force.

Based upon this mission the writer believes that the engineer of a corps should classify his duties somewhat as follows:

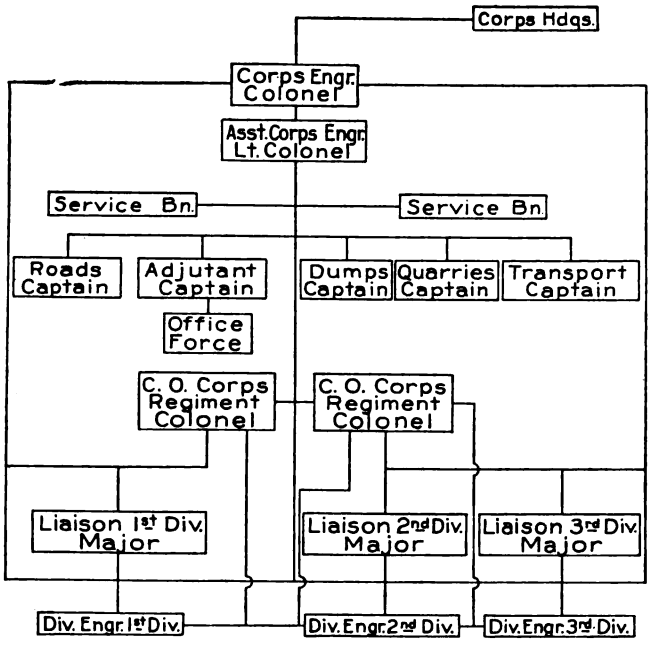
1. Close personal liaison with corps staff.
2. Seeking things to do.
3. Organization of available forces and assignment of duties.
4. Close and energetic personal supervision.
5. Informal and non-technical reports.

Col. L. H. Callan

Engineers, U. S. Army (National Guard), formerly Division Engineer, 32d Division, A. E. F.

Colonel Jones has covered the ground well. Two points within the writer's experience are worthy of mention. The corps should not take possession of the division engineers during the *entire* time the division is out of the line. Engineers need rest and recuperation as well as disciplinary instruction; as much or nearly as much as infantry. Divisional orders are issued covering general cleaning up and training during rest periods. But if the corps has taken over the engineers it is impossible for them to comply with the orders, and upon their return to the division when it is again called to enter the line the engineers have not been properly refreshed, and there is usually some criticism of their appearance. In the Meuse-Argonne the writer's regiment (107th Engineers) went in on the night of September 26 and was not relieved until the end of the war (November 11), although the division came out of line twice.

Engineers should be thoroughly trained as infantry for defensive operations, and used for such only in grave emergency. They should never be used in line for an offensive.



Lt. Col. J. Edward Cassidy

Engineers

The following remarks on corps engineer organization are based on the operations of the 1st Army Corps in the Meuse-Argonne sector from September 26 to November 11, 1918. These operations were conducted on all kinds of terrain, extending from the lower part of the Argonne Forest to a point just below Sedan, a distance of approximately

Digitized by Google

50 kilometers. The necessity for a more thorough organization of the corps engineers was fully emphasized by the experiences of these operations. The following chart shows a plan for an organization that would develop the activities of the corps engineers to the fullest extent, and which would be capable of meeting any conditions of service.

In connection with the execution of the corps engineer operations, the following points cannot be too strongly emphasized:

(*a*) The corps engineer must be an officer of broad experience, energetic, of quick decision, and not afraid to assume responsibility; to advise his commander or any members of the staff, or to issue definite instructions to his subordinate officers.

(*b*) The corps engineer as a general rule must remain at corps headquarters where he is accessible to the corps commander and his staff, and where he can be reached at all times by the commanding officers of corps engineer units. When his absence from corps headquarters is imperative, there must be an assistant on duty, who is an officer of wide experience, capable of acting for his chief, and who is fully informed of all the plans of the corps.

(*c*) All engineer troops or labor battalions operating in the Corps sector, excepting the divisional engineers, must come under the jurisdiction of the corps engineer.

(*d*) Specialist engineer regiments should not be used as corps troops although regiments assigned as corps regiments should be furnished special equipment. It is necessary that the corps engineers should be fully cognizant of all features pertaining to the operations of division engineers, and prior to being assigned to a corps should have experience at the front as divisional engineers.

While the line of demarcation of duties cannot be closely drawn between the division and corps engineers, the line can and should be sharply drawn between the corps and army engineers. The army engineers are more in the nature of specialists, and are too remote from the actual combat operations to appreciate fully the military necessities which always confront the division and corps engineers. In the Argonne-Meuse operations, the army engineer officers were to a large extent men from civil life who had not even had the advantage of a military training camp experience, and could not fully appreciate the military necessities of the situation. The success of an operation rests primarily with the division and corps engineers so far as the Engineers are concerned, and in a normal advance under average difficulties the greater burden of work will fall on the corps engineers, as the work of the divisional engineers will largely consist of assisting the infantry and blazing a way for the corps engineers to follow. It developed in the Argonne-Meuse operations that very often the divisional engineers were not able to open roads for the 75's, so that the burden of getting the divisional guns, ammunition and supplies forward, was on the corps engineers. The forward movement of the supporting corps artillery can follow only as the work of the corps engineers progresses. The tendency of the division G-3 to employ the divisional engineers as infantry, places an additional burden on the corps engineers who have to take over the divisional work as well as their own.

The organization of the corps engineers must be so constituted as to function to the fullest extent or its mission will not be accomplished, and a break-down at a critical period may mean defeat in a tactical operation. The old adage that if a thing is worth doing at all it is worth doing well, is particularly applicable to the organization of the corps engineer.

Combat Strength and Losses, A. E. F.; Figures Compiled by Statistics Branch, General Staff

Battle strength	1,300,000
Wounds	205,690
Deaths	49,498
Total battle casualties	255,188
Per cent battle casualties to battle strength	19.6

DATA BY ARM OF SERVICE.

	Infantry	Artillery	Engineers	All Others
Total battle strength	737,000	207,000	96,000	257,000
Battle strength percentage	57	16	7	20
Total battle wounds	183,369	10,110	6,945	5,266
Battle wound percentage	89.1	4.9	3.4	2.6
Battle wound percentage of total battle strength of that arm	24.9	4.9	7.2	2.0
Total battle deaths	44,889	2,039	1,256	1,314
Battle death percentage	90.6	4.1	2.5	2.8
Battle death percentage of total battle strength of that arm	6.1	0.9	1.3	0.5
Total battle casualties	228,258	12,149	8,201	6,580
Battle casualty percentage	89.4	4.8	3.2	2.6
Battle casualty percentage of total battle strength of that arm	31	5.8	8.5	2.5

For same strength, Infantry casualties are—
5.4 times as great as Artillery.
3.8 times as great as Engineers.
12.4 times as great as All Others.

Soldiers First?

By

Col. Ernest Graves

Engineers

THE article by Colonel Lee in the last number of THE MILITARY ENGINEER contains some fundamental principles which are correctly stated, but I cannot agree as heartily with his views as to the application of these principles. Man is an animal, a dog is an animal, but a man is not therefore always a dog.

The general principle that there should be one man in a definite territory, who is responsible and who is supreme, as a general principle, is good. We have the same principle in the administration of engineer work. One local engineer should supervise buildings, roads, water supply, etc., and be supreme over all. However, there is a limit to this. Anything that is carried to extremes becomes absurd. If the local engineer puts a pipe-fitter in a house to install a water pipe, he doesn't permit the carpenter who is building the house to order the pipe-fitter to leave his work and nail on plank for the carpenter. Just in the same way there is a limit to making army command entirely territorial. We all know that the division commander is supreme over all parts of his division; however, we doubt if this territorial supremacy of command ought to be carried any farther down. When the command is small enough to be properly supervised by one man it is unnecessary to carry the principle any farther.

The principle is again in question when we consider army special troops. The army authorities may desire to keep certain roads in condition for the entire army. Corps or a division may occupy, only temporarily, a certain sector. The commander of this corps or division is principally interested in his mission, and he will take no chances on falling down in that mission. What he leaves for the succeeding corps or division is of secondary importance to him. It is doubtful if he should be permitted to take auxiliary army troops to help him accomplish his mission. His job is certain to be most difficult and the decision as to whether such auxiliary troops are unnecessary is certain to appear to a division or corps commander only one way. The general principles laid down by Colonel Lee need some qualifications.

It is believed that when auxiliary troops are sent by a higher command into the territory occupied by a lower command for a specific purpose, they should be assigned to the lower commander with a restriction as to what they are to do. It should be stated that they are to remain in the territory and be transferred to the relieving command. If the lower command uses them properly, the scheme will work well; if they are not properly used, the higher command will have to keep independent command of them. Of course, if the lower command remains in one territory continuously, its authority over everything in that territory should be supreme in general. However, there are times when even this authority has to be qualified. For instance, a section of the S. O. S. in France sometimes contained a production which supplied both that section and the entire army. In this case the control of the producing forces by a section commander had to be qualified. In theory the section commander could be made responsible for the production and supply to the rest of the army. Practically, it wouldn't work, because a combination of red tape, and the "hogging" of the supply by that particular section left the rest of the army in the lurch. The qualifications necessary depend upon personalities of commanders. Regardless of theory, practically this cannot be avoided.

The above observations are made by a "progressive," not by a "conservative," despite the intimidating challenge contained in the last paragraph of Colonel Lee's article. They are also made by one who has had to get things done, not merely "supreme ly command" some one else to do them.

Value of Scientific Highway Location in Shortening Distance

In the past we have been too prone to build or improve roads along old established lines. The cost of new bridges, new rights of way, new cuts and embankments has been fully realized, but the saving effected by a shortening of the routes between centers of population has too often been overlooked. If we assume that, on the average, a saving of one mile of travel is worth 10 cents to every vehicle passing over the road (a very conservative figure) we have the following astonishing results:

Value of a Mile Distance Saved

No. of vehicles per day.	Saving to owners per year.	Value of saving capitalized at 5 per ct.
100	3,650	73,000
250	9,125	182,500
500	18,250	365,000
1,000	36,500	730,000
5,000	182,500	3,650,000
10,000	365,000	7,300,000

These figures, which are characterized by their compiler as "unassailable," prove that on any route which can be dignified by the title of "highway," first cost of construction is a secondary, almost insignificant matter, compared to distance.

The same economic principle is quite as applicable to all other routes of transportation.—*Eng. News-Rec.*

Retirement of Colonel Townsend

Col. CURTIS McD. TOWNSEND, Corps of Engineers, U. S. A., was retired from active service, February 15, 1920, at his own request after more than 44 years of service.

He was born in Brooklyn, N. Y., March 22nd, 1856, graduated from the College of the City of New York in 1875, and from the U. S. M. A., West Point, in 1879.

Col. Townsend's entire service was with the Corps of Engineers, in which he attained the grade of Colonel in 1906. By his retirement the Corps loses one of its most brilliant, distinguished and industrious members.

During his long and active career Colonel Townsend was engaged on many important projects of river and harbor improvement in the United States and its outlying possessions. He rose to international fame as an authority on all subjects connected with waterway improvements and water-borne transportation, flood prevention and other allied activities. His numerous lectures, essays, monographs and articles on waterways have been published in professional journals, society proceedings, etc., throughout the civilized world, and constitute an encyclopedia of authoritative information on all matters to which he turned his attention in the performance of his duties.

Early in his career Colonel Townsend was engaged in the improvement of the Mississippi River, and his last assignment with the Corps was as President of the Mississippi River Commission. The great river was his chief interest in life, and he is better acquainted with the characteristics, peculiarities, habits, and the many and varied problems connected with its improvement than any other living man.

Amongst other notable public works with which Colonel Townsend was actively identified are the American harbor at Manila, P. I., and the great locks at the "Soo." The modern port of Manila was developed under his direction, and brought out in most striking fashion the progressive methods of American engineers in contrast with the more conservative procedure of Europeans. The largest American lock at the "Soo" (Davis lock) was built by Col. Townsend.

Col. Curtis McD. Townsend
Corps of Engineers, U. S. Army

His devotion to waterway improvements and his pre-eminence in the field of civil engineering did not cause Col. Townsend to forget that he was a soldier, nor prevent his active participation in the two wars occurring during his career. At the outbreak of the war with Germany he by his own personal efforts created and organized the 12th Engineers, and embarked for the theatre of war in command of his regiment. This was one of the first American units to reach the battle-front, on August 21, 1917. Attached to the British Army, the 12th Engineers, under Colonel Townsend's command, took part in the great Cambrai offensive in the fall of 1917.

Colonel Townsend continued at the front in command of his regiment until February, 1918. At this time the urgent need of a qualified man as Engineer Purchasing Officer for the American Expeditionary Forces, resulted in his being called to Paris to fill this important post, for which his wide experience in construction had so well fitted him.

Colonel Townsend remained with the American Expeditionary Forces in France until the end of the war in November, 1918. He then returned to America and resumed his duties as President of the Mississippi River Commission.

In recognition of his splendid services as a commander and administrator he was elected an officer of the Legion of Honor of France. He is a member of many clubs and societies, including the American and Western Society of Civil Engineers.

Colonel Townsend is a firm and consistent believer in the inherent cheapness and practical value of water transportation, intelligently and scientifically developed; but he has been equally firm in his opposition to ill-advised and wasteful expenditures. The striking economic successes of the great waterway projects in whose planning and execution he was a moving spirit, are monuments to his keen far-seeing judgment, skill and energy, and mark him as one of the great waterway engineers of the world.

British Motor Transport in the War*

By

Capt. Richard Twelvetrees

R. A. S. C., M. S. E., A. M. I., Mech. E., M. Soc. Ing. Civ., France

Digest by Capt. G. R. Young, Corps of Engineers, U. S. Army

At the beginning of the war the British heavy motor vehicle industry was in an eary stage of its growth. Only a limited number of business concerns had interested themselves in this form of transport, which was regarded as experimental.

A few years before the war, the British War Department, in order to guarantee a satisfactory supply of motor trucks for the army, had provided a subsidy for manufacturers of trucks which conformed to certain requirements as regards construction and performance; the Government to have the right to take over such trucks on the outbreak of war. The plan undoubtedly did much to stimulate the definite idea of what the transport conditions of modern war would be. As a result, even after some years of the subsidy and four years of war experience, the ideal truck has not yet been developed. The purpose of this paper is to indicate the progress toward that end made during the war.

To provide transport for the original British Expeditionary Force, hundreds of vehicles were commandeered at the beginning of the war without regard to their condition. They were at once hurried overseas and put into service under the most difficult conditions of crowded roads, shortage of spare parts, supplies and continuous service. During the initial advance of the British troops to the fighting line, and the fighting connected with the first advance and retreat of the German Army, a great part of these vehicles broke down and were abandoned by the roadside, where they were stripped of spare parts to repair other vehicles.

As a result of this complete breakdown of British motor transport in the first stages of the war, steps were taken to organize the system; the most important action being elimination of types which were unsuitable because of mechanical defects or because of the difficulty of obtaining spare parts. The number of different makes of trucks in service in the British Army was eventually reduced to sixteen.

The question of developing a standard motor truck was considered during the war, but the project was abandoned for the reason that the British tractors were being worked to capacity either on their own products or on munitions, and it would cut down the production of necessary material to turn to the production of a standard vehicle, with the inevitable delay incident to tooling up.†

Four Periods in War Transport

The phases of mechanical transport development during the war can be divided into four, roughly parallel to the strategical phases of the war.

Mobile Warfare. Conditions at this time approximated what had been anticipated by the War Office in organizing its motor transport plans, that is, conditions of open warfare, with the roads still in good condition and with a supply of skilled drivers. Maintenance by the drivers was, however, sadly neglected. Maintenance difficulties were accentuated by the fact that the original plans had contemplated workshops hauled by steam tractors, which were found to be too slow and unwieldly for the service demanded. Fortunately, most of them were captured by the Germans during their advance, and mobile shops mounted on truck chassis were substituted for them.

Stabilized Warfare. Following the stabilizing of the battle line in the fall of 1914, an opportunity was at hand thoroughly to overhaul the vehicles of the army, and to establish a satisfactory maintenance and repair system. This opportunity was in the main overlooked, for the reason that higher staff officers did not understand the complexity of motor vehicles, or the elaborate organization and constant care needed to keep them up. Maintenance and repair were neglected, and the principal duty of the workshop officer was to write requisitions for spare parts, which were never filled.

Mechanical Period. About a year after the declaration of war, the Allied commands began to consider the assumption of the offensive on a large scale. This led them to give serious attention to the mechanical condition of motor vehicles, and a new attitude was assumed by the authorities. Steps were taken to increase the facilities for minor repairs at the front,

*An Address delivered before the Society of Engineers (British). †The British motor truck industry is composed principally of firms making what we call "built-up trucks," that is, vehicles for which they make nearly all of the parts, and assemble them, in their own factories. The so-called "assembled truck," put together out of standard parts which are manufactured by parts companies, has not been developed in England to nearly the extent that it has been in the United States. The development of standard trucks therefore presented to the British much greater obstacles than it did to us.—G. R. Y.

Digitized by Google

and to improve the supply of spare parts. It was provided that only a certain percentage of vehicles should be removed from a unit for repair at any one time; thus insuring a systematic overhaul. Pamphlets and circulars were issued broadcast giving instructions on operation, maintenance and repair. Manufacturers of trucks in army service were given an opportunity of inspecting their vehicles at the front, which resulted in many improvements and valuable suggestions. Finally, an inspection service, known as the Motor Transport Inspection Unit, was organized under the Director of Transport, which was responsible for making detailed mechanical inspections of all vehicles in service.

The general tendency throughout this period, which covered the greater part of the war, was a continually increased recognition of the importance of careful operation and of a thoroughly efficient maintenance system under rigid technical inspection. This bore fruit in the steady improvement of motor transportation.

Final Period. This covered the latter stages of the war, and saw the supreme test of the British motor transport organization after the lessons learned from the previous periods had been digested and put into application. The system was under the most extreme pressure; vehicles were becoming badly worn, spare parts were increasingly difficult to maintain, and skilled drivers were very rare; and under these conditions the British Army in the last phases of the war made great advances, in many cases over almost impassable roads. The success of their transport system under these trying conditions is attributable to their sound judgment and correct procedure,

Active Service Conditions

It is desirable here to give some idea of the peculiarly trying conditions imposed on motor transportation by warfare, in order to understand the rapid breakdown of vehicles and the great difficulty of maintaining them.

Difficulties of Production. This was due at first to a shortage of factory personnel. At the beginning of the war this personnel was greatly reduced by voluntary enlistments, and further reduced by the mobilization of men belonging to "Category C"—reservists who received a payment from the Government in time of peace, and were liable to call in war as motor drivers and mechanics. This reduction of personnel applied not only to the workmen but also to executive heads.

A second production difficulty was due to many motor vehicle factories being taken over by the Ministry of Munitions for other war work.

A third difficulty which soon developed, was the shortage of material. This was due partly to the diversion of material to munition and other manufacturing, and partly to the fact that much of the pre-war material had come from enemy countries. For example, magnetos, which before the war had been produced almost entirely by Germany. Again, iron castings for cylinders had been obtained principally from the foundries in the Ardennes, which fell into the hands of Germany.

Difficulties also arose with the factory inspection system, the personnel selected for this work being often quite unsuitable and incompetent to pass on the acceptance or rejection of vehicles.

Bad Storage Facilities. Inadequate storage and neglect of vehicles after manufacture and before shipping overseas caused great deterioration, and necessitated much unnecessary repair work on their arrival in France. There was also much deteriora tion due to their being shipped unprotected across the Channel.

Operating Personnel. At the beginning of the war there was an adequate supply of skilled drivers, but this condition soon ceased to exist. There was a tendency for men to enroll themselves in the motor transport service for the reason that they considered it an easy job. Many of these men were so thoroughly incompetent that systematic instruction in schools was attempted, but it was impossible to continue this instruction long enough to train them thoroughly. The result was not only that vehicles were abused by unskilled drivers, but that these drivers, having no idea of how to make minor repairs on their vehicles, had them turned into shops for the most trivial causes, causing excessive pressure on the shops.

Road Conditions at the Front. Typically French road construction consists of a strip of macadam, stone blocks or other paving, with a strip of hard dirt surface on either side, and fairly deep ditches. The paving ordinarily is not of sufficient width for two motor vehicles to pass each other, with both remaining on it. Consequently, trucks on these roads continually had to turn off and run with one set of wheels on the dirt portion of the roads. This was quickly torn up, and under the conditions of almost continuous rain prevailing in Northern France was ground in deep mud. Vehicles running with one set of wheels in this were in great danger of slipping into the ditches; and if they did not, often found difficulty in getting their wheels back on to the paved roads again. It is estimated that during the winter months, at least one truck was ditched in each night, out of every one of the hundred of convoys engaged in hauling supplies and ammunition. It was found necessary to introduce special courses in the motor transport school on getting vehicles out of ditches.

In addition to this, the frequently rough and irregular surfaces of the paved strip of road caused constant shocks and vibration, which accelerated deterioration and tended to crystallize the metal in

Digitized by Google

many parts of the machine. A considerable portion of the repair work in motor vehicles was due to parts which worked loose by vibration, and had been neglected by drivers.

Finally, the paved roads themselves were pounded to pieces by the continual passage of trucks, and adequate repairs were extremely difficult. Corduroy roads held together by wire were a common expedient, but gave a very poor surface for truck transport.

Work of Motor Transport Organizations. It is difficult for any one without experience of front line conditions to appreciate the difficulty, danger, and fatigue under which the motor transport operated at the front. In heavy artillery organizations, the ammunition train (3-ton trucks), and the caterpillar tractors used to haul the guns, had to be kept in readiness not far from the gun position. The gun positions were constantly shifted, this usually occurring at night after the enemy had located the battery and was engaged in counter-battery firing. To the ordinary difficulties of night operation on bad roads was thus added the danger caused by the fire of the enemy, which was always especially intense when he conceived that a change in artillery positions was contemplated.

As soon as the gun position had been changed, it was necessary for the ammunition train to come to the railhead and obtain a fresh supply of shells. It is impossible to make an accurate time-table for the movements of ammunition trains, and they were liable to many hours' delay on the road, while waiting for shells to arrive at the railroad. This period of rest had to be occupied by tightening up bolts and making minor repairs. Then the trucks would be loaded and the train would return to the battery. The return run must be made at night without lights, and the road had often been damaged by shells since the last passage of the convoy. The drivers were very tired, and any accidents which occurred would block the road and cause a frightful congestion of traffic.

Improvements in Design as a Result of the War

Conditions such as described developed many weaknesses in vehicles which operated satisfactorily on good roads under peace conditions. The following points in design are those where special weaknesses developed, and where improvements have been or should be made.

Frames. Many British designers had a preference for the pressed steel channel frame. This frame is too light for war service. The best results were obtained from frames built up of two rolled steel channels braced transversely by heavy drawn steel tubing, which is secured to the main members by stiff bolted brackets. The author considers it a mistake to allow any unnecessary resiliency in the frame; it should be as rigid as possible. Resiliency between the frame and parts such as the engine and gear box should be allowed for in the dsign of the suspension of these assemblies.

Engine Details. The principal defects developed were excessive wear on crankshafts and their bearings, due to insufficient bearing area; and lubrication systems which were complicated or difficult of adjustment. Failure of set screws securing the piston gudgeon pin gave much trouble.

Clutches. Best service was obtained from the external cone clutch. Improvements in this type would, however, result from the substitution of asbestos fabric for leather.

Universal Joints. Many designs of these are needlessly complicated. The best practice is to employ laminated fabric discs connected by coupling arms to the driving and driven shafts, respectively.

Final Drive. The author is of the opinion that the chain drive under active service conditions holds its own with the more modern types of shaft drive and double reduction gear.

Comments

The following comments on Captain Twelvetrees' paper, made by members of the Society before which it was read, are of interest:

Caterpillar Workshops. Valuable results were obtained in Egypt by mounting mobile repair shops on caterpillar tractors. This was especially important because in places there were no roads at all, and if the workshops had been mounted on trucks they would not have been able to come within many miles of where the tractors which they were serving were operating.

Wire Roads. Good results were obtained in Egypt and Palestine by clearing loose sand from the road surfaces, and pegging wire netting over the hard surface underneath. This was, however, suitable only for light traffic, including automobiles; not for trucks.

Comparison of Caterpillar Tractors and F. W. D. Trucks. It was stated that in France the F. W. D. truck with winch gave better service for hauling heavy guns than the caterpillar tractor. The latter made too much noise near the front, and on hard roads its machinery deteriorated rapidly.

Comments by Capt. G. R. Young

The foregoing record of British experience by Captain Twelvetrees agrees at almost all points with the experience of the American Motor Transport Corps during the war. We had the same difficulty that he mentions due to accumulating a great variety of makes of vehicles in the army, and were forced to the same solution of standardizing on a few makes. The difficulties with maintenance and spare parts supply existed throughout the war; and as in the case of the

Digitized by Google

British Army, this was largely due to lack of recognition on the part of commanding senior officers of the fact that a motor vehicle is a very complex and delicate mechanism needing a great deal of skill in repair and operation. Our authorities at home early appreciated, as did the British, the desirability of developing a standardized government truck with a view to increasing production facilities and simplifying maintenance problems. What was impossible in this line in England was possible with us on account of the difference in industrial organization in the two countries. Production difficulties were not so great in this country as in England, because our adoption of the draft at the beginning of the war gave a better opportunity for systematizing our calls for men and of reducing the interruption of basic industries. We suffered, however, from deterioration of vehicles, due to inadequate storage facilities, and especially from damage to vehicles during shipment overseas, until the adoption in 1918 of the system of knocked-down crating. We suffered also, as did they, from unskilled personnel; and though the United States had a much greater supply of men with experience in operating motor vehicles than did England, the damage to vehicles caused by poorly trained drivers is familiar to all officers who were overseas.

The lessons which the American Army has drawn from the war, as regards motor transportation—importance of standardization of vehicles, the need of a large and well-organized repair system and abundant spare parts, and the necessity for giving careful training under motor transport corps supervision during times of peace of all persons concerned with the handling or repair of motor vehicles in the army—are thus seen to be borne out by British experience and would, in fact, be borne out by any competent authority of any of the countries at war who had observed motor transportation in operation.

Vocational Education and Maintenance Allowances for Disabled Soldiers

There are two clases of disabled men entitled to vocational education—those who cannot follow their former calling, and those whose disabilities are not of such a nature as to entitle them to certain financial benefits. The first class are entitled to allowances which range from $80 a month for a single man without dependents to $150 a month for a man with a wife and six children, or other dependents.

It is only when a man's disability interferes with his following his former calling, that he is entitled to the maintenance allowance. But other disabled men, if their disability be ten per cent or greater, are allowed free tuition and books.

All applicants must furnish legal proof of honorable discharge from the service, preferably the certificate of discharge. The nearest district office of the Federal Vocation Board will also furnish to the applicant the required blank form, together with a medical examination by the Public Health Service surgeon, or, if one is not available, by a physician in the community.

When a man's eligibility for training has been established, he is assisted by skilled vocational advisers in making the choice best suited to his needs. He may even have a try-out or preparatory course in a shop or school. Training is given in agriculture, industry, commerce, transportation, and other professions, as well as "training on the job" in manufacturing establishments, industrial concerns, offices, and on farms.

A disabled man eligible for training and maintenance will receive traveling expenses, school expenses, fees and books, and $80 a month, or more if he has dependents. While being trained at a factory, a man is paid the same allowance for himself and family as if he were taking school training. No deduction is made because he earns wages for his work. Prior to a man's entrance into training, he and his dependents are not entitled to any support, and if they are in distress, the matter should be reported to the Red Cross.

After the course has been completed, the Federal Board finds a permanent position for the man, and keeps in touch with him. A man who receives no training pay from the Federal Board continues to receive the full amount of that compensation to which he is entitled from the Bureau of War Risk Insurance. The War Department especially desires to contradict the widespread rumor that a man loses his compensation because he takes vocational training. His actual money income cannot be diminished, but it may be increased.

Additional information may be obtained from any recruiting office of the Army, Navy or Marine Corps, from all welfare employment agencies whose work brings them into contact with former service men; from United States Army and Navy Hospitals, all posts of the American Legion, public health officers, chambers of commerce, and various commercial organizations; or by addressing the Service and Information Branch, Council of National Defense Building, Washington, D. C.

Cape to Cairo.—An air route from Egypt to Cape Town is now open. British surveyors and engineers have toiled for a year to explore and plan the route. Three parties of officers and men were assigned to as many sections. They collected information, established airdromes and landing places at intervals of two hundred miles or less, and laid in gasoline and other stores. The length of the route, measuring by the line of railroad, steamer and ground transport, is 6,223 miles and the journey consumes from 59 to 75 days. The aerial line is only 5,200 miles, or fifty-two hours flying time. It is a perilous route, however. In the central zone, especially, heavy jungle makes landing at other than prepared places almost impossible.

National Memorial Association.—The formation of the National Memorial Association, for the purpose of erecting a national memorial in the city of Washington in memory of the dead of the American Army, Navy and Marine Corps, and affiliated civilian welfare services, in the World War, is announced.

According to present plans this organization will be made up of representatives from the Army, Navy and Marine Corps, the American Legion, National Guard Association, Red Cross, Salvation Army, Knights of Columbus, Y. M. C. A., Y. W. C. A., Jewish Welfare Board, War Camp Community Service, Naval Militia Association and the Training Camp Association. Funds will be raised by popular subscription.

Military Road Building Not A Science—Only A Job

By

Ernest Graves
Colonel, Engineers

THE title of this article is Military Roads, and in the beginning it is desirable to explain what is meant by such a title. Numerous articles and pamphlets have been written on this subject and in every case the discussion has included much matter on road building, which does not pertain to a strictly military road. It is believed that over 90 per cent of the road data we read describes high class civil road work which is of little value in road work that is essentially military.

A truly military operation is offensive and active. It moves fast and there is little time for the elaborate road work usually discussed. Of course, this statement is not absolutely correct if one considers defensive or trench warfare where there is little movement. In such warfare, road work of a slow and permanent nature similar to civil work is of course practicable. However, in such cases, civil practice is in order, and it is useless to elaborate under the guise of giving military instruction. Again, in a military *occupation,* the work is largely of a civil nature and civil practices can be followed. However, even in the two latter cases time is sometimes so urgent that military practices must be followed.

By the above it is not meant that our military engineer should not be skilled in civil practices to a certain extent. He should be. However, in his instruction great stress should be laid on the military short cuts and he should always be cautioned to subordinate his knowledge of civil practices to his sense of the military requirements. It is too often the case that our military engineers are criticised by the army, because they let their knowledge of good civil practice dominate their actions where military results are desired. It is not always the case that the quick results desired by the military authorities is certainly the wisest procedure, but just the same we serve those authorities and it is essential that we think at least to a great extent as they do in seeking results. Possibly we are inclined to wish to play the game too safely and too soundly when a certain amount of gambling is an essential part of military action. While the safer methods may be thought by some to protect their work from failure and thereby protect them, their "reputation" is more injured by such timidity than by an occasional failure. Houses have been built and have fallen down and vehicles have gone through and stuck in roads constructed by engineers whose reputations have not been hurt by these occasional accidents, since by taking such chances they have many times "gotten away" with tasks that would have been impossible if no chance had been taken, and in which a timid would inevitably have failed.

I shall discuss principally some of the road work that has come under my observation from the standpoint of military expediency rather than from the standpoint of good civil practice. The latter is fully expounded in many text books.

My first acquaintance with road work in the army was made in the Philippine Islands. A grand manœuvre was ordered there in 1910. The troops in the Philippines were divided into two armies. One army was to defend Manila from an imaginary Japanese attack by land and the other army was to go up the coast by boat, land at Olongapo and march overland to attack Manila. I was serving in a company of engineers under Capt. P. S. Bond. Our task was to make passable the so-called road from Olongapo across the mountains. Like the war, it was largely imaginary. We came to a bridge which was imagined to have been destroyed, and we imagined it to be rebuilt. Here I obtained a good idea of army requirements. At first I imagined this bridge could be rebuilt in two days. Then I found that my army wanted to cross, so I then imagined it could be rebuilt in seven hours. My superior officer arrived on the scene and found that the army was irritated at being delayed by my imagination, so he imagined the bridge could be rebuilt in two hours and as two hours had already elapsed since I had arrived there, the army marched across.

The job was by no means easy. The trail we were traveling in the mountains could be made practicable for animals, but not for wagons. We decided to feed our army with pack trains while in the mountains, and to carry a wagon train across to operate on the other side, the food to be taken over the mountain trail

Digitized by Google

by the pack trains and then to be transferred to wagons. We represented the wagon train by two fully loaded wagons and proceeded to take them across, just to show that we could do it.

By three days of the hardest work I have ever seen we carried these two wagons across. We had to cut out trees, and move huge boulders out of the trail and out of the stream crossings. The wagons were dragged over the hills with a platoon of engineers or a whole company of infantry pulling on a long rope. This we did for a distance of about twelve miles. It could hardly be called road work. However, it is an extreme example of what we are expected to do. All the civil road literature in the world would have been of little use in this case.

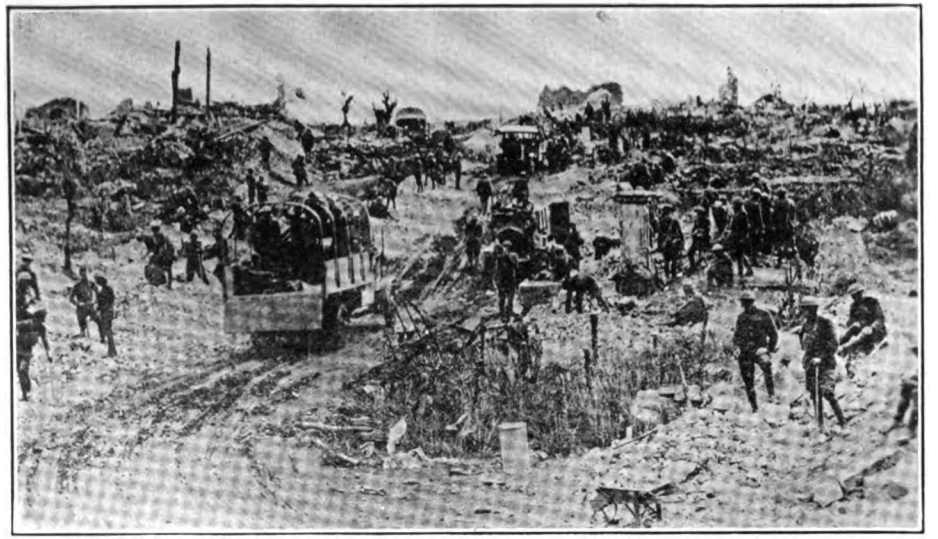
In Texas City, about 1915, there was a division in camp. During a rainy spell all the roads broke down. They were made of shell and in dry weather looked perfect, being as smooth as a billiard table. At that time the Army had no motor trucks and only one or two automobiles. These shell roads broke down under the traffic of ordinary escort wagons. The shell simply turned into mud. The battalion of Engineers with all the Infantry were put to work on the roads under the direction of the Engineer battalion commander. It was pretty difficult to do anything. I saw attempts made to help the roads by putting sticks of wood in bad places but these had to be dug out and removed. The only thing that could be done was to fix the drainage and after a place had dried out, add shell. It might be stated here that the first thing to do always is to get water off the road. Road work is always drainage, and then drainage, and then some more drainage. If the water is gotten away from a road, it can be made to serve with almost any materials and under almost any traffic. If water stands on or around a road, it is likely to fail no matter with what material it is made.

There have been several articles written about the road work on the Punitive Expedition into Mexico which give much detail more or less interesting. To my mind, this work was a perfect example of road building purely military. The trail was used before any work was done and it was used for about a year, during which time the work was always either just ahead of necessity or just behind necessity. It never stayed long enough behind necessity to cause anybody to be "canned" or to cause disaster, and it never got far enough ahead to allow one to sleep easy at night. One officer weighed about 240 pounds when he started and 178 pounds when he finished his part in it.

There were a few outstanding features about this work that are worth remembering:

1st. The trucks under necessity would go almost anywhere if large obstructions such as huge boulders and ditches with vertical sides were eradicated.

2nd. In wet weather the trucks could be kept going if the road was kept drained. We spent months grading up a pile of dust of which everybody made fun, but when it started to rain, this ridge of dust turned into a pretty fair road and stayed pretty fair if we kept it dragged and drained so that water could not stand on it. Of course, all trucks of more than 1½-ton capacity were taken off of it.

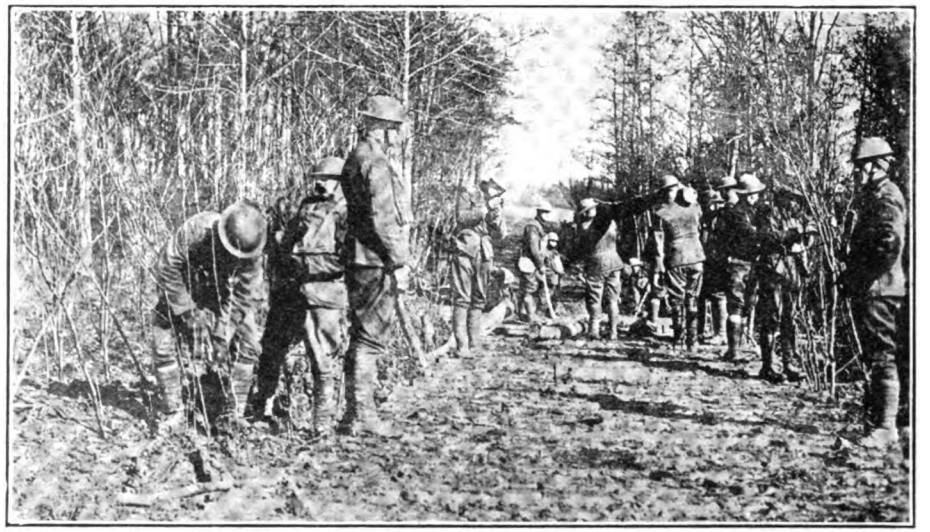


3rd. In dry weather the road was kept fairly smooth by scraping off the dust, and continually scraping the road deeper and deeper as fast as it powdered up. The road thus treated was, of course, on a different location from the graded wet weather road which was above the plane of the natural ground.

Both roads were kept up by continual maintenance, which was *drainage* in the case of the wet weather road, and removal of dust in the case of the dry weather road. Speed regulation also played an important part in dry weather maintenance.

As a matter of fact, the secret of success in this road work, as well as in all other work of whatever nature, is more a matter of organization than of special technical knowledge. In order to work properly it was necessary to subdivide the larger military units and to work in many separate small detachments. I have seen more engineering jobs hindered by a disinclination to send out separate detachments than by all other causes put together. I think the engineer officer who tries to keep his large military unit segregated in one small spot makes a most serious error. Engineers always have to separate. I cannot refrain from elaborating on this subject because it has more influence on road work than all the technical knowledge in the world. Separation gives the organization commander trouble in matters of discipline, rationing, etc., but the work cannot be done if men are herded together. If men are kept together good men, who have some initiative and who will accept responsibility, do not develop. The best engineer organizations I have ever seen, worked in detachments separated by great distances. The officers, non-coms, and even the privates developed remarkable resourcefulness and ability each to stand on his own feet. The occasional rows that happen, due to lack of constant and close supervision, bother inspectors a good deal but they can be kept within bounds, and the work accomplished more than compensates for disciplinary troubles. In Mexico we have had many road detachments with only non-coms in charge. In this connection, an incident that happened in Mexico is interesting.

About the 1st of August, 1916, a bridge at El Valle, 200 miles south of Columbus, washed away. Originally the bridge had been built with great difficulty, the lumber having been hauled from El Paso to Dublan on the railroad, and from Dublan to El Valle, 60 miles, by small Mexican teams. It had barely been possible to get enough lumber on the site to build a trestle 150 feet long. I was at Dublan when I heard this had washed away and I felt hopeless. I did not see how the lumber could be replaced in less than two months. I figured quite a bit about it and decided



Digitized by Google

Must be ready by nightfall. No chance for scientific road building here

Open up the ditches and put on plenty of rock. There is nothing else to it

Opening up a "cut-off"

Road rollers are fine—when you can have them. Note the activity of the workers. They are fighting men, bnt this is part of the game

Digitized by Google

to let somebody else worry if possible. So I wired the battalion commander of what had happened, then I promptly got out on the road and applied myself to supervising a grader I had working about ten miles from Dublan, thinking when people began running circles around themselves they would not be able to find me. I had not been with my grader long when an automobile from General Pershing's headquarters showed up with an order for me to go to El Valle in person and supervise the repair of *certain bridges* in that vicinity. About the same time I received a wire from my commanding officer reading: "Go to El Valle, see what is necessary and do it," so I could not dodge it and I did not see anybody else offering any advice as to what to do. That is always the way. When solutions are obvious, advice is plentiful. When there is no solution, the advisers disappear. This is perfectly natural.

I returned to Dublan where I had about 15 men, collected some two by fours there, took 7 men and started for El Valle. Just before leaving I remembered to take ten days' rations for ten men. I expected to pick up two or three men from a detachment of about ten men that were on the road half way to El Valle. One of my seven men said he would cook. I told him we would get cooking apparatus by splitting 50-50 with the detachment on the way. When we reached the detachment, I sent my cook to the detachment cook to get half his cooking utensils. Pretty soon both cooks showed up with worried looks. I asked them what was the matter. One said, "I have no cooking utensils, but one knife and one spoon." I said "What do you need to cook with?" He said, "A knife and a spoon." I told them that they had been out long enough to take care of themselves and they should not worry me with their cooking utensils as I had other troubles, that I had to eat the same thing they did, so they could divide what utensils they had and get along, that we were going to work on a bridge if we had to eat the food raw. I started off, but those cooks looked so up against it, I had to solve their problem for them, so I said to mine, "You come with me." Thereupon I went over to an Infantry company nearby and walked up to the kitchen, where I found the Supply Sergeant. I said "Sergeant, lend me a knife and a spoon a little while and I will return them. We are kind of short of tools over at our place." The sergeant handed the knife and the spoon to my cook, and we went back to our camp, jumped into our trucks and moved off. I expect that the infantry sergeant thinks my idea of a "little while" is quite a long time. However, I was desperate.

This story illustrates to my mind two exceedingly interesting and important principles:

1st. Order a man to go to a place and see what is necessary and do it.

2nd. Soldiers separated from constant supervision learn to take care of themselves. They get interested in the problems put up to them, and solve them just as those cooks learned to cook with only a knife and a spoon.

Now we come to road work in Europe during the World War. My ideas on the subject are so at variance with those of the majority of people that the two are more or less irreconcilable. I will have to discuss that about which I know and refer briefly to that concerning which my information is only hearsay.

During the war there were formed both in the English and in the French service, large and more or less independent road services, which are alleged to have operated efficiently and to have done an enormous quantity of road work. I have read treatises on both services, and I believe that they did much more such work in active operations than we did. I think such services functioning as they did were similar to civil organization, and were possible only in stationary or trench warfare.

We started off with a road service as part of our railroad transportation service. Quite soon this service, together with light railroads, was taken from the transportation service, and made a division of the engineer service. This division was in existence until after the armistice. In the S. O. S., road work was actually done by the section engineers under the Director of Construction and Forestry. In the armies road work was actually done by the Army Engineer force. The Division of Roads and Light Railroads tried to attend to the supply and distribution of road machinery, plant, etc., and to road materials to some extent. Perhaps it did, but I got my plant and matériel in general by rustling for it and I believe every body else did the same. I did not think the Division of Light Railroads and Roads knew where all the plant was. Their reports, I believe, cover all road work.

I am inclined to believe that separate road services simply clog the game and are unnecessary. The representative engineer in any territory, no matter what you call him, should supervise all construction work of whatever nature, including roads. It is essential that engineer labor and materials be applied to the most urgent necessity at all times and there should be one supreme coördinating head in each locality to supervise all engineering work.

Although the 1st Army had some little road machinery such as road rollers, etc., their most vital work was done by hand. They broke rock by hand, transported it by hand, and put it on the roads by hand. Of course, they did work by the slower and more elaborate civil methods, but the work which required the utmost mental and physical capacity was the hand work. Such work and traffic regulations are the salient feature of the army road work in so far as we, as military engineers, are concerned. While the heavy, slow work no doubt was useful, the other type of work gave the army most concern.

Digitized by Google

I should mention here that the English and French had adopted a plank 5 inches thick for plank roads, and that we had imitated them and provided a great quantity of these. I was never able to learn of any of these planks having been used. They could not be brought to the front on account of lack of transportation. A small quantity of them may have been used and I may not have heard of it. This size of plank was adopted by the English and French to stand the wear and tear of stationary trench warfare. We had no use for such a thick plank. If we had used plank roads to any great extent, we probably would have passed beyond them or changed them to rock roads before a 3-inch plank would have worn out. In other words, I think we should have provided for a plank road of 3-inch instead of 5-inch plank.

Road material was sometimes received by rail

Portable rock crusher. It was often cheaper to crush by hand

I have read an article in the PROFESSIONAL MEMOIRS on roads, and I do not agree entirely with it. I think it is useless to elaborate on a number of theories on what roads will have to be provided. One has to solve the problem after it develops according to the demands which develop. I take particular exception to the statement that concrete roads were not used on account of scarcity of coal to burn the cement necessary. As a matter of fact, when the armistice occurred our depots were stocked with more cement than was needed. There can never be any chance of building any kind of road which requires materials to be transported to it over very great distances. This is a fundamental principle of all road building, whether civil or military, but it is of vital importance in mobile warfare.

Most of the road work in Europe with which I was concerned, occurred after the armistice. About December 1, 1918, the French indicated no little uneasiness about their roads for the coming winter weather. This was shown by instructions from General Pershing in person, which started our work.

The instructions were that the Americans would make good any damage done by them; that is, they would keep up roads in continuous use by them. A separate road service to do this was suggested. It was proposed that there should be one strong man in charge of road work from the Rhine to the Coast. However, this suggestion was made after instructions had been issued to the 1st and 2nd Armies to take care of the roads used by themselves and these instructions had produced little or nothing in the way of road work. The road question was stirred up with life before the instructions had ever gotten through red tape out to divisions. I might explain that I was in on this because I was Section Engineer of the Advance Sector of the S. O. S., in which the 1st and 2nd Armies were billeted and in which G. H. Q. was located. In other words, the automobiles around Chaumont bumped over deteriorating roads in my area. As section engineer I was the representative of the Director of Construction and Forestry, and supervised all engineer activities in the advance section.

After the C. in C. had become interested in what was being done on his first instructions, or rather what was not being done, the Chief Engineer of the A. E. F. and the Director of Construction and Forestry, were called to Chaumont in conference. They opposed a separate road service and said the existing organization of the D. C. & F. could best do this work. The Division of Light Railways and Roads did not want the job. The result of the conference was G. O., No. 2, G. H. Q., 1919. On the basis of this the D. C. F. issued instructions to the various people concerned which are quoted later.

While the above mentioned conferences were going on, the idea was promulgated that an American soldier cost so much per day, which by adding up rations, clothing, transportation across the ocean, fighting submarines, etc., could be boosted to $10.00, and that it would be cheaper to pay the French to do the work. I took the position that the soldier cost $10.00 per day whether he worked on the road or snoozed in a billet, that the French neither could nor would do the work, that our movements would be stopped by roads breaking down, that we were told to get this work done,

Digitized by Google

and not to study economics, that the above mentioned argument would be considered by G. H. Q. as a device of ours to get out of work and that I would not subscribe to any such argument. We would go home when the C. in C. sent us home, and we had better get this road work done, so we went to work.

The following is a compilation of instructions issued on the subject which instructions I, of course, believe to be quite a masterpiece for the purpose for which intended:

HEADQUARTERS
ADVANCE SECTION, S. O. S., A. E. F.
OFFICE OF SECTION ENGINEER OFFICER.
20 March, 1919.

COMPILATION OF ALL ROAD INSTRUCTIONS.

I. ADMINISTRATIVE

1. All roads in continued use by the American Expeditionary Forces will be maintained and kept in repair by our forces. Since the enormous mileage involved and the scarcity of road machinery make it impracticable to do extensive resurfacing with machinery, the work will be done by hand, with simple hand tools improvised if they cannot be otherwise secured. The French cantonnier system will be adopted in principle and road maintenance detachments will also be so stationed that all parts of all roads can be reached for repair. These road maintenance detachments will be provided with quarters and attached to organizations for rations by the commanding officer of the districts in which they are distributed for this work.

2. All road work in France and Luxembourg is placed under the Department of Construction and Forestry; the Chief Engineer or the Director of Construction and Forestry, or his direct representative, will issue instructions direct to the chief engineers of the armies, corps and divisions on the subject of road work in the same manner as instructions are now given to section engineers in the S. O. S.

3. Commanding generals will supply their engineer officers with sufficient additional personnel to carry out the instructions of the Director of Construction and Forestry.

4. In Luxembourg, available personnel will be supplied by commanding generals, and, in addition, civilian labor may be employed by the Director of Construction and Forestry. He will also arrange to send to his representative such additional personnel as may be needed. (G. O. 2, G. H. Q., A. E. F., 1919.)

(*a*) The economic aspect of the work to be done is not the concern of officers who have received instructions for work. However, what is being done is the highest economy. Men are in France in abundance. The cheapest way to maintain roads is by using labor to continually replace worn out soft rock. It is cheaper to break rock by hand than by crushers, as men have to be maintained anyway. There is slight chance of any engineer or labor personnel being sent to the United States until the roads in use by American troops are in good condition. (S. E. O., Advance Section, S. O. S., 16 January, 1919.)

It is expected that Army and Corps Engineers will supervise Division Engineers. Every effort to supply the Division Engineers direct will be made, but if there is any lack of absolutely necessary tools, Corps and Army Engineers should inform the Section Engineer Officer, Advance Section, who will distribute as rapidly as possible all available tools and equipment. Supervising officers will instruct and educate the working force how to accomplish the results with what they have or can readily obtain rather than requisition what is not available in France.

Attention is especially invited to the natural disinclination of many regimental, battalion, and company commanders to dividing their organizations over large areas. The good company commander can divide a company in detachments of 5 or 10 men and feed and supervise his men properly. Junior officers and non-commissioned officers will take a pride if given the responsibility for specific sections. In other words, the supervision of the company commander will produce better developments both in his men and their work if the personnel of his company is so located as to give some responsibility to his subordinates instead of keeping them all near his headquarters. Corps and division engineers should educate their road personnel without delay along these lines, as the work in the various areas will be under frequent and irregular observation by higher authority and any backward area is quite likely to receive severe criticism. (D. C. & F. to C. E., 1st Army, 3 January, 1919.)

Note: There has been an opportunity to watch the results of employing colored soldiers in small isolated groups of two or three. They are very much better workmen when thus employed. When used in large detachments a great deal of man-power is wasted. When two colored soldiers have been assigned permanently to maintain a kilometer of road, the best work is accomplished, and roads are in best condition.

1. The Commander in Chief has made very clear his desire that this road work be promptly undertaken and that the best practical results be obtained. Road reconnaissances, reports and other substitutes for work will not meet his wishes. It is understood that you will attend to all roads in your area that you do not find already being cared for by my forces, and if not already done, it is requested that you get started at once as outlined in above mentioned memorandum.

2. The Section Engineer Officer, Advance Section, S. O. S., is my deputy in this matter in the Advance Section, and will in the interest of expedition attend to any matters for me which you present to him. In the event that you desire me to act on anything personally, mark the communication thus, and the Section Engineer Officer, Advance Section, S. O. S., will send it to me.

3. Road machinery will probably not be available for work except on the main roads from the ports to the 3rd Army. (D. C. & F. to all division engineers, 28 December, 1918.)

"Number 203, G-4. Details working on the road in the vicinity of Chaumont are loafing on the job. Little will be accomplished by such work. We realize that you have done everything in detailing personnel and material for this work, but it now becomes necessary to put some 'pep' in its execution. Please therefore detail some officers to supervise this work. Where officers and non-commissioned officers in charge of detachments fail to get the most out of the men rigorous disciplinary action should be applied at once." (Telegram from C. in C., 13 January, 1919.)

This work is expected to prevent the necessity of more extensive road work in the future, and work must be carried on regardless of difficulties encountered. (S. E. O., Advance Section, S. O. S., 28 December, 1918.)

II. TECHNICAL

In France roads are constructed with the shoulder above the rock surface, and through the shoulder drains carry water to the side ditches. In Luxembourg and in Germany, the shoulders slope from the rock surface to the side ditches, so that drainage from the rock surface is continuous. While the French system requires more care in maintenance, in order to keep the drains open, it has the advan-

Digitized by Google

tage that vehicles cannot easily run off the rock, wear holes adjacent to the macadam, and break down the edges of the rock road. The theory of the French road is the fine road surface is washed into the drains. When the drains are cleaned the material gotten therefrom is piled and used as binders for repairs. (S. E. O., Advance Section, S. O. S., 28 December, 1919.)

The maintenance of the French roads may be ordinarily divided into two classes: Maintenance of first-class roads, and maintenance of second-class roads. The first-class roads consist of those roads built of the harder rocks, such as trap rock, dolemites and the wash gravel. The second-class roads are usually built of the limestones which are usually found to be close at hand.

In the maintenance of the first-class roads the chief tools necessary are the mud hoe, shovel, pick, and roller,

Resurfacing a road by hand labor

American tractor train hauling road metal

and their importance is in the order named. All French roads may be considered as mud-bound macadam. It is this mud which appears on the surface of a used road after a rain, and it is of the utmost importance that this mud be moved immediately, for if it is left on the road it forms collectors for small pools of water which rapidly finds its way into the road and causes its rapid deterioration. The mud hoe is found to be the best instrument to move this material although the street broom (power-driven) may be used to good advantage. (S. E. O., Advance Section, S. O. S., 9 January, 1919.)

All roads are to be kept free of water, even if a man has to follow each vehicle and open drains. Men will be distributed over the roads for this purpose as often as it necessary to accomplish the result. (S. E. O., Advance Section, S. O. S., 16 January, 1919.)

The time to patch a road is when it is wet. On the first-class road throw small rock, usually No. 3, in the low spot and parallel with center line of the road. Then throw some good binder (usually any of the dirt alongside the road) on the rock. This should be thrown in the same direction. The ratio should be about two of rock to one of binder. If the patch should be made without the use of a roller, and the traffic is such as to not properly allow the proper binding of the patch, sod or its equivalent should be used as a binder. With this kind of patching, two men per kilometer of road have been found sufficient. (S. E. O., Advance Section, S. O. S., 9 January, 1919.)

It is expected that available materials will be used and that soft rock or any other kind of rock will be placed in holes as fast as it goes out, even if a man replaces it after each vehicle passes. (S. E. O., Advance Section, S. O. S., 16 January, 1919.)

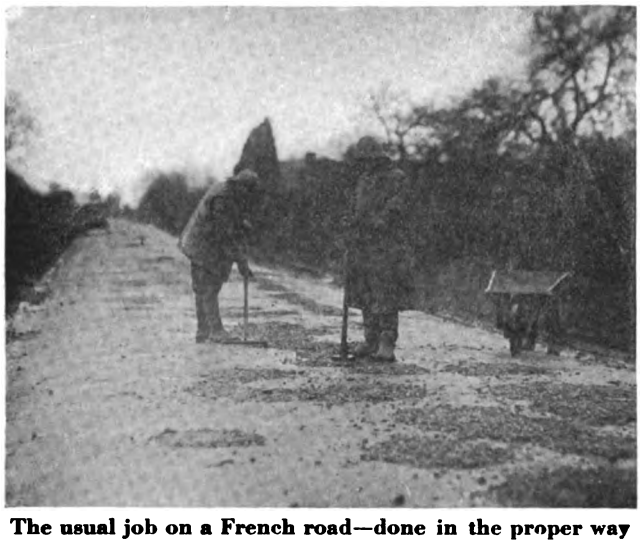
When the roller is to used, it is usually necessary to dig out the place to be patched. This not only permits the proper sizing of the rock, but anchors the patch, and at the same time the rock is locked. Experience has shown that the proper number of men per roller is 17. This puts 2 men on the roller and 15 on the ground. The cross section of a patch so made should resemble the frustrum of a pyramid. Small patches may be made without the roller, provided heavy tamps are used. Good results have been obtained from this method.

In ordinary patching of the second-class road, it rarely becomes necessary to take out the patch. Care should be taken that too small a rock is not used in the patching. In case a weak spot develops in the base, the road ought to be dug out, telford replaced and the rock sized as in the ordinary macadam roads.

The first things to be looked for in any road are the location and drainage. As the first is usually determined, drainage becomes the foremost question. Therefore, along with the maintenance be sure the road is properly drained. (S. E. O., Advance Section, S. O. S., 9 January, 1919.)

Roads in use by American troops are be gotten smooth and drained, and they are to be kept in this condition. (S. E. O., Advance Section, S. O. S., 16 January, 1919.)

In freezing weather drains can be cleaned, stone can be distributed, and rock can be broken. Short periods of thawing in the middle of the day can be used for patching. Small local quarries can be worked by hand, so that stone will not have to be transported long distances. The help of the nearest French Road Official should be gotten to obtain rights in such quarries. Cart loads of stone can be purchased delivered, in any locality where found practicable. (S. E. O., Advance Section, S. O. S., 28 Dec., 1918.)



The French have maintained their roads by a system of cantonniers living along the roads. These road tenders watch the roads constantly and make small repairs before serious damage is done. They work on particular features according to the weather. Of course, drainage is always kept open. The patching done by cantonniers is done, generally without digging, by grading the rock put into a depression, and tamping it in. A cantonnier my care for 10 kilometers of road.

Roads used by American Forces are to be put in repair and

Digitized by Google

maintained by our troops. The French cantonnier system will be used in principle, and every part of all roads will be maintained by a detachment so located as to constantly clean drains, patch and repair generally. Each officer will study carefully what he sees the French cantonnier doing, and will teach his men to do likewise. The road detachments and the officers supervising them should consider this work most excellent training and should see that valuable knowledge and training is obtained on this important engineering work.

While the necessary hand tools, such as hammers, shovels, tamps, rakes, hoes, wheelbarrows, etc., will be supplied

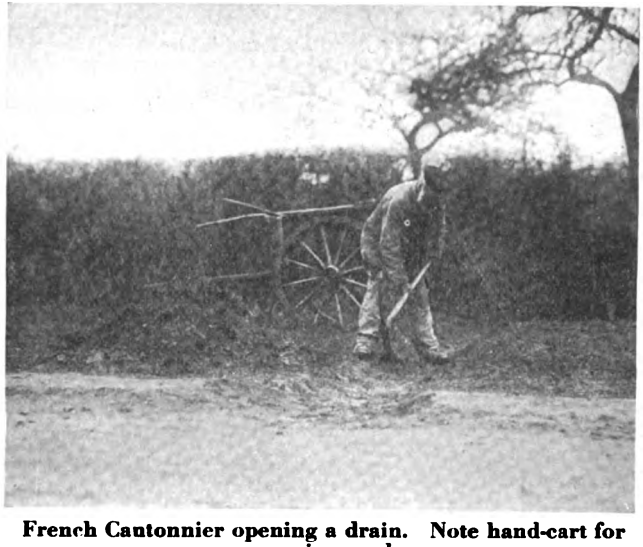
The usual job on a French road—done in the proper way

as rapidly as possible, mainenance should not be delayed for lack of some of these tools. Tamps can be improvised from a log of wood, and drains can be cleaned with almost anything. (S. E. O., Advance Section, S. O. S., 28 December, 1918.)

Note: Since the above was written, experience has shown that the methods employed are eminently sound. The French instructions require their cantonniers to dig out square holes before patching; observation shows they do not generally follow this theory, but use the rough methods of patching outlined above.

It took quite a time and no little trouble to get men separated sufficiently to do this work, but we finally accomplished this by persistent effort. The division engineers who complied with the principles of the instructions had to work but kept out of trouble. Those who did not get on the job with life were soon in serious trouble. I was more or less in trouble all the time, but managed to get by with the job, in the Advance Section. Other sections had about the same troubles I had. I saw to it that plenty of men and facilities were placed around Chaumont, and after several trials I got a man there who would keep me out of trouble by keeping smooth the road over which the C. in C. and his personal staff traveled.

The French roads have been sufficiently described in other literature, so it is useless for me to repeat. Luckily, their drainage system was fundamentally about perfect, so we only had to keep it clear.



The Creator supplied plenty of water (delivered on the job) for water-bound macadam.

The rock was mostly soft limestone varying from very soft to moderately hard.

As the instructions said, we simply had to keep the water off the road and put on stone, either soft or hard. As I said, it was mostly a question of supervision and drive to make men do the work by hand and not waste time figuring on economics.

I consider this work the most creditable with which I was connected abroad. When we started, everybody said it was impossible. Of course, after it was done, that was forgotten and it appeared easy, like Columbus' egg. There was no technical knowledge necessary other than "keep water off the roads" and "put rock on them." The roads could be kept smoother by properly grading the rock in patches but they would stand up if rock was put on, and rock would be put on if the officers properly supervised. There were plenty of men if they would work conscientiously and intelligently 50 per cent of the time, but it required no little push and drive to make them do this. The average infantry soldier would much rather be shot into ribbons and go to the hospital (or to hell) than work on a road. That is the spirit which wins battles, no doubt, but it leaves the roads in awful shape.

In Germany the 3rd Army had quite a little trouble, but I think no more than we did. The problem was different. In France, drainage was perfectly laid

French Cantonnier opening a drain. Note hand-cart for carrying rock

out; in Germany it was not. In France the roads were broad; in Germany they were not. In France the shoulders were broad and high; in Germany they were not. In France the rock was generally soft; in Germany it was hard. In France the rock surface was generally thick, in Germany it was generally thin. In France drains through the shoulder had to be constantly opened, but the shoulders prevented trucks breaking off the edge of the metal. In Ger-

Concrete Caissons for Breakwater Construction

Continued from page 130

narily taken. Occasionally a slight leak will be found after a caisson is launched, but it usually closes in a short time by the deposit of sediment from the water.

The largest caisson heretofore built, 54 feet long, 24 feet base and 21 feet 3 inches high, contains about 250 cubic yards of concrete. These caissons have been built in continuous operation in one 10-hour day. This necessitated employing 12 men in addition to regular crew, and so arranging the work that no one did more than the 8 hours prescribed by law. To accomplish this, a thoroughly organized and trained crew, working at high speed, is required. The construction of still larger caissons is in contemplation. Should larger caissons be undertaken, it will probably be necessary either to mold the caisson in parts on separate days, or to work 16 hours per day, using two shifts. In the former case it is probable that the bottom would be molded one day and the walls a subsequent day. It is believed the limit has been reached for a single day's work of 8 hours. The standard labor organization for molding the largest size caisson consists of twenty-two men, distributed as follows: One man loosening sand in bins; three men on sand and stone cars; two men loading cars in cement shed and transporting cement to mixer; two men emptying cement into side loader of mixer; one engineman on mixer; one fireman on mixer who assists in landing the concrete bucket at mixer; one man landing bucket at mixer and cleaning up around bucket; six men on top of form, dumping the bucket and puddling concrete; one engineman and one fireman on locomotive crane; one overseer on top of form, in charge of the dumping and puddling; one foreman at mixer; one general superintendent and engineer. In addition, two men are employed at the Milwaukee plant in operating the steam tug and gasoline launch and in general utility. For molding smaller caissons, the crew is somewhat less, the number of puddlers being reduced by one or two men, and only one man is used in the cement shed. During the season of 1919, the scale of wages paid for the foregoing was as follows: general superintendent and engineer, $200 per month; foreman, $140 per month; overseer, $120 per month; engineman on locomotive crane, $133.33 per month; engineman on mixer, $116.66 per month; fireman, $110 per month; laborers, $4.40 per day.

The foregoing crew, when not molding a caisson, is employed in taking down and erecting form, weaving reinforcement units, preparing caissons for launching and towing, etc. With no delays, with single crew working 8 hours, and with two sets of ways, it is possible to build three caissons per month.

Launching

Caissons usually remain for ten days on the ways before launching to insure sufficient set of the concrete. In favorable weather, when hardening progresses rapidly, and with the long ways now in use, whereby launching stresses are greatly reduced, caissons have been successfully launched on 8th day after molding.

Four shoes, each about 28 feet long, are used in launching. The shoes are trapezoidal in longitudinal section, so that when resting on the sloping ways the upper surface is horizontal. Shoes are made of 12 by 12 fir, except the bottom piece, which bears on the launching way, which is 10 by 20 oak, laid flat. A 6 by 12 inch ribbon or flange, bolted on one side of the shoe, prevents it from sliding off the stringer.

When ready for launching, the ways above water are thoroughly greased by pouring melted beef tallow thereon. Formerly the tallow was mixed with lard oil, but tallow alone has been found satisfactory. The shoes are then pulled tightly into place under the caisson by aid of the locomotive crane. As complete a bearing as possible is obtained by driving in thin wooden shims between the top of the shoes and the caisson, so as to prevent distortion due to unequal bearings on the shoes when the blocking is cut away and the caisson lowered from the jacks. The two outside shoes are then blocked with 8 by 8 struts, extending from a notch cut in the 10 by 20 inch oak timber to a pile cap of the ways. The ends of the struts next to the shoes are forced into position and there held by jacks. The end of the strut, which fits into the notch in the shoe, has to be cut with care, so that it will readily release in launching and still hold after the supporting jack is removed.

The blocking along the outside edges of the caisson is now cut away and removed, the caisson being now supported by the jacks. The jacks are then lowered and removed, throwing entire weight of the caisson on the four launching shoes. In the meantime, the releasing device has been placed. This consists primarily of two iron weights of about 575

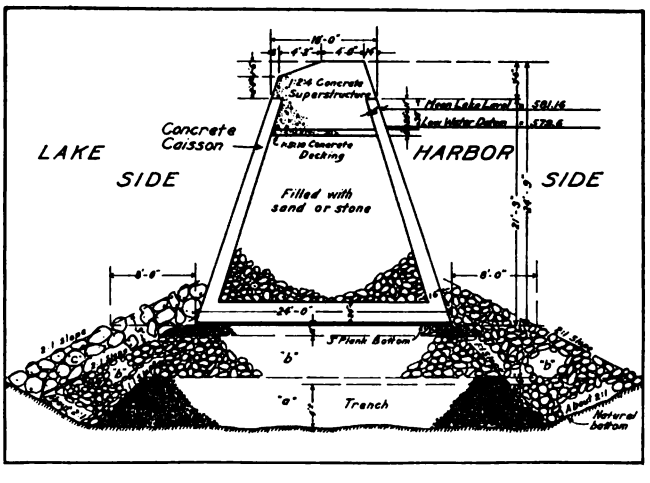

Fig. 3. Cross-section of completed breakwater

Digitized by Google

pounds each, suspended by a rope in a gallows frame, which when released fall through a height of about 8 feet, striking an iron bar, one end of which rests on the strut at its upper end and the other on a block placed for that purpose, which in turn knocks out the strut, entirely releasing the caisson. The ropes by which the weights are suspended are led around in front of the caisson and connected by a short piece of rope. The cutting of this short piece releases the weights. The releasing device and launching shoe are shown in Figure 2.

This launching device has proved very satisfactory. Formerly a caisson was released by two men knocking out the struts at each end. To effect perfect release, the struts must be knocked out simultaneously. Unfortunately, in one instance this was not effected, one man failing to knock out a strut. In consequence, the caisson started sidewise, tore the ribbons from the shoes, and crashed through the ways, completely wrecking them. Since then the releasing device above described has been used.

After a caisson is released, unless the ways have been recently and thoroughly greased, it frequently fails to move. Initial impulse is given by jack screws placed between the caisson and the adjacent wharf. Of course, in such cases there has been no pressure on the restraining struts, and even when the caisson starts without impulse, it is believed the pressure on struts does not exceed 10 tons each, or about one-third the theoretical pressure, disregarding friction. Struts are made of Pacific Coast fir, and show no signs of crushing.

Caissons are launched with open top, as the ways are extended to such a depth of water as will permit them to float off. Formerly the ways terminated in about 6 feet of water, the caisson plunging off the ends of the ways, and being completely submerged. This not only necessitated decking a caisson before launching, but was very destructive of the ways, the upward thrust along the stringers breaking and crushing the timbers. Since the ways were extended to their present length, about 40 caissons, some of them weighing 500 tons, have been launched without any damage to the ways, which in the past two or three years have required only very minor repairs.

The launching of a caisson, as above described, usually takes about 6 hours. The preparation for launching requires the services of about ¾ of the construction crew. The remainder of the crew is employed in taking out braces, bolts, etc., from the form of caisson last molded, and getting it in readiness for transfer. As soon as the caisson is launched, the work of laying foundation for the next caisson on the ways just vacated is begun.

Towing

On account of the cost of installing a suitable plant it is more economical to build the caissons at a centrally located plant and tow them to the harbor where they are to be used. This statement is, of course, subject to modification in a case where so large a number of caissons are to be used at one harbor that the cost of towage from the central plant would equal or exceed the cost of a new plant installation. This, however, could not occur, unless the distance was very great, exceeding say 150 miles, and the number of caissons was very large. The cost of towing caissons from Milwaukee to Sheboygan in 1914, a distance of about 55 miles, was about $75 each. At present high prices of labor and materials, it is estimated that the cost of decking and towing a caisson 100 miles will be about $250. This makes no provision for possible accident, involving the loss of one or more caissons. However, it can be stated that during the past 12 years 130 caissons have been towed in the open lake for distances varying from 12 to 55 miles, and but one caisson has been lost, which occurred through faulty decking, a cause which it is believed has been entirely eliminated. The risk is therefore no greater than ordinary marine risk.

The towing of caissons has been done by the U. S. steam tug *Manitowoc,* the United States assuming all responsibility for the caissons until delivered to the contractor at destination. Two caissons are taken at one time, the average speed being from 2½ to 3 miles per hour.

As ring bolts or any similar contrivance imbedded in the concrete, to which towing hawsers would be fastened, would probably tear out when towing caissons, especially if in a sea, an apparatus for towing has been devised whereby the entire pull on the main hawser is transmitted to the rearward end of the caisson. This consists primarily of 12 by 12 inch timbers placed across the ends of each caisson and held together by 1¼-inch turn-buckle rods extending fore-and-aft along the sides of the caisson. Wire cable bridles to which the Manila towing hawsers are fastened, are secured to ring bolts at the ends of the timbers. When two caissons are taken in tow, the forward caisson is provided with two of these frames, the hawser from the tug leading to the lower frame. The towing frame for the after caisson is placed so as to correspond with the lower frame on forward caisson, and the hawser connecting the two caissons leads downward from the upper frame on forward caisson. This method forms a couple and aids materially in towing, as it holds the forward end of the front caisson up, and tends to prevent it "going by the head." Formerly the tension in the turn-buckle rods was depended upon to create enough friction to hold the timbers in place; but it was found that the timbers were lifted by waves and the surging of the caissons in a sea. Recesses 1 inch deep and 12 inches wide are now formed in the end walls of each caisson, in which

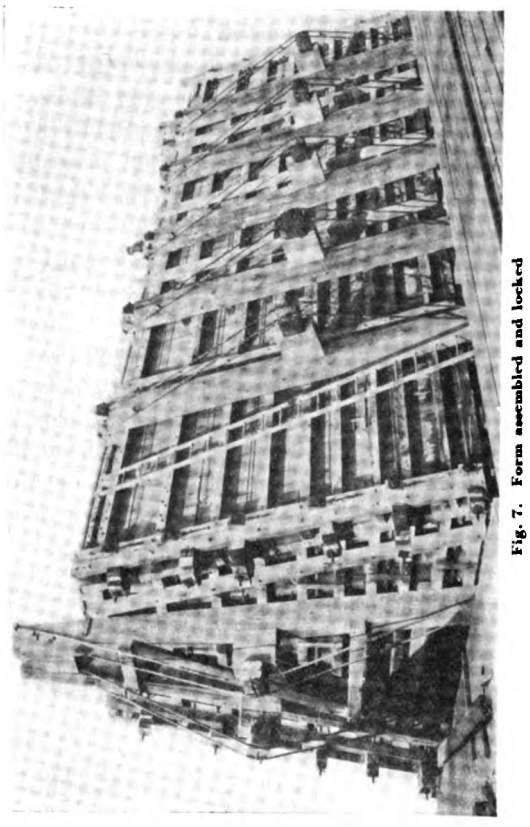

Fig. 7. Form assembled and locked

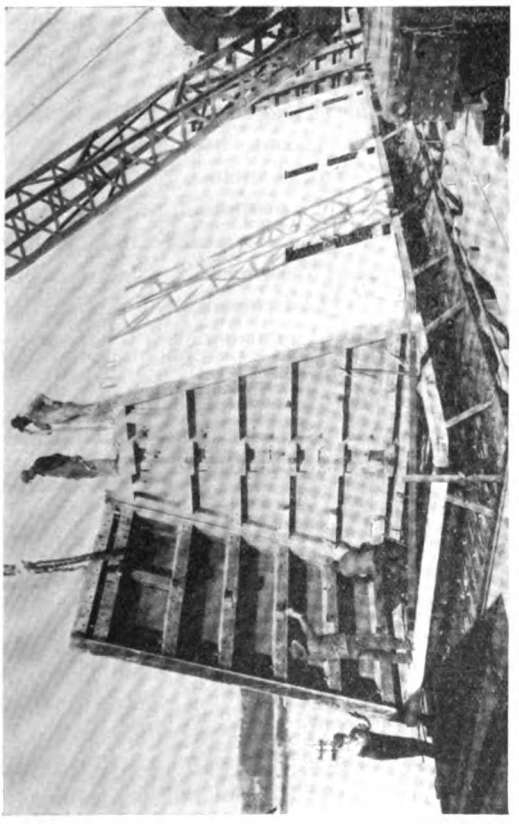

Fig. 4. Erecting Core Forms

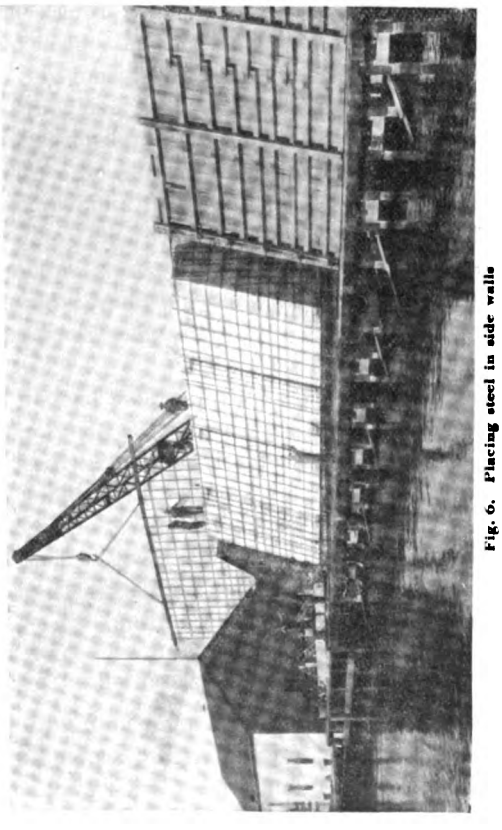

Fig. 6. Placing steel in side walls

Digitized by Google

the transverse towing timbers are placed. This effectually prevents displacement.

While it is unnecessary to deck a caisson for launching, it has to be carefully and thoroughly decked for towing in the open lake, so as to be completely water-tight. The standard deck for a caisson is made in four sections, one for each compartment. Each section is provided with a hatch through which access can be had to the compartment. Hatches are provided with waterproof covers which are securely battened when towing in open lake. The decking is 2 by 10 matched (tongue and groove) planks, covered with 15-ounce canvas, painted, which in turn is covered with 1 by 10-inch matched sheathing. The sections of decking are held down by bolts imbedded in the concrete, and passing up between two 4 by 4 timbers through long washers placed on top of the timbers. Ordinary ½-inch pliable rubber garden hose is placed between the decking and the top of the caisson wall, and is squeezed down tight by the anchor bolts, thereby making a water-tight joint. The joints between sections are calked and pitched. Figure 8 shows a caisson decked for towing, with towing timbers in place. This caisson will be placed in rear of tow, and therefore has but one set of towing timbers. Note the notch molded in end wall and the hatches in the deck (with covers removed).

This decking is very satisfactory. It is readily placed and removed and is absolutely water-tight. Caissons which have been out in very rough water and have been completely submerged, have been found entirely dry when the decking was removed. The decking is saved for future use. Formerly decking was made of a single layer of 3-inch planks over which canvas was spread, and ordinary cotton was used in place of rubber hose. This proved inadequate to insure water-tightness, and in consequence one caisson was lost while being towed in a severe storm, the compartments filling with water through the open seams. There has been no trouble since the present style of decking was introduced.

If caissons are not to be delivered at a harbor soon after launching or are to be stored over winter, they are parked on the natural lake bottom near the plant by filling them with water by means of ordinary pipe syphons. In parking caissons, consideration must be given to probable changes in lake level which may occur during the storage period, as well as allowance for some settlement into the lake bottom.

Placing in Breakwater

A caisson is sunk on its permanent foundation as part of the breakwater, by admitting water to the compartments. This is done either with syphons or pumps. This method of sinking is very advantageous, as should a caisson be sunk out of line, or if for any other reason it should be desirable to reset it on the foundation, it can be readily floated by unwatering. Caissons filled with water only are very stable and frequently have gone through severe storms in that condition without being moved.

Until recently most caissons have been placed on pile foundations, although as long ago as in 1909 a number at Manitowoc were placed upon a rubble foundation.

This has been discontinued not only on account of the expense and difficulty involved in properly preparing pile foundations, but also on account of their instability under certain conditions. Rubble stone foundations are quite as cheap in first cost, and are usually more stable. It is believed they should be used in preference to piling whenever the condition of the bottom will permit. If foundation piles project more than 3 or 4 feet above the bottom, and if the spaces between the projecting piles are not completely filled with rubble stone so as to provide lateral support, experience has shown that they are liable to be cracked or broken by the "weaving" of a caisson during severe storms. In very soft bottoms it may be necessary to use piling on account of the settlement under load of the stone into the mud. In sand bottoms it has been found advisable to dig a trench at least the width of the caissons, and from 4 to 6 feet deep, which is then filled with small stones, on which the rubble foundation is built. The stone filled trench prevents scour with consequent settlement of the foundation. Some of the stone filled timber crib breakwaters in this district, placed on stone foundations on sand bottoms without trench, have settled over 3 feet. Where trenches have been used with some of the later caisson breakwaters, settlements have not exceeded 3 or 4 inches.

After the caisson is properly sunk on its foundation, it is filled with either stone or sand to within about 3½ feet of the top. Water above the filling is then pumped out, and the filling temporarily sealed with a 6-inch layer of lean concrete. After the caisson has been thoroughly settled on its foundation, a concrete superstructure is molded in place to a height of about 4 feet above water surface. This mass concrete is carried down monolithically inside the caisson and rests on the concrete seal.

Costs

Information as to present costs of caissons is subject to modification at any time, owing to the constant changes in the prices of labor and materials. It may be said, however, that the field cost of caissons 18 feet 3 inches high, and 22 feet wide on the bottom, built during 1919, has been about $3,700 each. This is the cost of the caisson in the water at the construction plant, not decked. It includes a "rental charge" for the use of the plant, based on its maintenance and depreciation. The forms, as they are used repeatedly,

Digitized by Google

are included as plant. The materials entering into this caisson are approximately as follows: concrete, 200 cubic yards; reinforcing steel, 14,000 pounds; plank for bottom, 3,500 feet b. m.; wire spikes, 150 pounds. In addition there are steel knees for supporting cores, tarred paper for covering plank bottom and wire for weaving steel reinforcement units, all of which are incorporated in the concrete. From the foregoing, it appears that the concrete is reinforced at the rate of 72.2 pounds per cubic yard, and that the present cost of a caisson, including all materials, is about $18.85 per cubic yard of concrete. When a trench is used in forming the rubble foundation, this caisson is adapted for breakwater construction in depths of water varying from about 19 feet to 25 feet. For depths greater than 25 feet, it would be more economical to use a higher caisson, as maximum economy indicates that caissons should be set as close to the bottom as practicable. At present prices the cost of such a breakwater in 22-foot depth, filled with sand and provided with standard concrete superstructure, is about as follows:

Field cost of caisson, launched	$3,700.00
Decking, towing, etc. (100 miles)	250.00
375 cubic yards trench excavation, at 50 cents	187.50
400 tons stone, trench filling, at $2.50	1,000.00
650 tons stone, foundation and riprap, at $2.50	1,625.00
Sinking caisson on foundation	400.00
325 cubic yards sand filling, at $1.00	325.00
9 cubic yards lean concrete filling, at $12.00	108.00
105 cubic yards concrete superstructure, at $12.00	1,260.00
	$8,855.50
Overhead, contingencies, etc., 10 per cent	885.55
Total for 54 feet of breakwater	$9,741.05

Cost per linear foot, $180.39.

The foregoing estimate is based on prices in a recent contract awarded for a caisson breakwater at Indiana Harbor, Ind. The government will deliver the caissons to the contractor at this site.

It may be stated generally, that at present prices and availability of lumber and other materials, a caisson breakwater is, in this district, more economical in first cost than a timber-crib or rubble-mound breakwater. Also, as a result of about 12 years' experience it is believed the caisson breakwater is more durable and stable than one of cribs, and probably equal to rubble-mound breakwater. The choice between caissons and rubble mound would be then a matter of first cost, which of course will vary considerably in different localities. If only a small number of caissons are to be built and there is no manufacturing plant available, it would probably be cheaper to adopt some other form of construction, as the necessary plant installation is costly. The Milwaukee plant as herein described, has cost about $70,000, exclusive of floating equipment. The addition and enlargements proposed to be made before another season will probably cost about $30,000, making a total plant investment of $100,000.

With suitable construction plant available, caissons can be built as rapidly as timber cribs, and a caisson breakwater can be built more rapidly than can a rubble mound. It is believed that considering present first cost, durability, stability, and speed of construction, the concrete caisson breakwater is superior to any other type thus far used in Lake Michigan, and in many instances would probably prove equal, if not superior, to any other type for use in other localities, whether on the Great Lakes or elsewhere.

Fig. 8. Caisson decked, ready for towing

Discussion

Edward H. Schulz
Lieutenant Colonel, Corps of Engineers
District Engineer, Milwaukee District

Mr. Tompkins is the principal assistant engineer of this office, and during a part of the World War was in charge of the District. He gives a very clean cut account of the processes of constructing and placing concrete caissons for piers and breakwaters.

These operations include assembly of the plant and materials, placing the forms, mixing and placing the concrete, launching, storage, towage of the caissons, preparing the foundations, placing, filling and capping the caissons. The size of crews, cost of caissons and comparative cost of the caisson, crib and riprap constructions and other data, are also given.

It appears that caissons of iron, or metal, filled with concrete were constructed experimentally in Europe as early as 1905, but it remained for the Milwaukee District, under Col. W. V. Judson and his assistants (under a patent granted Colonel Judson in 1901), to design and develop a practicable reinforced concrete caisson. The first of these was built in 1908 and was of rectangular form about 24 feet in length. Later development has led to the trapezoidal form, the caissons being 10 feet wide at top, side slopes of 3 on 1, length 54 feet, and height varying from 18 to 21 feet. The standard rubble foundation on erodable soil is shown on Fig. 3. Some of the first caissons were placed on pile foundations. Where the soil is stable and erosion not to be feared the trenching and stone fill can be omitted or reduced in quantity, thus reducing the cost.

There are in the Milwaukee District, which now includes the former Grand Rapids District, 30 different lake harbor improvements. The 16 on the west shore include Manis-

Digitized by Google

tique, Menominee, Oconto, Green Bay, Sturgeon Bay, Algoma, Kewaunee, Sheboygan, Two Rivers, Manitowoc, Port Washington, Milwaukee, Racine, Kenosha and Waukegan. The 15 on the east shore include St. Joseph, South Haven, Saugatuck, Holland, Grand Haven, Muskegon, White Lake, Pentwater, Ludington, Manistee, Portage Lake, Arcadia, Frankfort, Charlevoix and Petoskey. These harbors have been under improvement during the last fifty years, some dating back to 1850.

The works comprise various forms of revetment, piers and breakwaters. These designations, while somewhat elastic, are nevertheless fairly descriptive. Revetments are generally the inner ends of the structures, of less generous proportions and strength and intended to stabilize the existing channel banks connecting the lake with inner harbor or river. The piers are the extensions of the revetments into the lake, generally parallel and 200 to 450 feet apart. The breakwaters are the most substantial, and of the arrow-head type, inclosing a stilling basin and harbor. The revetments are generally of pile, slab or sheet pile construction, the piers of piling or cribs filled with rock, and the breakwaters of crib or caisson type. No caisson construction has been built on the east shore, but in the Milwaukee District proper some 144 have been constructed and placed, having a total length of 5,916 feet. In addition 12 54-foot caissons have been constructed this season for Indiana Harbor.

The total lengths of the various structures of the district is close to 30 miles, being very evenly divided between the two shores of the district. In the old Milwaukee District proper, the works include about 23,000 linear feet of pile pier, 29,000 feet of cribs, 16,000 linear feet of pile and sheet pile revetment, 3,200 linear feet of slab pier and 6,000 linear feet of caisson construction. The pile pier construction has some 8,600 linear feet with concrete superstructure and 900 feet with rubble mound. The pile revetment has about 664 linear feet with concrete superstructure and 260 linear feet with rubble mound. The crib work has some 10,000 linear feet of concrete superstructure, and the cribs have been variously placed directly on the lake bottom, or on piles, or stone foundations. The width of structures has varied from 14 to 32 feet and the elevation from 5 to 9 feet above low water datum (79.6 feet above sea level).

In the former Grand Rapids District, the works include about 34,000 linear feet of pile pier, 39,000 feet of crib, 2,500 feet of plank revetment, 1,600 feet of sheet pile revetment, 1,185 feet of concrete superstructure on piles and 900 feet of rubble mound. The pile pier work has 2,200 linear feet with concrete superstructure and the crib work about 400 feet with concrete superstructure. The pile piers are 10 to 30 feet wide and extend 4 to 8 feet above low water. The cribs are 16 to 30 feet wide with timber superstructures extending 6 to 9 feet and concrete superstructures 4 to 6 feet above low water.

In recent years, repairs to timber piers and breakwaters have been made by cutting down the timber and removing stone to about 1 foot above low water datum, and placing a cellular concrete superstructure to elevation of about 4 to 6 feet above low water datum. Some new construction of concrete on pile and sheet pile foundation has also been built. This type bids fair to be especially successful in repairing old structures.

Mr. Tompkins gives the present approximate cost of construction, towing, and placing caissons at Indiana Harbor, including preparation and construction of foundation at about $180.00 per linear foot. These caissons are for depths of 22 feet and their construction is, in this locality, about 33 per cent cheaper than rubble mound of the same depth and stability, and likewise cheaper than any crib construction at present prices. As the depth becomes less, the relative cost of a rubble mound breakwater increases rapidly with the depth. To construct such a breakwater in water 30 to 35 feet deep would take enormous quantities of stone. Crib construction, even if otherwise satisfactory, would be costly and an unwarranted demand on the timber resources of the country. Moreover, the continued maintenance of timber structures above the water line is very expensive and tedious. It thus appears that future economy points to more general use of caisson construction or in case of repairs, of concrete superstructure on old timber substructures.

The present capacity of the caisson plant at Milwaukee will be doubled during the coming season, and steps are also under way to secure an additional and larger area near the harbor entrance, where rail, vehicle and water traffic will all be available. The new site will have 6 ways and with double crews, will provide an output of 12 caissons per month or about 60 per year, equal to 3,040 linear feet.

Regarding the heights of structures, the tendency in recent years is to bring the height down to 5 or 6 feet above low water datum. the object being to reduce the cost and at the same time to have the structure high enough to be visible in stormy weather. This question of height and width with respect to wave action will receive further study in the near future, including other features of construction and design and will be discussed in a paper at a later date.

W. V. Judson
Colonel, Corps of Engineers; M. Am. Soc. C. E.;
Division Engineer, Northwestern Division

In the article by Mr. Tompkins and the discussion by Colonel Schulz there is very fully covered the present state of the art of breakwater construction, employing floatable reinforced concrete caissons. I desire at this time to testify to the great skill, interest and persistency of Messrs. Tompkins, Lion, Reed and Hoeing, civil engineers on duty in the Milwaukee district office at the time the construction of caissons was inaugurated there, and all except Mr. Lion continuously in touch with caisson construction and emplacement from 1908 until the present time. These gentlemen gave me great assistance also in the preparation of the paper for the Western Society of Engineers, referred to by Mr. Tompkins, in which was embodied all we knew about such caissons in 1909, and many suggestions as to their future use under different conditions.

Perhaps I can perform no greater service at this time than to set forth various suggestions looking to the employment of caissons under unusual or novel conditions, trusting that some of these suggestions may assist other engineers in the solution of similar problems.

While I was on engineer duty for the War Department at Milwaukee from 1905 to 1909 I was also lighthouse engineer from Lake Michigan. During the earlier part of this period Congress appropriated funds for a lighthouse "at the end of the Milwaukee breakwater." Now as river-and-harbor engineer, I knew that the breakwater would probably be extended a thousand or more feet. Nevertheless, the lighthouse board pressed me to proceed with the lighthouse which Congress had directed be built. Under these circumstances the concrete caisson came to the rescue.

There was tentatively designed a caisson 60 feet square

Digitized by Google

and 24 feet high with five cross-walls equally spaced and parallel to the sides and the same number similarly arranged with relation to the ends. These cross-walls, with the sides and ends, made 36 compartments or air-chambers to provide flotation, and with the thickness of the walls chosen the caisson would float with a 7-foot free-board. At certain intersections of the cross-walls the angles were so filled in as to make columns of considerable cross-section and from these columns there was designed to arise a steel skeleton structure supporting a deck some 50 feet above the water, above which deck were provided quarters for light-keepers, a fog signal and a lantern for a suitable light, the latter about 90 feet above the water. With all the load of skeleton structure and lighthouse features the caisson would still float with more than 3 feet of free-board. Thus a design was reproduced for a movable lighthouse.

I proposed to sink this caisson upon a rubble-mound foundation "at the end of the Milwaukee breakwater," prepared so that the top of the caisson would project 2 feet above the water; fill the pockets with sand; seal each pocket at the top with a large concrete block and place the lighthouse in service where directed by Congress until the breakwater might be extended. When the extension was completed I proposed to lift out the concrete blocks, remove the sand from the pockets, float the caisson with its superincumbent lighthouse structure to a newly prepared foundation at the new end of the breakwater and fill the pockets and seal them up as before. Aside from the cost of preparing the new foundation the removal of the lighthouse would have cost but a few hundred dollars. I could not help regretting that Congress revoked its appropriation for the lighthouse before we started upon this caisson. Plans were later made for a foundation for a lighthouse at the end of one of the breakwaters at Colon, Canal Zone, Panama.

At Panama several other uses were made of the concrete-steel caisson. For instance, the guide wall projecting into Gatun Lake from the upper end of the Gatun locks was constructed in the form employed for concrete-steel caissons, being built in place, however, before the water rose in the lake, with a view to securing economy and relieving pressure upon the foundations.

At Colon when the first breakwater was begun, it was entirely uncertain whether the soft bottom would hold up an enrockment breakwater. At the request of General, then Colonel, H. F. Hodges, I made several tentative designs for concrete-steel caisson structures that might be used with little pressure upon the bottom if the latter proved impossible as a foundation for any other kind of breakwater structure. The most interesting of these alternative designs in my opinion was for a structure with one caisson placed upon another. The bottom caisson was 60 feet wide, 25 feet high, closed on all sides, including top and bottom, with hollow compartments into which water might be admitted to sink the caisson and ballast it in place. The superincumbent caisson was trapezoidal in section, 40 feet wide at the bottom, 28 feet wide at the top and 25 feet high. It also possessed a number of chambers into which water could be introduced. The upper portion of the upper caisson was to be filled with concrete and a superstructure of concrete placed thereon. All of the chambers designed to be filled with water were to contain nothing but the latter. The weight per square foot brought upon the bottom by a breakwater consisting of a combination of caissons as above described was but 1,866 pounds. It proved that the bottom would support an enrockment breakwater, however, and rock from Culebra Cut was a drug in the market, so that it proved unnecessary to resort to caissons.

Regarding the matter of patent, an application was made in 1900 and patent was granted me the following year to include the following claim:

"1. A caisson or similar structure, comprising a mass of concrete with stiffeners embedded therein, arranged to provide air-chambers or voids, so that flotation may be availed of to introduce the caisson into position as part or all of a foundation, breakwater, pier, retaining-wall or revetment, substantially as described."

In the description of the invention, forming part of the letters patent, occurred the following:

"It is the office of the metallic or wooden stiffeners to act by special virtue of their tensile strength, while the concrete or other masonry furnishes the necessary weight, surface areas, and resistance to compressive stresses."

At the time I applied for this patent I felt, as most inventors naively do, that many persons were doubtless about to develop the same thought into patentable form, and that there was imminent danger that the Government would be compelled to pay royalties for the employment of a method of construction for breakwaters and the like which appealed to me strongly as being at once cheaper and more durable, under certain conditions, than any other. My principal reason then for applying for a patent was to protect the interests of the United States, which purpose I certainly accomplished, for it came to my knowledge several years after my patent was granted that only the evidence it furnished of priority of invention prevented the issue of a patent to another party. I take the liberty of dwelling thus upon the facts above stated for the reason that some engineers, and probably some officers of the Corps of Engineers, do not believe in the propriety of patents for engineering inventions. I do not know whether today I am certain in my own mind as to the highest ethics in such matters. I can not speak of the great body of civil engineers of the country, but note that apparently most officers who have really conceived of things novel and useful in the field of engineering have in fact patented them. As to how many, like myself, have licensed the United States to the free use of such patents I am not informed.

War Teaches Us to Express Our Thoughts in Writing

The World War was a most potent force for education not only in matters military but in the fields of commerce and industry as well. Among its collateral benefits is noted an increasing appreciation of the value of a concise but clear and comprehensive literary style which is exemplified at its best in a well-drawn "general order," and is also characteristic of the letters written by military men on matters of military concern. That the faculty of brief but adequate expression had been neglected in civil life before the war was strikingly illustrated in the early days of the struggle by the correspondence of many, if not most, of the civilians inducted as officers into the military service.

The following on this subject is quoted from a recent magazine article:

"Many business firms have realized for a long time how costly a thing unskillfully constructed letters may become. Ambiguity, omission of essential details, unnecessary length, untranslatable signatures, lack of friendly personal touch, roughness of diction, omissions of enclosures, the clumsy or inadequate form letter—all these and other sins of correspondence are mischief-makers. In some large offices specialists review the daily correspondence, in the effort to effect improvement, and call attention of employees, and owners, too, if necessary, to the delinquencies and bad habits of their letter writing. They work out form

Digitized by Google

letters, and seek generally to reduce the length of correspondence wherever it is possible and otherwise act for efficiency. Not only does the result show itself in relations with those with whom the firm does business, but there is a direct money-saving in bills for stenography and typing and office supplies. The Army and Navy training has helped this work along. Many a man who thought he could write a first-rate letter has had his conceit destroyed by some one higher up in the service who received his efforts. The Army rule of typing the signature as well as penning it has been adopted in some establishments, which is an excellent plan, for many signatures are blind, though their owners do not always realize the fact. 'Dictated but not read' and 'signed in the absence of' are less often seen than formerly, because they could not be used officially in the service, though the protest against the practice had already been heard and in many cases heeded. At the top of a letter the subject to be treated is now often found. This, too, had previously been established as a practice in some offices. Altogether this new influence which came into business out of the war should work out results of a good deal of importance. The beginning has been made. The added impulse should send the movement for good letter writing a long step forward. Among the customs which might well become general is that of indicating, when answering a letter from some one connected with a large company, the person for whose attention the letter is intended. In every large office time is wasted almost daily in trying to determine for whom letters are intended."

The German Long-Range Gun

At 7.15 on the morning of Mar. 23, 1918, only two days after the Germans opened their offensive against the British Fifth Army before Amiens, the people of Paris were startled by an explosion of something that had fallen on the Quai de Seine. This explosion was of such magnitude that it was heard over practically all of Paris. A few minutes later it was followed by a second, near the Seine on the Rue Charles V. These explosions then followed regularly throughout the day at intervals of 15 minutes, covering the major part of the city. Up to that time Paris had never been bombarded except from aircraft, and naturally everyone thought at first that these were aerial bombs, probably dropped from aircraft at such great height that they could not be seen. This theory was soon found to be untenable, and in their surprise at these mysterious explosions the entire population of Paris practically suspended all their normal activities; the shops, ticket offices and even parts of the Metro System closed down, and the streets were thronged with people looking skyward to locate the source of the shells.

It appears that the Germans in emplacing long-range guns from which these explosive shells were fired had so timed the commencement of fire as to practically have it coincide with the beginning of the great Mar. 21st offensive, with the intention of throwing Paris into a panic and thus breaking down the French morale and at the same time improving their own. For a few days, while the source was a mystery, the effect seemed to be more or less in accordance with their expectations—certainly until the ordnance experts determined from the fragments and the direction of penetration of the shells that they were coming from the vicinity of Soissons, about 70 miles away. When this was discovered the shells no longer frightened the inhabitants of Paris, but simply angered them at this unjustified attack on their city.

Many interesting theories were advanced during the first few days after the commencement of this fire in the various newspapers. By some it was maintained that they were projectiles fired from larger projectiles, a fuse driving the smaller projectile forward at increased velocity at some point in the flight of the larger one. Other theories suggested that these shells were being fired from some of the abandoned quarries a short distance from Paris. It was soon determined, however, that the shells probably came from a long-range gun located near Soissons. It was found that points of burst of the shells had a very great dispersion in the direction of fire and relatively small dispersion perpendicular thereto. It was also possible, by consideration of the bursts and fragments, to determine the probable life of each gun firing, which was soon found to be about 50 rounds. The dispersion for the new gun was very small compared to that after the tube had been considerably worn. It was also calculated that the muzzle velocity of this gun should be about 4,500 foot-seconds, and it is interesting to note that the actual muzzle velocity used was between 4,750 and 5,000 foot-seconds, learned from the Germans since the armistice.

The material effect of these shells was decidedly less than that of the 500 to 750 pound airplane bombs, the latter frequently making holes as great as 30 feet wide by 20 feet deep, whereas these shell holes were rarely greater than 12 to 15 feet diameter and 4 to 6 feet deep. During the entire 44 days of bombardment, ending Aug. 9, 1918, 303 shells were fired, of which 183 fell within the walls of Paris, killing all told 256 persons and wounding 620. The greatest casualties were caused on Palm Sunday, Mar. 29th, by a shell which fell on the Church of St. Gervais, near the Hotel de Ville. On account of the attendant circumstances this may be classed with the invasion of Belgium and the sinking of the *Lusitania* in building up a feeling of hostility against the Germans throughout the world. Here, again, is a good indication of the faulty psychology of the Germans in their estimate of the effect of their frightfulness on the morale of their enemies.

The Germans used for this long-range bombardment seven guns and had three others under construction. The original caliber was 8.15 inches, but practically all of the guns were rebored after being considerably worn to a caliber of 9.3 inches. They were constructed from worn-out 38 cm. (15-inch), 45 caliber (17.1 m. or 56 feet in length) naval guns. A tube 98½ feet long was inserted within the 38 cm. gun, 40.23 feet projecting beyond the end of the original gun. This tube was reinforced by a jacket which extended beyond its end so as to support an additional tube 23 feet in length inserted within this jacket. One of the peculiar features of this gun is that this end section had a smooth bore with an inside diameter equal to that of the main rifle tube plus twice the depth of the grooves in the rifled section. This portion was assembled to the gun in the field and was not removed until the gun was worn out. The original weight of the 38 cm. gun was 152,550 pounds, and of the long-range gun 318,000 pounds.

There has been much speculation as to the reasons leading to the addition of the smooth-bore tube. The best ordnance opinion is that this smooth-bore section has a stabilizing tendency on the projectile tending to decrease the deviation from its theoretical path due to the increasing angular velocity caused by the rifling. There is, however, some evidence that the smooth-bore section allowed additional linear velocity to be given the shell.

Another interesting point in reference to the ballistics of the gun is the very high muzzle velocity secured, viz, about 5,000 feet, which was accomplished by the very long tube, about 121½ feet over all, and a very slow-burning powder developing high initial pressures. The maximum range of 76 miles was secured from this gun at 55° elevation, which,

Digitized by Google

according to theoretical considerations, would not give as great a range as an elevation of about 45°.

The carriage was of the railway type used for the 38 cm. rifle, from which the trucks were detached and the carriage set on a prepared base capable of rotating 360 degrees. This base was of built-up steel plates laid directly in a pit. In the emplacement in the Bois du Chatelet, 5 miles north of Chateau-Thierry, no concrete whatever was used. Inasmuch as the Germans held the site of this gun only about six weeks, it is evident that the emplacement was constructed in a shorter period than that, being carried to the site in large sections made up in the foundry.

The projectile used in this gun weighed 264 pounds, the charge for which was divided into two parts by a diaphragm, one fuse being provided for each of the two parts of the charge. A noticeble fact in connection with the projectiles from these guns is that there was not a single case recorded of a shell which failed to explode on impact, indicating a very perfect type of construction and also probable benefits from the two fuses.

There are some interesting camouflage features connected with the gun in the Bois du Chatelet. The spur track left the main railway line in the open field, and after passing over about ¼ mile entered a forest. The spur tracks through the open field were camouflaged by cut branches of trees laid over an area extending out several hundrd feet on each side of the track. The aviators could tell that some kind of work was under way, but were not able to discover the spur track. Within the forest and including the immediate vicinity of the emplacement, wooden boxes were set upright in the earth under the tracks at intervals of about 30 feet, and in these boxes small trees were inserted during the day, thus giving the original appearances to the forest During the construction camouflage screening was also used over cranes and other appliances.

It is the general opinion that these guns produced no effects, either material or moral, at all commensurate with their cost and the difficulty of constructing and operating them. It is unlikely that any such weapons will be again employed in the near future.—Lt. Col. H. W. Miller, in *Mech. Eng.*

A Motor Vehicle for Every Ten People

Ten million motor cars and trucks will be in service in America by the end of 1920, according to the statisticians of the B. F. Goodrich Rubber Co. There are now more than seven and a half million registered in the 48 States, which is an increase of 26 per cent over the preceding year.

The following are the numbers of people to each motor car in certain foreign countries:

England	270
France	400
Germany	680
Italy	1,000
Austria	2,700
Russia	5,300

In America there are about 10 motor cars to every motor truck, but the motor-truck output is increasing even more rapidly than the motor-car output. In 1904 America produced only 400 motor trucks, whereas in 1918 the production was 227,000. Astonishing as this increase has been, it is dwarfed by the rate of increase of tractors, of which the output was about 30,000 in 1916, as compared with 315,000 in 1919. Most of the tractors have been sold to farmers, but many also to contractors.—*Eng. & Cont.*

Military Road Building Not A Science—Only A Job

Continued from page 168

many, with low narrow shoulders, the road might break off on the edge. Trucks would tend to stay off the high French shoulders, while they would cut up the low German shoulders. Soft limestone in France was easily patched, while the hard rock in Germany did not lend itself to patching. Much more reinforcing was necessary in Germany, and, in addition, the thin German roads required extra thickness being put on in many places. There were in Germany more road rollers, proportionally, so this work could be done. The fact that the Americans had control of everything in Germany, including rail transportation, made heavy work much easier than in France.

About Christmas, 1918, great stretches of road in Germany broke completely down, due to a combination of insufficient drainage, thin metalling, and want of control over truck drivers. Roads were closed and reinforced, and traffic at times stopped. However, they got by without catastrophe.

I did not see any of our roads in France completely broken down, because we either put rock on them or stopped the traffic before the rock could be completely mashed into the mud. If we had let a road get thus, we couldn't have found the stone to rebuild it.

However, I saw one road used by the French turned into a continuous quagmire for 20 or 30 miles. The stone had entirely disappeared and nothing could be done but wait for summer and build a new road.

The frost heaves in France are interesting. The French road service issues voluminous and careful instructions about stopping traffic during them, in order that roads may not be ruined. Apparently this trouble breaks out only in spots, but might develop long stretches. It seems that water which gets under the road surface freezes and when it melts it produces a mass of stuff like very thick soup from the road surface down. If traffic strikes this before it dries or is repaired the road will be ruined. Such a surface has to be dug out and replaced with dry material. We had a few of them but we stopped traffic and repaired them, and so kept out of trouble. One division was completely tied up for a while because traffic was not stopped soon enough. Only animal transportation could be used until roads were repaired.

So, the technical road business from a military standpoint is nothing but good organization, drainage and rock, with traffic regulation if possible. The real problem is common sense in administration and supervision, which must be applied with punch on the job.

After this was written an officer familiar with the road work in Europe read it and said, "I see what idea the article intends to convey, but it doesn't say it." So let us say it. Technical road knowledge in war is of no importance compared to the ability to make men work, and to make them work with whatever facilities are available for the job on hand.

Vol. XII MARCH-APRIL, 1920 No. 62

The Construction Division—A Dispersion of Force

THE Construction Division of the Army was an emergency organization, brought into being by the War, for the purpose of taking over the construction work of the Quartermaster Department. Its operations did not extend to the theatre of war. They were limited to the home country, which was not touched by the war, and where the conditions were, in many respects, more favorable than those which usually exist in time of peace.

In the theatre of actual conflict, where construction work must be done under all the disadvantageous conditions incident to warfare, neither the Quartermaster Department nor the Construction Division was called on to execute any of the emergency projects of construction. This work, including all construction in the battle areas and under fire, naturally and logically fell to the Corps of Engineers, which for over a hundred years the Government has maintained for the express purpose of executing construction work under war conditions, where the agencies of peace cannot function.

To achieve success under such conditions our military engineers, our construction men, must be both soldiers and engineers. They must be thoroughly trained soldiers, thoroughly conversant with military methods and the fundamental economics of warfare, which differ in some essential respects from those of peace. The direction of all construction in the theatre of war must be in the hands of such men. To place non-military men, however efficient in civilian practice, in control, would be to court disaster. This was fully appreciated by the military authorities of the American Expeditionary Forces, and all work in the theatre of war was directed by the Corps of Engineers.

The officers of the Corps of Engineers proved themselves qualified to do the work—they proved this by doing it. They were qualified first because they were thoroughly trained soldiers, and second because they had been given practical experience in engineering construction in time of peace.

In any future war in which the United States may engage, the difficult emergency construction work within the theatre of war, from the battle line to the base ports, to our own frontier, or even within the frontier, will fall again to the Corps of Engineers. Such work, under such conditions, is their special and natural function.

To keep the Corps of Engineers constantly trained and ready to do this work when necessary, to "deliver the goods" when called on, is vitally important to our national security, and an essential part of any plan of preparedness, or national insurance, or military policy.

In the past the Corps of Engineers has secured this vitally necessary construction experience in the execution of the public works on rivers and harbors, lighthouses and other similar projects. Without such experience they would not have been equal to the mighty task which devolved upon them in France.

In the early days of our history the Military Academy at West Point was the only engineering school in the country and, in consequence, its graduates in the Corps of Engineers were called upon to organize, direct and execute numerous public works, many of which were only remotely connected with the national defense. They organized all the public surveys; they built lighthouses and public buildings, were connected with the construction of railroads, organized the public works in all new possessions, and were invariably

Digitized by Google

called upon whenever an emergency in the way of construction confronted the Government. This excellent and varied experience was one of the important causes of the reputation for efficiency in construction which the Corps of Engineers established over a hundred years ago and which it has since consistently maintained.

But, with the growth of the nation and the reorganization and reassignment of its activities in connection with new Governmental departments, many of these duties have been taken out of the War Department and the Corps of Engineers has lost these opportunities for its necessary training. The government surveys are no longer in its charge (except the survey of the Northern and Northwestern Lakes); the construction of lighthouses is placed elsewhere; civil public works departments have been established in the outlying possessions, and the reclamation of arid land, though akin to the work of the Corps on Rivers and Harbors, was assigned to another department. If a Bureau of Public Works should be established, it may, unless special arrangements to the contrary are effected, result in depriving the Corps of the work on Rivers and Harbors, the only field in which engineer officers can now obtain the experience so essential to them. Such action is by no means necessary and, in fact, would be most unwise for, if the World War demonstrated anything at all, it proved that the rôle of the engineer in war is more important and more diversified than ever before in history. The so-called military engineer must now be not only a specialist in the design and construction of works of defense and offense, but must be thoroughly versed in those practices of engineering which find their principal application in times of peace. War has become a vast and complex affair and the engineering of war is involved in the complexity. A sound training and a broad experience, both of a military and an engineering nature, are indispensable.

Notwithstanding this very recent lesson in national needs, it is apparently one of the chief aims of some who are now agitating the establishment of a Department of Public Works, to deprive the Corps of Engineers of the last opportunity that remains to it for gaining experience in time of peace. This is a very short-sighted policy from a patriotic point of view, as all should be able to see. It gives ground for some suspicion as to the real motives of some of those behind the agitation, which is undoubtedly entitled to support in so far as it aims to bring about the coördination or correlation of similar activities in the various governmental departments.

Contrary to the practice of all other countries, and for some reason which is difficult to understand, or more probably through lack of definite policy and without any good reason, the construction work of the Army in time of peace, has never been assigned to the Corps of Engineers, although they are always called upon to do it in time of war. Army construction work during peace has heretofore been performed by the Quartermaster Department. The late war indicated the advisability of relieving the Quartermaster Department of this work, for the reason that it had too many other important and unrelated functions to perform. Yet instead of turning it over to those who are in every way naturally fitted to perform it, and who in the interest of military preparedness, need the splendid experience which it would afford, it has been proposed to organize an entirely new department to perform such work.

It is very difficult to perceive any good reason for adopting such a policy. Of all the government construction work, that for the Army most nearly approximates in time of peace the work that the Corps of Engineers is inevitably called upon to do in time of war. It would afford the officers and men so far as it goes (it being normally very limited in amount and variety), the most valuable construction exper-

General Pershing indorses aims of the Society of American Military Engineers

The following letter has been received from G. H. Q., A. E. F.

AMERICAN EXPEDITIONARY FORCES
OFFICE OF THE COMMANDER IN CHIEF

Washington, D.C.
March 23, 1920.

Gentlemen:-

I have been much interested in reading the February issue of the official journal of your Society, The Military Engineer. I am glad to see that steps are being taken to interest the engineer in civil life in the military aspects of his profession. The complete cooperation of the engineering profession throughout the country is necessary to any policy of National Defense, and I feel certain the Society of American Military Engineers will serve a valuable prupose in furthering this cooperation and interest.

Very sincerely yours,

John J. Pershing

The Directors, Society of American Military Engineers,
Washington Barracks,
Washington, D.C.

Digitized by Google

ience which they can obtain in time of peace. It is purely military work and not open to the objection of being a "civil function," however little justification such an objection may have when it is against the best interests of the national defense. In an effort to avoid giving to the Corps of Engineers the work which is logically its function, in order to prevent the Corps from obtaining any experience which might render it more useful in case of war, it is proposed to establish a new department, with additional personnel and additional overhead expenses. And the Corps of Engineers is to be maintained in time of peace in comparative idleness while those who will *not* be called upon to do the work in war are gaining the experience which the Corps must have if it is to continue to be dependable in an emergency.

It is stated by the advocates of a separate Construction Division that the efficiency of the division "will be impaired" if it be turned over to the control of the Corps of Engineers, because "such men do not have the kind of technical training which is required in the construction work." This is equivalent to saying that officers of Coast Artillery or Cavalry, or Infantry, or any branch of the service except Engineers, are better qualified to direct construction work than Engineer officers, because generally speaking they (the officers of other branches) have had no previous experience in such work; whereas, generally speaking, Engineer officers have had previous experience. Is such an attitude in accord with reason, experience, and common sense?

The work of the Construction Division was actually performed largely by civilian experts and will in any emergency again be thus performed. The most expert of these civilians have long since left the military service, which they entered for the war only for patriotic reasons. To transfer the activities of the Construction Division to the direction of the Engineer Department simply means that the chief and superior officials of the division will be engineers with previous experience in construction and in the direction of public works of all classes, instead of officers formerly of the line or staff who generally will have had no such previous experience. Is an Engineer officer less qualified to direct construction work than an officer of the line of another staff department?

Because the Corps of Engineers is a carefully selected body of technical men, because it has a reputation for honesty and efficiency extending back to the beginning of our history as a nation, because it "made good" on the Panama Canal and still better on the huge construction project in France, because the nation needs a trained corps of engineers for war, because that corps needs construction experience in time of peace to prepare its officers for their duties in war, because the army construction is the best construction training that can be given our Corps of Engineers in time of peace—because of all these things, is it wise that a new and expensive department should be created to do the work that the Corps of Engineers can do and should do?

We wish to cast no reflections upon the work of the Cantonment or Construction Division in the late war. But however well it may have done its work it was not, and never will be, the organization that is relied upon to do the real emergency construction incident to a great war. That work, as always heretofore, will, of military necessity, be done by the Corps of Engineers, and its officers should be given every possible opportunity in time of peace to acquire the construction training necessary to maintain their efficiency for *war*.

Under the new army organization, proposed by Congress, which provides for promotion from a single list, the Corps of Engineers will receive no increased rank or emoluments from the work of army construction. They will get nothing out of it except experience and training which will be of the greatest value to the country. And the government will save expense by not creating a new and wholly unnecessary department.

The statement that "the Corps of Engineers has never had any experience which would qualify it to do the work of army construction," has been made so often in certain quarters that certain people who have not sought the facts are beginning to believe that it must be true, simply because it is so frequently repeated As a matter of fact, no statement could be more utterly untrue or absurd. There is no other organization in existence whose experience so well qualifies it to perform the work of *army* construction. The Corps of Engineers has for over a hundred years performed a large part of the construction work of the army during peace, and during several great wars. The variety of this work, as shown in the article on Army Construction appearing elsewhere in this issue (and in that describing the work in France in our January-February issue), is almost infinite. If a hundred years of continuous experience is "no qualification," how long will it require for a *new* organization to really qualify itself?

The Regular

The shouting and the tumult dies,
The Captains and the Kings depart.

EVEN SO! The shouting has long since died out. The glory of war and of warriors has faded. The reaction has become chronic. But this is not all.

Economic pressure, ruthless and severe, forces the regular soldier and his family, living on his reduced pay, to face discomfort, embarrassment and hardship—even privation and despair. Professionally, the

Digitized by Google

bottom seems to have dropped out. His capacity, demonstrated in war, counts for naught. He is back again in the rut, little job, little prospect, little pay to meet greatly increased needs. And who cares? The regular feels he's quite forgotten, if not indeed despised.

Then, through old friends, or through the citizen-officer whom he commanded during the war, come offers from business people who have achieved new business successes. Great advances are in progress. Able men are in demand. Men who proved their quality in emergency can obtain positions bringing more than present army pay, and offering greater financial prospects for the future, and the regular thinks hard.

He can do it. He has faced worse difficulties and won. And who cares, anyway? Hasn't he been forgotten in the service? What does his experience count for now? What prestige has a soldier and what can he expect? Will not the pacifists and the pro-German and the reds all hate the uniform the more bitterly in the future? Yes, and what about all the buncombe that is being put over on the soldier now— being put over by men who know not war? And what of his poor, dear wife? (This hits him hard.) She is doing all the work now in the little apartment—all they can afford. And then what of the children and their future?

There, awaits the new position, big work, big prospects, the old pay guaranteed and more promised—a splendid opportunity!

The regular reasons that he ought to accept for his own good, and for his family's. He owes it to them. He owes it to himself to do work worthy of him.

Well, why not? Somehow, the regular doesn't say "Yes," but why not? Back in his head something says quitely, "No." It isn't laziness; it isn't fear of failure; it isn't love of the pomp and glory of war. No, the regular has been through the fire; the crystal of his vision is purified and clear. The "No" is something deeper and beyond. The very soul of the regular is struggling—his instinct says he *must not*—and this is why:

Granting success, wealth, fame, ease and comfort for himself and his family "on the outside," granting this and even return to the colors in the next emergency with increased grade, prestige and relative personal advancement; granting all these benefits and justifications, the regular remembers that he is a Regular and therefore he can't quit.

He can't quit, for the Army is in a hole. It's the darkest hour of its and of his career. Everything is against him and the Service. He must not quit. He realizes the Service needs him now as never before. Someone must hold on. Someone must stick by the ideals and true worth of the Army, to keep it fit, keep it ready, keep it clean of inefficiency, to weed out the dead timber, ruthlessly, and it takes strong, fearless men to do that. True men must stay, unbaffled by false doctrine, weak follies and oft-repeated fallacies. They must stand staunchly, holding to the faith, quietly remembering in all the clamor, clatter and criticism the old motto we learned as lads to hold sacred: "Duty, Honor, Country."

That is the reason.

Old pal, have courage. Set your teeth. Be a Regular—dependable, constant, worthy. And don't quit—YET. For there is still hope, and the Army and the country need you now.

This is the spirit of the regular. This is the spirit which has held the army together in spite of what sometimes appear to be deliberate efforts to destroy not only its morale, but even its patriotism.

Let us be steadfast, true to our ideals, worthy of our glorious record in war as in peace, superior to abuse, criticism, contempt, hardship and poverty. For America needs her army, and the backbone of that army must not give way under the strain. Let us hold on yet a little while, and hope for better days.

—J. C. H. L.

Standardization in Military Operations

THE war has taught us, if we needed any teaching, the vital necessity of standardization in quantity production. It has also taught, what we did not before fully realize, that the nation that leads in quantity production must, unless overwhelmed at the start because of unpreparedness, eventually win any war.

Standardization is essential, yet invention and improvement must continue. Therefore we must standardize; continue improvement, and move forward by long, not mincing strides, to new standardizations. Progress must be made in large strides which permit the standardization of each improvement, and not by continual changes which prevent standardization and hence limit quantity production.

Engineering and Contracting says that *excessive* standardization tends to lessen progress by invention, and refers to recent progress in the development of the steam railway and the motor vehicle. The former has arrived at an era of unchanging repetition, whereas the latter is still improving at a rapid rate. The point of view is interesting. Standard designs are not necessarily economical, says our contemporary. The answer would seem to be that too much of anything is bad. Standardization has a value which cannot be denied. We have only to think of what lack of standardization in pipe-fittings, for example, would mean. What we need is temperance, not abstinence. not too much standardization which discourages in-

Digitized by Google

vention, not too much invention which disregards the value of standards.

The beginning of any industry is the natural period for invention, but standardization makes for progress on a large scale. As time passes more standardization and less invention is the logical process of development. The two should not be natural enemies, but natural helpmates. Standardization, like invention, should keep up to date. Let invention devote some of its efforts to giving us intelligent standardization.

This matter is of particular interest to the military engineer. There is no practitioner who is more frequently called upon to improvise to meet emergencies—this being a form of invention. Yet on the other hand, there is none who benefits more by standardization. Standardized materials and methods reduce the time required in construction, which is always the chief concern of the military engineer. During the late war every effort was made to standardize our materials and methods wherever this could possibly be accomplished. Standardized buildings, standardized trenches, dugouts, pill-boxes were found to be absolutely essential. As indicated in the article on Military Roads by Colonel Graves, which appears in this issue, standardized methods of road repair were vital to the continuance of transportation. The lack of standardization in artillery calibers and ammunition, due to the alliance of many nations and the rapid developments in ordnance manufacture, was most embarrassing. The lack of standardization in aeroplane construction threatened our superiority in the air. The future developments in the interest of national security will consist largely in the standardization of our equipment for war. The vast amount of supplies and equipment consumed in modern war could not be produced without the aid of standardization.

We witness then the peculiar paradox that warfare, while the least subject to rules and precedent and the most stimulating to invention of all human endeavors, is yet the most dependent on standardization. The belligerent who clings slavishly to his prewar standards will soon find himself hopelessly distanced by an active, resourceful and inventive enemy. But the belligerent who attempts to improvise all his equipment new as he goes along will find himself smothered by the standardized shells and standardized aeroplanes of a foe who is prepared for the conflict. And so invention and standardization must march hand in hand along the road of progress. We cannot dispense with either. Each is a check or balance for the other, but cannot be permitted to become a hindrance. As in most other affairs there are two sides to the question, and the golden mean between unreasonable extremes must be found.

The Dempsey Case

THE wave of indignation from the American Legion announcing that Jack Dempsey, the American heavyweight champion pugilist, is a slacker, has brought about an investigation and now indictment before Federal Grand Jury in California. The ex-soldiers of the American Legion say if Dempsey is proven to be a slacker he must not appear as the American heavyweight champion against Georges Carpentier, the Frenchman who fought all through the war.

It has been claimed that this man fulfilled his patriotic obligations by working in the shipyards, and that he was thus excused from rendering actual military service. Nevertheless, it is humiliating to Americans to feel that their champion fighter failed to fight in France. The American Legion is taking the legal means of expressing a just and deep indignation. The man whom Dempsey deposed as champion seems to have been even less worthy of national respect during the war. These two great fighting men, who should have displayed the best of courage and good example, now receive only the contempt of the nation.

Whose fault is it?

It's our own fault. We have degraded and debased the sport of boxing by legislating it into almost a criminal class. Before the war it had lost public confidence, and contests could not be staged in any state in the Union.

When the war came America called for all the strength and manhood of the nation to serve the flag. The better to fit our men for battle, instruction in "the manly art of self defense" was inaugurated at all the training camps. Hundreds of ring fighters and former ring fighters volunteered their services as instructors. But very few of them actually went overseas, and very few fell in action. As a body, ring fighters did not make in the war the showing we had a right to expect of them.

This is not true of other sports. The sporting instinct, which is developed in football, tennis, baseball, polo, and many other games, proved itself in the great struggle, since with few exceptions practically every outstanding performer in these sports came to the colors. The exceptions were mainly in baseball, a sport which, like pugilism, has become too highly commercialized. Nevertheless, hundreds of baseball stars did, as individuals, volunteer for combat service. The same is true of every other clean sport in America. The leaders of sports were leaders in the fighting. Athletics more than justified themselves in the struggle.

Now if boxing were really a *sport*, recognized as such by the country and worthy of our respect, this

Digitized by Google

humiliating circumstance of our national "champion" appearing as a national "slacker" could not exist. Had the American people kept boxing a clean, manly sport; had they given it proper support and encouragement and prevented it from becoming sordid and commercialized, we would not now be witnesses to what must be regarded as a national disgrace. Dempsey and his managers would have been ruled by the same fine instincts as the devotees of other sports, and our national champion could not have done otherwise than prove his manhood and sportsmanship on the field of battle.

We have wondered why England is apparently so backward in pugilism at the present time. It is largely because so many of her pugilists lost their lives in the bitter struggle. Many of England's ring fighters went to battle and many of them never came back. Boxing is an honorable national sport in England and all through the British Empire. Throughout the great British Armies boxing contests are of regular occurrence, and at each such affair there is at least one bout between officers. Boxing is a cleaner sport than under our rules. When one opponent downs his man he steps back and gives him a perfectly fair chance to regain his feet.

At one of our training camps in the winter of 1918, a group of British officers, training specialists, attended the American boxing bouts. During one of these affairs a boxer floored his opponent, and stood over him in a menacing attitude, apparently on his toes to knock him out as soon as he had regained his feet. A British Major jumped to his feet and started to climb into the ring. He was red with indignation at the apparent violation of the rules of sportsmanship. He was pulled into his seat by his fellow officers, and then realized that he had no part in the game. The incident indicates the difference in the American and British points of view. When a British boxer floors his man he stands back until he is completely on his feet. Every Britisher knows this and the officers who father the game in the Army are keenly and vitally interested in the observance of the sporting rules, which to them is of far more importance than who wins the contest and pockets the "prize" money. In America we commonly call the sport of boxing, "*prize* fighting"—a term which too well expresses what it has become.

We should learn a lesson from this Dempsey affair. We should give boxing a fair chance, put it on a clean, sporting basis, make it again the "manly art" which it once was and always should be. A clean boxing contest brings out the best there is in a man of courage, stamina, endurance and self-sacrifice. "Prize fighting" as conducted in America too often develops the lowest and most sordid traits. It is not the fault of the pugilists alone. It is chiefly the fault of the American people who have degraded and commercialized a manly sport.—J. C. H. L.

Civilian Engineers in the U. S. Engineer Department

THE Corps of Engineers of the U. S. Engineer Department is not an exclusively military organization. In the vast program of construction which the Corps has planned and executed it has at all times relied greatly on the civilian engineers who are an essential part of the organization. The reputation of the Corps is built upon the splendid work of its civilian assistants, as well as that of its officers. These civilians are highly trained experts in various lines, but they do their work with so little noise and so little thought of advertising themselves that they have never received the public recognition which is their due. But the Corps of Engineers fully appreciates their efficiency and above all their loyalty, and it is fully aware and gratefully acknowledges that without these splendid co-workers it would never have accomplished the great projects with which it has been charged, and would not enjoy the reputation for efficiency which it has to-day.

That most of these civilians remain long years in the service is sufficient refutation of the statements that military and civilian engineers cannot work harmoniously together in producing results.

It will thus be apparent that the Engineer Department is composed of both military and civilian engineers, who by long coöperation have learned each other's worth and how to work harmoniously together. In other words the organization is the same as that proposed for the new Construction Division, except that all its members are *engineers* with practical experience in construction.

Civilian engineers without any military training cannot *alone* conduct *army* construction in the most efficient manner. Military construction must be done by a military organization whose directing heads understand military requirements as well as the best and most up-to-date methods of construction. This organization in time of peace must necessarily employ civilian engineers and civilian labor. In time of war it will of necessity be assisted by temporary officers of the reserve corps and will employ the labor of troops. The Corps of Engineers is such an organization, and is the only one which exists or which has been even proposed. It has been eminently successful in peace and still more so in war, and may be "judged by its works."

The Use of Aerial Photography in Mapping

By

E. H. Marks

Major, Corps of Engineers

There has been a great deal of publicity given to this subject and there is a tendency in many quarters to believe that it has entirely superseded the orthodox methods of surveying or is a science complete in itself. These ideas are erroneous and should not be allowed to continue, for they will serve only to hinder the proper development of aerial photography.

Now just where does aerial photography fail in being a thing apart from surveying? *In no case, at the present time, can we obtain from aerial photographs alone the data necessary for the principal uses to which maps will be put.*

The main omission in these photographs is the representation of relief or relative elevations of points on the ground, and inasmuch as nearly all engineering and military uses of maps require primarily this data as to relief, a photographic map will not itself fulfill the general needs of the country. This data as to relief must of necessity be secured by surveyors or topographers on the ground.

Another vital necessity for maps which cannot be obtained from the air is the control. Projection must also be considered, the necessity for which is brought about by the fact that the earth is a globe and our maps are flat surfaces.

Aside from the three essential and fundamental elements necessary in map construction mentioned above, and upon which too much stress cannot be laid, the photographic mosaic gives a very good pictorial idea of ground, so far as certain features are concerned, but it is not a map as engineers understand the term, or as required for engineering and military purposes.

The photographic mosaic is subject to errors, caused by the tilting of the camera at the tme photographs are taken, those due to ground relief, those due to shrinkage or expansion of individual photographic prints in developing or printing, those due to the personal errors in pasting photographs together, those due to curvature of the earth, those errors in scale caused by a varying height of the plane in flight, and errors due to lens and certain types of shutters, and a number of others.

Individual photographs, as opposed to the mosaic, can however, be used to excellent advantage by surveyors and topographers to assist the orthodox methods of map making, and when properly taken and used will probably lessen the cost of the work and certainly hasten its completion. If we have a system of ground control tied to points which can be recognized in photographs, it is possible in territory of low relief to restitute the photographs, and by plotting the desired information in connectioin with the established control, obtain a plane map showing roads, woods, houses, and other cultural features, as well as streams, lakes, and so on. This plane map can then be taken into the field by topographers, and the contours showing relief added, thus giving us a complete map for practically all uses.

To illustrate more fully how closely the question of aerial photography is connected with that of surveying, take the very simple case of a plane flying over absolutely level ground, plane and camera being held horizontal. In this case, the plate resulting from a single exposure would represent a true map were there no distortion caused in developing, but to determine the scale of this map it is necessary to measure with transit and tape some distance on the ground which can be compared with the corresponding distance in the picture. The scale could, of course, be determined without the ground measurement if the exact height of the plane were known at the moment of taking the picture, but there are no altimeters in existence so accurate as to determine this elevation, with necessary precision. This simple case of an absolutely horizontal plane and camera is practically impossible to secure, and a true map will not result from a tilted picture or one over other than level ground, without further treatment. There are, however, well known methods of restituting photographs, providing the location and elevation of four points on the ground and visible in the photograph are known, but the means of restitution are laborious, and when applied to photographs over considerable territory, stupendous. The problem of horizontalization is, then, one for which some solution should be made to obtain the full benefit of aerial photographs. I, personally, do not think it will be practicable to secure a gyroscope to hold a camera level, but I believe that a gyroscope may be developed and probably has been developed, which can be connected with some form of indicator to determine the tilt of the plane at the instant a photograph is taken, and it would be comparatively easy were this tilt known to use a transforming camera to restitute photographically, and thus avoid the laborious hand restitution.

The complications caused by relief of the ground are difficult of solution, but it is possible that this present complication will be of assistance in determining the relief of the ground from photographs by the application of stereo-photographic principles, and investigation is being made on this line.

It is scarcely necessary to mention the great value of aerial photography in map revision, but here again the question of laborious and costly restitution enters and awaits the solution of the horizontalization problem.

To sum up, aerial photography has not reached a point where it can supplant the present day methods of surveying, and its application for accurate original map work is to-day pretty much limited to comparatively flat terrain, but the advantages in surveying which will arise from the use of aerial photography in this type of terrain are enormous, and in revision work aerial photography has to-day a wide field of usefulness.

Tractor replaces the elephant.—Teak is cut in the forests of Burma, hauled to the nearest stream, floated to market, where it is hauled out of the river. This work has been done for many years by the elephants sung about in Kipling's "On the road to Mandalay." A leading lumber firm of Burma has recently employed tractors with considerable success, on ground too soft for elephants.—*Forest Service Bulletin.*

The Infantry Must Dig as Well as Fight

By

Harold C. Fiske

Major, Corps of Engineers, late Colonel, Division Engineer, 3rd Division and Corps Engineer, 3rd Corps, A. E. F.

THE necessity for trenches in almost all phases of modern warfare and their proper relation to the activities of all branches of the service are so well established that a discussion of these points is here unnecessary. The force on the offensive advances against the enemy, meeting at first with only nominal resistance. Eventually this resistance increases. The attacking force proceeds more slowly and makes increasing use of the protection afforded by the natural features of the terrain. Finally, the point is reached where the enemy's fire prevents further movement forward, and the attacking force must prepare to hold the ground already occupied. Natural protective features are used to the utmost extent; where these do not exist artificial protection must be obtained and the soldier equipped with his entrenching tool begins, each man for himself, to dig a hasty rifle pit. This affords the individual the most quickly obtained means of protection. If the enemy's resistance weakens the command again advances, and abandons these temporary shelters, but if the resistance does not diminish, and particularly if it increases, then more elaborate protection is needed, and that perhaps very promptly. In this case each man first strengthens his own personal defense and then, if possible under the supervision of his immediate commanders, begins to connect his defense with those of the men adjacent to him. In this way the beginning of the trench system is formed.

Prior to 1914, military training in trench work did not extend in much detail far beyond this stage, but during the first three years of the World War it was learned that this stage is but the first and most elementary part of what may become a very extensive and complicated system of trenches. If the enemy cannot be driven from his position, and if, on the contrary, his resistance augments to the verge of his taking the offensive, this action on his part must be prevented by a continued development and elaborate strengthening of our own trenches, and the soldier, in addition to being a fighting unit, assumes the character of the day laborer, doing the hardest kind of manual labor, that is, excavating earth and carrying by hand enormous quantities of material for the further strengthening and development of the system of trenches which have been started.

A trench system having thus been begun, work on it never ceases. The first temporary work disintegrates and must be done over, new units replace those first occupying the trenches and they bring to the sector different needs and plans, which mean further work. Our plan of defense brings about corresponding developments on the part of the enemy. He endeavors to minimize the effectiveness of our work. This must be met with further changes and developments on our side. Thus, as long as the infantryman occupies trenches a large part of his time must be spent in manual labor.

The moving of huge quantities of earth and the utilization of the immense amounts of materials which are involved in any extensive trench system, form a problem in engineering, and in the World War this problem developed into one whose magnitude was, perhaps, the greatest of any engineer operation in history. Armies have long contained a certain percentage of engineer troops, provided to meet engineer problems, and as trench warfare develops their duties and responsibilities continually increase. Because armies contain this engineer organization and because the construction and maintenance of trenches are primarily an engineer problem, the question sometimes arises why at this stage engineers do not take over altogether this engineer problem and leave the infantry free to devote its whole time and energy to its primary duty, that of fighting the enemy. In other words, why is it that engineers require assistance from infantry in the performance of engineer tasks, and if they need this assistance, just what is it that is expected of the infantry soldier and officer?

The answer to the first question, "Why is help needed?" is that a very large amount of engineer work must be done, often very quickly at critical moments. Calculations could be made for a typical sector to show the amount of earth that must be handled and the quantity of heavy material, corrugated iron, timber, broken stone, sand, water for concrete, etc., which would be needed for its proper development. However, perhaps, a better mental picture will be formed by listing the work which was done in the preparation for an actual attack made during the second year of the World War. Note that all of this work had to be done by one division, in our service a body of men consisting roughly of 1,500 engineers and 25,000 other troops, and in the

Digitized by Google

army where this work was actually done the division and the number of troops available was much less than would have been the case in our service. Also note that all this work was done simply to prepare for an attack, that most of it was done above ground where it could not be concealed from the enemy's aircraft, and that, therefore, it had to be completed as quickly as possible so that the attack could be delivered before the enemy could make equal preparations to meet it. The following is a summary of the engineer work in one division during the period of preparations for attack:

(*a*) Eight miles of new trenches:
10,630 yards of main approach trenches;
2,450 yards of communication trenches;
2,370 yards of assembly trenches.
(*b*) Thirty miles of other trenches were cleared, deepened, repaired, improved, traversed, etc. Many were blown in by shell fire and had to be repaired more than once.
(*c*) Eighty-six dugouts of more than 14,350 square feet floor space, excluding those in (*k*), (*l*), and (*m*) following.
(*d*) Thirty-three observation posts:
1 for survey;
3 for division;
4 for infantry brigades;
25 for artillery.
(*e*) Thirty-six special emplacements in front line for ten gas cylinders each. (Cloud gas was not employed towards the end of the war.)
(*f*) Thirty-one bridges to carry vehicles over trenches of which four were for heavy motor traffic.
(*g*) One and one-half miles steel trench tramway for taking up ammunition and evacuating wounded in daylight. The trenches had to be widened considerably for this purpose.
(*h*) Six sets of trench water tanks, capacity 3,350 gallons each, with pipe connections.
(*i*) Deep-well pump and engine, with steel-concrete shelter. During operations this was the only water supply available in the trenches owing to the pipes of the main supply being continually broken by shells.
(*j*) Twelve ration dumps to hold rations and water for 10,000 men for two days.
(*k*) Emplacements and dugouts (not included in (*c*)) constructed for twenty-one medium trench mortar batteries close to the front line.
(*l*) Dugouts and gunpits for sixteen batteries of artillery.
(*m*) Five deep-mined approaches, total 2,500 feet, were run to within 30 yards of the German lines, and twenty Stokes mortar emplacements were constructed off them in the middle of No Man's Land for intensive bombardment prior to assault.
(*n*) All trenches, trench junctions, and other routes signposted.

In addition, the following work was carried out for the Corps in the back area:

(*o*) One-hundred huts to accommodate four battalions, four huts for a field ambulance, and seven for officers, etc.
(*p*) Two wells dug, 28 and 57 feet deep, with tanks and pumps to supply the above hutments.
(*q*) Two wells dug to a depth of 130 feet each, with boreholes 130 feet lower, pumps, tanks and standpipes erected.
(*r*) Two reservoirs of 21,000 gallons capacity, and 3¼ miles of 4-inch pipe for a water point. Troughs were erected to water 8,000 horses, and standpipe to fill 75 water carts per day.
(*s*) Two artillery and one grenade and mortar ammunition dumps.
(*t*) 2,600 trees felled to provide timber and brush.
(*u*) Several cross-country roads were laid out and prepared for the movement of troops.
(*v*) 3,800 cubic yards of stone (mostly flint) quarried for repairs to roads.
(*w*) Cage for prisoners of war.

The foregoing were the principal items only. A multitude of miscellaneous small tasks were performed.

It will be noted that in this case an elaborate trench system already existed, and that all this engineer work was done in addition. At the time the United States entered the war in force in 1918, methods of attack had changed to such a degree that many of the operations above listed would not have been carried out at this later period. On the other hand, new weapons and methods not previously employed on a large scale at the outset, such as tanks, heavy artillery, etc., had come into prominence, and the engineer preparations for their full development would probably have compensated for the classes of work which had ceased to be of importance. In the future, the detailed operations of the past will not be exactly duplicated, but it is safe to say that the volume of engineer work, routine or emergency, will never grow less. Surely, then it is a self evident fact that the rapid performance of such work requires vastly more than 1,500 men per division. Therefore, throughout the period of trench warfare, and particularly at moments of greatest activity, every available man, irrespective of the arm to which he may belong, must be called upon for the important engineer work.

Military engineering is sometimes divided into two classes, called pioneering and construction. Under "construction" are usually included all engineering operations which require special engineering training on the part of officers and skilled workmen or mechanics among the soldiers. Pioneering may be said to include those engineering operations where special training and the services of skilled men may be dispensed with if necessary. In trench warfare the infantryman must expect to perform more or less pioneering work as long as he is in the front-line trenches, and he must be prepared to furnish a certain amount of unskilled labor for the more technical operations under the heading of construction.

In order to determine the amounts and kinds of pioneer work which the infantry will be called upon to do, let us first consider the various situations in which an infantry regiment finds itself when taking

Digitized by Google

over a sector of an established trench system. Such positions will include fire trenches, connected by communication trenches, flanked by machine-gun emplacements and strengthened by wire entanglements, together with command posts, observation posts, and shelter for the garrison in the shape of deep dugouts. The immediate task of the infantry will be the maintenance and repair of the various works. In an active sector the constant repair of damage caused by shells will be a considerable item, and this will be in addition to the maintenance which is inevitable because of the comparatively rapid deterioration of hasty works done by men with little skill or aptitude for such work, and inadequate tools and materials.

The enemy is constantly trying to improve his position to neutralize the effectiveness of opposing trenches, gunpits, etc., and as he succeeds in doing this, as he surely will from time to time, wholly new work must be begun to counteract his advantage. In a quiet sector the works require less labor because they are subjected to less destructive fire, and less new construction will be necessary. But the regiment will be extended over a wider front and the total amount of engineer work will be about the same.

In an attack, after the objective is gained, the position must be held against the enemy's artillery fire and counter-attacks. The protection offered by our barrage cannot be continued indefinitely, and immediate steps must be taken to strengthen or consolidate new positions by providing a strong firing line with cover, an obstacle of some sort, even if it is only a simple wire entanglement, and communications to replenish the firing line with ammunition, rations, water, and engineer supplies. The work to be done in consolidation may be divided into four main parts:

1st. The establishment of an observation or outpost line from one to two hundred yards beyond the position to be consolidated or as close as possible to our final barrage line.

2nd. The preparation for the defense of the captured terrain, including the provision of a fire step, traverses, some shelter and wire in front of the trenches.

3rd. The organization of a line of trenches and strong points further to the rear to give depth to the position.

4th. The opening up of communication trenches to the new position.

Of these the first two must, of necessity, be initiated and carried through by the men on the spot, which will be infantry with as many engineers as can be made available. The third item is the duty of the engineers aided by as much infantry as can be made available; and the last item is the duty of the engineers with the assistance of large infantry working parties. All of this work will be complicated by the fact that it will presumably have to be done under a more or less destructive fire from the enemy, much of it will have to be done over two or three times, and the transportation of material and supplies will often be effected with great difficulty; but on the rapidity and efficiency with which the work is prosecuted may depend the success or failure of the entire operation.

In all of this work the infantryman will take a prominent part, he will also be furnished engineers for technical supervision when engineers are available; but frequently, or in major operations, perhaps, as a rule, the volume of engineer work will be so great that the infantry officer will be expected to perform the simpler operations without technical advice, all the engineer personnel being required for the more technical operations. It will be evident that the infantry officer's education is not complete when he knows only how to function with his branch of the service as a part of the troops in combat. He must also be familiar with the laying out and construction of standard types of trenches, obstacles and shelters. He must know how to organize his command and how to direct it to get the most effective results when called upon to do this simpler type of engineer or pioneer work.

The recent war has put the intrenching tool on an equal footing with the rifle. Nowadays, the soldier is at the same time a combatant and a workman; one cannot be imagined without the other. He uses his rifle sometimes; his intrenching tool every day. When the soldier has conquered the ground, if he counts on his rifle to hold it he will be greatly disappointed. He must, tired as he may be, immediately start digging; he must know that each shovelful lifted, in spite of fatigue, is a check to the counter-attack which the enemy is preparing against him at that very moment. For officers and non-commissioned officers to lead their men to the field is a rather easy matter; but to make exhausted and decimated troops work without rest or delay is a far more difficult task. It is, however, just as imperative a duty as the first; the least counter-attack may turn an apparent victory into defeat if the infantry does not immediately "dig in" and hold its gains.

Two great principles must always be present in everybody's mind:

1. Never delay starting a work because the necessary time for its complete achievement may be lacking. This principle holds under any circumstances.

2. In the fight, after the advance, the best means of reforming the troops consists in showing the work to be done and obliging the men to start it at once.

To thoroughly inculcate the second principle, it is necessary in training exercises to order that every infantry maneuver must be closed with a staking out of the lines and commencing work on the final position occupied. Officers and soldiers will thus get the habit of considering maneuvers and intrenching as one and the same thing; both of which are to be executed with similar means and commands. It is wrong to have separate maneuver and intrenching exercises. Intrenching is a part of the maneuver to the same degree as extended order or assault drill. During the active operations of the American Army many

Digitized by Google

infantry units moved forward in attack; some of these made assaults, some did not, but all had to intrench sooner or later. Whether on the offensive or defensive, there is no maneuver without intrenching.

What is the relation between the engineers and the infantry in the various classes of engineer work with which both may be concerned? First comes the elementary task of pioneer work which consists in developing a line of rifle pits or shell holes into a trench to be occupied by infantry units. As a general rule this task will fall to the infantry alone and the infantry officer and his men must be trained to handle all problems arising under these conditions with confidence and without technical advice. It is not sufficient for the infantrymen to know the dimensions of the profile of the trench, the thickness of traverses, etc., he must have his unit so trained that the proper dimensions will be obtained automatically, and he must further have trained both himself and his unit so that this trench will certainly be begun the instant that the intensity of combat begins to diminish; and furthermore the trench as it develops must be properly located. Dimensions of profiles, etc., are found in various official War Department documents, and are included in the infantry drill regulations. All infantrymen should be thoroughly conversant with these dimensions and with the general principles governing the location of fire trenches. Further, the infantry unit must be so trained that its commander can place them on the line to be occupied and direct the course of their work with the same ease and certainty that he can handle them in close-order drill. Sometimes it may happen that engineers are present with the infantry at this time. If there is no technical engineer work on which they can be employed they should assist the infantry in laying out and constructing the line of trenches. Presumably, they are more thoroughly trained in this than are the infantry, and if so full advantage of this should be taken. They should be able to locate the line easier and quicker. They should be able to act as foremen and overseers in directing the efforts of men of less skill. The infantry officer should consult the engineer officer, or non-commissioned officer, in command of the engineer detachment, with a view to utilizing the technical troops to the best advantage. But whether engineers are present or not the responsibility of the infantry commander on the ground remains unchanged. He alone is responsible that the work is begun promptly, that the lines are properly located, and that his men work efficiently. The presence or absence of engineers cannot change his responsibility.

Next comes that class of work wherein the bulk is to be done by the infantry but where engineers are present to give technical advice and assistance. Examples of such work would be the maintenance and repair of trenches, the construction of simpler forms of shelter, and in open or semi-open warfare, the repair and maintenance of roads. Here an infantry unit is given a certain area in which it is responsible that the trenches are maintained, or that the highway is kept in good condition. To this unit is attached an engineer detail, commanded by an officer or non-commissioned officer. The theory is that the infantry are fully capable of doing practically every task that may arise if they know how, and that it is not a difficult matter for one who does know how to teach one who does not. The engineers are then present first as teachers, and when the infantry have been taught the special task at hand they remain as inspectors to see that the technical standard is maintained. They also give special assistance in the matter of obtaining technical supplies, tools, etc. The engineer is not forbidden to wield a pick or shovel if there is nothing better for him to do, but if numbers have been properly apportioned he should have his time and attention fully occupied with instruction and the supervision of the work, and he would be open to serious criticism if the technique of the work fell below par while engineers were doing manual labor, or if other technical work suffered because engineers were detailed elsewhere performing non-technical tasks for which unskilled labor was available.

In this case, as in the preceding case, the infantryman is responsible for the quantity and quality of the work and for the discipline of the troops engaged upon it. Again, the presence of engineers can not in any way diminish the infantry officer's responsibility. Quantity is entirely in the hands of the infantry officer. As to the quality, it is sufficient for the engineers, when necessary, to bring to the attention of the infantry commander the fact that it is below par. The engineer may not take any disciplinary measures to secure better workmanship. A cordial understanding between the infantry and the engineer detachment is essential to proper and harmonious work. In general, it is desirable that the engineer and infantry details be independent of each other as regards discipline, rations, transportation and billeting arrangements. In this work a certain amount of engineer instruction for the infantry is necessary. It will, therefore, be obvious that once an infantry unit has received this instruction its whole energy can be devoted to the performance of its task, and as long as the same unit is detailed to the same task, time once devoted to instruction will not have to be spent again in new instruction. In other words, if the same unit can be continued on the same class of work for a long period of time more useful work will be done than if a number of independent units are in succession assigned to the same task, each in succession having to be taught how to do the work. At the beginning of trench warfare the importance of this continuation on one task was not fully appreciated by our Allies

Digitized by Google

but by the winter of 1917-1918 the Allied armies had included in their regulations orders which assigned infantry units to this class of work for periods of a week, a month, or even longer. This is a sound policy and one to be encouraged in our own service.

Finally comes that class of work which is primarily technical and the duty of engineers, and there the infantry is present either in the nature of unskilled helpers to skilled workmen or as carrying parties for the transportation of material by hand where the nature of the terrain, or the enemy's fire, or both, prevent transportation by other means. Instances of the infantry being used as unskilled helpers would occur often in road building, in the construction of deep dugouts, etc. Infantry would be used as carrying parties to bring up timber for a plank road, or a deep dugout, sand, gravel and even water for the concrete in an observation post, gun emplacement, etc. Here the engineer soldiers and officers are present in larger numbers and the engineer officer is chiefly responsible for quantity and quality of the work performed. The infantry commander in this case must not, however, feel that he is without responsibility in these matters. Whenever infantry is detailed for engineer work each detachment must be accompanied by its usual quota of officers and non-commissioned officers, and while on engineer work the infantry officers and non-commissioned officers have the same responsibility with respect to discipline and attention to duty on the part of their troops as they would have at an infantry drill. It is not proper for an engineer officer to attempt to discipline an infantry soldier. It is the duty of the infantry commander to see that his officers and non-commissioned officers are properly distributed, constantly on the alert, and that they maintain the same activity and attention to duty as would be required if at extended order infantry drill. Here also cordial relations and a good understanding between the infantry and engineer commanders are essential, and here, as in the preceding case, continuance of the infantry unit on the same task is of high importance, and the precedent set by our Allies was to keep such infantry units on these engineer details for periods up to three months.

When engineer officers are present with infantry detachments on simple pioneer work, it is proper for the engineer officer to aid the infantry commander by suggesting suitable reliefs and the number of spare men, to suggest the best method of securing a good output (explanation of the work, piece work, competition, smoking, times of rest), and how long it ought to take to complete the work. The engineer officer should assist in every possible way in getting the men to work where difficulties arise, but in no case is it his business to drive the infantrymen or to enforce discipline among them. Cases have occurred where the infantry officer, or non-commissioned officer in charge, has thought that his duty consisted in marching the parties to and from the work, and in distributing tools, leaving the supervision of the work entirely to the engineers. Under no circumstances is such conduct justified.

If possible a visit should be made to the site of the proposed work by daylight, and the work should be marked out before the actual workers arrive. The main cause of the small amount of work sometimes done is lack of organization. The infantry non-commissioned officer should work with the men as much as possible, in our service it is a rule "that a corporal works," that is, that he both supervises his squad and encourages it by his example. Even the senior non-commissioned officers should encourage their men and set them an example by themselves working for short periods. The output is also bad when company officers go away and smoke or sleep, and when the battalion or regimental staff officers do not inspect the work in progress. Work should be allotted by sections or platoons. The same section, or platoon, should, if possible, be employed day after day on the same piece of work, so that there may be no loss of time in beginning each day and that the men may take interest in the progress and the completion of the job. Sections, or platoons, should be allowed to rest or cease work or return to their billets when their own particular piece of work is finished.

It must be impressed on all that tasks given to working parties are of just the same importance as orders issued for an attack, and that the work must be carried through with the greatest determination. The success of a whole operation may be endangered by the failure of a working party to carry out the task allotted to it. Special arrangements must be made to see that working parties do not retire prematurely if shell-fire is opened.

The secret of getting work done is keeping at it steadily and deliberately, even slowly, without stopping to look about and talk.

Continual smoking during the working hours is to be discouraged; it is unnecessary and unusual in civilian work except when men are exposed to stenches or in exceptional conditions. It is generally advisable to adopt the principle of the 10-minute halt.

Much energy is sometimes wasted in carrying tools several miles back to billets instead of forming a dump near the job.

As a matter of principle men should not be allowed to go to work without their rifles and fighting equipment, which should invariably be placed so that they can be rapidly picked up both by day and night.

When infantry and engineers are to work together at night, special care must be taken in the selection of the rendezvous, so that there can be no chance of their missing each other. Guides who know the way must be distributed along the infantry column, other-

Digitized by Google

wise touch is sometimes lost in the dark and a large part of the column may fail to reach the work. Sufficient time is not usually allowed for working parties to reach the site of the work; it is not safe to assume that large parties will move faster than one mile per hour at night across country or over roads congested with traffic.

Finally, it should be remembered that no two engineer problems are alike, and that each one will have difficulties and phases peculiar to itself. It is for these special features that the presence of engineers is always to be desired, even for presumably simple operations, and where they are present a cordial understanding between the infantry and engineer commanders is always essential to success. The engineers should always be able to give appreciable assistance in the details of organization, in the obtaining of engineer supplies and tools, and in suggesting the expedients to be adopted in overcoming unforeseen difficulties. When an infantry commander has been detailed for pioneer duty he should first of all get in touch with the engineer officer with whom he is to work and discuss freely with him all phases of the task. If possible, they should together visit the site of the work, familiarize themselves with the terrain, the best means of bringing in the details, and material. They should visit the dumps and assure themselves that the engineer material and tools, which will be needed, are actually available and can be obtained when wanted. Details as to billets, rations, transportation, and the like should be settled at the start.

The following classes of trench work will usually be executed by the infantry under the direction of their own officers, with technical supervision by engineer officers and soldiers, though in busy times this supersision may be lacking:

Excavation of trenches,
Erection and repair of wire entanglements.

Less frequently:

Revetment,
Drainage and flooring of trenches,
Sentry or lookout posts.
Camouflage of working parties, trenches, and lookout posts.
Latrines.

Sometimes the construction of light shelters, or simple machine gun or light mortar emplacements, will also fall to the infantry alone.

The above mentioned work represents a large amount of labor. In order that this labor may be directed economically, it is essential that all infantry officers be familiar not only with the simple types of construction for the above mentioned items, but also that they should have a practical knowledge of the principles necessary to plan and organize the work so as to obtain the maximum result with the minimum effort when engineer supervision is not available.

The different points to be considered and determined before starting on any work include the following:

The kinds and quantities of material required.
The number of men required.
The kinds and quantities of tools required.
The kinds and quantities of transportation required for tools and material.
An estimate of the time required.
A study of the technical and tactical conditions.

In considering the material required, effort should be made to utilize material immediately available in close proximity to the work, in order to reduce transportation. Material will not be called for which is difficult to obtain, when other material more available will answer the purpose. At least 10 per cent in excess of the amount estimated should be provided in order to allow for errors in computation, and avoid the risk of the work being stopped on account of lack of material.

In computing the number of men required, the work should be organized in advance, so as to make full use of every man in the working party. For certain work, such as construction of wire entanglements, the duties of each man can be definitely assigned before starting the work and the exact number of men required, called for. In general the smallest party, consistent with effective work, should be used in order to avoid unnecessary fatigue of the command. If the proposed construction is concentrated in a small space, such as a machine gun emplacement, or an observation post, there is little advantage gained in increasing unduly the size of the working party, for too many men would be in each others' way, and would not increase proportionately the work accomplished. If, on the other hand, the work is extended over a large area, such as the construction of a long line of entanglement, the work can be expedited very materially by dividing it up into short sectors and assigning a squad to each sector, so that the work will be proceeding simultaneously along the whole front. In allotting tasks, every effort should be made to utilize men with special qualifications in doing work similar to that in which they are skilled. In certain forms of work, such as barbed-wire entanglements or revetments, it is important to drill certain men to perform each operation in order to obtain speed in construction. These men then should be used wherever possible for the duties in which they are trained.

The transportation of material and supplies should be assigned to a definite detachment designated for that purpose and nothing else, and a careful computation should be made of the number of men needed, taking into account the distance to be traveled and the average load of each man, in order to provide a carrying party of just the right size to properly supply the working party, so that no time will be lost either by the working party in waiting for the material to come up, or by the carrying party in stand-

Digitized by Google

ing around waiting for orders. Great care must be taken that the working parties are not ordered to the site of the work until the supply of materials is assured.

Computation of the time required is important in order to provide enough tools and men to complete the work in a given time. So many conditions enter into the estimate of time for doing any piece of work that it is difficult to adopt or use any standards, but in order to plan the work properly, some estimate must be made even though it is at first inaccurate.

The best rules to follow are those gained from one's own experience, as no manual can be made to fit every case. However, the Engineer Field Notes issued by the Engineer Department were prepared after a careful study of the best engineer practices in our own army and in those of our Allies, they give definite rules and tables for the guidance of the man in the field, and until the officer has acquired an extensive field construction experience himself, he should make these notes his chief reliance in laying out his work and in organizing his working parties.

The amount of work accomplished can usually be increased by allotting tasks to each man. Care should be taken that these tasks are not excessive at first, so that by energetic work a man will complete his task and be relieved earlier than the usual working period of 8 hours, which stimulates him to put forth his best efforts.

The technical considerations, which must be thought out beforehand, consist mainly in having a clear idea of the work to be constructed, dimensions, etc., and if necessary rough sketches or plans should be made, showing all dimensions, method of making joints, or other details likely to arise in the prosecution of the work.

The tactical conditions which must be considered and allowed for in executing work often impose restrictions which materially alter the plans, for example: All the material may have to be brought through the communication trenches; possibly the work must be executed, if not under the enemy's fire, within reach of his fire if discovered, in which case the working party should not be too numerous in order not to attract attention or present too large a target, if discovered. Possibly the work will be done in such close proximity to the enemy that no noise can be permitted, and very often it must be done at night. These conditions impose restrictions which will influence the organization and conduct of the working party.

In any event, the importance of carefully planning work beforehand in all its details, including computation of material, men and tools and the consideration of the technical and tactical conditions is evident. The time spent in planning and organizing the work will be saved many times in the execution.

The engineer duties of infantry have been here discussed chiefly from the viewpoint of trench warfare. It is to be remembered that trench warfare is but one phase of warfare in general and was chosen as the basis of this paper because under these conditions infantry finds its engineer duties greatest in magnitude and in variety. It is true that this special phase of warfare may not recur soon, perhaps not even during the lifetime of this generation, but the infantry officer who is prepared to meet his engineer duties under these conditions is ready to meet them under the simpler conditions of open or semi-open warfare.

What has been said concerning these duties applies most forcibly to trench warfare but it must be remembered that all this also applies in some degree to any type of warfare where trenches appear, and trenches will undoubtedly appear whenever any army remains stationary in the presence of the enemy for a period of 24 hours or more. Such pauses, or temporary halts, are usual in any campaign and infantry must then expect, in all warfare, to apply the principles here discussed, and perform to some extent the duties mentioned.

Every officer must be thoroughly impressed with the fact that when an infantry unit is detailed on engineer work its commander is responsible for the quality and quantity of the work performed.

An Army Association. In a letter to the Editor, concerning the Society of American Military Engineers, a member says:

I feel that with conditions as they are, the time is ripe for the formation of an Army Association and the consolidation of all our military publications into one Service Journal. We now have the Infantry Journal, Cavalry Journal, Field Artillery Journal, Coast Artillery Journal, etc., etc., with their corresponding associations in most ceses, each striving to keep its head above water and issuing a lot of stuff of greater or less merit. One single journal, with a section devoted to each arm of the service, would be of great advantage; for it would tend to break down the splendid isolation of each arm and keep the work and aims of all the arms before all, for every officer could subscribe to one journal, whereas, he cannot subscribe to all that are now being issued.

Such a Service Journal would necessarily be devoted to purely military matters, and technical matters would, so far as the engineers are concerned, have to be disseminaed by "Professional Papers" or "Occasional Papers", as above indicated, and in the Artillery by "Artillery Notes". It would, however, never be handicapped by the financial problem, as it would naturally include among its subscribers practically all army officers, and as a medium for advertisements would appeal to advertisers such more than the many exclusive publications we are cursed with now.

NOTE. Our correspondent's ideas are interesting and we are inclined to agree with his as to the need of a service journal. But it does not seem possible that such a journal could *replace* all the journals of the various branches without being unduly bulky. Every trade and profession has its own journals, and the arms of the service must likewise have each their own. But there is still a field for a journal, devoted to the interests of the service generally, The *Army & Navy Journal* and *Register* fill most of the need, and a Service Journal would be primarily technical and tactical. A few efforts have been made to start such a journal, but none of these was over successful. ED.

Operating Experiences at the Keokuk Lock and Dry Dock

By

M. Meigs

United States Civil Engineer

AS is well known, the Keokuk lock and dry dock were built by the Mississippi River Power Company in connection with construction of a power dam across the Mississippi River at the foot of the so-called Des Moines Rapids, and the drowning out of the old Des Moines Rapids canal. These rapids are in a gorge between the hills, with a low water slope between Keokuk and the head of the rapids of 22 feet in a distance of 12 miles.

The bed of these so-called rapids consisted of flat ledges of limestone rock nearly horizontal. The stream being nearly three-quarters of a mile wide, the low water flow of 20,000 cubic feet per second was insufficient for even flat-boat navigation. It is related that on several occasions the river has even been waded at low water.

The old Des Moines Rapids canal extended upstream 7.6 miles from Keokuk, was 300 to 350 feet wide, and formed by building a long embankment parallel with the shore and three locks 80 feet by 350 feet, one at the head and one at the foot of the canal, and one 2½ miles above the foot. But little of the canal was in excavation. The cost of the project was about $5,000,000. It provided for 5-foot draft on the lock sills at low water and, except in later years when the increasing silt in the river made continuous dredging necessary, this depth was maintained, though with some difficulty.

A passage through the canal was, for the larger boats, a slow and tedious maneuver, with the added difficulty and danger of landing a heavy boat three times in locks not much wider than the boat.

In addition there was the danger incurred in navigating a 200-foot open channel excavated in rock, which connected the canal with the head of the rapids at Montrose, 3½ miles away.

All of this old canal with its locks and dry dock are now submerged from 6 to 26 feet.

The Engineer Department as well as river men generally, when the new dam was proposed, recognized the great benefit to navigation that a single lock of larger size than those of the old canal would afford. It would provide a lake with deep water for many miles above the dam, allowing full speed at all times, and there would be a further advantage if the locks were built so that the time required to pass a vessel were held to anything near what it was at a single lock in the old canal.

Accordingly little objection was raised to building the dam and power plant. It was recognized as a great improvement to navigation as well as a notable conservation project, in that it made available in the heart of the country an immense water power which had previously gone to waste.

To the genius and perseverance of one man, Mr. Hugh L. Cooper, M. Am. Soc. C. E., the fruition of the project is due. After six years of unsuccessful effort to finance the project, he enlisted the help of the Stone & Webster Corporation of Boston, Mass. Together these two built and placed in operation the entire plant in the space of 2½ years.

One thing that made the project feasible and comparatively easy was the excellent foundation everywhere available. Fig. 8 shows the 25-foot cut for the tail-race of the power-house and the nature of the bed of rock on which the dam and power-house stand.

It is the purpose of the writer to describe herein the general operation of the lock, dry dock and gates, the difficulties encountered and overcome, and the experience gained in this operation.

The engineering magazines in the last four years have all published a number of articles, many of them quite complete and well illustrated, giving the details of construction of the dam, power-house and lock. One of these is particularly authoritative, being written by Mr. B. H. Parsons, the mechanical engineer assistant to Mr. Cooper, the chief engineer, and who designed all the machinery. It is in two installments contributed to the *Engineering Record,* September 18th and October 9th, 1915. Full descriptions and detailed plans will be found in these papers.

Both the lock and dry dock, and especially the gate mechanism, are built on bold and original lines, and after operating them six seasons it is possible to form a conclusion as to the value of the new forms of gates and appurtenances, hitherto untried, so far as the writer knows.

The general view of the whole group of works, Fig.

1, shows the power-house and dam, in their general relation to each other. The only access to the power house from the Iowa side is across the lock and dry dock.

Upper Gates

At the upper end of the lock the problem was to build a gate and a bridge that would allow loaded railroad cars and locomotives as well as foot traffic access to the site of the extended power house when it came time to install the second set of 15 turbines with their accessory machinery. Fig. 2 gives a view of the foundations for these units, extending north from the lock site.

The use of ordinary mitering lock gates would have required in addition the construction of two bascule bridges crossing the openings at the head of the dry dock and lock. To combine the functions of gate and bridge was of manifest advantage. This led to the design of floating gates to serve both as gate and bridge. It was also found that by making the guard gate, the upper-lock gate, and the dry-dock gate interchangeable, any one of them could be taken out and docked for painting and repairs when necessary, without unwatering the lock. Fig. 3 shows the upper gate of the lock in dry dock for painting.

The floating submersible gates, three in number, consist of trusses framed vertically for carrying a loaded train of heavy cars and horizontally to resist the thrust of the water. The skins of the gates are on the downstream side. The lock being 110 feet wide and the depth of water on the sill being 14 feet, the horizontal thrust amounts to 340 tons.

To float the structure there are five tanks enclosed in the lower half of the gate. Two of these at the ends, with a displacement of 4,600 cubic feet, are always empty, and are insufficient alone to float the gate. Two tanks 3 feet deep with open bottoms below these, and a larger one in the middle, all three connected, with a combined displacement of 5,990 cubic feet, receive air from below when the gate is to be raised and are emptied of air as necessary when the gate is to be lowered. The air pressure in these three tanks determines the amount of water in the gate and hence its buoyancy.

The inlets for air are in the bottom of the lock under the gate, and consist of four short pipes opening upward and discharging air into the water through which it bubbles up and enters the open bottoms of the three gravitating tanks. To raise the gate the operator opens a valve on the air line connected to the storage tanks and as soon as air enough has escaped into the three tanks the gate begins to float and ascend.

It was soon noticed that this ascending movement accelerated as the gate moved up. The lessening pressure allows the air to expand on nearing the surface and it expels part of the water from the tanks. The combined weight of water and gate thus become less and less, the buoyancy of the gate increases, and if allowed to continue it would finally rise until it had attained equilibrium. On emptying enough air to start the gate downward the reverse occurs. The gravitating tanks admit more water as the pressure increases, which accelerates the downward speed and, unless prevented, the gate would settle on its supports at the bottom of the lock with a very considerable shock.

The air for supplying the gate passes through controlling valves in the lock operator's house at the upper end of the lock. (Fig. 6.) The air discharge valve connects by a flexible metallic hose 6 inches in diameter with the top of the gravitating tanks. This hose unwinds from a drum or reel on the lock wall as the gate descends, and by means of counterweights winds up as the gate rises.

At the opening of the lock, June 12th, 1913, on account of the number of boats below waiting for pas-

sage, no proper opportunity was had for getting practice in the operation of the machinery, which was an experiment at best. When the first boats entered the lock and the lower mitering gates had been closed, the floating gate which had been raised to position, suddenly started lifting again and to the consternation of the engineers the bottom of the gate rose 6 inches or more above the miter sill. A sheet of water escaped under it and passed over the sill into the lock chamber. Up to this time no stops had been provided to limit the upward travel and the operator, inexperienced of course with this particular gate, had allowed air to accumulate so that the flotation became enough to lift the gate against all the friction generated by the 340 tons of water pressure against it. The gate, however, was easily lowered by exhausting the air, and no damage ensued. Stops were of course at once provided.

This experience, however, was in a way a happy one. It tested the gate to an extent never contemplated, as the sill was supposed always to take the thrust at the bottom, and the strength of the structure was thoroughly demonstrated. Also it showed that should the miter gates be carried away by a boat entering the lock from above, as has sometimes happened at other locks, it would still be possible to raise one or both floating gates and so shut off the flow of water, making the upper gate a true guard gate.

Since this occasion, the two floating gates at the lock and the gate of the dry dock have given no trouble whatever. Small adjustments have been required occasionally, when concrete expanded and pinched the sliding latches, but they have been of minor importance and easily made. One rocker arm of cast iron, operating the gate latch, broke and had to be replaced, a simple matter. Once the gate after being lowered suddenly rose again just as a boat started to leave the lock. This was because the operator failed to blow out enough air to keep it down. The boat struck the gate with some force, but fortunately little damage was done to either, and it was a lesson the operators will not forget.

The gate operates easily and smoothly and the lock men like it better than mitering gates, to which they were long accustomed. They have learned to give it excess air as it nears the bottom and thus settle gently on its seat. Likewise, they have learned with little trouble to raise it smoothly until it touches the cushioned stops without shock. In short, it operates perfectly and more cannot be said.

For locks of great lift where the height of the upper sill above the lock floor is sufficient to provide for lowering it, the writer would recommend this type of gate and prefer it to mitering gates for the following reasons:

1. It requires much less length of lock wall than mitering gates.

2. At Keokuk, with a dry dock close by, it can be docked in summer and properly painted and cared for. Those who are accustomed in our northern latitudes to clean and paint their gates in winter weather after the close of navigation, will appreciate this advantage.

3. It makes an excellent bridge of ample width for all traffic, much preferable to the narrow, indirect track across the tops of mitering gates. At Keokuk the gate is used by perhaps 150 employees of the lock and power house. In addition, there are visitors who come from great distances to see the power house and lock. According to the records the number of such visitors is from 25,000 to 30,000 per annum.

4. Either floating gate can be lifted should the lower gates be carried away and no collapsible or other cofferdam above them will ever be necessary.

5. The gate can be operated even under a considerable head of water due to leaky valves in cases where mitering gates could not be opened (see post).

Mitering Gates

These gates are of novel design and have always operated perfectly. The miter posts were built plumb and when first swung on their pivots by removing the blocking underneath they hung less than ⅛ of an inch out of vertical. This small variation was corrected later by adjustment of the anchors, so that the gates mitered to within one-tenth of an inch. This close adjustment has been maintained up to the present time. The only trouble in operation was with the upper pintle. Some difficulty was experienced in properly lubricating it, as is often the case with pins that revolve through only part of a circle. The difficulty was overcome by providing a grease cup that is operated with a long wrench and gives enough pressure to force grease (mixed with graphite) between the surfaces to be lubricated.

The design of this gate is unusual but it has demonstrated its success. The distortion common in circular gates, due to hanging a curved shape on one edge, is entirely absent in the Keokuk gates, which are stiff and miter perfectly at all times. (See Figs. 4 and 5.) The principal dimensions of the gate are: height, 49 feet; length, 66 feet 4¾ inches; depth in middle, 11 feet.

On unwatering this gate in the winter of 1915-16, a very rapid corrosion was noted at the heel of the quoin due to the bronze bearing which carries the weight of the gate and on which it turns. This should have been provided for by attaching zinc to the iron parts, as is done in the navy next to all bronze attachments to the skin of the vessel, and in the neighborhood of a bronze propeller, where such is used. It is proposed to do the same thing at these gates.

The air chambers in these mitering gates are not, at lower stages, fully submerged. Some water leaks in and has to be pumped out once in two months or so. It keeps the inside of the tanks damp and promotes corrosion. The experiment is being tried of protecting the steel inside the tanks with whitewash.

Digitized by Google

At present this practice, after two years, seems to be perfectly successful.

The swinging of the gates is done by a bull-wheel and strut, in principle the same as used at Panama. This gives a strong thrust to put the leaf in motion, a swift movement at the middle of the swing and a slow, powerful closure at the end. The bull-wheel is operated by gears connected to a double reversing engine operated by air pressure. It is so arranged that overrunning is prevented by a self-reversing mechanism connected with the bull-wheel. A cam on the wheel turns a cock at the end of a stroke and reverses the engine. If the operator fails to shut off the power the engine keeps reversing itself and turns the bull-wheel back and forth, about 10 inches of travel. This travel, being at right angles to the strut at either end of its stroke, communicates no appreciable motion to the gate.

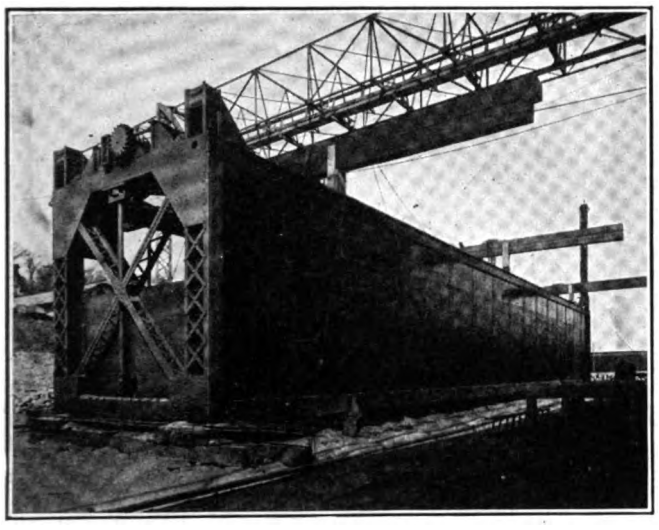

Fig. 3. Guard gate in dry dock for repairs

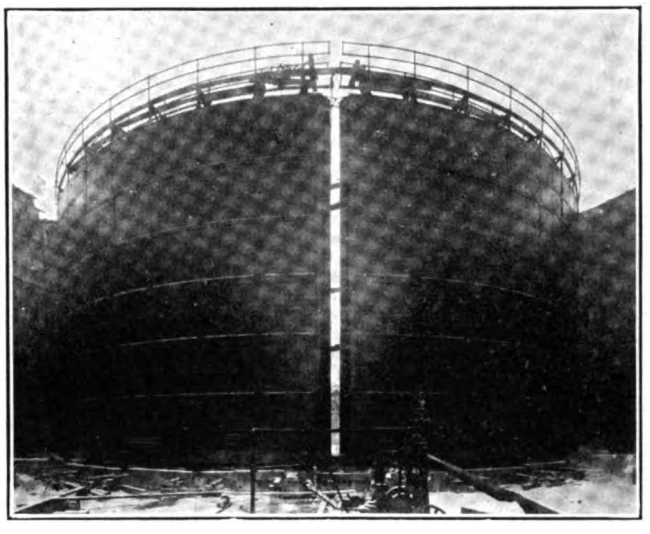

Fig. 4. The mitering gates

Air Control

The gates are all controlled from the operator's house at the upper end of the lock. The air is introduced into this house in a header from which branches run to all gates. The operator has before him an inclined table with the handles of all the valves grouped together for each gate. (Fig. 6.)

The groups are: Lower gates, upper gate, guard gate, dry dock gate. Separate valves control the two leaves of the miter gates, the bull-wheel engines and the miter forcing machine on top of the west gate. Similarly, the floating gates have one valve for admitting air, one for discharging it, and two for the cylinders that operate the latches on which the gates hang in the raised position.

In addition, there are panels and valves for the intake and discharge valves. All the operations of these various engines, etc., are made visible on the board by miniature electric bulbs—red, white, and green. These light-up in succession as each movement takes place, and tell of the progress and completion of each movement. No interlocking system was attempted or has been found necessary. Besides the lights on the board, visible signals turning from white to red are provided for the floating gates to show when the latches are out or in, as these gates are being operated.

Filling and Discharge System

The lock is filled and emptied by means of a steel penstock or tunnel buried in concrete under the toe of the east wall. This tunnel is 13 feet in diameter to the discharge valves on top of it, and tapers thence to 8 feet at the farther end. The water is delivered to the lock by means of 8 cross conduits of steel, 6 feet in diameter, buried in the lock floor, each one carrying 7 openings, 3 feet in diameter, discharging vertically. There are 56 of these 3-foot openings. The greater part of the head in the lock or tunnel is taken by the steel of the penstock since there is not concrete enough around the outside of this penstock to sustain the pressure due to 40 feet of water. Since it withstood the shock of a water hammer that broke all the discharge valves, as hereafter related, it is apparently strong enough, though only 3/8-inch thick.

The filling valves are not placed as is usual, on both sides of the entrance to the lock, but all on one side. This arrangement has a distinct advantage in that it tends to draw all drift, of which there is a good deal, away from the entrance to the lock, and facilitate its removal through a drift gate located in the cross wall joining the lock to the power house.

Both admission and discharge valves are situated on the axis of the 13-foot penstock or tunnel. There are four admission and four discharge valves, each 7 feet in diameter. They are exact copies of the

Panama valves and were specified by the Board of Engineers, U. S. A. They are of the balanced sleeve type, consisting of a cylindrical drum with closed top suspended above a 7-foot circular shaft communicating with the main 13-foot penstock. The drum sits on four legs or pedestals, leaving an opening the height of the legs for the passage of water. Sliding vertically inside the legs and drum is a sleeve of proper diameter open at bottom and top. This sleeve is raised or lowered by a stem that connects it to the piston of an air cylinder, 15 inches in diameter, on the lock wall.

This valve is a variation of the familiar bath-tub stopper, which acts as stopper and overflow at the same time, except that in this case the drum takes the place of the long pipe that would be necessary to reach above the water level. Objections to the bath-tub form of stopper for a lock inlet are that it is very heavy and that it sucks in enormous quantities of air with the water. On the drainage canal at Lockport, Ill., is a lock with 40-foot lift contrived on this plan, and when the valve is raised to its full height it takes in so much air with the water that, on the lock filling and the velocity of the intake falling off, the air returns to the uptake and spouts large volumes of water 20 to 30 feet in the air, endangering the lock men.

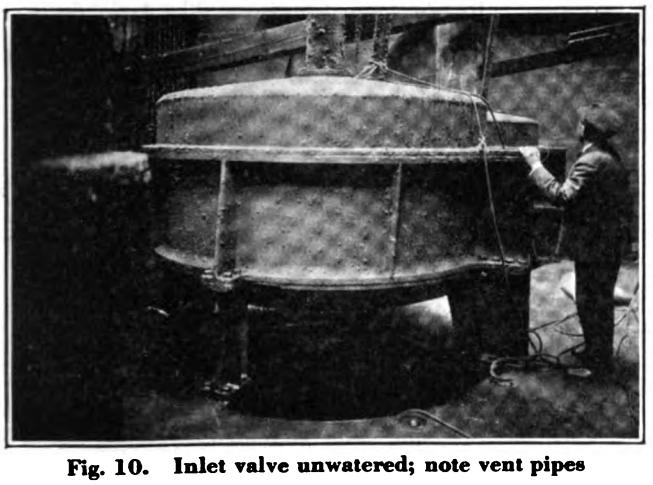

Fig. 10. Inlet valve unwatered; note vent pipes

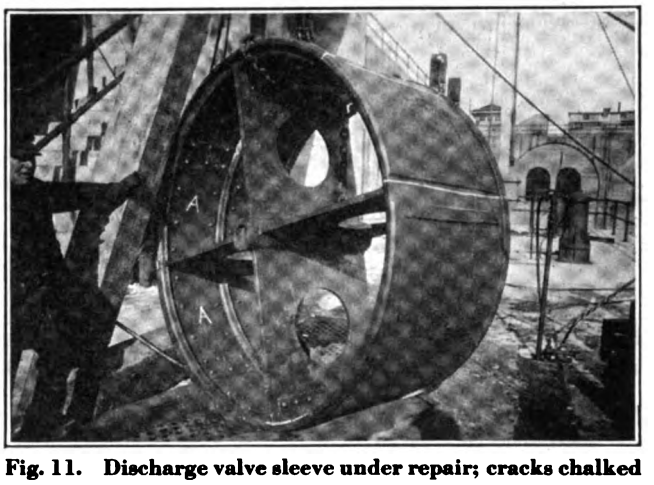

Fig. 11. Discharge valve sleeve under repair; cracks chalked

At Panama the locks are operated entirely by electricity, but at Keokuk the motive power is compressed air. The cylinders are 15 inches in diameter with 31-inch stroke, and are piped top and bottom to the table in the lock operator's house at the upper end of the lock.

An interesting experience was had with these valves soon after the lock was put in operation in June, 1913. One night the lock operator in raising the valves to fill the lock heard a loud noise like an explosion from the neighborhood of the valves, followed by the sound of falling water. Nothing further happened and the valves closed properly but the same thing continued to happen at intervals and was the cause of much speculation. It was finally discovered that the valves, while deeply immersed, nevertheless entrain more or less air by way of the grating protecting the valves from drift. The air collects in the tunnel at the far end and is held there by the rush of water until its velocity falls off. It then comes stealing back along the top of the tunnel and collects in the first uptake, that of valve No. 4. It there forms a partial vacuum under the valve. If the other valves have solid water under them, as soon as the valves lift, especially if the other valves lift before No. 4, the downrushing stream meets inert water in the tunnel and shoves the slug of water in No. 4 against the dome of the valve, constituting water hammer of the most serious kind. The valves are of semi-steel like those at Panama, and of considerable tensile strength. It has been calculated that the pressure against the top of the valve must have reached 500 pounds per square inch to break the pedestals as it did. On unwatering the valves after navigation closed it was found that this water hammer had broken 15 of the 16 pedestals of the four valves. Fortunately, the shape of the fractures was such that the dome or cover of the valve after lifting returned to its place so accurately that the valves continued to function. The covers acted as check valves. Nevertheless, it was thought best to renew the pedestals and this was done. This trouble was overcome by venting the valves to the air, so that no vacuum could form. Accordingly, two air inlet pipes were added by drilling through the top of the dome and the valves have since performed without trouble of any kind. The writer was a little afraid of the effect on the tunnel of letting a mass of water 7 feet in diameter fall 40 feet into the tunnel, but on applying a gauge to the interior of the tunnel fluctuations of only 5 pounds were indicated. The cure has been complete. Fig. 10 (valve unwatered).

Outlet Valves

The outlet valves sit directly on top of the main penstock and are also of semi-steel and otherwise identical with the intake valves. These valves, however, receive the pressure on the inside instead of the outside, and discharge outwards. After three years of successful operation there was an accident to valve No. 4. The operator started to empty the lock by raising the valve, when there was a sound like a heavy explosion that rocked the lock to its foundation. When he started to fill again there was a considerable leak from valve No. 4 and the lock did not fill completely by 6 inches. Examination by a diver showed the valve closed but a piece was gone from the movable sleeve amounting to about ⅛ of the circumference of the valve. It is worthy of note that it was possible to operate the upper floating gate even with this 6-inch head and the friction caused

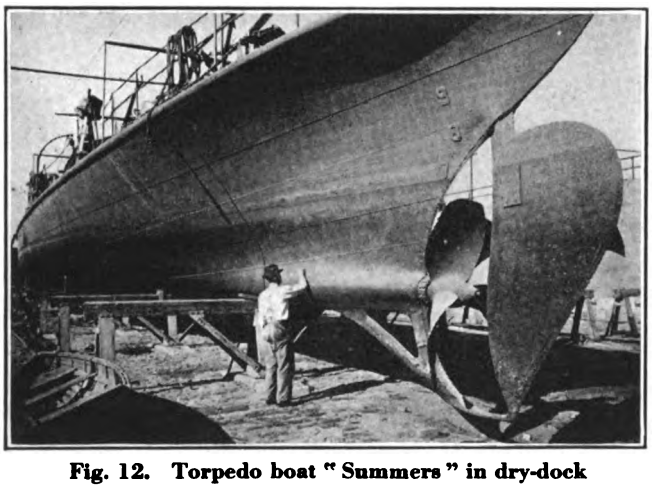

Fig. 12. Torpedo boat "Summers" in dry-dock

thereby, so that no boat was delayed. Under the same circumstances it is very doubtful if ordinary mitering gates could have been opened at all until repairs were made. In this lock the mitering gates have very powerful machinery which will open them against a 16-inch head.

Repairs were at once made to the valve by closing the gap with 4-inch by 6-inch needles put in place by the diver, though that particular valve was for the rest of the season out of commission. Later the same explosion occurred in No. 3 and No. 2 valves and they were repaired in the same way by a diver, leaving only one valve for use.

On unwatering the valves at the close of navigation it was found that all four were broken. No. 3 was minus a piece amounting to one-quarter of the circumference, No. 4 had lost one-eighth of its circumference, No. 2 was cracked and swelled under pressure so that it could not be used, and No. 1 was cracked but *could* be operated. The cause of these breakages was the shocks resulting from the dropping of the sleeves closing the valves suddenly when letting water out of the lock. In one valve the nut had come off the stem allowing the sleeve to drop, another had the stem broken just at the top of the sleeve, another had the stem pulled in two where the two pieces of pipe that connected with the piston rod of the operating cylinder were united at a screw joint.

To unwater the lock the trestles of the collapsible dam were raised, the needles placed and a large sheet of canvas spread over the needles to make them water tight. The drainage pump provided for such occasions (located in the gallery under the power plant) was started under air pressure and soon the lock and valves were dry.

The first thing done was to take out the stems. These consisted of double-strength 6-inch pipe in two lengths coupled together. The sleeve uniting the two pieces was a bronze casting and it was found, as is often the case where bronze and steel are in contact under water, that the threads of the steel pipes had corroded away (from galvanic action) allowing the pipes to pull apart. In making repairs extensive resort was had to acetylene welding. The two pieces of pipe were thus united, and a weld was made between the pipe and the steel bar or spindle which connected the stem to the sleeve of the valve. The pipe and the cap which connected it with the piston rod of the air cylinder were likewise welded together. Where the bar or spindle passed through the spider of the sleeve it was found there was no fillet under the 6-inch portion of the bar and all were filleted at this point to avoid breaking at the right-angled joint where the spindle reduces from 6-inch to 4-inch diameter.

To repair the sleeves a rig was built and the sleeves hoisted to the operating deck above the valves. (See Fig. 11. The cracks are chalked.) This was a matter of some difficulty, as the sleeves weigh 5,000 pounds each. The work was carried on under great difficulties because of the extremely cold weather of December, 1917.

That winter found all the large machine shops loaded up with war work. The patterns from which the valves had been built had been burned. The Panama valve patterns had been shipped to Panama, and to be ready for navigation in the spring it was decided to repair the old valves, since new ones could not be built in time. A diver was used to recover the pieces broken out of the valves, and after examination it was thought best to replace the fragments and hold them in place by riveting them to boiler plate properly shaped and placed on the inside of the sleeve. The plate was riveted with many rivets countersunk on the outside to give a smooth surface and the ends of the plates were bent at right angles and also riveted to the spider connecting the sleeve and stem.

Digitized by Google

Fig. 11 shows one of these valves in process of repair. The cracks where the piece came out are marked with chalk and can be seen in the picture. It was evident on examination that the water hammer was most severe, for every valve was cracked in several places. Originally an effort was made to construct the Panama valves of steel, but after losing many castings it was decided that it was impossible without enormous wastage to obtain perfect results and accordingly they were cast from semi-steel, not so strong, but, with some thickening of the parts, strong enough for their purpose. The Keokuk valves are of the same material.

Before the winter was over the main tunnel was nearly full of ice and great trouble occurred from small leaks that froze and had to be constantly chopped and removed. The work too was deep down in a damp hole, and caused a good deal of suffering to the men, but the opening of navigation found the valves replaced and they have functioned for two whole seasons since. It takes air pressure of about 55 pounds to lift the valve off its seat when the lock is empty. When filled it takes from 75 to 90 pounds. The operation of these discharge valves has not been as satisfactory as that of the inlet valves. If the water which is inside these valves, with a bursting pressure, entered and left the valve vertically and unimpeded on all sides they would probably have operated satisfactorily. But the water which flows toward the valve horizontally is turned upward through a very short connecting piece or saddle. Consequently the flow is angular or oblique, and the water striking against the sides and the spider of the valve, sets up tremors and oscillations that are undoubtedly the cause of their failure. There are grooves in the outside casing or drum of the valve in which certain guides slide to keep the sleeve from rotating, but these grooves are very shallow and the guides too small to take care of the work they have to do. For outlet valves these grooves and guides should be much enlarged and more powerful in controlling the movements of the sleeve. (See Fig. 11, at right.)

The water leaving the lock goes through the same tunnel as the water entering. The valves being located about 300 feet from the lower end of the lock do not quite unwater it because of the slope in the river, and in emptying the lock there always remains a head of about 3 inches on the mitering gates. This gives no great trouble as there is power enough to open them against a head of 16 inches, the operating mechanism being so designed. The lock fills in 15 minutes.

Spouting

At low water with a water cover over the inlet holes in the bottom of the lock of only 7 feet, there is naturally some spouting. Jets rise to a height of 5 feet. But here again the delivery of water, from one side of the lock only, proves an advantage in the handling of river boats. This comes from the fact that the holes nearest the tunnel spout but little water and leave that side quiet, so that a boat strains but little at her moorings. The water spouts highest from the last hole of the cross conduit. This is due to the effect of velocity, as is pointed out in an admirable contribution to the International Marine Congress by Mr. Whitehead, U. S. Asst. Engr. at Panama, who discusses mathematically the flow of water in the Panama conduits, and shows that given head enough and length of cross conduit enough it is perfectly possible that several of the holes nearest the entrance from the main tunnel would pass no water at all.

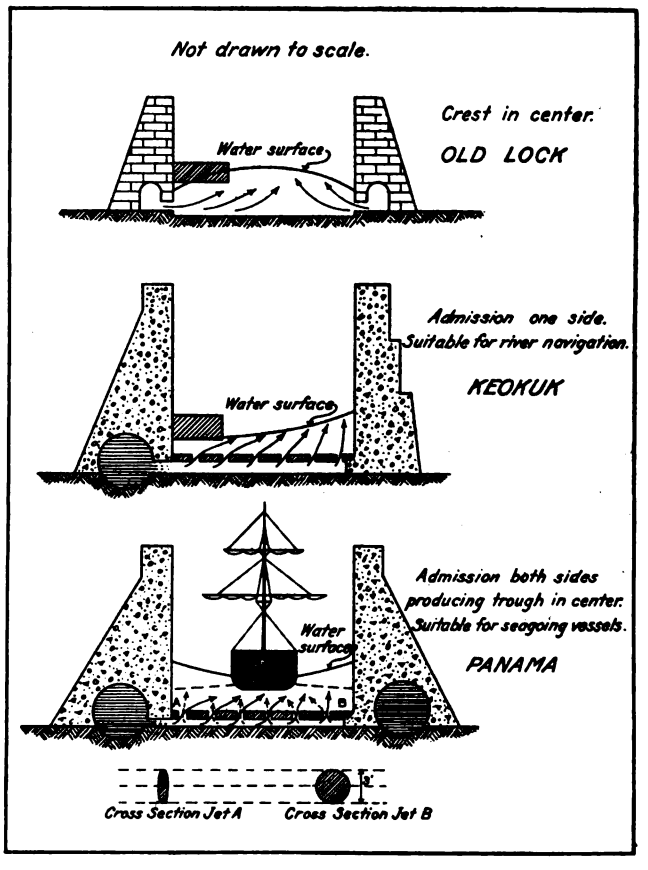

Fig. 13. Methods of filling lock

In plain language, the entering water moves so swiftly that it cannot make the turn. The circular openings, on account of the very oblique approach of the water become elongated ellipses with but small cross-section, while at the end the water flows vertically utilizing the full section of the aperture. At Panama the conditions are different. From Keokuk, sea-going ships cannot lie along a wall without damaging gear of all sorts that projects from their sides, hence they must be held in the middle, clear of the walls. At Panama they open the valves on both sides at once and the stronger spouting of the last holes raises the level of the water at the sides of the lock, keeping the boat in a trough in the middle.

Digitized by Google

But in providing quiet water for river steamers and barges the entrance on one side has advantages. (Fig. 13.)

Steamboat men have learned not to tie their boats on the west side of the Keokuk lock when they are to be lifted to the upper level.

The Lock

The lock is wholly of concrete except that occasional "plums" were introduced in the heavier parts to save expense ("cyclopean" concrete). The forms were of wood, in sections of about 5 feet in height. Every 40 feet there is an expansion joint toothed into the adjacent section of the wall. The walls were built in alternate sections. Tarred paper was used in the joints and the cracks were filled with tarvia. The walls are of gravity section, except that there is a top 20 feet wide, the overhang being carried on arches. This liberal width is a great advantage since it affords plenty of room on top of the walls for all purposes. At times as many as 2,000 excursionists disembark from a river steamer to visit the power house. As many as 30,000 have visited the power house in one year and most of these came by water. Such crowds if allowed to spread all over the lock wall would make the work of the lock crews almost impossible, and it was found necessary to place a low rail 6 feet back of the face of the lock chamber with trespass notices thereon, to secure room for the lock men to do their work unhampered. This rail has been extremely useful and has no doubt prevented some accidents.

The concrete in the lock walls is of 1:3:6 proportions. This seems to have given good results. The work was prosecuted winter and summer, being suspended only on the coldest days. At such times the aggregate and the water and the sand were heated and the concrete when placed was protected by tarpaulins. That laid in winter seems to be as good as any and there are very few blemishes in the work which has now been exposed for six seasons.

The bottom of the lock is not concreted, as the natural rock was quite good enough and nearly level. The side conduits for filling were channeled out so as not to disturb the bottom. No fissures were found in this rock except one small crevice which was filled with grout. No leaks have been discovered.

The walls are about 53 feet above the lock floor and have 5 feet freeboard at highest water in the pool. The depths are 14 feet on the upper sills and 7 feet on the lower sill. There is a collapsible set of trestles at the lower entrance to the lock. When raised the trestles carry a girder against which needles are placed and water-tightness is secured with a sheet of canvas. This dam has been used twice and performs well.

There is a service and a guard gate, both of the submersible type. As the guard gate can be taken out and floated to the dry-dock for overhauling, the need of a cofferdam above the lock is avoided. It would naturally be very difficult to put one in in 40 feet of water.

When the new lock was being planned it was proposed to alter the old lock and strengthen it so as to make it serve. It was soon found, however, that this was impracticable, the old lock being too small and having only 6 feet on the sill instead of 7 feet. A number of public meetings were held and river men pointed out that several boats built on the upper river had been too large for the old lock and had been obliged to go through unfinished to be completed below, or had gone over the rapids. Now that the rapids would be closed forever, they thought the lock should be large enough to accommodate anything that might come along. The power company through Mr. Cooper, the Chief Engineer, offered to make the lock 110 feet wide (like the Panama locks) and 400 feet long, or 50 feet longer than the old lock.

The extreme lift of the lock at low water is 40.4 feet. The dam has formed a lake above, which backs the water up to Keithsburg, some 64 miles north.

Very few locks have been built on better foundations than that obtained at Keokuk. The limestone ledges are fairly hard and vary from two to four feet thick. They are nearly horizontal and seem not to have been disturbed since they were laid down. Only a few cracks were found during the construction of the power dam and lock and these were easily closed by grouting and tested by air pressure. Fig. 8 shows the nature of the foundation.

Lighting

By the terms of the contract with the Power Company the only electricity they are to furnish the U. S. is for lighting. The 400-horsepower compressed-air plant makes other power unnecessary. A set of special transformers in one of the galleries of the lock walls furnishes electricity for all lights. The lock is lighted by 8 ornamental posts on each wall, each post supporting three globes. This gives ample illumination of the walls and is far preferable to arc lights for the purpose on account of the blinding effect of arc lights on approaching boats. There are signal lights at each end of the lock and all the pipe galleries and stairways thereto are well lighted. In addition to this the office and all the lock buildings and grounds are well lighted. (Fig. 2.)

Compressed Air Plant

This plant was built and turned over to the Government (with the lock and dry dock) for its exclusive use. It consists of two 200-horsepower turbines with horizontal shafts belted to two compound-air compressors with intercoolers. The compressors have 16 and 22-inch cylinders—16-inch stroke, and are provided with governors. The two turbines are

Digitized by Google

independent and either or both compressors can be used. The governors start the turbines whenever the pressure in the tanks falls off a few pounds, and they operate perfectly. Either or both machines are used according to the demand for power, and are completely automatic, but of course an attendant is required. This plant furnishes air for all the operations of the lock and dry dock, even to blowing the blacksmith's fire and siphoning out leaky barges.

While it is estimated that air plants deliver only 40 per cent of the effective energy put into them, there has always been a surplus of power for use at this plant. It has proved most economical and satisfactory in every way.

Ice Pressure

It is a matter of common knowledge that the ice sheet on a lake of any size grows through the winter by reason of its shrinkage in cold weather and the freezing up of the cracks, and expansion of the ice when warmed. Stone buildings which were partly submerged by the formation of the lake above the dam were shorn off at the water level the first winter. Light piers that had been built for the light-house service were also pushed over and destroyed.

Steamboat men have long known that a barge tied up for the winter crossways of the river has its sides caved in. It is probable that many dams in northern latitudes have been injured from this cause, so it was desirable to contrive some way to relieve the pressure on the 110-foot floating gates of the lock exposed to 7 miles of ice sheet expansion. Relief is sometimes given to barges that are being squeezed by cutting a trench alongside. This seemed to be at most a temporary expedient. From this came the idea of making an artificial air hole in the ice and it was tried with complete success.

A small air-pipe was led down to the bottom of the lake in front of the gate and the warm bottom layers thus drawn to the top. It takes very little air to do this and the relief is complete.

The Power Company has now adopted this plan for relieving the strain on their 119 flash-gates which are all supplied with air pipes in front of each and they say it takes very little air to keep a good air hole open. The ice remains thin for quite a long distance around the air hole.

It looks as if this idea might be usefully applied at high dams in northern latitudes.

The Dry Dock

This dock is so placed that it fills and drains by gravity. It replaces an older one of somewhat smaller dimensions on the old canal. It is 140 by 450 feet on the bottom. One side to the east is formed by the land wall of the lock, the other is a paved slope of 1½ to 1. Stairs are built at intervals to afford access to the dock grounds. The slope and bottom of the dock are paved with rubble blocks like the stone pavements in city streets. The dry dock occupies part of the site of the old lower lock of the abandoned canal, the old lock being filled to the depth of about 25 feet. The dock grounds stand about 26 feet above the top of the old lock walls, making a total fill of 51 feet. The settlement of the floor of the new dry dock has been less than expected. As seen in Fig. 9 the dry dock is furnished with steel cradles for carrying the boats when docked. At the old dock the cradles were of wood and consisted of solid blocking. The new cradles are a great improvement as their open work construction permits a free flow of water and they do not collect dirt. The floor of the dock is built on a slope of one-half per cent, so that all dirt is carried towards the outlet valve at the south end. The boat cradles have wooden caps to which any blocking necessary may be spiked. Each trestle or cradle rests on three concrete blocks embedded in the floor and these blocks are furnished with iron stirrups by which they can be lifted should they settle, and levelled by pouring grout under them. The trestles can be moved sideways to allow of calking the block spots, but it is generally easier to partly flood the dock and move the boat to a new position.

The half per cent slope of the dry dock floor is found very convenient when docking barges or boats. The tops of the cradles are all in one plane since nearly all the river boats and barges are built with flat bottoms. Some ocean-going boats have been docked, however, one of which, the navy torpedo boat *Summers,* was of thin plating and 20 years old, and required special arrangements. As will be seen in Fig. 12, bilge blocks were made in this case to fit the hull of the boat. These slid on the tops of the cradles and were pulled against the hull by ropes passed under the bottom of the boat. When the water was drawn off and the boat had settled firmly on its keel these ropes brought the bilge blocks against the hull and docked the vessel very securely.

The inlet and outlet valves of the dry dock are of the butterfly balanced type, are two at each end. They operate by a rod and screw stem with a stand and handwheel on the dock wall. It was soon found that the operation of this screw was slow and at full head it took five or six men to operate the outlet valve. Both valves were, therefore, fitted with small engines driven by air pressure and now operate quite easily. The valves are screened. It takes about one hour to dock a boat, not because it requires that time to fill the dock chamber, but because of the difficulty of holding the boat in place when the currents are too strong.

The cradles are 16 feet long and 4 feet high. They are spaced 16 feet apart along the dock and 3 feet apart endways, making a platform 73 by 368 feet on

Digitized by Google

which boats may be placed. There are 96 cradles in all. When the construction of the power house and dam were finished there remained four cantilever cranes which would just fit the dry dock. One of these was bought and re-erected in the dry dock where it has proved invaluable. It picks up material delivered on cars at the side of the dock and delivers it to the work. It has two-trolleys, each of 5 tons capacity.

The dock yard has a complete saw mill, with a large beveling ship saw that has proved most useful; also a planer, a jointer, a cut-off saw, a sawing table to trim the edges of bottom plank for calking seams, and the usual automatic saw and knife sharpeners. There is also a good machine and blacksmith shop. It has the usual lathes, planer and shaper, grinding tools and a light steam hammer. Much use has also been made in the last years of the acetylene torch, which has become invaluable for repairs of all sorts.

Standard gauge track reaches all parts of the dry dock grounds. The shifting of cars is by haulage from three air-driven capstans suitably located. This system has worked well, and while slow, appears much cheaper than to maintain a yard engine which would be idle most of the time.

The air supply from the lock power house is piped all over the grounds, and replaces steam everywhere except for heating. Extensive use is made of this power for driving hand-boring machines, hammers, etc. A useful tool lately added is a hand air-planer. This tool is driven by a turbine in the tool, and is used for outgauging plank, for which it is most effective. It operates at 100 pounds pressure.

The work at the dock consists mostly in construction and repair of the extensive fleet of boats which are used for river improvement in the upper Mississippi River. Much plant has also been built for the Mississippi River Commission. Under certain restrictions the dock is available for the use of commercial boats. The old dock, which this one replaced, could be used only to repair boats damaged in going over the Des Moines Rapids, a matter of frequent occurrence. Since the decline of steamboating the private yards have fallen into disuse and there are only one or two docks, both at a great distance from Keokuk, that can accommodate the largest boats. It has been found helpful, therefore, to dock these big boats for extensive repairs when it could be done without interfering with government work. Permits must be secured from the Chief of Engineers in every case, and evidence furnished that no other dock is readily available. The boats must furnish their own materials and pay dockage fees according to tonnage. They also pay all labor at a somewhat higher rate than prevails locally, being the scale rates at larger places, like Davenport, Iowa. The instructions in force are to make the rates such that vessel owners will not choose the U. S. Dry Dock for repairs solely for economy and thus do an injustice to private boat-yards. There is also a price scale for the use of all tools operated. This covers air tools, saw-mill tools, blacksmith's forge, steam hammer and the like.

Regulation of the River

In such a power plant as that at Keokuk on a large navigable stream, it is easy to see that interference with the natural flow may easily occur, leading to trouble with the navigation interests. When the power company applied for a permit to place a dam across the Mississippi River this difficulty was foreseen, and under authority of an act of Congress, rules were promulgated by the Secretary of War which it was thought at that time would obviate trouble from fluctuations of river level that would be hurtful to navigation. The original regulations provided for water storage in the pool at night, during low water, provided no less than the normal flow was passed down the river in any one day.

The first attempts to regulate the flow were to keep the pool above the dam at all times at a certain designated height. If its height did not change, the flow through it was normal.

This was done by opening and closing the flash gates on the dam as occasion required. It was soon found, however, that this method led to varying levels below, for the lake surface is sensitive to wind effects and often the mistake was made of shutting down the gates when the lake level fell, when the fall in the pool was due, not to lessened water supply, but to an upstream wind. Similarly, floods below were occasionally the result of downstream wind effect being mistaken for increased flow from above. The third year of the operation of the power plant the complaints of the steamboat men became loud and finally resulted in a suit for damages against the power company for interfering with the natural flow of the river. The suit was never tried, but the whole subject of regulation was reconsidered, and a new method proposed for insuring the natural flow and avoiding the fluctuations complained of.

Copies of the new and of the old regulations are appended. The new method consists in predicting the proper flow at Keokuk from a gauge at Keithsburg at the head of the pool, and beyond the influence of the dam. There is no tributary of any size between Keokuk and Keithsburg, except Skunk River, and at low water when the flow of the river is small and the necessity for regulation is great, Skunk River is almost dry, being like all the streams in this region, a mere sluice that flows only when there is a rainfall.

The system operator, as he is called, at the power house, has a daily record of the gauge at Keithsburg from which the proper gauge height at Keokuk is calculated. This record he plats on a sheet before him, together with the wind velocity, temperature,

Digitized by Google

kilowatts delivered, number of flash-gates open, etc. As the flow through the wheels varies he opens or closes flash-gates so as to keep the gauge reading correct for normal flow. This record is from hour to hour, and at the end of a day there is a complete power-house history of the day. The aim is to make the gauge readings below the dam conform to the predicted stage as nearly as possible.

There are 119 flash-gates on the dam which are 11 feet high and 30 feet long. The normal height of the pool is elevation 525.00 Memphis datum.

The system operator can open as many of these gates as he wishes. They are manipulated by two electric cranes, and there is a steam locomotive crane that can be used in emergencies. Sometimes there are as many as 60 flash-gates open, somtimes only one. After navigation closes all the flash-gates are sometimes closed for a day or two, and at this time the discharge of the river is less than the needs of the power plant, and the level of the pool falls to rise again when the water arrested by ice gorges above is released.

The post of system operator requires considerable judgment in predicting the proper gauge height at Keokuk to pass the normal flow. It is filled by a special engineering assistant.

When the original permit for the operation of the dam and power house was granted (see Appendix A), it was thought that it might be permissible to vary the normal flow for a few hours of the day, provided the daily total was maintained. This permission has never been used, however, for the needs of the power house up to the time the regulations were changed were always such that no advantage could be taken of it. Still there were fluctuations of the water surface that were directly traceable to the dam, and steamboat men, when they ran aground during low water, always blamed the dam. The new set of rules has now been in force for two seasons, and has given much better satisfaction. Gauge records kept for some years at various distances below the dam have shown that waves of 12 inches at the dam diminish to 0.2 foot at Canton, 23 miles below. Also the speed of the crest of the wave is found to be three miles an hour. It requires just 13 hours to travel to Quincy, 39 miles downstream.

The new regulations (Appendix B) have almost entirely done away with any fluctuations of river level which interfere with navigation. As the height of a wave rapidly diminishes as it moves downstream and practically disappears at 23 miles below, it is only near the dam that it is felt at all. Of late there have been no complaints on this score from the navigation interests.

After the close of navigation regulation is not attempted; in fact, with the spillway gates frozen in they can be operated only with great difficulty, and after thawing out.

A reference to the table of discharges at Keokuk (see Appendix C) and a calculation of the water horse-power, gives the following for stages at lower lock river gauge:

Gauge height 0.1 ft. Discharge 20,000 sec. ft. Water horse-power 72,500.

Gauge height 3.0 ft. Discharge 36,500 sec. ft. Water horse-power 144,700.

The water is lowest at about 5 a. m. and highest about 6 p. m. This results from the nature of the load at the power house, which is mostly absorbed by public utilities in St. Louis—street cars and lighting. The power delivered averages about 79,400 K. W. per day.

Close regulation of the flow can be attained only by the greatest care and attention, but it is possible and is at present attained at Keokuk. In the figures above, the head at stage 0.1 ft. of the gauge was 38.3 ft. but that at the 3-ft. stage was only 35.8 ft., due to the drawing down of the pool temporarily. The draft on the pool served to tide over a shortage of water during the period of ice formation on the river and was made good a few days later when the normal flow was resumed. Such drawing on the pool is not permissible in summer or during the season of navigation. But it is very seldom that the pool is drawn on or that the power house has had to buy power owing to deficient stream flow, and then for only for a few days at a time.

The power company has encountered much hostility from certain people and interests. It must be said, however, that in the conservation of natural resources going to waste, it has been a success.

This was never better demonstrated than during the late coal strike when it was furnishing power the equivalent of 6,100 tons of coal daily, or six trainloads of 21 40-ton cars.

To sum up the subject of the lock and dam at Keokuk, the writer thinks the government made a good bargain in exchanging the old Des Moines Rapids Canal with its three small locks of but 5-foot depth and maintained by constant dredging, for the one lock of liberal size and most modern construction. In addition, it obtained a new and larger dry dock supplied with abundant compressed-air power generated by water turbines at no cost. It also obtained an improved river with deep water for at least 40 miles, all at no cost to the United States.

As happens constantly in all industrial enterprises, the wisest procedure is frequently to scrap machines that when built were considered the last word in progress, and in scrapping the old canal this wisest course was followed.

General A. Mackenzie was Chief of Engineers when the project for the dam was approved by Congress,

Digitized by Google

and saw most of the construction. The District Engineer, during the preliminary studies of the project, was Major (now Colonel) C. S. Riché. The building of the lock and power plant was under the supervision of Major (now Colonel) Charles Keller. Since the operation of the lock began Colonels George M. Hoffman and H. Burgess have had charge. During all this time the writer has had local supervision on behalf of the government.

It was an experience of the greatest engineering interest to see this important work proceed to completion in the short space of two and one-half years. The chief engineer, Mr. H. L. Cooper, had opportunities such as fall to few men in unrestricted authority and unlimited means, the only thing asked of him was results. The methods employed and the morale of the working force were also matters of the greatest interest. The power was turned on one day sooner than the date set at the inception of the work and this, too, was no small matter. It showed what unlimited means and undivided authority can do when combined on a project like this.

In conclusion, the writer thinks that the whole plant has operated for six years with remarkable success. In all that time no serious accident has occurred and all the machinery has given full satisfaction except the discharge valves of the lock. As now vented to the air the inlet valves cannot be improved on. The outlet valves, when rebuilt, should have some changes made in better guides for the movable sleeve, which involves only slight alterations in the present design.

That all this intricate machinery of novel type should have operated so well is a high tribute to the chief engineer, Mr. H. L. Cooper, and his mechanical assistant, Mr. B. H. Parsons. In six years no boat has been denied passage, though for a month or two it was slow when but one valve was available for unwatering the lock.

APPENDIX A

Original Regulations Governing the Operation of the Power Dam in the Mississippi River at Keokuk, Ia., by the Mississippi River Power Company.

Approved March 26, 1903.

1. During the hours of daylight, during the navigation season, between sunrise and sunset, the Power Company shall not store water behind the dam.

2. During the navigation period and during the hours of darkness between sunset and sunrise, the Power Company may store water behind the dam provided that during at least two hours of such interval of darkness the power house shall not pass water at less than an average rate of flow of 15,000 cubic feet per second, and during at least six other hours of the period of darkness referred to in this paragraph, the power house shall pass water at an average rate of not less than 10,000 cubic feet per second, and for the remaining hours of darkness the power house shall discharge not less than 5,000 cubic feet per second.

3. That when the flow of the river is not greater than 20,000 cubic feet per second, the Power Company shall pass through the dam during the daylight hours in addition to the then flow of the river, an additional quantity of water equal to that stored during the next preceding hours of darkness from sunset to sunrise.

4. That at any future period if the flow in the Mississippi River should fall below 20,000 cubic feet per second and the Power Company should not be passing water through the dam for power purposes equal to the total average discharge mentioned above, the Power Company shall be required to draw from its storage in aid of navigation, under stipulations to be specified from time to time by the engineer in charge of the district, that amount of storage that exists behind the dam above elevation 519, which is equivalent to drawing the pond 4 feet in aid of navigation during the time when discharge of the river might be less than 20,000 cubic feet per second.

APPENDIX B

Regulations to Govern the Operation of the Power Dam in the Mississippi River at Keokuk, Ia., by the Mississippi River Power Company.

Approved January 12, 1918.

1. All previous regulations of the Secretary of War relating to the use of the Mississippi River for the generation of power by the Mississippi River Power Company, including the Memorandum of March 24, 1908, approved by the Secretary of War March 26, 1908, are rescinded and the following regulations will govern the operation of the dam until further orders.

2. Excepting as herein specially provided, the normal flow of the river shall be discharged below the dam at all times of day and night.

3. The Mississippi River Power Company shall not, during the period of navigation, raise the level of the pond behind the Keokuk dam when the natural flow of the Mississippi River is falling, or when such natural flow is less than approximately 64,000 cubic feet per second, which corresponds to a normal stage of 6 feet above low water at Keokuk, Iowa, except upon the written permission of the United States District Engineer in charge at this locality, such permit to state the period which such ponding may cover and the maximum variation in stage below the dam which may be caused by such ponding.

4. The granting of permits by the District Engineer shall be governed by the provision of the law authorizing the construction of the dam and its accessories, as follows:

> "Section 2. That the withdrawal of water from the Mississippi River and the discharge of water into the said river, for the purpose of operating the said power stations and appurtenant works, shall be under the direction and control of the Secretary of War, and shall at no time be such as to impede or interfere with the safe and convenient navigation of the said river by means of steamboats or other vessels, or by rafts or barges."
>
> . . .

5. The Power Company, when proposing to raise or lower the pond either under general authority or special permission, shall give due notice to the District Engineer or his authorized agent, of its intention.

6. The Power Company shall hold all records relating to operations affecting the river discharge open to the inspection of the District Engineer or his authorized agent.

7. It shall be the duty of the District Engineer or his authorized agent to observe closely and carefully the operations of the Power Company and to maintain, in addition to such as may be maintained by the Power Company, such river and pool gauges as may be advisable, and make from time to time such examinations as may be necessary for determining the effect of the operation of the power dam and accessories on the river channels.

8. The War Department approves the method of regulating the flow below the Keokuk dam by estimating the flow 24 hours in advance and maintenance of the stage corresponding to such flow as indicated by the river gauge at U. S. Lock. (The method employed during 1917.) The general rules above stated are not intended to apply to unavoidable small compensating variations in pond level behind the dam, inherent in such method of regulation.

War Department:
Approved, January 12, 1918.

B. CROWELL,
Assistant Secretary of War

APPENDIX C

Discharge of the Mississippi River at Keokuk, Ia.

By stages on the lower lock gauge.

Gauge height	*Sec. ft.*	*Gauge height*	*Sec. ft.*
1 ft. below	14,000	6 ft. above	64,000
Zero	19,000	7 ft. above	75,100
1 ft. above	23,600	8 ft. above	87,000
2 ft. above	29,600	9 ft. above	100,500
3 ft. above	36,500	10 ft. above	114,000
4 ft. above	44,500	18 ft. above	230,700
5 ft. above	54,000

CURRENT NEWS

NOTE.—This department will include news items of professional or personal interest concerning individuals and organizations in the Army, National Guard, Reserve Corps, Reserve Officers' Training Corps, the Service Schools, the U. S. Engineer Department, other departments or bureaus of the Government, and other related activities, both civil and military.

In the PROFESSIONAL NOTES section will appear news items, short articles and digests on matters relating to current developments in engineering and allied sciences and the art of war—of special interest to the military engineer.

Contributions to these columns, whether from original sources or from other periodicals, are solicited from all our readers. Such contributions should be submitted in time to reach our office not later than the 15th of the month preceding each issue of THE MILITARY ENGINEER.

News of the Services

Engineer Districts

BOSTON DISTRICT.

Col. F. R. SHUNK.

The construction of emplacements for two 12-inch long range rifles at Nahant, Mass., has attained 40 per cent completion. A channel and turning basin have been dredged to wharf site at Hog Island, Boston Harbor, Mass. The wharf is 60 per cent completed and it is expected that construction of the emplacements of two 12-inch rifles will be begun in the early Spring of 1920.

The project for a 24-foot channel, 200 feet wide from that depth in the bay to Quincy drawbridge, Quincy, Mass., is assisted by contributory funds from the State of Massachusetts, the City of Quincy, Mass., and the Fore River Shipbuilding Corporation. The entire project is 30 per cent completed and it is expected that contract for the completion of the dredging will be made in December.

FIRST DISTRICT, NEW YORK CITY.

Col. EDW. BURR.

Dredging economics.—The district is continuing a series of test loads with seagoing dredges to ascertain the correct time for loading, and the proper load, analyzed as to costs, all as a part of current dredging operations. The work described herein was done by the dredge *Raritan* in the Weehawken-Edgewater Channel, Hudson River. This channel is about four miles in length on the west side of the river from 60th to 150th Streets, Manhattan. The material is a clayey mud, which does not settle well in the bins, and which, after pumping a partial load, runs away in the overflows, so that full bins can not be retained. The round trip to the dump and return is about 60 miles.

The prime object of the tests is to ascertain the economical time of loading: this is independent of the cost of dredge per working hour, which cost can be taken from any convenient data. The costs below were taken from those for the month of October, 1919, as follows:

Cost of *Raritan*, including field cost, plus rental and office supervision____$14,108.32
Total capacity of dredge, cu. yds.__2,884
Hours dredging, turning, going to and from dump ----------372.1
Cost per hour worked ----------$37.92
Cost of disposing of one load------$241.17

Example, 1st load, supposing loading to stop after two hours pumping:

Pumping and turning----------$ 75.84
Disposing of load----------241.17
Result: 1301 cu. yds. at 24.37c per cu. yd.

The data in the table herewith were determined as above.

		Pumping and turning.					
Hours	2	3	3.5	4	4.5	5	5.67
1st load, cubic yards	1,301	1,744	1938	2,084	2,461	2,513	2,578
Differences		443	194	146	377	52	65
Average cost, cts	24.37	20.35	19.29	18.85	16.73	17.14	17.65
2nd load, cubic yards	938	1,562	1,744	2,017	2,315	2,467	2,552
Differences		624	182	273	298	152	85
Average cost, cts.	33.80	22.72	21.44	19.48	17.79	17.46	17.38
3rd load cubic yards	933	1,374	1,944	2,296	2,473	2,558	2,596
Differences		441	570	352	177	85	38
Average cost, cts.	33.98	25.83	19.23	17.11	16.65	16.84	17.57
Average cubic yards per minute	8.9	8.7	8.9	8.8	8.9	8.4	6.1

The figures in the table indicate that the proper economic time to stop pumping is 4½ to 5 hrs., when the dredge has a load of about 2,500 cubic yards.

The loads were measured with a sounding pole with a wooden disc about 8 inches in diameter attached. Soundings were taken in bins and when pole met with about the same resistance as when sounding similar material in the river, measurement was recorded and contents of bins taken from tables.

Results vary with the character of material and distance to dump and must be determined by experiment in each case. The foregoing statement applies to the dredge *Raritan*, pumping soft mud, with a distance of 30 miles to the dump.

Results of dredging in Ambrose, Gedney and Coney Island Channels.—Ambrose Channel, the main entrance to New York Harbor from the sea, was dredged 2,000 feet wide, 40 feet deep, at mean low water for a length of 7½ miles: completed in April, 1914, with total excavation of over 66 000,000 cubic yards. Immediately after completion, one of the dredges worked a few months deepening the edges of the channel where shoaling was anticipated. Since December, 1914, no dredging for maintenance has been needed.

Examination of the channel, in 1915, showed no filling. The last examination, in the summer of 1919, showed not only no filling, but a slight increase in depths, both in the channel and in the shoal banks on either side.

The last part, about 71 per cent. of the excavation, was done by U. S. self-containing seagoing hydraulic dredges. The same dredge deepened Coney Island Channel: work suspended since 1913. The 30-foot Gedney Channel was dredged, 1884 to 1891, by dredges of similar type. Neither Ambrose Channel nor Gedney Channel yet show any tendency to shoal. Coney Island Channel has shoaled very slightly, in the same place where dredging done by a clam-shell dredge in 1907, and wholly filled in by June, 1908.

These seagoing dredges plane off the bottom in small furrows, 3 to 6 feet wide and 2 to 6 inches deep. It seems probable that, on bars of this kind, the gradual deepening of the entire channel way induces a modification in the regimen of the currents, which tends towards permanence.

PHILADELPHIA DISTRICT.

Lt. Col. W. B. LADUE.

Work of dredging in the Delaware River below Philadelphia under contract, in prosecution of the 35-foot channel improvement; and maintenance work on the 30-foot channel with government plant, was suspended for the season during December on account of cold weather, accompanied by heavy running ice in the river, and the plant removed to Philadelphia for overhaul.

The sea-going dredges *Delaware* and *Manhattan* will be overhauled at the Philadelphia navy yard. Fuel oil tanks and oil burning appliances will be installed, fitting these dredges to burn oil during the coming season.

The large bucket-ladder dredge *Corozal* was purchased from the Panama Canal in the fall of 1919, and brought to Norfolk, Va., in tow of the U. S. navy collier *Vulcan*, arriving December 25, 1919. After minor repairs, the dredge sailed for Philadelphia under her own steam on January 6 and tied up at the dredge depot below the mouth of the Schuylkill River, January 8th. She is now being overhauled.

A contract was made on November 3, 1919, with the Arundel Corporation, of Baltimore, Md., for repairing the dike at Bulkhead Bar. The estimated expenditure under this contract is about $45,000.

Bids will be opened on February 18, 1920, for dredging to a depth of 35 feet in Philadelphia Harbor, from about Jackson Street to about Queen Street, along the front of the city south of Market Street. About $400,000 is reserved for payments to the contractor for this work.

The project channel along the city front of Trenton, between Lalor Street and the upper railroad bridge, was practically completed in November, when work was suspended due to exhaustion of fnuds. A few small rock shoals in the channel and a small area in the northwest corner of the turning basin, remained unfinished. These rock shoals in the channel will be removed in the spring under an allotment recently made.

Work on the Schuylkill River is still in progress, not having been stopped by ice as on the Delaware. It is expected that this project will be finished by midsummer of 1920.

Digitized by Google

JACKSONVILLE DISTRICT.

Lt. Col. W. J. Barden.

Reducing current velocities through New Cut entrance Miami Harbor.—Work on the New Cut entrance to Miami Harbor was begun in 1902. Prior to that time access was had by a dredged channel entering the Bay south of Biscayne Key, this channel being about 10 miles long. The new project provides a short, straight channel giving direct access to the wharves at Miami. Jetties 1,000 feet apart have been constructed extending from the shore into the ocean, and a navigable channel, 300 feet wide, was cut through the key. The City of Miami has dredged a channel connecting the new cut with the city water front. The dredged material was used to form a causeway on the north side of this channel, this causeway be-

Miami Harbor, Fla. New Cut Entrance

ing connected by bridges with the land at each end.

The tides flow through the various openings in the keys into Biscayne Bay. The velocity of the tidal currents in the New Cut reached a maximum of 5½ miles per hour, which seriously interfered with navigation, and a reduction of this velocity was imperatively necessary. Authority was granted for the removal down to rock, of the points extending into New Cut Channel between the shore ends of the jetties. This work was completed January, 1920, by the removal of about 147,000 cubic yards under contract with the Bowers Southern Dredging Co., following which the maximum velocity of tidal currents through the cut does not exceed 3.5 miles per hour.

The impounding of the tidal waters north of the causeway also operates to reduce velocities by limiting the area from which water is discharged through New Cut.

MONTGOMERY DISTRICT.

Maj. W. A. Johnson.

Artificial rubble for jetty construction.—A novel method is being used in this district for providing stone filling for jetties on the Alabama River in localities where the distance from stone quarries renders the cost of hauling prohibitive. The coarse gravel and sand bars are utilized for making artificial stone by spading or loosening the gravel over a small area of the size of the stone desired. A cement grout is then poured into the area, reaching all parts of the mass. Upon setting the artificial stones are removed and successfully used for filling jetties.

MOBILE DISTRICT.

Maj. R. S. Thomas.

Mobile outer bar.—Authority was granted by the Chief of Engineers, December 4, 1919, to shift the Mobile Outer Bar Channel westward of present location in order to avoid the encroachment of the bar upon the channel from the east, to locate the channel in the natural deep water over the bar, and to avoid an angle in the channel at the north and leading into the deep water. These objects were accomplished by shifting the south end of the channel about 1,700 feet to the west and keeping the north end at practically the same location. The change was made preparatory to beginning work on the enlarged channel of the existing project adopted August 8, 1917, which provides for increasing the depth from 30 to 33 feet, and the width from 300 to 450 feet. The change is due to the rapid westward movement of the bar in recent years.

Work on the new channel was begun December, 1919, and will be finished by the end of 1920. Mobile Outer Bar is in the Gulf of Mexico about five miles south of the entrance to Mobile Bay and the channel through it is about one mile long.

Fuel-oil burning equipment on dredge "Wahalak."—An installation of fuel-oil burning equipment of the low-pressure steam atomizing type was recently completed on the 20-inch hydraulic pipe-line dredge *Wahalak*, which operates in Mobile Bay. This equipment consists of Hammel burners, extension fronts to the boiler furnaces and a Worthington Duplex oil pump set, 4 by 2¾ by 4 inches, with heater. The dredge is equipped with four Scotch marine boilers of approximately 250 horsepower each, but when operating three only are used. This fact made it possible to change the dredge from coal burning without losing any time from dredging operations.

It is intended to install oil and hot water meters for the purpose of obtaining records of oil and boiler feed water consumption, and when the crew becomes accustomed to burning oil a series of boiler efficiency tests will be made to compare the results obtained with the two kinds of fuel. It was intended to convert two other dredges in the district to oil-burning, but the recent advance in the cost of fuel oil makes it advisable to defer these installations for the present.

Ship building and commerce on Black Warrior, Warrior and Tombigbee Rivers.—The Chickasaw Shipbuilding Company, on Chickasaw Creek, about five miles above Mobile, recently launched its first steel vessel of 9,600 tons displacement, and expected to follow with others at a rapid rate as it has a very large plant thoroughly equipped with modern facilities for building steel ocean-going vessels. This is of considerable significance because of the fact that the company will use the canalized Black Warrior, Warrior and Tombigbee Rivers for transporting steel from its plant at Fairfield, Ala., in the Birmingham District, to the shipyard, which will add appreciably to the traffic on these streams. The shipments of steel began last December, and during the month amounted to 600 tons. There was an increase of nearly 100 per cent during January and the shipments are estimated to reach 3,000 tons during February. This includes steel rails shipped from the Birmingham district for export from Mobile.

NEW ORLEANS DISTRICT.

Maj. E. J. Dent.

South Pass, Mississippi River.—A contract was entered into January 9, 1920, with Lester F. Alexander, of New Orleans La., for constructing a stone breakwater along the sea side of the outer portion of the inner east jetty at the South Pass.

The breakwater will be of rip-rap stone, ranging from 75 to 10,000 pounds, brought to an elevation of 2 feet above mean high water, crown width of six to eight feet, side slopes of one on two on the sea side, and one on one on the river side. The breakwater will rest on a substructure of willow brush brought to elevation of mean low tide.

The outer portion of the main east jetty has subsided to such an extent as to no longer afford protection to the inner east jetty, which is constructed of willow brush held in place with small rip-rap and round piling. The breakwater is for the purpose of protecting the inner east jetty against the heavy seas which sweep over the submerged main jetty.

A wireless station has recently been installed by this office at Port Eads, South Pass, for handling Government business only. The first message sent was on March 1, 1920.

Intracoastal Waterway.—Bids were opened January 29, 1920, for dredging a portion of the Intracoastal Waterway from Mermentau River to Calcasieu River. The contract will be awarded to the Lake Arthur Dredging Co., of Beaumont, Texas, 12 cents per cu. yd., place measurement. The estimated quantity to be removed with the funds available is 1,200,000 cu. yds. A party is now in the field staking out the right-of-way.

The bucket-dredge *Grossetete* began work on February 20, 1920, in Bayou Black, Terrebonne Parish, deepening and widening it where necessary to provide a channel 5 feet deep at mean gulf level and 40 feet wide on bottom. This will form a portion of the Intracoastal Waterway from the Mississippi River to Bayou Teche.

Bayou Teche.—The pipe-line dredge *Delatour* began work on February 21, 1920, at Shadyside Bridge, about 8½ miles above the mouth of Bayou Teche, to provide a channel 8 feet deep at mean low gulf level and 80 feet wide, up to New Iberia, 54½ miles above the mouth. The lower 8½ miles already has sufficient depth and width. This project was authorized by the river and harbor act of March 2, 1919.

The dredge *Captain Huston*, recently purchased at New Orleans by the Porto Rico District, was taken to Mobile, Ala., and placed in dry dock where it was overhauled and bulkheaded, preparatory to going to sea, under the supervision of this office. The dredge is now awaiting the arrival of the tug *San Luis* from New York, which will take it to San Juan, P. R.

The dredge *H. S. Taber* arrived in New Orleans on February 28, 1920, and will be overhauled at the naval dock here, after which it will be bulkheaded and taken to the Norfolk district.

Mr. Arthur McFarland, Assistant Engineer of this office, has just returned from the office of the Chief of Engineers, where he had been for nearly two weeks in consultation as to the standardization of the design of seagoing-hopper and hydraulic pipe-line dredges.

Lieut. Col. Herbert Deakyne was relieved from the charge of this district on March 1, 1920, by Maj. E. J. Dent, who was relieved from the Fourth Mississippi River District on the same day.

GALVESTON DISTRICT.

Lt. Col. Spencer Cosby.

There have been a number of flashy rises in the Brazos River that have rendered difficult keeping open the channel at the mouth of the

Digitized by Google

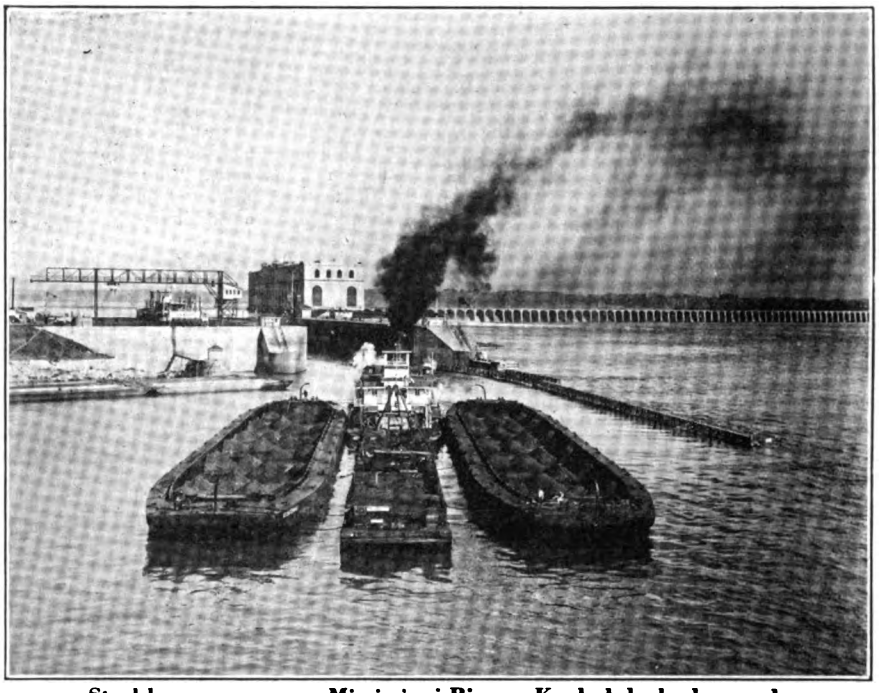
jetties at Freeport Harbor, Texas. These rises have brought down a considerable quantity of silt from the interior of Texas, and deposited it in the turning basin and between the jetties. This river is unique on the coast of Texas in that it empties directly into the Gulf of Mexico. All other Texas rivers, except the Bernard, empty into lakes or bays.

The tugboat *Major R. C. Smead* was launched on January 31, 1920. This boat is being constructed by hired labor at the U. S. Engineer Department shops at Fort Point, Tex. Its dimensions are 75 feet 6 inches by 17 feet 2 inches by 7 feet 2 inches, with 5-foot draft. It is twin screw, the motive power being two 100 H. P. Fairbanks-Morse crude oil engines. It is expected that the vessel will be completed by March 1, 1920.

ST. LOUIS DISTRICT.
Maj. W. WILLING.

Steel barges and towboats Upper Mississippi River.—This district has charge of the design and construction—now well under way—of a fleet of very large steel barges and towboats for towing iron ore on the Upper Mississippi River from St. Paul to St. Louis, for the increase of production of pig iron in the middle west. In order to balance the traffic, coal and fuel oil are carried on the upstream trip between those cities. As this is to be entirely through traffic in bulk freight of low "tariff" grade, the barges have been designed in extreme size for that river section and will carry a maximum load of 3,000 tons each.

These vessels are being built under an allotment of $3,860,000 made during the war by the Emergency Fleet Corporation.



Three barges will constitute a tow, and the tow boats are to be in size comparable to the largest stern paddle-wheel steamers that have yet been built, and equipped probably with more powerful propelling machinery (about 2,000 h. p.) than has ever been installed on such boats.

The design of the whole fleet and its various power installations has presented many difficult problems in order to attain power with the least possible weight, as an over-draft of the boats in so shallow a stream would be fatal to the enterprise, which was begun as a war measure and is now being carried to completion and into operation under a lease of the fleet by the Government to private parties operating the furnaces at St. Louis.

Of the many problems, the propelling wheel presented one of the most serious difficulties. The river is too shallow during long low-water seasons to permit the use of propellers of sufficient size to develop the power required. The stern type paddle wheel, long characteristic of river navigation, was therefore decided upon, and, because of its greater weight, the feathering type of paddle wheel, with its intricacy of moving parts, was rejected, and the usual fixed radial paddle wheel was chosen; but even at that, the great size of wheel required will result in an overhanging or cantilevered weight of fully 60 tons at the stern of the boat, nearly one-third of which will be absorbed in the great shaft.

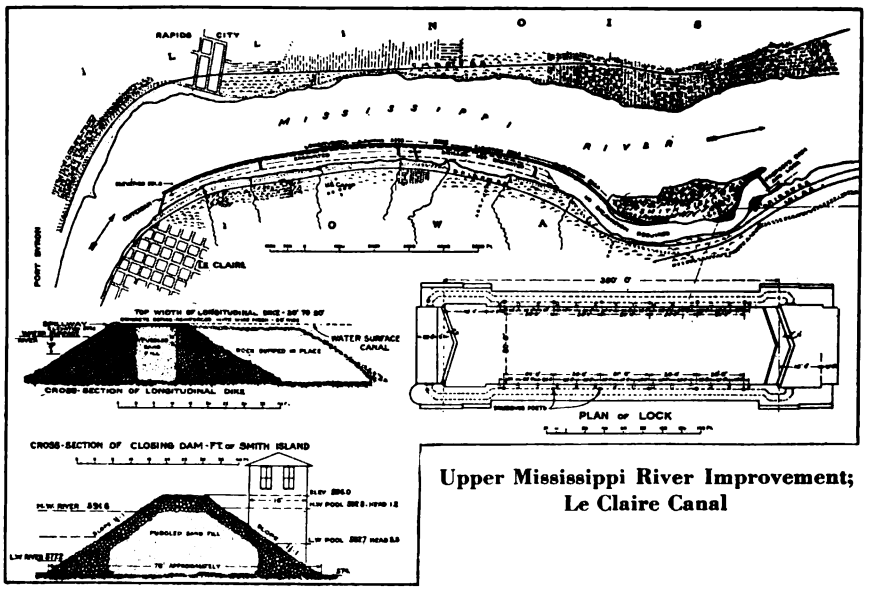
The shaft of nickel steel, double annealed, will be over 46 feet in length, 25 inches in outside diameter, and bored or forged hollow, to an interior diameter of 19 inches. The ends, at the cranks and journals, will be thickened to 6 inches gradually tapering in a length of 3 feet to 8 inches.

The finished weight of the great shaft will be 18 tons, although it will take an ingot of about 50 tons to produce it. Each crank, with its wrist, will weight over 2 tons, and each flange will weigh about 1 ton, the combined weights of these parts of the wheel being nearly 30 tons.

Steel barges on upper Mississippi River. Keokuk lock, dam and power-house in the background

The problem of forging and finishing these large and heavy shafts is a serious one for the forges, of which there are probably less than half a dozen in this country adequately equipped to handle the work.

These barges and steamboats were designed by Mr. W. S. Mitchell, U. S. Assistant Engineer, while he was in charge of the St. Louis Engineer District during the war period.



The dimensions of the barges are 300 by 48 by 10 feet, they weigh 500 tons, and will cost, under contract, about $110,000 each. which is 11 cents per ton of metal, and $37 per ton of ultimate carrying capacity. The barges may be unloaded by clamshell or Hulette machine. Their carrying capacities at different drafts are:

3 ft. draft, 475 tons.
6 ft. draft, 1,660 tons.
9 ft. draft, 3,000 tons.

The photograph shows two barges loaded with 650 tons of ore each, leaving the Keokuk dam in tow of the *Taber*.

ROCK ISLAND DISTRICT.
Lt. Col. H. BURGESS.

Lateral canal at LeClaire, Iowa. The most important work under way in the district is the construction of the lateral canal at Le Claire, Iowa, for the purpose of surmounting the upper Rock Island rapids. This portion of the rapids is about 3½ miles long, and has a maximum fall of about 5½ feet. The canal lies along the Iowa bank, and is formed by a longitudinal dike or dam, beginning at LeClaire and extending downstream approximately parallel to the right bank of the river as far as the head of Smiths Island.

Upper Mississippi River Improvement; Le Claire Canal

Digitized by Google

This island then takes the place of the dike, and upon it there is to be constructed in prolongation of the dike a levee to prevent flow across the island during high stages of the river.

At the lower end of the island chute is a lift lock and a closing dam. The project includes the construction of a longitudinal dike about 2½ miles long; the excavation of about 253,000 cubic yards of ledge rock to form the canal prism; the construction of about ¾ of a mile of light levee on Smiths Island; the excavation of about 60,000 cubic yards of rock on the shore of Smiths Island and on the Iowa shore to straighten the channel; and the construction of a lock and closing dam from the lower end of the island to the lock. In addition some rock excavation in the upper and lower approaches is necessary to provide unobstructed entrances for navigation.

Work was started in 1915, but the progress has been seriously handicapped by lack of funds. To date, the work done consists of the construction of the longitudinal dike with a concrete paving on the greater part of it (all that part which will be overtopped by high water in the canal); the drilling and blasting of ledge rock in the canal prism, and the removal by steam shovel of 190,000 cubic yards, place measurement; the construction of about 70 per cent of the levee on Smiths Island; the construction of the cofferdam closing the island chute just above the lock site; the construction of the puddled sand core of the closing dam; the removal by dipper dredge of the soft material overlying the rock at the site of the proposed lock; and the drilling, blasting and removal of about ¾ of the rock in the upper approach to the lock.

The program for the current year, so far as funds are available, contemplates the completion of the Smiths Island levee, the drilling, blasting and excavation of about 40,000 cubic yards of ledge rock on Smiths Island for widening and straightening the island chute; the construction of the lower cofferdam for the lock; the filling of the low area on the Iowa shore adjacent to the lock, by use of suction dredge; and the removal by dipper dredge of the blasted rock in the canal prism which cannot be conveniently removed by the steam shovel. Actual work on lock construction will also be started if the pending river and harbor bill provides sufficient funds.

The total estimated cost (preliminary) was $1,283,000; but because of the delay in prosecuting the work, and the extraordinary increase in prices of labor and material which has taken place in the past few years, the present estimated cost is $1,800,000. The total amount expended to date is approximately $934,000; and the amount available for the current year, unless additional funds are provided, is about $123,000. With ample funds at hand the entire work should have been completed within five years, and at a cost considerably less than will be required in the eight or nine years over which the construction will extend.

KANSAS CITY DISTRICT.

Maj. R. T. Ward

In making repairs to Chittenden drum weirs at Lock and Dam No. 1, Osage River, great difficulty was encountered in raising the weirs. The automatic device did not function in many cases and the weirs were lifted by means of hydraulic jacks aided by a derrick boat. Great quantities of sand were found in the drums.

FLORENCE (ALA.) DISTRICT.

Lt. Col. Lytle Brown.

Progress on Wilson Dam.—The Wilson Dam, at Muscle Shoals on the Tennessee River, will soon be ready for the major concrete operations. Practically all the equipment for placing 900,000 cubic yards of concrete is now on hand. The preparations at the north and south abutments and on Jackson Island in mid-stream are well advanced.

On the north shore of the river the mixing equipment, including conveyors, bins and warehouses, with two two-yard concrete mixers, is in readiness for work. The two four-yard concrete mixers, the 48-inch rock crusher, with its additional battery of six 14-inch crushers, will soon be erected on Jackson Island A cement shed, capacity 20,000 barrels, has been built for the island mixing plant. On the south side of the river, a coffer is being constructed at the site of the power house. When completed, four turbine generators, each of 30,000 H. P. net, will furnish Nitrate Plant No. 2 with the bulk of the electricity thus generated. Emplacements will be provided for eleven other similar generators which, when installed, will bring the aggregate to 375,000 H. P. for some ten months of the year.

Two large air compressors are now in operation, furnishing the driving power for forty air drills and jack-hammers. Transformers have been installed to furnish the dam with light and power, the electricity being transmitted at 13,000 volts from the power plants of the Alabama Power Company on the Warrior River.

The material for seven traveling tower derricks has been received. These will operate on a four-track railroad construction bridge built alongside the dam just below the structure proper.

The 12-inch suction dredge *Indiana*, and towboat *Scioto*, transferred from the Cincinnati district, together with the 15-inch dredge *Pettus* from the Montgomery district, will supply sand and gravel from the Tennessee River for concrete.

Construction railroads on both sides of the river connect the two abutments with Florence and Sheffield, respectively. About fifteen miles of track have been constructed, including yards. A boiler shop, machine shop, blacksmith shop, and several warehouses are in operation along the north shore railroad contiguous to the dam site.

The heel trench for a cut-off wall along the upper side of the dam has been carried to full depth in coffer No. 1, and the stone thus exposed has been found to be of satisfactory quality.

The removal of 250,000 cu. yds. of overburden from the lock site at the north abutment, is nearly finished.

A motor transport section operating twenty-six trucks, two 26-passenger busses and twenty automobiles covers a monthly mileage of about 40,000 miles in the transport of labor, employees and supplies. About five miles of road have been built and metalled for this traffic.

The population of about 3,000 at the construction camp on the north side of the river constitutes a community independent of the adjoining towns of Florence, Tuscumbia, and Sheffield. Thirty permanent dwellings have been erected for the employees who will eventually operate the dam and lock. Between four and five hundred buildings have been erected since the commencement of the work. These include many temporary dwellings for employees who could not be housed in any of the crowded towns nearby. There are mess-halls, and entertainment halls, stores, offices, dormitories, and hospital. Sanitary conditions are excellent, and the health of employees at the camp is very good.

PITTSBURGH DISTRICT.

Lt. Col. H. B. Ferguson.

Bids for the construction of Lock and Dam No. 4, Allegheny River, about 24 miles above Pittsburgh, have been requested and will be opened February 14, 1920. The usable dimensions of the lock are 56 by 360 feet. It is similar to the newer ones constructed on the Monongahela River. The dam is 889 feet long. All walls, including the abutment and dam, will be placed on rock and will be of concrete.

WHEELING DISTRICT.

Lt. Col. G. P. Howell.

This District covers the Ohio River from Steubenville, Ohio, to a point six miles above Huntington, W. Va., a stretch of river 224 miles long and comprising Dams Nos. 11 to 27, inclusive. All the locks and dams are completed and in operation except Nos. 23, 25 and 27, on which work is in progress. Three dams, Nos. 21, 22 and 24, were operated for the first time last summer. Dams Nos. 23 and 25 are being constructed by contract, and No. 27 by hired labor. It is probable that No. 23 will be placed in operation in 1920, and Nos. 25 and 27 in 1921.

LOUISVILLE DISTRICT.

Lt. Col. G. M. Hoffman.

Lock and abutment No. 45. Ohio River, at Addison, Ky., twice advertised for construction by contract during 1919, and no bids received, was again advertised in January, 1920, bids to be opened February 28, 1920. Again, no bids received.

Navigation on the Ohio was interrupted by running ice for only ten days this winter, though boats had some difficulties on this account for about twenty days. The Louisville and Portland Canal was used during this time as an ice harbor by most boats in this vicinity, and some from Cincinnati.

Construction on Lock and Dam No. 48, Ohio River, will soon be started for the season.

The contractors, the MacArthur-Hanger Co., have opened up their quarry on the Green River, and begun work of towing riprap to the site. The project, started in 1912, will probably be completed in 1922.

Levee Districts have been organized on both banks of the Wabash River, Indiana and Illinois, for the purpose of building levees to protect crops from damage by flood. No levees exist on the Wabash now, and serious damage has been done by the floods of the past two seasons.

Assistant Engineer Frank I. Louckes, in charge of the Louisville and Portland Canal, resigned on December 9, 1919, and is now in the sand and gravel business at LeMars, Iowa. During the war Mr. Louckes served in France as Lieutenant Colonel of Engineers.

MILWAUKEE DISTRICT.

Lt. Col. E. H. Schulz.

Milwaukee harbor.—The Board of Harbor Commissioners presented to the District Officer plans for an outer harbor, to be forwarded to the Chief of Engineers, with survey report. The plans contemplates a series of wharves and slips for passengers, general merchandise, and car-ferry vessels, extending about 4,800 feet from Wisconsin Street south

Digitized by Google

to harbor entrance; and a series of coal, ore and grain wharves about 8,500 feet, extending from the harbor entrance south to Russell Avenue. The wharves are to have a length of 700 feet each and belt line connection with all railroads. To carry out this work, an extension of the north breakwater and a new south breakwater are requested by the Harbor Commission.

The extension of caisson construction, wharf and plant at root of north breakwater, is in progress by the Engineer Department. It is contemplated to double the capacity of the plant and to construct during 1920, 30 caissons, each 54 feet long, 8 for Indiana Harbor, and 22 for Chicago Harbor all pertaining to the Chicago District.

Ludington Harbor.—Severe damage was done to the south breakwater during fall of 1919. It is proposed to issue specifications next month to reconstruct 1,000 feet of same by placing a new concrete superstructure, by contract, work to be done during coming season.

Wreck of the steamer Muskegon.—Work has continued on the wreck of the *Muskegon* at Muskegon Harbor. The wind, cold and ice, have been unusually severe, frequently delaying, holding and endangering vessels a week at a time. The contractor, Mr. T. L. Durocher, has cut down the wreck to a least depth of 10 feet, and the work (now temporarily suspended) will be finished as good rarily suspended) will be finished as soon as good weather allows.

Captain F. S. Skinner, Corps of Engineers, reported on November 20, 1919, for duty as assistant to the District Officer.

Lieut. Col. Arthur P. Christophel returned from overseas, was mustered out of the military service Oct. 7, 1919, and re-employed in this district Oct. 27, as inspector.

Captain Sidney R. Hartwell, who returned from service overseas on May 30th, 1919, was re-employed as inspector in this district on July 25, 1919.

CHICAGO DISTRICT.

Col. W. V. JUDSON.

Two very important improvements will be shortly undertaken, one by the State of Illinois and one by the City of Chicago.

On recommendation of the Chief of Engineers, the Secretary of War recently approved general plans for the "Illinois Waterway" and for reclaiming certain submerged lands along Chicago's water front.

Illinois waterway.—Under this permit, the State of Illinois has been authorized to construct, operate and maintain a deep waterway from the water power plant of the Sanitary District of Chicago at Lockport, Ill., to a point in the Illinois River at or near Utica, Ill., a distance of about 64 miles.

The fall between the two points named is about 140 feet and will be overcome by locks and dams at Lockport, Brandon Road, Dresden Island, Marseilles, and Starved Rock.

The locks are of the same general type, the dimensions of the chambers being 600 feet by 110 feet, with 14-foot depth over the lower miter sills. The channel is to be not less than 150-foot bottom width, with a minimum depth of 8 ft. in earth and 10 ft. in rock sections.

The lifts vary, that at Lockport being 41.4 feet and that at Starved Rock only 19 feet. The improvement confines itself to the present river bed except at one place, opposite Marseilles. There it is proposed to dredge a canal about three miles in length

This improvement is to be carried out by the State of Illinois under a bond issue of $20,000,000. The permit "does not authorize the construction of any power development works, nor the appropriation and use of any water power that may be incidentally created or developed by the navigation structures." Such construction, development, appropriation and use of water power must await the action of Congress. Work will commence in the near future.

Reclamation of submerged lands, Chicago waterfront.—Under this permit, authority is granted to the City of Chicago, the Illinois Central Railroad Co., and the South Park Commission, to fill in and reclaim certain submerged lands along Chicago's lake front.

The tract to be reclaimed covers an area of about 1,600 acres about one-half mile wide. Its northern boundary is the center line of East 11th St. (extended east) and it extends south to the south line of East 67th street (extended east) a distance of about 5 miles. The object of the improvement is to allow the extension of the park system and the addition of track and other facilities to the Illinois Central Railway, the City of Chicago having placed upon this company the duty of providing a great Union Passenger Terminal at 12th Street, which will accommodate some 15 railways and constitute the principal passenger terminal of Chicago and one of the great terminals of the world. One provision of the permit reads as follows:

> "That, the eventual need being foreseen for the use of purposes of commerce and navigation, of a part or the whole of the lands hereby authorized to be used for park purposes, the South Park Commissioners shall on demand of the City of Chicago, or of its municipal authorities, grant, convey, or release any of the lands, whether then filled or submerged, covered by this permit and under the jurisdiction of the said Commissioners, to the City of Chicago, under such compensation for the filling when accomplished as shall be just and equitable."

After a decade of negotiation between the City of Chicago, the South Park Commission, various railways and the War Department, an arrangement has been made which is satisfactory to all concerned. As an issue of bonds to the amount of $20,000,000 was approved by the voters of the South Park District at a recent election, the dream of a quarter of a century bids fair to be realized. The total cost of the improvements proposed may reach $100,000,000.

Deepening Calumet River rock cut.—Specifications have been recently approved for deepening the "rock cut," so-called in Calumet River, Ill. This rock section extends over a length of about 1,700 ft. and it was deepened in 1907 to about 21 ft. The project for this river provides for a navigable depth of 20 ft. and this has been construed to allow an actual depth of 21 ft. While this depth is sufficient in soft material, it is considered that an excess of at least two feet must be provided over a rock bottom to insure safe passage of vessels with 20 ft. draft, and the specifications provide for that increase to the limit of available funds, which will probably allow at least the completion of the west half of the 200 ft. channel. Calumet River, being at the South end of Lake Michigan, is subject to sudden oscillations, in extreme instances reaching several feet in magnitude, known as seiches, due to wind and barometric conditions. The possibility and frequency of these oscillations have prevented vessels loading to their usual depth with grain, great quantities of which are housed in elevators above the rock cut.

Assistant Engineer Geo. W. Freeman, late District Engineer, St. Paul, Minn., District, has been transferred to this district.

CLEVELAND DISTRICT.

Lt. Col. R. R. RAYMOND.

Cuyahoga River straightening. — The straightening of the Cuyahoga River is the most interesting and difficult problem connected with Cleveland harbor to-day.

This extremely crooked stream is navigated by large lake freighters, and along its bank are numerous important industrial plants. Thus the growing demands of business and the increase in size of vessels, make the straightening of the river, to facilitate commerce and to protect the industrial plants from flood damage, at once imperative and costly.

The federal government admits only a partial interest in the matter, and the burden of the improvement is thus placed chiefly upon the local community.

The local government is unable to appropriate funds sufficient for so large a project, and recourse has been had to the formation of a "flood conservancy district." Under the laws of Ohio, such districts are created as needed in order to finance and execute projects for protection against floods and for certain other purposes.

Technical difficulties are now in process of settlement in the courts; and when final agreement has been reached, the formation of a plan of co-operation between the federal and local authorities will be undertaken. Funds for this purpose are available.

Captain Geo. V. Sage, Master of the U. S. seagoing dredge *Burton*, died at Toledo. Ohio, on the 23rd of February, 1920.

BUFFALO DISTRICT.

Lt. Col. C. S. SMITH.

Erie Harbor, Pa.

Under contract with the Great Lakes Dredge and Dock Co., of Cleveland, Ohio, dated August 7, 1919, operations begun October 6, 1919, were continued with hydraulic dredge *Chicago*, until December 11, 1919, when owing to ice and weather conditions, work was suspended for the winter. An estimated quantity of 10,000 cu. yds. of sand was placed during December, 1919, between stations 26 and 47, and a total of 150,000 cu. yds. to date.

Buffalo Harbor, N. Y.

Weather conditions prevented work during December, 1919, in redredging the Buffalo River entrance channel, under contract with the Empire Engineering Co., and dredging in area at the junction of the Buffalo River and Black Rock Channel and two areas in the outer harbor, under contract with the Great Lakes Dredge and Dock Co.

Black Rock Canal was open to navigation and the lock in commission until December 31, 1919, when the guard gates were closed and operating discontinued for the winter, 47,410 short tons of freight having passed through the lock during December, 1919.

Oswego Harbor, N. Y.—Dredging the eastern part of the outer harbor to a depth of 21 feet at low water datum in anticipation of the completion of the enlarged Welland Canal by the Dominion of Canada, was begun October 27, 1919, and continued until November 28, then suspended and the dredging plant laid up for the winter. A total of 22,748 cubic yards, scow measure, sand, mud and clay has been dredged to date at a field cost of $3,539.59, or 15½ cents per cu. yd. The dipper dredge *Sodus* and attending plant was used in this work.

Ogdensburg Harbor, N. Y.—Dredging under contract with William J. Daly of Ogdensburg, N. Y., began October 6, 1919, and was continued with the dipper dredge *Lincoln* un-

Digitized by Google

til suspended for the winter, December 16, 1919. The work comprises the widening and deepening to 19 feet at low water datum, of part of the city front channel, the upper entrance channel, and easing the bend at the junction of these channels, also re-dredging of shoaled portions of channels. A total of 141,578 cu. yds. scow measure, sand, mud and clay, has been dredged to date, at a field cost of $27,300.04. The unit price is 18.7 cents per cu. yd., scow measure.

LOS ANGELES DISTRICT.

Maj. F. B. Downing.

A contract was entered into January 20, 1920, with the United Dredging Company of Los Angeles, Cal., for dredging to 32-foot depth, Areas A and C, and to 35-foot depth the Middle Ground Channel at San Diego Harbor, Cal. Areas A and C lie southerly and northerly, respectively, of the entrance channel to the municipal pier at San Diego, and are estimated to contain 307,000 and 1,077,000 cu. yds., respectively, of material. The Middle Ground Channel lies just within the entrance, and is estimated to contain 200,000 cu. yds. of material. The prices to be paid for this dredging are 24.25 cents per cu. yd. for Area A and the Middle Ground Channel, and 26.8 cents for Area C. Work will probably begin in April.

SEATTLE DISTRICT.

Lt. Col. J. A. Woodruff.

Lake Washington ship canal.

The navigation through the Lake Washington Ship Canal continues to increase. The total number of vessels passed through the locks during the calendar year 1919, was 24,636 while the number through the St. Marys Falls Canal Locks was 15,537 in 1918.

The freight tonnage increased from 765,429 tons in 1918 to 1,020,710 tons in 1919. This of course does not compare with the tonnage through the St. Mary's Falls Canal—72,758,680 tons in 1918.

Plans are now being prepared for an emergency dam for the Lake Washington Canal locks. It will be of a type similar to that used on the Panama Canal. The main lock is 80 ft. wide and 825 ft. long and has a lift of 25 ft., with a depth of 25 ft. on the lower and 36 ft. on the upper mitre sill at extreme low water.

Port of Seattle.

The Port Commission of Seattle has recently completed pier "B" at Smiths Cove, which is one of the largest commercial piers in the world. It is 2,530 feet long and 397 feet wide, with a water depth at fender line of 35 feet at extreme low water.

Pier "A" which is adjacent, is of the same length but is 310 feet wide. Each of these piers provide about 4,000 feet of berthing space.

Pier "B" is to be equipped with a 100-ton stationary revolving crane and two 10-ton portable gantry cranes. Pier "A" is equipped with a travelling gantry crane, two locomotive cranes of 15 and 35 tons each and a stationary shear leg derrick of 100 tons capacity.

Bids were opened in December for dredging about 2,000,000 cu. yds. in Willapa River, Washington, over a length of about 9 miles, in the channel to Raymond, Washington. Only one bid was received which was rejected as informal and in excess of the available funds, amounting to about $400,000.

HONOLULU DISTRICT.

Col. H. C. Newcomer.

Kahului Harbor, Island of Maui, Hawaii.—The approved project for this harbor was completed November 6, 1919. It consists of two rubble mound breakwaters, each having a length of about 2,000 feet, and a partially protected basin having a width of about 900 feet, with a minimum depth of 35 feet.

Honolulu Harbor, Hawaii.—Dredging in "Reserved Channel" was begun on October 14, 1919. This is an extension westerly from the main harbor basin, which will add about 22 acres to the harbor area when it is completed as far as authorized under the present project.

FIRST AND SECOND MISSISSIPPI RIVER DISTRICTS.

Maj. J. N. Hodges.

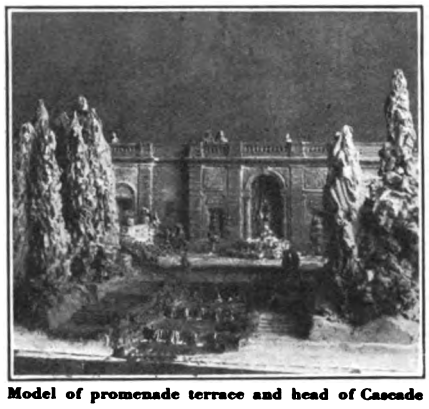
Tower excavators for levee construction.

With a view to decreasing the cost of levee construction in these districts, four tower excavators have been purchased. Two of these machines are of steel construction, both head and tail towers with caterpillar traction, and operate a 6 cu. yd. bucket on a drag-line with a maximum span of about 650 feet. The bases of the head towers are constructed on a slope of 1 in 15, in order to operate on the inclined slope of the banquette while placing an enlargement on the levee front. The other two machines have wooden towers; the head ower being constructed on four 4-wheel trucks and moved on track sections which are shifted and placed by light cranes attached to the machine. The tail tower is of a very imple wood construction which is skidded back and forth by the use of dead-man anchorages and electric motor, the power being supplied from the head tower.

The main principles of operation are the same in all four machines except that in the case of the first two mentioned the bucket is carried back to the pit by a back-haul line passing over a sheave on the tail tower, while in the case of the other two machines the bucket is carried back to the pit by gravity. The capacity of all of these machines is about 50,000 yards per month, single shift.

There is every reason to believe that, when all of these machines have been erected and are in operation, the cost of levee-building in these districts will be greatly reduced.

Caving in the vicinity of Wyanoke Landing, Ark., having reduced the margin between the river bank and the controlling levee to such narrow limits as to endanger same, it became necessary to construct a new levee loop or install bank protection work at this point. The estimated cost of the new loop was $180,000, while that of the necessary bank protection work was $120,000. In view of the fact that the St. Francis Levee Board of Arkansas proposed to contribute $60,000 toward the latter project, it was decided to install bank protection work. Operations were, accordingly, begun on November 1st, 1919, and will be pushed to an early conclusion.



PUBLIC BUILDINGS AND GROUNDS DISTRICT OF COLUMBIA.

Col. C. S. Ridley.

The Meridian Hill Park Development.—Washington, D. C.

This office has had under development since 1912 a tract of high ground lying along 16th St. between W and Euclid, extending east to 15th St. It contains about 15 acres, two-thirds of which are fairly level with the balance sloping to the south. The side toward 16th St. had been left, in the process of street construction, with a sharp cut averaging thirty-five feet in height. From its relation to the meridian of Washington, the place was named Meridian Hill Park.

The development of this park contemplates having in the capital of this country a public

Model of promenade terrace and head of Cascade

garden which shall be in every way comparable to the great formal parks of Rome, Paris and other foreign capitals, a park which shall serve as a model for other American cities. On account of similar needs resulting from similar climatic conditions, inspiration has been sought in the old garden types of the Italian Renaissance.

The features of the design are the maintenance of the maximum level area by double retaining walls along Sixteenth Street and the construction of a great promenade terrace, sixty feet wide and three hundred feet long, across the park from east to west,—a platform developing the unique panoramic possibilities and the decided advantages of unimpeded southern breezes. The balance of the design is accessory to this one feature. Directly north of it is a concert pavilion and grove; viewed from Euclid Street, one sees a broad grass mall flanked with hedged walks leading to the pavilion. South of the terrace feature through the wooded hillside, bordered with hedges of ilex and lines of cedars, will be a series of pools carrying the water from the terrace fountains to a broad receiving basin on a lower level. On the outskirts of the park are to be heavy tree plantations and winding walks.

Work on the project has been carried on with limited appropriations but enough has been accomplished to give a fair idea of the effect to be attained—except that due allowance must be made for the effect of great trees both in front of and above the masses of masonry, and for its further reduction in importance by the use of heavy shrubbery and overhanging vines. A new type of decorative concrete has been one of the interesting developments of the study to date. A steady improvement in quality is demonstrated from year to year, and an adaptability to architectural detail has warranted its introduction on the market as a new medium of construction in any color combination or surface texture, in poured, precast or stucco form.

In England, gardening developed ideally from a domestic point of view. In France, great effects and display carried to the opposite extremes. In Italy, the gardens of the nobility, developing from climatic conditions and social requirements during a period of unparalleled culture and wealth, resulted in an intermediate type combining in a remarkable way the broad, logical plannings of the French parks and the informal livable qualities of the English gardens.

The translation of the spirit of these old gardens, with their lavish display of water, their studied relation of light and shade, and their happy combination of architecture and planting will demonstrate the adaptability of the types to modern materials and American conditions.

Deming

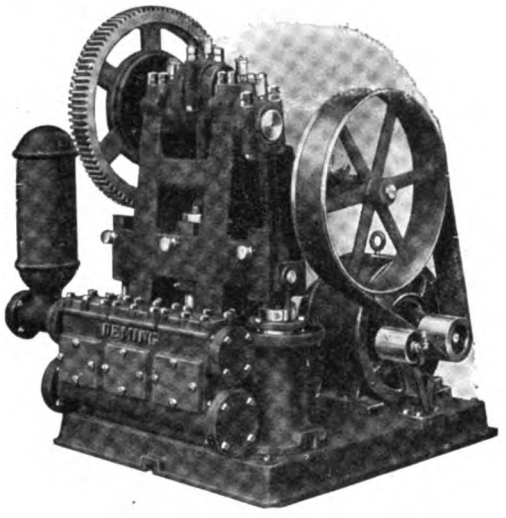

Fig. 50. Single-Acting Triplex Pump 5 1-2 x 8 Type, "C" Drive

Power Pumps

Triplex and Double-Acting Power Pumps; Deep Well Power Working Heads and Artesian Well Cylinders; Hydro-Pneumatic Water Systems, etc.

Deming Triplex Pumps as shown above are the acme of efficiency—seldom need attention such as repacking, etc. Operating expenses in many cases more than 50 per cent less than steam pumps. Made both single and double acting for various duties and in capacities up to 132,000 gallons per hour for operation by belt, electric motor, gas engine, etc.

Catalogue to engineers, architects and manufacturers on request.

Engineer Troops

1st ENGINEERS, CAMP TAYLOR, KY.
Col. J. J. Loving, *Commanding.*

Every available man is out on the recruiting drive. There are parties at Indianapolis, Cincinnati, Louisville, Huntington, Knoxville, Nashville and Greensboro. Recruits are beginning to arrive, and good results are expected before the end of March.

The division has not forgotten the great usefulness of a regiment of engineers, as evidenced by the frequent calls for the performance of numerous constructions jobs. These are generally accomplished in good order notwithstanding the handicap of limited personnel and other obstacles, and provide excellent training for the regiment.

The morale of the regiment is splendid in spite of rather trying conditions, as shown by the very infrequent need for disciplinary action, and by the fine spirit displayed in every undertaking.

The combined regimental mess won first place in a recent competition between unbrigaded units for the best kitchen, and there is every reason for a spirit of optimism in the camp competition now going on. A similar competition to determine the best corral is also in progress, and there, too, we have "great expectations."

A coat-of-arms for the regiment has been tentatively adopted, and forwarded to Bailey, Banks & Biddle for completion.

The officers of the regiment are enthusiastic over the prospects for polo. A number of likely ponies have been received, and are being trained for the game. It is expected to develop a first-class engineer team.

During the recruiting drive, which ended Mar. 31, practically nothing could be undertaken in the way of training except for recruits. However, a plan for intensive training is being worked out, including general service and engineer instruction, and training for specialists. It is expected before the end of the coming summer to produce an efficient engineer regiment.

The division has entered upon an enthusiastic and energetic campaign for the purpose of raising a fund to erect a monument in memory of its members who died in France. The objective is $100,000. Every member of the regiment at this camp has subscribed at least one day's pay. Plans are under way to organize in each a committee of ex-members of the division, to aid in the drive. It is planned to erect on a suitable site in Washington, or in Arlington, a monument similar to the Battle Monument at West Point.

Citations have recently been issued by the Division Commander, Maj. Gen. C. P. Summerall, commending the regiment for gallantry in action and efficiency under fire, both as infantry in the line and as engineers, during the operations near Soissons, under command of Col. L. V. Frazier, and in the Meuse-Argonne Offensive under command of Col. F. B. Wilby. Also, by authority of Lieut. Gen. R. L. Bullard, the regiment has been cited for the conspicuous part borne by it in the capture and defense of Cantigny, under Col. Frazier.

The regimental colors were decorated with the Croix-de-Guerre by Marshal Petain in Coblenz, on July 18, 1918.

It is especially gratifying that the First Engineers has won honors for its conduct and action, not only in its special mission, but also as infantry, fighting in the line. Every member now with the regiment is impressed with its gallant record, and is determined that the standard established during the war shall be always maintained during peace.

2nd ENGINEERS, CAMP TRAVIS, TEX.
Col. G. E. Egerton, *Commanding.*

The schedule of instruction at Camp Travis has been changed to provide for general military instruction by organizations from 7:30 to 9:30 a. m.—elementary educational and business schools from 9:30 to 11:45 a. m., and advanced educational and vocational schools from 1:00 to 4:30 p. m. Only men not desiring to attend any schools and not required to take elementary educational instruction or duty after 9:30 a. m. From 3:30 struction or duty after 9.30 a. m. From 3.30 to 4:30 p. m. all administrative offices are closed and all officers and men not attending schools are required to spend the period in athletics.

A short course in road construction for all men in the regiment covering 2½ hours daily for four weeks, was completed on February 19. A course in photography for selected men only has been added to the regimental schools for enlisted men. The first course in mining, demolitions, and explosives was completed about the middle of Feb. On Mar. 1, the regimental schools took over the drafting classes of the Educational and Vocational Schools of Camp Travis.

The officers' class in military law, under divisional schedule in which the officers of the 4th and 5th Machine Gun Bns. were attached to the 2nd Engineers, completed their final examinations Feb. 13. A new class in military administration began Feb. 16. For this class the officers of the regiment are attached to the Field Artillery Brig.

The regiment was represented at the San Antonio motor show by a booth containing a terrain board showing in miniature features of engineer construction. The exhibit also contained the more unusual items of engineer equipment and trophies captured from the Germans. Master Engineers Senior Grade Maurice Long was on duty at the exhibit to explain its features to those interested.

Capt. T. H. Nixon, Corps of Engineers, reported for duty Dec. 22, 1919, and has been assigned to command Co. "E."

Capt. Fernando T. Norcross, Corps of Engineers, reported for duty Jan. 8, 1920, and has been assigned to command Co. "D."

2nd Lieut. D. A. Newcomer, Corps of Engineers, left Camp Travis on January 20, 1920, with a recruiting party consisting of Master Engineers Jr. Gr. Thomas Hinton and George A. Wilkinson, Sergeant 1st Class Earl V. Cullar, and Sergeant Harry Atkinson, 2nd Engineers. This party is operating in the vicinity of Dallas, Texas. Capt. F. H. Norcross relieved Lieut. Newcomer in charge of this party on February 11, when the latter joined the regiment.

Capt. Peter E. Bermel, Corps of Engineers, in charge of a recruiting party consisting of 1st Sergeant Fred Fenner, Stable Sergeant Harold Davis, Sergeant Dwight M. Fowler, and Corporal Wilbur F. McCarty, 2nd Engineers, left Camp Travis on January 28, 1920, and is operating in Oklahoma.

Capt. Thomas H. Nixon, Corps of Engineers, in charge of a recruiting party consisting of Master Engineers Sr. Gr. Thomas F. Burke, Sergeant 1st Class Nelson J. Moore, Sergeant Daniel J. Madison, and Corporal Fred J. Watters, 2nd Engineers, left Camp Travis January 31, and is also operating in Oklahoma.

4th ENGINEERS, CAMP DODGE. IOWA.
Maj. S. L. Scott, *Commanding.*

After fifteen months' service in France and Germany the regiment returned to the United States July 29th, 1919, arriving at Camp Dodge August 4th.

The first work of any importance after arrival here was strike duty in Gary, Ind. This regiment furnished one company for the Provisional Regiment of the 4th Division. Capt. A. B. Skoien, Lt. W. J. Lamon and 2nd Lt. B. C. Parr were detailed for duty with the company and the engineers proved that they were capable of performing any duty assigned them.

Twenty-six men of this organization are on duty with recruiting parties making the drive in the states allotted to the Division.

Lieutenant Lamon has arranged a very attractive display of engineer equipment in a Des Moines shop window for recruiting purposes.

2nd Lt. I. C. Lawrence who went to New York for examination for promotion has returned to duty.

Lt. Bruce C. Hill is on temporary duty with the Motor Transport Corps of the 4th Division. He commands Company 131.

A regimental exchange has been opened under management of Lieutenant Parr.

Major Scott is conducting a school for regimental officers.

The enlisted men's mess has gained quite a reputation since the return of the men from Gary. The santitary inspector has given it the highest grade in the camp. The menus are excellent.

A very enjoyable smoker was given for the men of the regiment February 21st. A good program was arranged by Chaplain J. L. Blakeney. Refreshments were served.

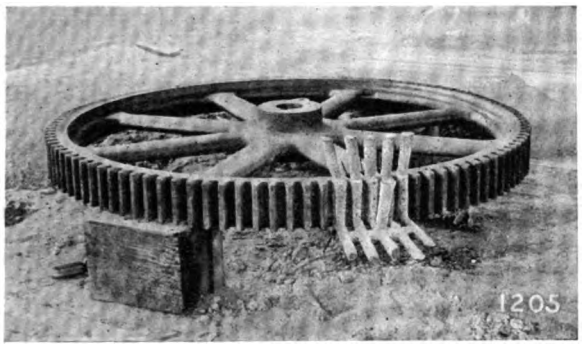
5th ENGINEERS, CAMP HUMPHREYS, VA.
Colonel Richard Park, *Commanding.*

The regular training schedule was carried on until the 19th of December, when inclement weather forced the abandonment of outdoor engineer drill. During the winter the following schedule was followed:

7:30-8:30 a. m.—
Physical drill, boxing and wrestling, and infantry drill.

9:00-1:00 a. m.—
Small problems in infantry tactics for all men, conducted by the officers of the regiment, using a large scale reproduction of the Hunterstown sheet on the blackboard. Men were called upon in turn to give their solutions of the various situations.

10:00-11:30 a. m.—
Regimental schools, each in charge of an officer, as follows:
Mondays—Model bridges;
Tuesdays—Model field fortifications in sand box;
Wednesdays—Military sketching and map reading;
Thursdays—Topography, elementary study of drainage and contours;
Fridays—Military roads and railroads.



All men of the regiment, with the exception of those on special duty, attended these drills.

Afternoons from one to four, except Wednesday, were given over to vocational schools. Wednesday afternoons were devoted to athletics.

On February 4th sixty eight men of Company "B," First Engineers, who had been atached to the Fifth for training for one to two months, were sent to Germany to join their organization.

Recruiting—Recruiting has engaged the serious attention of the regiment during the entire winter. Fifty seven of our best men have been sent on this duty in the eastern states and in the divisional recruiting area, which includes Kansas, Nebraska, and Minne-

THERMIT WELDS ON LARGE GEAR WHEEL

THERMIT

is the only reliable process for Welding Heavy Steel Sections

SUCH AS BROKEN

Crankshafts, Locomotive Frames, Steel Plant Equipment, Sternframes of Ships and Many other Heavy Steel Sections.

The steel required to make a Thermit Weld is produced in bulk at a temperature of 5000° F. instead of drop by drop, as in other welding methods. It therefore makes a perfect amalgamation with the adjacent metal and secures a Homogeneous Weld free from shrinkage strains, unattainable in any other way.

sota. The 7th Division, to which the 5th Engineers belongs, is stationed at Camp Funston, Kansas.

Lt. O. G. Hoaas has been traveling in Virginia with a motor party of four men and has had good success.

Portable machine shops, mounted on Mack five-ton trucks, each with a crew of four men, were sent to Harrisburg, Pa., Huntington, W. Va., Richmond, Va., and Cleveland, Ohio. These trucks have proved very valuable for recruiting as they draw an interested crowd wherever they are set up, and so furnish opportunity to approach many men who would not otherwise be reached.

Parties of two men each are working under the direction of the Recruiting officers at Wichita, Kan., Omaha, Neb., Minneapolis, Minn., all of which are in the divisional recruiting area. Outside of the divisional area, partes of two men each have been sent to the following cities: Albany, Buffalo, New York, N. Y.; Baltimore, Md.; Scranton, Pittsburgh, Philadelphia, Pa.; Springfield, Boston, Mass.; Newark, N. J.; Portland, Me.

In January Colonel Park visited the 7th Div. at Camp Funston, and inspected the work of the recruiting parties at Wichita, Omaha, and Minneapolis. Maj. H. V. Pittman has just returned from a visit of inspection of the eastern cities. The men on recruiting duty are interested and are working well; they have sent in more than fifty recruits to date, all good, clean-looking youngsters, who will make good soldiers.

At the same time a campaign has been carried on in the regiment itself to induce men to re-enlist as their time expires. The results have been encouraging, both among the old soldiers and among the emergency men who enlisted for one year in the spring of 1919.

Future Plans—The present plan of the War Depart. is to recruit the regiment to full strength, and divide it beween Camp Humphreys, Va., and Camp Funston, Kans.; one battalion at each. At Camp Humphreys the troops will be engaged in administrative duties for the camp and in engineer drills and demonstrations for the Engineer School. At Funston there will be opportunities for training of a broad, varied, and interesting nature in connection with divisional maneuvers. At both camps there are good facilities for the vocational training of the men, not only in the technical branches necessary for the engineer service but also in general education and in agriculture. Camp Funston has a model farm now under operation by the vocational schools and Camp Humphreys is making arrangements to start one.

6th ENGINEERS, CAMP PIKE, ARK.

Col. C. L. STURDEVANT, *Commanding.*

The 3rd Division has recently organized the 3rd Division Horse Show Association, with May 15th set for the first show, and preparations are well under way to make it a big success. The purpose of the show is to bring the people of Little Rock into closer touch with the division and to promote interest in horses, horsemanship and animal transportation. Maj. Henry Hutchings, Jr., 6th Engineers, is treasurer of the association. The horse show will be an all-day affair, with special encouragement given to civilian entries; mounts will be furnished them if desired. Arrangements are being made in the officers' messes to serve a buffet luncheon to the many guests expected.

Two officers and a large percentage of the enlisted men are engaged in the general drive for recruits. While the results are not up to expectations, recruits have been coming in at the rate of about one per day and that rate has been increasing recently. All recruits are being assigned to Co. "E", which boasted 63 members on March 1st.

Several of the officers are training polo ponies and it is expected that the regiment will be represented by a team in the Camp Pike Polo Association, recently organized.

ARMY ENGINEERS IN GERMANY.

Lieut. Col. B. A. MILLER, *Chief Engineer, American Forces in Germany.*

The phenomenal rise of the Rhine and Moselle Rivers during the month of December has greatly interfered with road work in the occupied areas and has placed considerable additional work upon the engineers in maintaining the operation of the public utilities and insuring the safety of government property threatened by rising water.

A large percentage of Company "A" has been engaged in the above work.

Company "B," 1st Engineers (railway operating unit), arrived December 30, 1919, and will be transferred to the engineer compound upon completion of quarantine required of all arriving troops.

Company "D," 1st Engineers (Silesian expedition), operates the engineer dock at Andernach, care and maintenance of all buildings of the Silesian expedition, and has also assisted in moving government supplies threatened by the rise of the river, to places of saftey.

A great lumber dock at the junction of the Rhine and Moselle has been moved to a point adjacent to the engineer dock on Moselweisserweg.

A great shortage of supplies in local markets has compelled purchases at distant points. Great difficulty has been encountered in obtaining necessary supply of fuel.

Transportation needs have been met by the continuation of shuttle trains to Essen and Hamburg and the commandeering of barges designated for other points.

Conferences of all Allied representatives were held at Weisbaden on December 8th, and Cologne on December 15th.

The engineers erected and wired the "Christmas Tree of the American Forces in Germany" in front of Headquarters and placed an electric star on the heights of Ehrenbreitstein.

An engineer lithographic equipment (regimental) has now been installed, with which the engineers can meet all requirements of the American Forces in Germany.

Service Schools

ENGINEER SCHOOL, CAMP A. A. HUMPHREYS, VA.

Post Graduate Section; Col. W. T. Hannum, Assistant Commandant.—During the months of Jan. and Feb., 1920, instruction has been carried on in the following subjects:

Field fortification,
Military art,
Bayonet training, hand to hand fighting and boxing,
Hygiene and sanitation,
Hydraulics,
Military law,
Contracts, specifications, estimates and accounts,
Equitation.

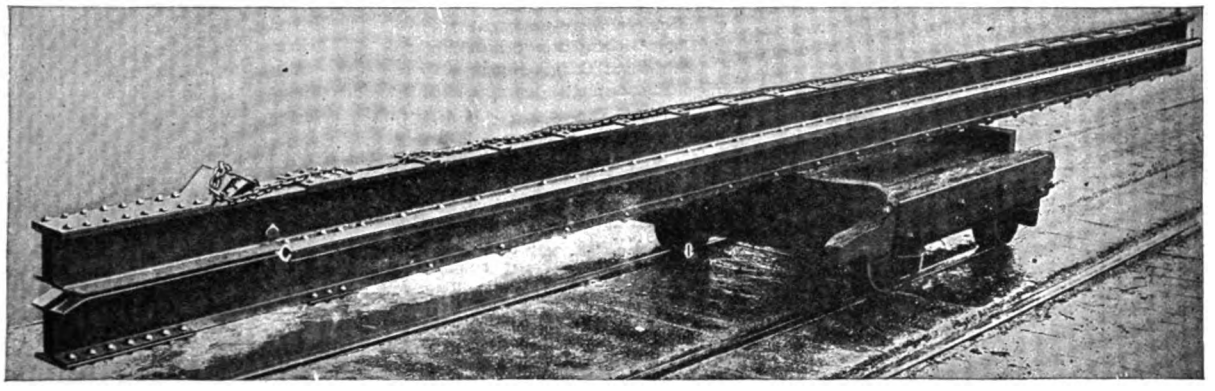
The course in field fortification started the first of the year and is to continue until Mar. 5, 1920. It is under the direction of Maj. F. C. Harrington with Capt. W. E. R. Covell and Capt. T. B. Larkin as assistants. The basis of the course is a series of practical problems, as follows:

Four on organization of the ground,
Two on construction of trenches and obstacles,
Two on shelters,
Two on military roads,
Two on light railways,
Two on demolitions.

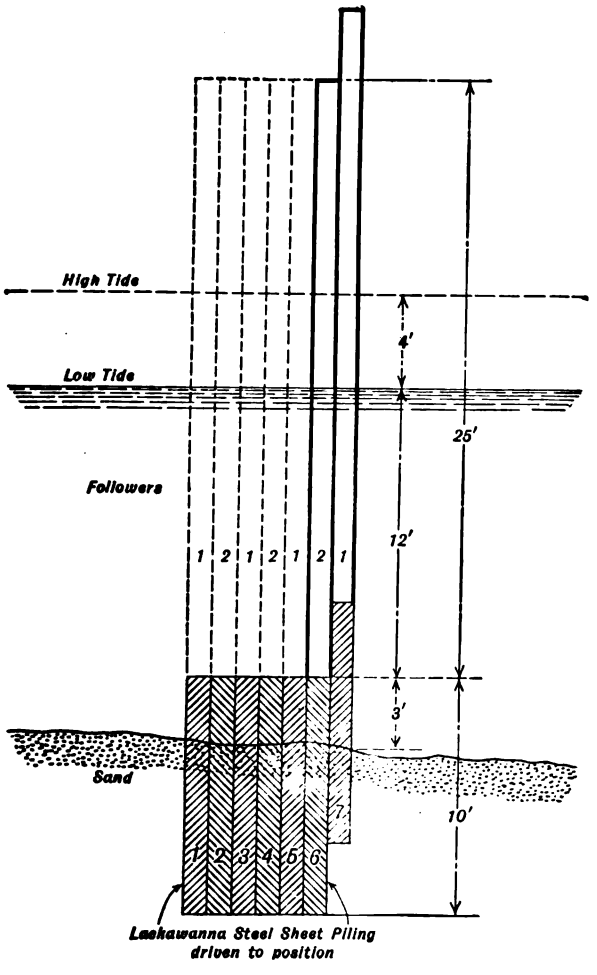
All the problems were co-ordinated and tied into the same general tactical situation. The course was rounded out by many discussions of problems, conferences, demonstrations and lectures. The latter have proved most interesting and instructive. There follows a list of the lectures given during this course:

Objects and scope of course, Maj. Harrington.
Lessons of the World War as affecting field fortification, Col. Wilby.
The Hindenburg line, Col. Pillsbury.
Camouflage, Lt. Col. Bennion.
Military roads, Col. Graves.
Light railways, Maj. Peek.

The course in military art under, Maj. L. M. Adams with Maj. O'Connor and Capt. Styer as assistants, was continued through the last two months. This course consists of a series of map problems, war games and terrain exercises with the addition of several conferences and lectures. In general, it is similar and preparatory to the course at the Army School



of the Line at Fort Leavenworth, Kans., though being limited in extent and in size of units handled.



The courses in hygiene and sanitation under Col. Schriener of the Medical Corps, in hydraulics under Capt. Bond, in contracts, specifications, estimates and accounts under Capt. L. W. Miller, and in military law under Capt. Arthur, consisted in conferences on these subjects conducted by the officers in charge.

The course in bayonet training, hand to hand fighting and boxing, and in equitation were practical in nature, and were conducted by Capt. Davison and Capt. Bock, respectively.

The Post Graduate Section began the year with thirty students. During the months of Jan. and Feb. five were lost to the school. Maj. Gillette was ordered to England as assistant to the Military Attache at London. Capt. Heavey was assigned as instructor in the Undergraduate Section. Maj. Robb was detailed as Provost Marshal of the camp. Captains Love and Curry resigned.

A Helpful Follower for Driving Submerged Walls of

LACKAWANNA STEEL SHEET PILING

Driving a submerged wall of steel sheet piling involves no particular driving difficulties if the right kind of a follower is used. Such specially designed followers have been arranged to set and drive one to five piling sections at a time, a diver being employed to interlock the sheet piling sections and release the follower. If for any reason the use of a diver is not practical a follower which can be released from above the water level is entirely practical.

A good type of releasing follower is shown in the picture and its use illustrated in the diagram. In this particular instance two were made and used together for driving 10-foot lengths of 8⅛-in. by 7-32-in. Lackawanna Straight Web Sheet Piling in a groin for beach protection and reclamation. The top of the finished sheet piling line at the outer end of the groin was to be 18 feet below low tide.

The sheet piling section to be driven is entered into the bottom of the first follower and held by a latch entered into the standard pulling hole. The steel sheet piling section is set and driven, after which the second pile to be driven is similarly set in the second follower, interlocked with the one in the first follower and driven. The first follower can then be released by pulling on the chain, which extends above the water level. The third pile can then be handled with the first follower and the process continued indefinitely, the follower on the last pile driven always extending above the water level.

Take advantage of our engineering service whenever you need it, and be sure that your files contain our book, "Lackawanna Steel Sheet Piling."

We Also Offer for Better Construction

Elcannes

Concrete Reinforcing Bars

The Elcannes Bar combines maximum bonding surface, minimum weight, and uniform strength. The bonding surface is 15 per cent greater than that of a plain square bar of equal nominal size. The cross-sectional area is practically the same at all points and the regular surface facilitates fabrication and handling.

Digitized by Google

Several officers of the Corps of Engineers who have not finished the course at the Engineer School are being given some of the subjects by correspondence. In the two last months study in reinforced concrete construction with the University Extension Division, University of Wisconsin, was carried on. There were ten officers enrolled in this course all of whom were on duty at points other than Camp Humphreys.

Under Graduate Section; Col. V. L. Peterson, Assistant Commandant.—During Jan. and Feb. instruction in the following subjects was given:

Reinforced concrete design,
Water supply,
Building construction,
Electrical and mechanical engineering.

Under the first of these subjects, instruction covered the design of columns, girders, cross beams, floor slabs, walls and retaining walls. The course was completed Mar. 1, 1920.

The course in water supply consisted of investigation and design of the water system of this camp, including storage reservoir and the main pipe line. A trip was made to Washington, D. C., to inspect the aqueduct system; the pumping plant, laboratories, filters, sand washers, etc.

In building construction the methods of design and construction of an office building in New York City, of a lock tender's dwelling for Lock and Dam No. 29 on the Ohio River, and of a temporary timber warehouse to be erected in time of war at Camp Humphreys were all studied. During the trip to Washington mentioned above a visit to the Union Station was made to study the roof trusses, suspended ceiling, roofing, ventilation, power plant, kitchens and lighting system.

The electrical and mechanical engineering course, made up largely of experiments, continued during this period. Since the first of Jan. student officers have finished the following experiments:

Resistance,
Electrical rotating machinery phenomena,
Motor starters,
Controllers,
Direct current motors,
Steam indicators,
Simple engines,
Direct current generators,
Storage batteries,
Boiler testing,
Flue gas analysis.

There are two directors, fifteen instructors and eighty-six students in this section of the Engineer School. Nearly all of the students at some time since Jan. 1st have been preparing for promotion examination and have been allowed one week off for study. In this connection, in order better to prepare the officers in river and harbor work, which they have not yet studied, two lectures were given, one on "River and Harbor Improvement" and one on "Administration of a Typical District Office."

One of the existing large buildings of the camp has been completely remodeled into a riding hall, with several indoor practice cages for polo.

Vocational School; Capt. B. C. Dunn, Assistant Commandant.—The Vocational School for enlisted men of the camp, which is the third division of the Engineer School, is giving instruction in the following:

Elementary reading, writing and spelling,
Blacksmithing,
Welding,
Machine shop,
Automotive,
Sheet metal,
Electrical,
French and Spanish grammar.

The school had originally seventy-five men enrolled, but due to recruiting duty, shipment of men over seas, and other causes the number has been reduced to fifty-one.

Engineer School Library.—A branch of the Washington Barracks Engineer School Library has been established at Camp Humphreys and is in charge of Mr. Langdon, former A. L. A. Librarian at the latter place. The collection now consists of about 2,000 books, with more being added daily. It is planned to increase this number to 8,000 volumes from the stock at the main library.

The technical portion of the former A. L. A. library, consisting of some 3,500 books, largely on engineering subjects, is being transferred to the Engineer School library and will prove a valuable addition.

A collection of lantern slides, the property of the Engineer School, is being catalogued, indexed and arranged by the librarian; work has also begun on organizing an extensive map library for the use of the school.

A complete file of the courses of the Army Service Schools in the various camps throughout the country has been compiled and indexed by the librarian and a catalogue has been issued on this collection; supplements are added to this bi-weekly.

ARMY SERVICE SCHOOLS, FORT LEAVENWORTH, KANS.

"Leavenworth" vindicated itself during the great war. Leavenworth ideas and methods and Leavenworth spirit were pitted against the best that Europe could muster, and proved their superiority on the field of battle over all the world. It was Leavenworth that "leavened" the great forces America sent over to win the war, and the nation may justly regard those who founded and developed our service schools as the saviors of civilization. Burning the midnight oil on the outskirts of a little town in Kansas, earnest and patriotic American officers laid the solid foundations of the great victories of the Marne, St. Mihiel and the Meuse-Argonne. Here the American army outwitted the German great general staff, here years before the war the end of German militarism was in the making.

The Army Service Schools are again to-day, as they were before the war, the world's greatest university for the study of tactical science, and "the Frenchman" is still the tactical center of the universe. For the benefit of our new readers we should explain that "the Frenchman" is a little inn, at a cross-roads west of Fort Leavenworth, whence gallant (imaginary) troops, the products of the "brain-trust," sally forth on campaigns of conquest, whilst their commander, the unequalled General A, who never makes a mistake and never dies (continued life to the greatest of commanders), sips his beer (or near beer) inside the house.

Mailing List and Book Department.—The Service Schools maintain a subscription mailing list by means of which all officers of the army, national guard, reserve corps and R. O. T. C. may receive the instruction pamphlets and problems of the schools and follow the work which they are doing.

The purpose of this mailing list is to stimulate tactical study by all officers. It aims to keep those connected with the military service in touch with the work of the General Service Schools. Subscribers receive from time to time throughout the year problems and their solutions, lectures, maps and other matter prepared and used in connection with the regular work of the schools and in the several courses of instruction.

The quantity of matter sent out each year on this mailing list varies, depending upon the production of the schools. No regular schedule is maintained; subscribers are charged each year according to the amount sent out. To date the charge has never exceeded $1.50 per year. Bills will be rendered on July 1st. New subscribers are supplied with all matter for the current year in which they subscribe. A subscriber's name is removed from the mailing list only upon request, or for other sufficient reason. A simple request, addressed to the secretary of the schools, to be placed upon the mailing list is all that is required to secure this service.

This list now has approximately 13,000 subscribers, and will no doubt reach 20,000 by the end of the present school year.

All officers who truly desire to improve their knowledge of the art of war should place their names upon the mailing list without delay. The cost is nominal and the value beyond price.

In addition to the mailing list the schools maintain a Book Department, where all books on the art of war in all its aspects may be obtained at the lowest rates.

THE INFANTRY SCHOOL, CAMP BENNING, GA.

The Infantry School is at Camp Benning, Ga., nine miles south of Columbus, on the Chattahoochee River.

The school as now organized is comparatively new (April, 1919), but is a combination and combination in co-ordinated and amplified form of the old Infantry School of Arms and the Machine Gun School. The real forerunner of the Infantry School was the Musketry School, established by the War Department at the Presidio of Montery, Calif., in Feb., 1907.

The Infantry School is a special service school having a mission in relation to the infantry and the army generally, similar to that of the Engineer School in its field. The need for such a school in our service has existed, certainly, for a long time, but the experience gained in the recent war, together with the increased complexity and technical nature of infantry service, has made its development to its present form and position logical and essential.

The infantry is unquestionably the dominant arm in our service, not only in numbers but from the nature and importance of its functions in battle. Other arms and services are all auxiliary to the infantry.

Leadership is the most essential qualification of any infantry commander. But the ability to lead demands exact knowledge of many things; such as how to handle men in extended formations over varied terrain and the technique and coordination of many weapons. The infantryman may be called upon to fight any one or all of the following weapons: Rifle, machine gun, automatic rifle, one-pounder, light mortar, grenade and bayonet. The infantryman of to-day knows he must also be able to understand ground, read maps, follow a compass bearing, site trenches and construct them.

The Infantry School is organized into three divisions:

1. School,
2. Experimental,
3. Executive.

The Assistant Commandant is the direct head of the school division, which includes all instrumental work. Instruction is given directly in six departments:

1. Tactics,
2. Engineering,
3. Rifle and pistol,
4. Machine gun,
5. Miscellaneous weapons,
6. General subjects.

Service—First, Last, and All the Time

Flory Hoist

For every purpose. We build electric, steam and oil hoists equipped with Werner Patent Band Friction, which eliminates shipping and stress on the drum shaft—gives perfect balance and absolute safety control.

Flory hoists are selected by engineers who know their records on big jobs.

Get our literature and complete detail from our Engineering Department.

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

"Camouflaged" houses on the battle-front at Camp Benning

The experimental division is charged with all testing and research work pertaining to infantry equipment and supplies, from the point of view of usefulness in actual service. It is an important agency of the Infantry Board.

The executive division is charged with general administration and control of all school troops. The 29th Infantry and a machine gun battalion are, at present, stationed at the school. It is planned to have also one battalion of artillery, one battalion of tanks, one aero squadron, one company of engineers and one of signal troops, with detachments of other services, for purposes of demonstration.

The courses in prospect, to be organized as rapidly as facilities become available, with number of students and length, are as follows:

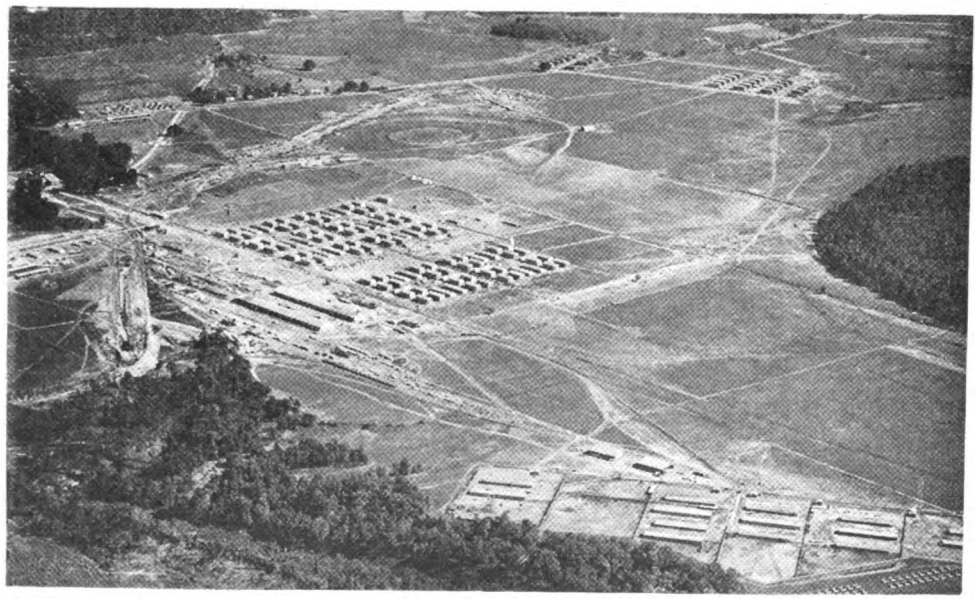
1. Field officers, 20, 10 months,
2. Company officers, 110, 10 months,
3. Basic officers, 110, 10 months,
4. National guard officers, 120, 3 months (2 classes).
5. N. C. O. candidates for reserve corps commissions, 120, 3 months.
6. N. C. O. of rifle company, 210, 3 months (2 classes).
7. N. C. O. of machine gun company, 90, 3 months (2 classes).
8. N. C. O. of headquarters company, 90, 3 months (2 classes).
9. Scouting (enlisted men), 50, 3 months (2 classes).

The character of the instruction to be given in each course is indicated by its name. The "basic course" is for young officers of infantry upon their entry into the service. The instruction covers fundamentals and has for its purpose the creating of competent platoon leaders. With the present basic class (125 recent graduates of the Military Academy) the assignments of time to the various subjects are as follows:

Subject	*Hours*
Tactics	441.5
Infantry drill	59.5
Rifle and pistol	195.
Automatic rifle	74.
Musketry	78.5
Sketching and map reading	105.5
Field fortification	43.
Machine guns	25.5
Miscellaneous weapons	78.
Chemical warfare	5.
Administration	117.
Law	66.5
Hygiene	10.
Military courtesy	8.
Guard duty	7.
Psychology	12.5
Care of equipment	5.
Equitation	17.
Saber	2.

The instruction in the department of engineering has been planned and prepared to give the young infantry officer a sound knowledge of the fundamentals of sketching and map reading, a real understanding of distance, direction and relative elevation, followed by as much sketching and map reading as time permits, with a view to increasing the ability of the student to understand topography and show him the usefulness and application in practical infantry problems. In field fortification the work will cover the simple standard traces, profiles and accessories, handling of working parties, siting of trenches and elementary organization of ground.

The applicatory system of instruction developed at Fort Leavenworth is being followed, and the student will not go away with any false conceptions. He will take part in demonstrations with actual war-strength units, operating over varied terrain and using live ammunition.



Camp Benning is most favorably situated for the particular purposes of the infantry school. It is in a mild climate, allowing work to be carried on ten months in the year. The reservation will ultimately contain some 97,000 acres of the most varied topography. The Chattahoochee River forms the western boundary. Many small streams, including Upatoi Creek, which is unfordable run through the area.

The main ridge lines vary in elevation from 400 to 500 feet (above sea level); the secondary ridge lines from 300 to 400 feet. The 300-foot contour outlines the secondary drainage system. The camp and target ranges are located on a large plain at an approximate elevation of 330 feet, 80 feet above the river.

Wooded and open areas are approximately equal in extent, but so interspersed as to make all terrain suitable for maneuvers and exer-

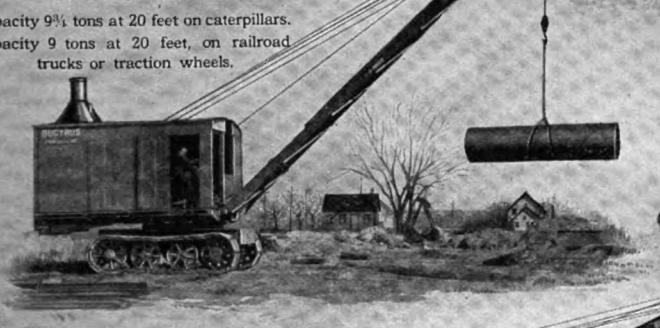
INTRODUCING

THE UNIVERSAL SHOVEL

THE BUCYRUS-30 B

30-B REVOLVING SHOVEL

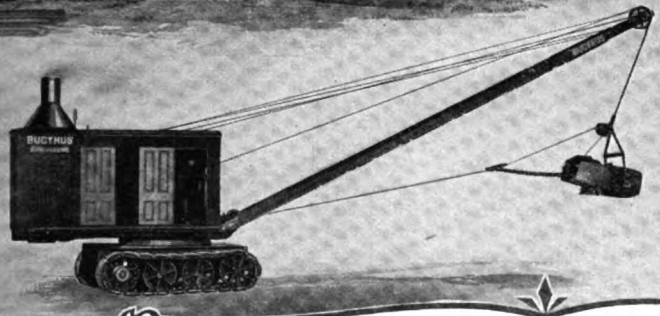


Dipper, 1 cu. yd.
Mounting, caterpillar traction, traction wheels, railroad trucks.

For Sewer Excavation
¾ yd. dipper, 30 ft. handle, max. ditch 20 feet.
¾ yd. dipper, 24 ft. handle, max. ditch 14 feet.

For High Lifts — Special combination.

30-B CRANE



Capacity 9¾ tons at 20 feet on caterpillars.
Capacity 9 tons at 20 feet, on railroad trucks or traction wheels.

30-B CLAM SHELL

1 yd. bucket, 35 ft. boom
¾ yd " 40 " "
Any Mounting

30-B DRAGLINE EXCAVATOR

1 yd. bucket, 35 ft. boom
¾ " " 40 " "
Any Mounting

The Bucyrus 30-B is so designed that it may readily be changed, in the field from any of the above combinations to the other.

It is the last word in excavating machinery. Nearly 40 years of Bucyrus sturdiness and reliability is built into it.

cises. Oak and pine are the most common trees.

A complete system of roads and narrow-gauge railways will make all parts of the reservation available for instructional purposes. Some three miles of the narrow-gauge system is in operation, connecting the camp with the temporary target range.

Maj. Gen. C. S. Farnsworth, U. S. Army, is Commandant; Lieut. Col. L. M. Nuttman, Infantry, Assistant Commandant; Maj. H. B. Fiske, Infantry, Senior Instructor, Department of Tactics. Col. E. J. Atkisson, Engineers, is the senior instructor in engineering.

The infantry school serves an important purpose in our military establishment, and now that it is becoming a real institution, military engineers will watch its growth with interest and appreciation.

Officers' Reserve Corps

Strength of Reserve Corps, Jan. 31, 1920

Infantry	16,830	Med. Corps	5,973
Cavalry	463	Air Service	8,445
Field Art.	7,956	Sig. Corps	1,262
Engineers	3,432	All others	6,388
Coast Art.	2,430		
Q. M.	7,435	Total	60,614

Engineer Reserve Corps.—The total strength of the Engineer Reserve Corps by grade on Feb. 28, 1920, was as follows:

Colonels	32	Captains	1,274
Lieut. Colonels	118	First Lieuts.	1,360
Majors	460	Second Lieuts.	1,048

Total 4,292

Of this number approximately 80 per cent are officers who served during the World War with the Engineers and Transportation Corps, 10 per cent are engineers who served under commissions in other branches of the service during the emergency, the remainder being former enlisted men and civilian candidates who were examined and recommended for appointment during the emergency, but whose appointments were stopped by the armistice.

At the present time there are approximately 3,200 applications of discharged engineer officers awaiting action by the examining board for appointment in the Officers' Reserve Corps. An effort is now being made to increase the number of cases considered each day, and it is hoped that all applications for appointment now pending will receive early action.

The War Department has adopted a definite policy governing promotions in the Reserve Corps, as follows:

In general, discharged emergency officers are appointed in the Reserve Corps in the grade held at time of discharge. An advance of not to exceed one grade, and in no case account of special fitness, long and distingaccoun of special fi ness, long and dis'inguished service or because of recommendation for a promotion not received due to the termination of hostilities. Promotion received after Nov. 11, 1918, is considered to have been given under such special conditions that increase over grade held at time of disharge, in general, will not be given.

All data on file in the War Department pertaining to each applicant's record is carefully considered and appointments offered in conformity with the above policy. Appointees should accept the commissions as offered, for the above policy is prescribed in order to be fair and just to all, and such inequalities as may result therefrom will be eliminated by future promotions.

Training for Reserve Corps.—The following memorandum issued by The Adjutant General under date of Feb. 18, 1920, is published for the information and guidance of reserve officers:

1. The plans for annual training for reserve officers have not been perfected and must necessarily await the enactment of legislation reorganizing the Army. Since training is essential to fitness it is contemplated that such training will be provided, probably for a period of fifteen days each year during the months of July and August. The camps no doubt will be located at various places and reserve officers will be sent to the camp nearest their homes. Sufficient advance notice will be given in order to allow time for arrangement of private affairs and every effort will be made to cause as little inconvenience as practicable to reserve officers designated to attend. It is hoped that all reserve officers designated will be in a position to comply; however, where such attendance will work a serious hardship, an application to be excused will receive careful consideration, and unless exceptional circumstances intervene probably will be granted.

2. The desire of reserve officers for exact information concerning annual training is appreciated and the need for a definite policy is recognized. As soon as it is practicable to complete the plans, which is contingent on the enactment of pending legislation, immediate steps will be taken to give this question the widest publicity.

3. Notices in the press concerning R. O. T. C. camps, which will commence operation on June 17, 1920, do not concern members of the Officers' Reserve Corps. The camps in question are only for students who are members of R. O. T. C. units at various educational institutions and not for members of the Officers Reserve Corps.

The Military Point of View.—This journal has occasionally pointed out that, from a strictly technical point of view, there is little or no difference in the operations of civil and military engineering. The latter is merely a simplified and *accelerated* application of the former. The civil engineer, in applying his knowledge must learn the military point of view, which is that *something* must be done and done *quickly*. In war *time* is the all important consideration. This does not mean that cost is no consideration, but it does mean that time is relatively of vastly greater value than in the operations of peace and loss of time accordingly much more costly. The ultimate economic principle that the result must justify the cost is as applicable to military as to civil procedure. In peace the result sought is economical production. In war the result sought is *victory in battle*, which is worth so much that we should not stop to count pennies in making our estimates. The duration of military operations is so brief as to make calculations or refinements looking to the reduction of maintenance and operating costs a matter of little or no concern whatever. In this connection the following has been received from a former citizen-officer who went to France with the 24th (Mechanical) Engineers and has remained there since in a civilian capacity:

"I have been very much impressed over here by the inability of the average temporary officer to look upon war engineering problems from the point of view required by war operations. You, of the regular establishment, realize that the engineer officer must take up any kind of engineering problem at a moment's notice and immediately reach *some* workable solution. Many of our temporary officers were enthusiastic over undertaking problems along the lines of their previous civilian activities, but when presented with a problem along lines where somebody else had specialized, they were not trained so as to readjust themselves and in some instances did not seem to realize the imperative necessity of instant readjustment and consequently many very capable civilian engineers were not efficient in the engineer establishment of the A. E. F. because they only knew how to do one thing and did not happen to be placed where that particular thing was needed. It seems to me that personal contact between men who have been or may become temporary officers and the officers of the Corps of Engineers should bring about a better understanding of the war requirements of engineer officers and prepare the civilian engineers so that they could average more efficient and broad-gauged work in a future war.

There is also the personal element which must always be considered, and if the engineers of the temporary and permanent establishments are kept in touch with each other they will understand the others' point of view much better and in time of stress their combined efficiency would of necessity be much higher. There are ways in which the civilian engineer can help the regular officer and the converse is equally true."

It is the special purpose of the Society of American Military Engineers, and of this journal as the organ of that society, to enable the engineers in the military service and those in civil life to be mutually helpful in giving each other a better point of view.

Reserve Officers' Training Corps

Enrollment in R. O. T. C.—The total enrollment in R. O. T. C. units is about 117,000 cadets at 260 schools and colleges. Of these 51 per cent are in senior units. There are 392 army officers on duty as instructors, or about one to 300 cadets, and 900 enlisted assistants or one to each 127 cadets.

Yale University—The present enrollment is 130 Field Artillery, 98 Signal Corps, 49 Engineers and 25 Ordnance. All of these except the first have been enrolled this year.

In the engineer unit instruction includes lectures and two hours per week in the field. A museum of models of engineer equipment is being made up. A model in molding sand of a battle position, including trenches and accessories, has been completed.

Virginia Polytechnic Institute.—The college has allotted a building for the use of the Military Department, each unit having a room.

EMERSON

STEAM PUMPS

Emerson Foot Valve and Quick - Cleaning Strainer

Adapted to All Pumps or Intakes

Emerson Standard
Made in Eight Sizes

The EMERSON is a steam vacuum pump designed and built to handle air, sand, mud and grit in percentages with the water impossible by any other kind or make of pump.

It is invaluable for all work in cofferdams, caissons, and for keeping excavations dry—continuously.

EMERSON PUMPS are in daily use by U. S. Engineers in River and Harbor Work, Reclamation, and on the Panama Canal, where 64 EMERSONS have been in service

The Latest Type EMERSON is built of steel pipe instead of cast iron, is increased in capacity 10 per cent, with a decrease of 35 per cent in weight, less parts and steam consumption.

A museum of engineer models, including bridges, revetments, knots and lashings, sand-tables, etc., is being installed in the room allotted to the engineer unit. The engineer unit is the largest, and 6 of the 8 cadet captains belong to it.

The first illustrated lecture on military bridges was delivered by Lieutenant Ketchum to all the units. Moving pictures of ponton and spar bridge construction at Camp Humphreys, and lantern slides showing the famous bridges of the U. S. Army in the World War, were exhibited. The next illustrated lecture will be on road construction.

Missouri School of Mines.—The unit at this college is exclusively engineers. It was formed in January, 1919, and now numbers 104, of which 5 are in the advanced course. It is hoped to send about 15 men to Camp Humphreys in June.

The army personnel includes Maj. H. J. Wild, Engineers, Master Engr. Arthur Scott, and Sgt. Erskin James. Regt. Sgt. Major Rosenthal, tranferred to the unit, lost his life in a hotel fire at Hennessy, Okla., March 1st.

[We are glad to see these three hardy pioneers. They form a good advance guard. We hope soon to have "stories" from all Engineer units of the R. O. T. C. It is helpful and stimulating to know what our co-workers and rivals are doing. And to help the R. O. T. C. is one of the functions of this journal.—ED.]

Engineer Unit. Missouri School of Mines

National Guard

Progress in Re-organization of the National Guard.—During the month of January the gain in strength of the National Guard was 3,025. The organizations extended Federal recognition during the month were as follows:

Infantry.—New companies, N. Y. 15, Wis. 1, Va. 1, N. C. 1, Vt. 1, Ga 1, S. C. 2, Porto Rico, 1, H. T. 1.

Field Arty.—New batteries, N Y., 2, Utah 1.

Cavalry.—New troops, Wis. 2, N. C. 1, Utah 1.

In addition to the above the following units were inspected and will be extended Federal recognition as soon as minor irregularities are corrected: N. Y. 2 Batteries Field Artillery, 2 Companies Infantry, 1 Field Hospital Unit.

The States of New York, Oklahoma and Oregon have engineer units in course of organization. The Adjutant General of Arkansas has been authorized to organize certain national guard units under the provisions of the National Defense Act. Amongst these is included one battalion of engineers, replacing the former organization whose disbandment has been authorized. Included in certain new units of the national guard of Massachusetts authorized under the National Defense Act, is one divisional regiment of engineers, including headquarters and supply section of an engineer train, and one regiment of engineers or corps or army troops. This authority will afford opportunity for the rehabilitation of the 101st Engineers which, under the command of Col. G. W. Bunnell (U. S. M. A., 1899), rendered such excellent service as the engineer regiment of the 26th Div. in the World War. This regiment included the old Boston Corps of Cadets.

The following table shows by states the present status of the authorized and actual enlisted strength of the guard and the percentage of authorized strength attained.

State	Authorized	Actual	Per cent.
1. Minnesota	3,688	3,548	96
2. Oklahoma	3,339	2,585	77
3. Maine	1,361	1,046	77
4. Hawaii	546	368	68
5. Colorado	1,859	1,025	55
6. Washington	2,107	1,135	54
7. Utah	713	362	51
8. Oregon	2,152	1,096	51
9. Tennessee	2,294	1,148	50
10. Vermont	874	399	46
11. Kansas	4,043	1,719	43
12. Rhode Island	1,096	396	36
13. Missouri	4,429	1,458	33
14. Dist. of Columbia	801	218	27
15. New Jersey	4,030	1,074	27
16. South Carolina	1,727	475	27
17. Virginia	2,865	594	25
18. Iowa	4,580	1,124	25
19. Alabama	2,432	579	24
20. New York	20,497	3 735	18
21. Wyoming	560	92	16
22. Idaho	562	90	16
23. California	3,594	505	14
24. Arkansas	1,758	210	12
25. Ohio	13,221	1.284	10
26. Florida	1,563	146	9
27. Georgia	2,877	191	7
28. North Carolina	2,581	150	6
29. Porto Rico	1,888	109	6
30. Mississippi	1,879	100	5
31. Wisconsin	9,293	344	4
32. Texas	11,427	11,164	
33. Other States	47,665	0	4
Total	163,775	38,469	

Nineteen states have presented no units for recognition and are not listed.

The following states have not accepted the allotment of units for the fiscal year 1920: Delaware, Massachusetts, New Hampshire, Arkansas, Louisiana, Texas, Illinois, and West Virginia. New Mexico and Wyoming have partially accepted while the state of Nevada has declined to organize any National Guard.

Personals

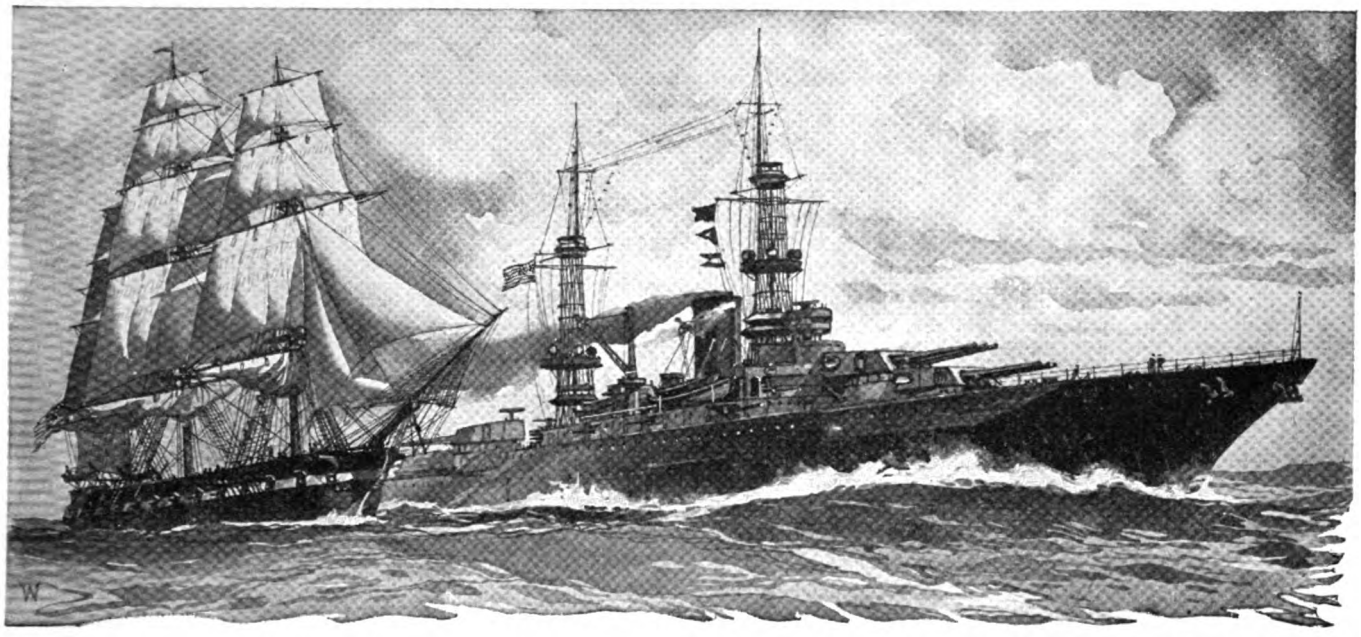
Col. F. B. MALTBY, formerly Section Engineer, Base Section No. 1, under the Director of Construction and Forestry of the A. E. F. in France, was recently decorated with the Cross of the Legion of Honor by General Coldet of the French high commission at Washington, in recognition of his services in port improvement, water supply and general construction. Colonel Maltby had his headquarters at St. Nazaire while in France; he recently secured his discharge from the Engineers, U. S. Army, and takes passage this month for Liberia, where he will make harbor works estimates for J. G. White & Co., of New York City.

Dr. F. B. JEWETT, chief engineer of the Western Electric Co., New York City, has recently returned from an extended trip through the West, during which, as the guest of various technical and scientific organizations, he lectured on "Some Wartime Developments in Electrical Communication and Allied Fields." During the war Dr. Jewett held the rank of lieutenant-colonel and won the distinguished service medal, which, together with his position on the U. S. Naval Consulting Board, permitted him to speak authoritatively on the subject. In each city which he visited his address was received with great enthusiasm, and the opportunity to learn something at first hand of the invention of the submarine detector, perfection of wireless telephony and other developments was keenly appreciated.

Major EDWARD VAN WINKLE, formerly with the 24th Engineers in France, in charge of most of the layout and survey work for the depot, at Is-sur-Tille, has become associated with Frederick A. Waldron; and will have charge of the design and construction of the three million dollar office building for the John Hancock Mutual Life Company in Boston, also the cord tire plant for the Middletown Rubber Company of Middletown, New York.

Capt. R. A. LOVE, Corps of Engineers, resigned from the service, March 2, 1920, and enters the employ of A. G. McKee & Co., at Akron, Ohio.

Lt. Col. J. P. HOGAN and Major L. B. ROBERTS, Engrs., recently discharged, have accepted positions as division engineers with Parsons, Klapp, Brinckerhoff and Douglass, New York. During the war Col. Hogan and Maj Roberts served overseas with G-2-c (topography) G. H. Q., A. E. F. Col. Hogan was later Chief of G-2-c, 2nd Army.



E. W. FASSETT, Assoc. M., Am. Soc., C. E. recently received his discharge as captain of engineers, U. S. A., and is now with the Midwest Refining Co., Casper, Wyo.

NATHANIEL O. GOULD, who was released from the Air Service, U. S. A., in June, 1919, has been appointed structural engineer for the firm of Aaron H. Gould & Son, architects and engineers, with offices in Detroit, Mich.

ALBERT L. UPHAM, recently honorably discharged from the 23rd Engineers, U. S. A., after fifteen months' service overseas, is now located at Hartford, Conn., as field engineer for Stone & Webster.

GEORGE R. PUTNAM, commissioner of lighthouses, and John C. Hoyt, of the U. S. Geo-

The "Constitution" of Today—Electrically Propelled

THE U. S. S. "New Mexico," the first battleship of any nation to be electrically propelled, is one of the most important achievements of the scientific age. She not only develops the maximum power and, with electrical control, has greater flexibility of maneuver, which is a distinct naval advantage, but also gives greater economy. At 10 knots, her normal cruising speed, she will steam on less fuel than the best turbine-driven ship that preceded her.

The electric generating plant, totaling 28,000 horsepower, and the propulsion equipment of the great super-dreadnaught were built by the General Electric Company. Their operation has demonstrated the superiority of electric propulsion over old-time methods and a wider application of this principle in the merchant marine is fast making progress.

Figures that tell the Story of Achievement

Length—624 feet
Width—97 feet
Displacement—32,000 tons
Fuel capacity — a million gallons (fuel oil)
Power—28,000 electrical horsepower
Speed—21 knots

Six auxiliary General Electric Turbine-Generators of 400 horsepower each, supply power for nearly 500 motors, driving pumps, fans, shop machinery, and kitchen and laundry appliances, etc.

Utilizing electricity to propel ships at sea marks the advancement of another phase of the electrical industry in which the General Electric Company is the pioneer. Of equal importance has been its part in perfecting electric transportation on land, transforming the potential energy of waterfalls for use in electric motors, developing the possibilities of electric lighting and many other similar achievements.

As a result, so general are the applications of electricity to the needs of mankind that scarcely a home or individual today need be without the benefits of General Electric products and service.

An illustrated booklet describing the "New Mexico," entitled "The Electric Ship," will be sent upon request. Address General Electric Company, Desk 44, Schenectady, New York.

logical Survey, both of Washington, have been elected president and vice-president, respectively, of the Cosmos Club, Washington.

The following changes of assignment of retained "emergency" officers have occurred since our last issue:

Major EDMUND J. BARRY, relieved from duty at Washington, D. C., and assigned to duty at Fort Leavenworth, Kansas, as Constructing Quartermaster.

Lieut. Colonel BOWYER B. BROWN, relieved from duty at New Orleans, La., and assigned to duty with the 318th Engineers, Camp Grant, Illinois.

Captain SAMUEL M. DAMON, relieved from duty at Fort Leavenworth, Kansas, and assigned to duty with the 2nd Engineers Fort Riley, Kansas.

1st Lieutenant EDGAR G. DAVIS, has returned from France and has been assigned to duty with the 6th Engineers at Camp Pike, Arkansas.

The following named emergency officers have been honorably discharged from the Service:

Lieut. Colonel WILLIAM O. HICKOK,
Major RAYMOND IVES,
Major EUGENE KELLY,
Captain WALTER H. ADAMS,
Captain DAVID T. BJORK,
Captain DURBIN H. BRADLEY,
Captain BENJAMIN COHEN,
Captain WILLIAM CROSS,
Captain JOHN H. DEVINE,
Captain JAMES M. FARRIN,
Captain ALBERT A. KEESLER,
Captain BERNARD LAMB,
1st Lieut. LEO J. DILLON,
1st Lieut. HEADLEY E. JORDAN,
1st Lieut. JACOB M. MERY,
2nd Lieut. GEO. W. EVANS.

Lieut. Col. ALLEN S. PECK, recently discharged from the 20th Engineer (forestry) has been appointed district forester for the mountain district of the U. S. Forestry Service. The district includes Col., Wyo., S. D., Neb., Mich. and Minn. Col. Peck served nearly two years with the A. E. F., and was awarded the distinguished service medal and made a Knight of the French Legion of Honor in recognition of his services.

Lieut. Col. W. P. WOOTEN, Corps of Engineers, has been named by the United States government as its engineering representative in connection with the investigation of the St. Lawrence river ship canal and power development project. The Canadian government has not yet appointed its engineering representative, but will do so at a very early date.

Losses of Personnel in the Corps of Engineers

During the months of January and February, 1920, the Corps of Engineers suffered a loss of seven officers, as follows:

Colonel C. McD. Townsend, retired; Colonel A. B. Barber, resigned; Major Joseph H. Earle, retired; Major Harold S. Hetrick, died; Captains T. M. Curry, Jr., and H. V. Fay, resigned; Lieut. R. C. Knight, retired.

Colonel MASON M. PATRICK, Corps of Engineers, has been assigned to duty as Assistant to the Chief of Engineers. Colonel Patrick went to France in command of a railroad regiment during the war, was promoted to the grade of Major General and served successively as Director of Construction and Forestry, and Chief of the Air Service, A. E. F.

Colonel EDGAR JADWIN Corps of Engineers, recently returned from overseas, has been assigned as Department Engineer, Southern Department, Fort Sam Houston, Tex Colonel Jadwin went to France as Colonel of the 15th (Railroad) Engineers and during the war was promoted to grade of Brigadier General and served as Director of Light Railroads and Roads, and of Construction and Forestry, A. E. F. He was later engineer member of the American Peace Commission to Poland.

Colonel THOMAS H. REES, Corps of Engineers, has been relieved from duty as Division Engineer, Southeast Division and assigned as Department Engineer, Western Department (Military) at San Francisco. Durthe War Colonel Rees commanded the 152nd Artillery Brigade, A. E. F., with the rank of Brigadier General.

Colonel H. DEAKYNE, Corps of Engineers has been assigned to temporary duty as Division Engineer, Gulf Division, and as a member of the Mississippi River Commission. He will be relieved of the District work at New Orleans by Major E. J. Dent, Corps of Engineers. During the war Colonel Deakyne was Chief Engineer of the 2nd Army, A. E. F. with the rank of Brigadier General.

Lieut. Col. W. J. BARDEN, Corps of Engineers has been assigned to temporary duty as Division Engineer, Southeast Division in addition to his duties as District Engineer, Jacksonville Fla. During the war Col. Barden served as Corps Engineer of the 6th and 9th Corps, A. E. F.

Brigadier General WILLIAM D. CONNOR, recently returned from oversease, was assigned to duty in the Office of the Chief of Staff. and subsequently to command Camp Humphreys, Va. General Conner served in France during the entire course of the war, and successively performed the following duties: Assistant Chief of Staff, A. E. F. (G-4); Chief of Staff, 32nd Division commanding 63rd Brigade, 32nd Division; Commanding General of Bordeaux, Chief of Staff, S. O. S.; Commanding General of the S. O. S.; and Commanding General of the American Forces in France after the departure of G. H. O. The office of the Commanding General of American Forces in France was closed on January 5, 1920, and the last American troops sailed on January 9th.

Lieut.-Col. S. A. CHENEY, Corps of Engineers, has been assigned to duty as Department Engineer, Eastern Department, relieving Lieut.-Col. John C. Gotwals, Engineers. Colonel Cheney has recently returned from overseas where he served as Director General of Transportation, A. E. F., with the rank of Brigadier General.

Lieut. Colonel WILLIAM P. WOOTEN, Corps of Engineers, has been relieved from duty in the Office of the Chief of Engineers and assigned to the charge of the Lake Survey at Detroit. Colonel Wooten served in France throughout the war, successively as Colonel of the 14th (Railroad) Engineers, Corps Engineer, 3rd Corps, and Chief Engineer, 3d Army, A. E. F.

Colonel WILLIAM KELLY, Corps of Engineers, has been assigned to duty in charge of the 3d Engineer District, San Francisco, and as Secretary of the California Debris Commission, relieving Lieut.-Col. L. H. Rand, Corps of Engineers. During the War Colonel Kelly served as Division Engineer, 42nd (Rainbow) Division, and Corps Engineer, 4th Corps, A. E. F., and later as commanding officer of he port of Antwerp.

Lieut.-Col. L. H. RAND, Corps of Engineers, has been relieved from duty in the 3d Engineer District, San Francisco, and assigned to the command of the 6th Engineers, Camp Pike, Ark.

Colonel T. H. JACKSON, Corps of Engineers, has been assigned to duty as Department Engineer, Northeastern Department. During the War Colonel Jackson served as Chief Engineer Advance Section, S. O. S., and Engineer Purchasing Officer of the A. E. F. He is now at the Walter Reed Hospital.

Major A. E. WALDRON, Corps of Engineers, has been relieved from duty in charge of the Mississippi River Dredging District and assigned to the command of the 8th Engineers at Camp Baker, Tex. During the War Maj. Waldron commanded the 35th Engineers.

Major E. J. DENT, Corps of Engineers, has been assigned to duty as District Engineer at New Orleans, relieving Lieut. Colonel H. Deakyne, Corps of Engineers. During the war Major Dent commanded the 4th, 26th and 104th Engineers.

Lieut. Col. JOHN C. G. GOTWALS, Engneers has been relieved from duty as Department Engineer, Eastern Department, and appointed President of the Alaskan Road Commission. During the war Colonel Gotwals commanded the 56th Engineers (searchlight) and was Chief of Searchlight Service in the A. E. F.

Captain J. E. HARRIS, Corps of Engineers, has returned to the United States from London where he was on duty in the office of the Engineer Purchasing Officer.

Major D. H. GILLETTE, Corps of Engineers, has been assigned to duty as Assistant Military Attache, American Embassy, London.

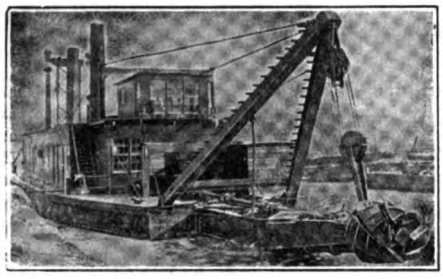
Lieut.-Col E. G. BLISS, Engineers, recently with the Transportation Corps in France, has been assigned to duty in the Office of the Chief of Transportation Service, Washington, D. C.

Captains H. H. POHL and G. H. COUNTS, Corps of Engineers, have been assigned to duty with the 6th Engineers, Camp Pike, Arkansas.

W. B. Greeley to Succeed H. S. Graves as Chief Forester

Colonel W. B. GREELEY, assistant forester in the U. S. Forest Service has been appointed chief forester by the Secretary of Agriculture to succeed Colonel Henry B. Graves whose resignation from that office becomes effective May 1.

Colonel Greeley is from California, a graduate of the University of California and the Yale Forest School, and has been in the Forest Service continuously since 1904 except for two years of military service with the American Expeditionary Forces. He has had long and varied administrative experience advancing through all the technical grades to his position as assistant forester.



To prepare the way for American operations in the French forests, the chief forester, Colonel Graves, was sent to France in 1917. He sent for Colonel Greeley to aid in the work. Colonel Greeley finally became chief of the American Forestry section in charge of 21,000 forestry troops and 95 sawmills.

Colonel Graves' letter of resignation to the Secretary of Agriculture contained the following statement:

"Since the pecuniary return afforded professional and scientific men in the Government service inadequately provides against the exhaustion of their working powers which must inevitably take place in time, and entail sacrifices from which employment elsewhere is free, the only course consistent alike with self respect and a regard for the public interest seems to me to be retirement from office before efficiency has been impaired."

Albert F. Potter, associate forester tendered his resignation at the same time and for the same reason.—Eng. News-Rec.

LESCHEN
WIRE ROPE

BACK of every Leschen Wire Rope is a large modern factory directed by experienced wire rope engineers and operated by skilled workmen. Every Leschen rope is proven to be up to the Leschen standard by rigid tests.

For heavy and exacting work we recommend HER ULES (Red Strand) Wire Rope, for the unusual strength, toughness and durability of this rope make it safe and economical on even the most severe conditions.

Professional Notes

of Military and Engineering Interest

Shortage of Enlisted Personnel in the Army.—There is a shortage of enlisted personnel in the Army, which will soon be increased by the furlough to the reserve of men who have completed their period of active service. After March 1st, the one-year enlistments will also begin to run out, so the Army will be further reduced by losing all one year men who do not reenlist.

An Army recruiting drive was started with a view to securing 75,000 men before March 31, 1920. For recruiting purposes, the regiments of the various branches of the service have been allocated to states or groups of states, with the idea that men from the same locality may serve in the same organization, thus fostering local *esprit*.

The allocation of engineer regiments and mounted battalions within the continental United States is as follows:

1st Engineers,
  1st Division,
    Camp Taylor, Ky.
      West Virginia,
      Kentucky,
      Tennessee,
      North Carolina.
2nd Engineers,
  2nd Division,
    Camp Travis, Texas,
      Oklahoma,
      Texas.
4th Engineers,
  4th Division,
    Camp Dodge, Iowa,
      Iowa,
      Wisconsin.
5th Engineers,
  7th Division,
    Camp A. A. Humphreys, Va.,
      Minnesota,
      Nebraska,
      Kansas.
6th Engineers,
  3rd Division,
    Camp Pike, Arkansas,
      Missouri,
      Louisiana,
      Arkansas.
7th Engineers,
  5th Division,
    Camp Gordon, Georgia,
      South Carolina,
      Georgia,
      Florida,
      Alabama,
      Mississippi.
8th Engineers (Mounted),
    Camp Baker, Texas,
      Wyoming,
      Idaho,
      Montana,
      Oregon,
      Washington,
      North Dakota,
      South Dakota.
9th Engineers (Mounted),
    Camp Courchesne, Texas,
      California,
      Arizona,
      Mew Mexico,
      Nevada,
      Utah,
      Colorado.
318th Engineers,
  6th Division,
    Camp Grant, Illinois,
      Illinois.

The shortage of men in engineer units is particularly acute. Readers of this journal can assist in the vitally necessary work of building up our greatly depleted army by directing men who may be interested in the service to the nearest recruiting office, or advising them to write to the Chief of Engineers.

The army in future, will offer to young men opportunities for educational, including vocational training, far greater than those of the past.

Notes of the Regular Army.—Two thousand two hundred forty-two regular officers had resigned from the service up to Jan. 29, 1920, or 21 per cent of the total.

Between Feb. 28, 1919, and Jan. 24, 1920, 170,841 men were enlisted for the regular army.

Of 488 distinguished-service medals awarded to date to officers of the regular army, the distribution was as follows:

	Per Cent		*Per Cent*
Infantry	29.9	Gen. officers	5.7
Cavalry	19.9	Q. M. C.	2.8
Engineers	9.7	Ord. Dept.	1.6
Med. Dept.	9.7	J. A. G.	1.4
C. A. C.	8.8	Sig. Corps	1.2
F. A.	8.2	Others	1.6

The strength of the regular army on Feb. 1, 1920, was:

Officers	18,739
Men	221,674
Total	240,413

Of the officers 8,641 are "emergency."

Wireless Operated Airplane Bombs.—A. H. G. Fokker, designer of the Fokker plane, states that Germany was about to discard the long-range gun in favor of wireless-controlled aeroplane bombs. It was planned to use a very cheap plane, capable of about 4-hours travel, carrying a large bomb, and guided by wireless control. The control was to be exercised by a large control plane flying with the fleet of aerial bombers. The pilot of this fleet would guide the flock to its destination and then release the bombs, either singly or simultaneously. It was considered that this method would be cheaper and more effective than the long-range gun.

Changing a Frame House to Stucco.—A writer in *Concrete* describes an interesting case of an old frame house transformed into a stucco building. The work was done in truly American fashion with no unnecessary labor or cost. Tar paper was tacked to the old lap siding, ¼-inch furring strips were nailed on and a stiff wire mesh (1½ by 3¼ inches) was stapled to these strips. The stucco was then at once applied with a Hodges stucco machine (electric). A plasterer rough-floated the base course of stucco and the finishing course was applied with the same machine 24 hours later. The writer points out that hand-applied stucco would have required two and possibly three coats.

The result was to add several thousand dollars to the value of the house, to reduce insurance rates and the maintenance costs (especially painting) of a frame structure. Also, it is claimed the interior temperature in summer is reduced 18° and fuel costs in winter 20 per cent.

Ten per cent of hydrated lime was added to the mixture of stucco. The rate of application of the base coat was 18 square yards, and the unit labor cost 22 cents. The labor cost for the finishing coat was less than 7 cents per square yard.

Decrease in Building Operations.—Building operations in the larger cities of the United States for the year 1918 showed a decrease of 39 per cent as compared with 1917, and 59 per cent as compared with 1916. The figures of cost for 143 cities, having a population of over 35,000, are:

1914	785,525,746
1915	821,120,657
1916	1,046,276,549
1917	700,700,815
1918	430,014,365

When the increased cost of construction is considered, the shrinkage in building construction is even greater than would appear from the above figures.

The new buildings constructed in these cities in 1918 are of the following classes:

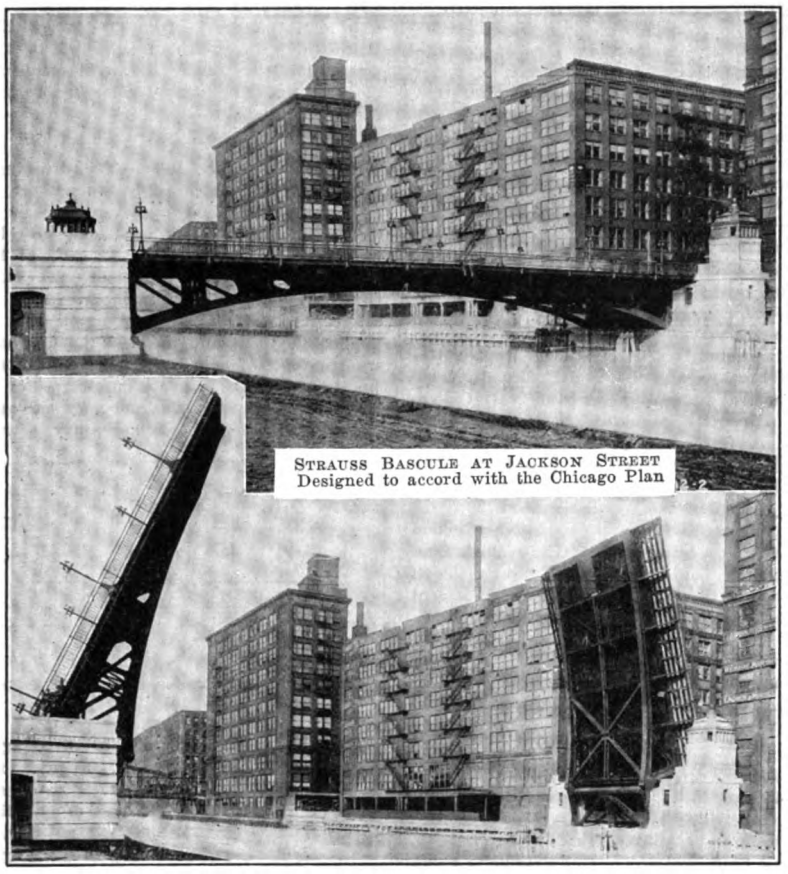
Wood	33 per cent of total cost
Brick or tile	50 per cent of total cost
Stone	1 per cent of total cost
Concrete	11 per cent of total cost
Steel skeleton	5 per cent of total cost
	100

The tendency toward economy as a result of the war is indicated by an increase in the expenditures for repairs, alterations and additions.

The University in Khaki.—Under the plans of the War Department the Army is to be a vast "University in Khaki" where men will be taught not alone the duties of the soldier, but will be given vocational training which will increase their earning power, industrial efficiency and moral training, which will make them better and more patriotic citizens.

The work is being conducted under great difficulties, as appropriations for the purpose are only $2,000,000. Nevertheless, the results that are being obtained are most encouraging.

This work will be a splendid demonstration of the educational possibilities of military training and will form a powerful argument in favor of making such training universal for the young men of America.



Among the subjects taught or to be taught are: Reading and writing, mathematics, geography, history, civil government and modern languages. Vocational instruction will include: Carpentry, blacksmithing, machinery, shop work, engine repair and operation, including motor vehicles; drafting, stenography, bookkeeping, telegraphy and telephony (including wireless), pharmacy, dentistry, truck gardening.

Upon completion of courses the men will be given certificates which will aid them in securing employment in civil life.

Education in the Army is in charge of Gen. W. G. Haan. Says Gen. Haan:

All training, whether purely military or educational, has as its main object the development of the soldier's mind to make him a responsible thinking human being. Every soldier, however poorly he may be educated, or however limited his experience, has still a thinking mind, and that mind is active practically all the time. Such a man is perhaps

incapable at the moment of looking at affairs in a broad sense, but the object of all training must be to guide that mind in the direction of right thinking. In order to accomplish this the instructor himself must be able to estimate about what are the channels of thought in the mind of the man being trained in order that he may so conduct his own part of the work as to gain the confidence of the men he is instructing or leading.

In developing the soldier's mind the most rapid progress is made by placing upon the man, as early as practicable, as much responsibility as he can stand. This placing of responsibility on the man stimulates his pride, raises his self-respect and urges him to better effort. This is applicable in all kinds of training. It is character building, frequently called moral training, and the most effective means of stimulating self-development.

Importance of Construction Industry.—Construction industries in the United States furnish 27 per cent of all railroad freight. They employ more labor and produce more wealth than any industry except agriculture.

American Association of Engineers.—The A. A. E. now numbers over 13,000 members and is the largest engineering society in the United States.

What the Roads Have to Carry.—There are in the United States over 7,000,000 passenger automobiles and over 500,000 trucks.

Progress in Scientific Road Building.—A writer in *Engineering World* informs us that there are three standard classes of "durable" road pavements in common use, to-wit:

1. Bituminous concrete.
2. Cement concrete.
3. Brick.

The chief source of failures in the first class was lack of standardization in materials and proportioning. This has now been eliminated, chiefly as a result of the aid extended by the Federal government. The oil dropped from motor cars is relied upon to replace the evaporation of volatile oils in the bitumen.

The uneven surfaces formerly complained of in concrete roads were due to bad screeding and poor joints, also to improper proportioning.

Difficulties with brick pavements were due chiefly to the sand cushion between the bricks and their concrete base. The sand absorbed moisture which froze and heaved the brick, or it shifted and allowed the brick to settle. The "trouble maker" is now eliminated, the bricks being set in the concrete and grouted to form a monolith, or the sand cushion is solidified with cement. Further improvements is effected by better brick and by lugs to permit more effective grouting.

The areas of these different classes of pavements contracted for in 1919 are as follows:

1. Bituminous concrete, square yards, 50,000,000.
2. Cement concrete, square yards, 50,550,000.
3. Brick, square yards, 12,000,000.

Good alignment has a tremendous value in shortening distance and eliminating curves, saving time, money, life, limb and property. All curves are widened and banked and railroad grade crossings eliminated as rapidly as possible.

The large and responsible contractor employing an up-to-date plant is replacing the small, irresponsible, improperly equipped contractor.

The author believes that the weakest links in highway construction are the bridges, which are lacking the requisite carrying capacity.

Removal of Stumps from Cleared Land.—"Stumping" cleared land is a task of terror and uncertainty to the engineer and contractor. Difficult indeed is it to estimate what it will cost in time, labor and money even when done on a large scale. That our machines and methods for this work are very crude and inefficient is pointed out by John Swenehart in a paper read before the American Society of Agricultural Engineers. That we have by no means removed all the stumps is indicated by his statement that in Wisconsin alone there are some 600,000,000 of them still to be tackled.

The removal of stumps is a fine art, well worthy of study when we consider the frightful cost that may result if it is not efficiently done.

Character of soil and ground water conditions enter the problem. Some stumps rot after standing a few years and are easily removed. Others retain their tenacity for long periods. The application of chemicals to promote decay does not promise success.

Explosives having a slow, heaving action are preferable to those producing a quick shattering effect, both as to cost and results. T. N. T. produces excellent results, but under present market conditions cannot compete with dynamite.

For very tough stumps the best results are obtained by a combination of explosives and stump-pulling machines. The machine should be able to pile the stumps.

Chief of Engineers Designated as Custodian of Military Maps.—The following decision has been rendered by the Secretary of War:

(*a*) That the Military Intelligence Division, General Staff, will decide all questions of policy pertaining to the procurement, reproduction and issue of maps.

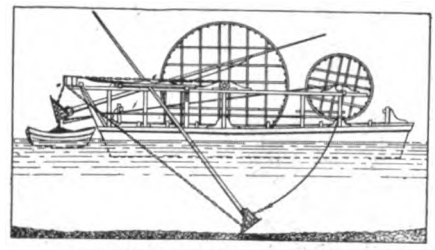
(*b*) The Chief of Engineers is designated as the custodian of all military maps based on surveys executed by the agencies of the Government, and intended for quantity distribution, including survey data relating thereto. He is also charged with the quantity distribution of such maps to the army, in accordance with tables of issue prepared by the general staff (M. I. D.).

(*c*) Based upon requirements announced by the general staff (M. I. D.), the Chief of Engineers will prepare programs for survey and map work which, upon approval of the Chief of Staff, will be carried into effect.

Permanence of Concrete in Sea Water.—The curious anomoly of wood substituted for concrete because of its greater durability is found in Santa Monica, Cal. Concrete piles are so badly damaged by sea water that creosoted wood piles will be substituted.—*Jour. West. Soc. of Engrs.*

German Submarine Construction.—During the war Germany constructed 372 submarines, of which 170 were in commission Nov. 11, 1918. The aggregate displacement of the undersea boats was 210,000 tons. The largest constructed had a displacement of 1,000 tons, but the average was about 800.

Toward the end of the third year of the war the rate of construction was two boats per week.—*Jour. West. Soc. of Engrs.*



Public Works in France—Improvement of Rhone River.—The French government plans to expend in the Rhone River improvement 820 million francs for water power, 610 millions for navigation, 200 millions for irrigation and 150 millions for transport.—*Eng. News Record.*

The Victory Flagstaff.—The "Victory Flagstaff" erected in Kew Gardens, London, consists of a single Douglas fir presented by British Columbia. The tree, felled in 1914, was 220 feet in height, 6 feet in diameter at the base and 18 inches (under the bark) at the top—quite a tree.

Dredges of Other Days.—The dredging of rivers and harbors probably began when vessels were first used.

The earliest dredging was done with long-handled spoons or dippers. As early at 1586 a dredging machine was patented at Venice, consisting of spoons operated from two pontons lashed together. Horse power was first applied in 1685, and in 1708 the first crude machine of the chain-bucket type made its appearance. This was the prototype of the "ladder dredge," but was not very successful.

Early in the eighteenth century a really

The forefather of the dipper dredge

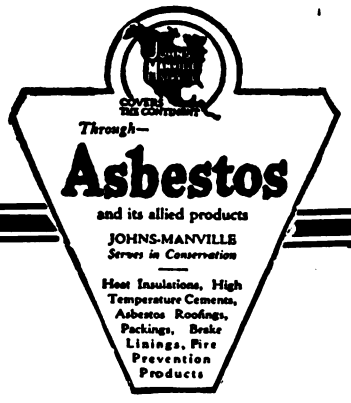
ingenious device was used for dredging the harbor of Toulon, France. Reference to the diagram herewith shows that it involves the essential principles of the present-day dipper dredge. The larger "squirrel wheel" furnishes the power for making the cut, there being two dippers, one on each side. The smaller wheel was used to draw the dipper back for another cut. As the dippers operated alternately, both wheels were continuously employed.

An improved type of ladder dredge, having buckets on an endless chain, was used at Orleans in 1750.

The first clam-shell type was used at Genoa in 1773. It consisted of two bucket leaves attached to pivoted arms like the legs of a compass, operated from a scow by means of hand winches.

In 1797 the first steam engine for use on a dredge was built by Boulton & Watt in England, and used in the harbor of Sunderland. It operated four dippers, each having a capacity of one ton.

The year 1811 witnessed the first application of steam power to the ladder dredge. In 1814 such a dredge was used on the Caledonian Canal. The ladder frame was 42 feet long with 25 buckets, driven by a 6 horse power engine. Steam ladder dredges were used on the Delaware and Raritan Canal in 1830-34.



The first modern steam dipper dredge was patented in the United States in 1845. The hydraulic dredge was invented in France in 1867.—*R. L. Zimpel in Scientific American.*

The Concrete Ship.—The concrete ship program of the Emergency Fleet Corporation called for 42 vessels of this type. Of these 12 only remain on the program, of which four are actually completed and in service and three large tankers have been launched. In addition 21 500-ton concrete barges were built by the Railroad Administration, of which 20 are in service.

In carrying out the program all structural difficulties were successfully met, but the high speed of construction hoped for has not been realized thus far.

The vessels in service have proved them-

THE efficiency of Johns-Manville Products in severe service merely bears out their performance under laboratory tests conducted by Johns-Manville engineers. Every Johns-Manville product must prove itself correct in design, manufacture, and functioning before it is put on sale with the backing of Johns-Manville responsibility.

Asbestos and Magnesia Materials

Locomotive Lagging, Locomotive Spiral Pipe Covering, Locomotive Packings, including Air Pump, Throttle, Valve Stem, Cab Cock, Gaskets, etc.

Power Plant Specialties

Pipe Coverings for all classes of Service. High Pressure, Low Pressure and Sheet Packings, High Temperature Cements, Steam Traps, Insulating Cement, Electrical Supplies, Roofings, Mastic Flooring, Transite and Ebony Asbestos Wood, Transite Smoke Jacks, Refrigerators and Steel Passenger Car Insulation.

For Air Brakes on Locomotives and Cars

Automatic Slack Take-up, Packing Cups and Gaskets, Expander Rings.

selves very seaworthy, having less vibration than steel ships. No leakage whatever has been reported. Their greatest weakness is that actual impact against hard substances, which in the case of a steel ship would produce only a dent, is apt to cause shattering of the concrete shell. Repairs, however, are easily made, and it is believed that the danger can be greatly reduced by the use of oak fenders.

The cost of these vessels is from $210 to $300 per ton of deadweight capacity, which is approximately that of steel vessels.—*Eng. News-Record.*

Renewing Bridge Chords Without Interrupting Traffic Above or Below.—In *Proceedings Am. Soc. C. E.*, Feb. 1920, Mr. H. C. Keith presents an entertaining paper describing the methods of renewing the lower chord members of the 203-foot swing span of the Washington Bridge over the Housatonic River.

The method adopted after much study was the apparently simple expedient of carrying the stresses by temporary adjustable timber struts while the permanent chord members were being renewed. This resulted in "a very material saving of time and money, without impeding traffic." Half the width of the roadway was at all times available for traffic, and the span could be opened at all times for the passage of vessels.

There being no other bridge within a reasonable distance to which the traffic could be easily diverted, the first plan considered was to construct a temporary drawbridge alongside, open the draw to be repaired and block it up on the fender piers. This plan was very naturally abandoned on the score of expense.

The next idea was to employ false work on piles. Mr. Keith, with humorous sarcasm, explains that this plan was frowned upon by the Federal government, that jealous guardian of the rights of navigation, which will not for an instant permit the obstruction of even a "theoretically" navigable stream, however great the hardship imposed on the weary foot passenger or tired "strap-hanger" in a trolley car, who is compelled to cross the great highways of water transport. Of course the Government would permit obstructions in the river during the winter season, when it is closed by ice, provided they are promptly and thoroughly removed in the spring. However, the cost of this would have been so great that no such permission was sought.

We believe that Mr. Keith should be (and we have no doubt that he is) grateful to the Federal government for its wise restrictions, which induced the engineers in charge of this work to abandon several very expensive schemes and finally hit upon what was apparently the best plan from every point of view. It all goes to show that necessity is the mother of ingenuity, that overcoming difficulties strengthens our professional fibre and that we never know what we can do until the Government makes us do it, no less in peace than in war. At any rate it was a consideration of these facts, especially the attitude of the Government, that led to this "surprisingly economical solution." In fact, says Mr. Keith, with a most entertaining ingenuousness, the method adopted (under the restrictions of the Federal government) was so "decidedly economical" that there was "no hesitation in choosing safety" and "less incentive to reduce cost or to use *too delicate scales* in balancing safety against cost." In all respects this was apparently a most excellently conducted and highly successful piece of work.

The total cost was but $5,900, whereas a temporary bridge with draw span would have cost at least $100,000.

We commend this instructive and entertaining paper to the attention of all engineers who may at any time have chafed under governmental restrictions on construction. The author encountered these restrictions, refused to chafe and overcame them in most cheerful and intelligent fashion, did a better piece of work than he might otherwise have done and is a happier and wiser engineer in consequence. "Go thou and do likewise."

International Commission on St. Lawrence River Improvement.—Under the provisions of Article IX of the treaty of Jan. 11, 1909, between the United States and Great Britain, an international joint commission will consider certain problems with reference to the improvement of the St. Lawrence River in the interests of navigation and power development.

The specific questions referred to the commission are as follows:

Question 1. What further improvement in the St. Lawrence River, between Montreal and Lake Ontario, is necessary to make the same navigable for deep-draught vessels of either the lake or ocean-going type; what draught of water is recommended, and what is the estimated cost?

In answering this question the commission is requested to consider:

(*a*) Navigation interests alone, whether by the construction of locks and dams in the river, by side canals with the necessary locks or by a combination of the two.

(*b*) The combination of navigation and power interests to obtain the greatest beneficial use of the waters of the river.

Question 2. Which of the schemes submitted by the government or other engineers is preferred, and why?

Question 3. Under what general method of procedure and in what general order shall the various physical and administrative features of the improvement be carried out?

Question 4. Upon what basis shall the capital cost of the completed improvement be apportioned to each country?

Question 5. Upon what basis shall the costs of operation and maintenance be apportioned to each country?

Question 6. What method of control is recommended for the operation of the improved waterway to secure its mos beneficial use?

Question 7. Will regulating Lake Ontario increase the low-water flow in the St. Lawrence Ship Channel below Montreal? And if so, to what extent and at what additional cost?

Question 8. To what extent will the improvement develop the resources, commerce and industry of each country?

Question 9. What traffic, both incoming and outgoing, in kind and quantity, is likely to be carried upon the proposed route both at its inception and in the future? Consideration to be given not only to present conditions, but to probable changes therein resulting from the development of industrial activities due to availability of large quantities of hydraulic power?

Pending the receipt of plans, estimates and other engineering data necessary for the final consideration of this reference, the commission is requested to hold such public hearings as may be considered necessary or advisable in order to obtain all information bearing, directly or indirectly, on the physical, commercial and economic feasibility of the project as a whole.

To facilitate the preparation of the desired report each government will, from its official engineering personnel, appoint an engineer with full authority to confer with a similar officer of the other government for the purpose: First, of acquiring, each in his own country, such data as may be found necessary to supplement the existing engineering data and surveys and second, of preparing complete outline plans for the estimates of the cost of the proposed improvement, including the value of all property, easements, damages and rights connected therewith. These plans and estimates are to be submitted to the commission as soon as practicable, but not later than one year from the date of appointment, and the commission is requested to forward to the two governments its final report with recommendation not later than three months thereafter.

Lt. Col. Wm. P. Wooten, Corps of Engineers, U. S. A., has been appointed as the engineer representative of the United States Government.

The first public hearing of the international commission was held at Buffalo, N. Y., March 1 and 2. The Canadian section included C. A. McGrath, H. A. Powell, P. Urgnault, Wm. Hearst and L. J. Burpee. The American commissioners are O. Gardner, R. B. Glenn, C. D. Clark and W. Klutts.

Two Brigadier Generals in Corps of Engineers.—Senator Ransdell on Feb. 21 proposed an amendment to the Senate Army bill providing for two brigadier generals for the Corps of Engineers. Secretary Baker, in discussing this matter, stated that there should be a brigadier general, assistant to the Chief of Engineers, in charge of the civil functions of the corps and one in charge of its military activities.

Army Reorganization Bill in House of Representatives.—The Army reorganization bill introduced in the House on Feb. 25th resembles the Senate bill noted in our last issue so far as concerns the size of the Army and the provisions for promotion and elemination of officers. The House bill is modeled more closely on the National Defense Act of 1916, of which it is in fact an amendment, and it omits all provision for universal training. This means that universal training will be considered separately and that meantime Congress does not wish to delay the necessary reorganization of the Army. A special committee of Congress will study the question and prepare a measure for consideration at the next session. Meantime it is probable that universal training will be an important issue in the coming Presidential campaign.

On March 10 the House by a decisive vote of more than 3 to 1 overruled the efforts of certain members to reduce the strength of the regular army to the pre-war figure of 185,000. This action, while not final, indicates a strong sentiment in Congress in favor of an army of 17,820 officers and 289,000 men.

Ratio of Officers to Enlisted Men, U. S. Army.—In 1850 the ratio was 10 officers per 100 enlisted men. During the late war the rato was 5 per 100 (200,000 officers, 4,000,000 men). At present the rato is about 4.25 per 100.

Distance Record for Wireless Telephone.—The Air Service established at Ft. Sam Houston a new distance record of 12 miles for transmission by wireless telephone.—*A. & N. Journal.*

Bombing Aeroplanes Break Ice Gorge.—The great ice gorge in the Susquehanna River near Port Deposit has been broken by 500-pound T. N. T. air torpedoes dropped from De Havilland bombing planes. Smaller bombs having proved ineffective, large projectiles equipped with "delayed action" fuses were successfully employed by the army authorities.

How to Give and Carry Out Military Orders.—There were some of our reserve officers in the World War who had very sound fundamental ideas as to how to give and to execute military orders, as the following anecdote of good military procedure illustrates:

In the fall of 1917 the A. E. F. organizations were being formed and work was starting. The means to accomplish work were exceedingly scarce. Personnel of all kinds was lacking and machinery was almost unobtainable. A call came from one field job for a steam shovel. The job was urgent, and there was not time to wait for anything from the United States. The Engineer Supply Office in Paris had no machinery and very little personnel. How a steam shovel was to be obtained was hard to see. The colonel in charge was equal to the emergency. He solved the difficult problem in a most simple and direct fashion. He called in one Lieut. Reidy and said "Get a steam shovel and deliver it to Col. ——— at ———, and don't appear in this office until said shovel is delivered."

The lieutenant also was equal to the emergency. He looked a bit startled, but he did not argue or ask any questions. Indeed there was nothing more to be said. The lieutenant could not speak a word of French and had no idea where a shovel could be obtained. He saluted and disappeared. After about two weeks he reappeared and reported that the steam shovel had been delivered at the place designated. The results were so astounding that the lieutenant was questioned as to how he had succeeded in carrying out his instructions.

It developed that this officer wandering along had found a French steam shovel lying idle alongside of a narrow-gauge railroad track, had loaded it on cars and carried it to the end of this track, which was about a mile from a standard-gauge railroad. Then he had unloaded it, "jackassed" it a mile to the standard-gauge road, reloaded it on cars and conveyed it to destination. All this had been done without money and without help. In some way the labor, etc., had been obtained on credit. The shovel had been taken apart and assembled twice. Considering the scarcity of French labor, both skilled and unskilled, the lieutenant must have had many difficulties. What language his negotiations were conducted in is not recorded.

It is believed that such men as this, although they worked unsung in the S. O. S., could be shown little in the way of getting results by those who were fortunate enough to serve within the smoke of battle, where any performances, however small, received prompt recognition and wide publicity.

A Wooden Railroad.—The United States has a railroad 15 miles long laid with wooden rails. It is in Alaska, and extends from the head of navigation on the Tolovana River up to some gold mines. A single locomotive, Dodge automobile, has done very profitable work throughout the last seasons. The automobile has flanged wheels and hauls three cars at a time, aggregating 6 tons under favorable conditions. The principal traffic consists of logs from the river to the sawmill, about the half-way point, and lumber from the sawmill to the mines. The freight rate is $3 per hundred pounds. The past season the automobile traveled 6,000 miles, sometimes making eight trips a day.—*Railway Age.*

Light Railways in New Countries.—Light railways of 30 cm. gauge can be constructed with greater rapidity and more economically than standard-gauge lines or roads to carry motor traffic, and cost much less to maintain. On the western front of the British army in France, where the existence of a network of motor roads favors that form of transportation, it was proved that motor transport on the whole could not compete with light railways, either in cost per ton hauled or in reliability. —*Geographical Journal.*

Opening of Railroad from Persian Gulf to Bagdad.—An item of considerable political and military significance is contained in recent press dispatches to the effect that the first through train from Basra northwest to Bagdad, containing British military and civil officers and Arab Sheiks, left Basra at midnight on Jan. 13th and arrived at Bagdad on the afternoon of Jan. 15th, where Lady MacMunn, in the presence of a large gathering, fixed the last fish-bolt and declard the line open.

Basra is a river port 60 miles from the Persian Gulf. From Basra to Bagdad is 352 miles. It is expected that a daily through passenger train each way will be put on to make the run in 28 hours.—*Railway Age.*

Status of Alaskan Railroad Construction.—The project of building some 470 miles of railroad in Alaska, begun a few years ago by the United States Government, has been progressing very satisfactorily, according to the annual report of the Secretary of the Interior, under whose direction the work is being done. The road is now more than two-thirds built and Congress, after making an exhaustve investigation into the project, has authorized additional appropriation sufficient for its completion. Secretary Lane states that the best estimate that can be made to-day as to the newly constructed line is that it has cost between $70,000 and $80,000 per main-line mile, or between $60,000 and $70,000 per mile of track. This cost per mile includes the building of the most difficult and expensive stretch of line along the entire route from Seward to Fairbanks—that running along Turnagain Arm, which is sheer rock rising precipitously from the sea for nearly 30 miles. There are miles of this road which have cost $200,000 per mile. Even to blast a mule trail in one portion of this route cost $25,000 a mile.—*Eng. and Cont.*

Susitna River Bridge, Alaska.—Bids were opened Jan. 26th for the Susitna River bridge at Gold Creek on the Alaska government railroad. The structure is to be a steel truss, weighing 1,650 tons and having a span of 504 feet. Bids ranged from $7.97 to $9.57 per 100 pounds. The main span is to be completed by Nov. 15, 1920. The American Bridge Co. was the low bidder.—*Eng. World.*

Proper Width of Paved Highways for Motor Traffic.—A writer in *Mun. and County Eng.* presents some logical arguments as to the proper width of a road for motor transport. However unimportant a road may appear, it usually becomes a well-traveled highway if provided with a good pavement. Therefore it is important that this pavement be given ample width to safely and efficiently carry the traffic that will develop. Motor cars travel at a speed of from 20 to 30 miles per hour on an open road. At such speeds it is not safe to run off the paved portion of the road onto the earth shoulders. A vehicle cannot travel safely at 30 miles per hour with a clearance of less than 2 feet between the wheels and the curb or edge of pavement. Passing vehicles should have a clearance of at least 4 feet. Assuming that a motor vehicle measures 6 feet wide over all, the width of the pavement should be 2 feet clearance on each side, two vehicles each 6 feet wide, and 4 feet clearance between vehicles, total, 2 plus 2 plus 12 plus 4 equal 20 feet. Such a width has the further advantage that when not passing other vehicles motor cars distribute their travel more evenly over the surface instead of moving always in the same place as on a narrower road, whereby the formation of ruts is avoided.

A writer in *Engineering and Contracting*, discussing the proper minimum width of paved roadway for motor-truck transportation, arrives by a similar course of reasoning at the same figures—20 feet. He assumes a speed of 10 to 15 miles per hour for trucks, allows 1 foot clearance between the truck body and the edge of the road, 8 feet for the overall width of each of two passing trucks, and 2 feet clearance between them.

Further evidence of the proper economic width of roadway is found in the figures adopted for the new interstate tunnel under the Hudson River, which is 20 feet, as recommended by the two writers mentioned. The traffic in each tube of the tunnel is to be in one direction only, but it is assumed that there will be two lines of traffic—slow and fast—so that continual passage of vehicles traveling in the same direction at different speeds will occur.

Rental Value of Construction Plant.—Arguing for a more intelligent and systematic procedure in charging plant rental against construction jobs, Mr. T. J. Herliby, in *Engineering News-Record*, gives an interesting table as indicating the manner in which such charges should be estimated. It shows that many elements enter into the question and that the crude method of charging the first cost of the plant against the job and crediting it with the value of the plant at its conclusion does not solve the problem. The figures given in the table are merely fair averages to illustrate the method of scientifically figuring the real cost. In any particular case the actual figures should be substituted. Thus, if the plant were purchased second-hand a lower original cost, but a higher depreciation and repair charge would be appropriate. The number of earning days per year is a matter of vital importance in the calculation, whose effects have too often been merely nervously guessed at.

The table includes items from steam shovels to water pipe, and the various entries for each are as follows:

1. Original capital cost.
2. Equivalent annual interest rate on original cost.
3. Annual rate of depreciation on original cost.
4. Annual insurance and storage rate.
5. Total annual rate of accrued charges, per cent.
6. Total annual charge, dollars.
7. Average earning days per year.
8. Daily charge for interest, depreciation and storage, dollars.
9. General shop repairs, daily, dollars.
10. Daily rental.
11. Field repairs, daily, dollars.
12. Total daily rental including field repairs.

Geographical Work on the Western Front.—When the war started in 1914 the British army consisted almost entirely of fighting men, and scientists did not figure greatly in the original expeditionary forces. Gradually, however, the need for men who had expert knowledge on different scientific subjects became apparent. The majority of the scientific departments were organized in the early months of 1915.

Geological work included advice on questions relating to water supply in the occupied area and ahead of the lines, listening and test boring for mines and dugouts, inundations, especially in the Yser district, behavior of ground under shell fire, sources for road metal

Digitized by Google

and flint gravel for concrete, foundations for bridges and the many related and subsidiary problems.

In many cases the geological solution did not meet the military requirements, therefore, *the geologist must know the military* as well as the scientific aspect of his work.—*Geographical Journal.*

The Aeroplane in African Exploration.—In spite of the lack of suitable machines and efficient photographic equipment, experience during the East African campaign demonstrated the possibility and also the difficulty of exploration by aeroplane. It was proved that for making a first reconnaissance of a district not previously mapped the aeroplane, carrying a *well-trained observer*, gave better results within an hour than a ground party in a week.

On photographing an entirely unmapped district, a modification of a range-finding method was employed, requiring the assistance of a ground party to determine the range and azimuth of smoke bombs or Very lights dropped over the objects photographed. In this way a satisfactory map of the German positions in the flat, swampy valley of the Mgeta River was made.

Along the coast the aeroplane and camera were profitably employed in locating sunken coral reefs; also the constantly shifting mud and sand banks in the numerous estuaries.—*Geographical Journal.*

Emergency Shelter for Troops.—All army officers should be familiar with some of the devices that have been used for sheltering troops. This is especially true of some of those used on the Punitive Expedition into Mexico. On this expedition, neither canvas nor lumber was obtainable when it was needed, principally due to lack of transportation.

The troops that went into Mexico in 1916 lived at first in shelter tents. Later, all kinds of facilities were improvised out of "dobe." The soldiers learned to use this by seeing what the Mexicans had done and were doing. The soil in Texas and in Mexico can be made into a very serviceable brick by simply mixing it with water, and moulding it for the sun to dry. The dirt found almost everywhere is mixed with sufficient water to make it plastic, a little straw is added to help bind the brick together; the bricks, about 4 by 10 by 20 inches, are moulded on a smooth piece of ground and left for the sun to bake. Moulds can be improvised from scraps of lumber from commissary boxes. The bricks may dry sufficiently to handle in three or four days, although they are better if left a week or more in the sun.

On the Punitive Expedition our troops made houses for themselves out of these bricks. The principal difficulty was the roof. Poles were very scarce, and were extremely crooked. However, roofs were improvised with these by covering the poles with brush, and plastering adobe on top. If carefully done, such a roof is waterproof. The broad walls made of brick 10 inches thick would support such a roof up to about 20-foot span. Generally, it would also have to be supported by one or two posts inside.

In addition to huts of adobe, our soldiers made bake ovens, incinerators, water heaters, etc., out of the same materials. Sheets of iron, and gasoline cans split open and hammered out flat were used for moulds. The bake ovens were all that could be desired. Water heaters for baths were made by placing coils of pipe in adobe ovens. The pipe would be connected at both ends with a barrel of water, set up on posts. The water would, of course, circulate through the coils in the oven until the barrel was full of hot water. A soldier could stand under the barrel, and pull out a plug in the bottom and thus get a nice hot bath. Of course, the pipe, barrels, etc., were hard to get, but everybody managed to "rustle" them in one way or another. We never know what we can do until we have to.

The American soldier soon became awfully tired of making dobe brick, so the ingenuity of company commanders was brought into play. One company commander had a scale of company punishments, each prescribing so many brick. Finally, when his soldiers grew still more tired of this and asked for court martial and capital punishment in lieu of company "discipline" he thought he had reached the end of his rope and would have to go out of the brick business. However, he held a profitable interview with the Summary Court officer, and when the sentence was promulgated, it prescribed just twice the number of brick that company "discipline" had provided for. No further courts were necessary.

German Chemical Patents taken over by Americans.—The alien property custodian has sold some 4,500 German chemical patents, which have been bought by a corporation organized for the purpose—a Chemical Foundation. These patents will be licensed to American manufacturers. The corporation will also protect the manufacturers in the use of these patents.

The underlying purpose of this plan is to destroy the German monopoly in dye, and certain other chemical manufacturers, which existed before the war.

During the war the chief sources of supply of poison gas, high explosives and other chemicals were the dye and pharmaceutical plants. This was especially true in Germany, and constituted one of the strong elements in her scheme of preparedness for war. The stimulations of the dye and chemical industry in the U. S. is accordingly an important item in our own program of preparedness.

Water Power Bill.—The Senate on January 15 passed the bill providing a Federal Water Power Commission having broad powers in the issue of licenses for water power development. Considerable opposition developed to the bill on the ground that it was too liberal in giving away the government's water resources. An amendment to the bill provides that the secretary of the commission shall be an officer of the Corps of Engineers, U. S. Army. This amendment, designed to safeguard the interests of the public, as against those of a "predatory" nature, appears to have caused a feeling of great nervousness in certain quarters.

Who Furnished the Generals?—General officers in World War:

Inf.	137	A. G.	2
Cav.	72	J. A. G.	4
F. A.	51	Gen. Officers	38
C. A. C.	39	Retired	21
Engrs.	29	Natl. Guard	48
O. U.	10	Marines	6
Ord.	8	Civilians	10
Sig.	4		
Med.	10		489

Average age of regular general officers, 51.3; average years of service of regular officers, 27.4.

Resignation of Officers of Regular Army.—Since the date of the armistice 2,302 *regular* army officers have resigned from the service, or more than in the previous 70 years. This figure exceeds 22 per cent of all regular officers in the service on November 11, 1918.

Enlistments in the Regular Army.—On February 13, with 36 per cent of the time allowed for a recruiting "drive" for the army only 7.7 per cent of the quota needed had been obtained. In the past year 175,000 men have been enlisted; of these, 61,518 are infantry and 3,727 engineers.

Officers in Service, Feb. 17, 1920.—Regular officers, 8,540; emergency officers on duty, 8,283; emergency officers under treatment, 1,307.

Major JOHN A. GRIFFIN, who was with the 316th Engineers in France, has been elected city engineer by the Board of Public Works of Los Angeles, Cal., to succeed the late A. C. Hansen.

Col. F. M. GUNBY, formerly associated with Charles T. Main, of Boston, during the war head of the Engineering Branch of the Construction Division of the Army, has renewed his connection with the above-named firm as engineering manager.

Col. CHAS. L. POTTER, Corps of Engrs., has been appointed President of the Mississippi River Commission, succeeding Col. C. McD. Townsend, who has retired from active service.

Capt. P. C. POINTER, Engrs., recently discharged, has joined the staff of the Eastern Paving Brick Mfrs. Assn. While with the A. E. F., Capt. Pointer was engaged in road work.

Major H. H. WADSWORTH, Engrs., (recently discharged) Principal Asst. Engr. of the California Debris Commission, has resigned from the U. S. Service to enter private practice as a consulting engineer specializing in hydraulic engineering.

Col. ERNEST GRAVES, Engrs., has been relieved from duty in the Office of the Chief of Engineers and assigned to the Command of the 2d Engineers, Camp Travis, Tex.

Maj. Gen. W. L. SIBERT, has been relieved from duty as Chief of the Chemical Warfare Service and assigned to the Command of the 5th Division, Camp Gordon, Ga.

Col. G. E. EDGERTON, Engrs., has been assigned to duty in the Office of the Chief of Engineers.

H. T. CORY of the U. S. Reclamation Service has gone to Egypt to serve on the international commission which will pass on plans for irrigation in the Nile Valley.

R. F. RAGLAND, recently discharged from the Army as captain of Engineers, has opened an office in Livingston, Park Co., Mont., where he will engage in a general engineering and contracting business.

Lieut. H. J. LALONDE, recently discharged from the 71st Field Artillery, has accepted a position with the St. Louis office of the Portland Central Association.

Col. G. R. SOLOMON, recently discharged from the Construction Division of the Army, has resumed his engineering practice as vice-president of the Fuller Industrial Engineering Corp., New York City. Before entering the military service Colonel Solomon was a member of the Solomon-Norcross Co., consulting engineers, of Atlanta, Ga.

Maj. C. W. OTWELL, C. E., has been assigned to the charge of the Wheeling, W. Va. District, succeeding Lt. Col. G. P. Howell, During the war Maj. Otwell commanded the 319th Engrs., with the rank of Colonel.

Constitution of the Society of American Military Engineers

PREAMBLE.

The Military Engineers of the United States, having associated themselves for the advancement of military engineering knowledge, do hereby adopt the following constitution and by-laws:

CONSTITUTION

ARTICLE I.

NAME AND HEADQUARTERS.

1. The name of this organization shall be "The Society of American Military Engineers."

2. The headquarters shall be in the City of Washington, D. C.

ARTICLE II.

OBJECTS.

1. The objects of the Society shall be in the interests of the national defence to promote the efficiency of the military engineer service of the United States; to maintain its best standards and traditions; to disseminate professional knowledge concerning developments in engineering with special reference to their application to military purposes; to develop between the military engineers and other arms of the service a spirit of co-operation and a mutual understanding of their respective duties, powers and limitations, and to foster relations of helpful interest between the engineering profession in civil life and that in the military service.

2. Among the means to be employed for this purpose shall be meetings for the presentation and discussion of appropriate papers, and for social and professional intercourse, and the publication of such periodicals and other papers as may be deemed expedient.

ARTICLE III.

MEMBERSHIP.

1. *Classification.* The membership of the Society shall be classified as Active, Associate, and Honorary.

2. *Active Members.* The following persons shall be eligible to active membership, viz, all persons holding commissions as officers in the engineer service of the military forces of the United States, or who, having held such commissions, have been honorably separated from said engineer service; all persons qualified as technical engineers, serving in any capacity in any arm, department or service of the military forces of the United States, or who, having so served, have been honorably separated from the military service: *Provided*, That any technical engineer serving in a civilian capacity exclusively shall not be eligible to active membership until he shall have completed six months' continuous employment in any one arm, department or service of the regular army of the United States.

3. *Associate Members.* The following persons shall be eligible to Associate Membership, viz, all persons not included in the provisions of preceding paragraph, holding commissions as officers in the military forces of the United States or in the United States Navy, including the Marine Corps, or in the Coast Guard, or who, having held such commissions, have been honorably separated from the service of the United States; all persons duly enrolled as members of technical engineering units of the Reserve Officers' Training Corps; civilians of suitable technical qualifications, interested in military engineering affairs, and all persons serving in any military capacity in technical engineering units of the military forces of the United States or who, having so served, have been honorably separated from the military service: *Provided*, That no person eligible to Active Membership shall be classified as an Associate Member.

4. *Honorary Members.* Persons who have rendered distinguished service to the Society, or who have otherwise attained distinction deserving of recognition by the Society may be elected to honorary membership for life: *Provided*, That the total number of honorary members shall not exceed fifteen at any one time.

5. Active members only shall be empowered to vote and to hold office.

ARTICLE IV.

GOVERNMENT.

1. The government of the Society shall be vested in a Board of Directors consisting of a President, a First and a Second Vice President, and eighteen active members. The President and the two Vice Presidents, all of whom shall be directors, shall be elected to serve for one year and until their successors shall have been duly elected: *Provided*, That no one of the three officers herein first named shall be eligible to immediately succeed himself in office.

The eighteen directors, other than the three officers above named, shall be elected to serve for three years: *Provided*, That six of their number shall be chosen from the regular army, six from the other military forces of the United States subject to active service, and six from the active members at large, exclusive of the foregoing two sub-classes of members: *Provided further*, That the term of office of two directors of each such group of six shall expire each year.

2. The Board of Directors shall elect from its own number a Treasurer to serve for one year and shall elect from the active members, though not necessarily from its own number, a Secretary whose term of office shall be one year.

ARTICLE V.

ANNUAL MEETING.

The Society shall hold an annual meeting of the members for the election of officers and directors and for the transaction of other business pertaining to the Society.

ARTICLE VI.

AMENDMENTS.

This constitution may be amended at any annual meeting by an affirmative vote of two-thirds of all ballots cast by the members of the Society voting in person, by written proxy, or by letter-ballot: *Provided*, That notice of proposed amendments shall have previously been submitted to all members of the Society not less than sixty days prior to the date of the meeting.

BY-LAWS.

ARTICLE I.

MEMBERSHIP.

Admissions and Separations.

1. The election to membership of all classes shall be intrusted to the Executive Committee of the Board of Directors, hereinafter provided for, and the decision of that committee as to eligibility shall be final.

2. Any person desiring to become an active or associate member shall make written application to the Secretary. Such application shall be in such form and contain such data as to military and technical experience as may be prescribed by the Board of Directors. The applicant shall give the names and addresses of at least three persons competent to serve as references.

3. Honorary members shall be proposed by at least ten active members and a unanimous vote of the Executive Committee shall be necessary to election.

4. Any member may withdraw from the Society at any time by tendering his resignation in writing, but such resignation shall not become effective until said member shall have paid all sums due the Society at the time of such resignation.

5. Any member may be dropped for cause by a three-fourths vote of the entire executive committee: *Provided*, That he shall have been given full opportunity for a hearing in his own defense; *Provided further*, That any member so dropped may be reinstated by a three-fourths vote of the entire executive committee: *Provided further*, That prior to such reinstatement he shall liquidate all indebtedness which may be due the Society.

6. Members whose dues remain unpaid on February 1 shall be notified of that fact and no publications of the Society shall be sent them pending adjustment of dues. Members five months in arrears may, after a further formal notice of one month, be dropped from the rolls of the Society: *Provided*, That the executive committee is further empowered to act in the best interests of all concerned in any case which may arise relating to dues or fees.

7. For the determination of eligibility qualifications and for other purposes of this Society the following definitions shall obtain, to wit:

The term "the military forces of the United States" shall include the Regular Army, the Reserve Corps, the organized militia of the several states, territories and the District of Columbia (otherwise designated as the National Guard), the National Army and any other forces which may heretofore have been or may hereafter be authorized by Congress and formally inducted into the service of the United States.

The term "technical engineer" shall apply to any person who possesses such qualifications as would entitle him to an unrestricted voting membership in one of the four leading national engineering societies, namely—civil, electrical, mechanical or mining, or in any other technical society of national scope affiliat-

Digitized by Google

ed with the engineering profession and requiring for an unrestricted voting membership therein a degree of technical education and experience equivalent to that required for similar membership in the said national engineering societies.

ARTICLE II.

BOARD OF DIRECTORS AND OFFICERS OF THE SOCIETY.

1. The Board of Directors shall be the judge of the qualifications of its members and, subject to limitations herein prescribed, shall have power to fill vacancies arising in its own number: *Provided*, That any member so elected shall serve until the next annual election only at which time the vacancy shall be filled in the manner herein prescribed for other vacancies occurring in the regular course: *Provided further*, That a vacancy in the office of President shall be filled by the First Vice President, and *Provided further*, That the Second Vice President and the Senior Director in point of service as such shall succeed to the offices thus vacated by the First and Second Vice Presidents, respectively.

2. The Board shall have charge of the business, financial, military, technical and social interests and activities of the Society and, in the discharge of its duties, shall have power within the limitations of the constitution and by-laws to initiate and execute any measures whatsoever which in its judgment seem necessary or expedient to further the interests of the Society and to achieve its objects.

3. The Board of Directors shall meet at least once in every six months for the transaction of business and five members thereof shall constitute a quorum. Special meetings of the Board of Directors may be called by the President on his own motion or on the recommendation of the Executive Committee.

4. The Board shall submit at the Annual Meeting of the Society a report on the affairs of the latter and such suggestions as it may deem appropriate.

5. At its first meeting after the annual election, the Board of Directors shall elect from its own number a Treasurer to serve for the appointed term: *Provided*, That a majority of votes cast shall be necessary for election.

At this meeting the Board shall also appoint a Secretary to serve for the appointed term: *Provided*, That he shall be an officer of the Corps of Engineers on the active or retired list of the United States Army.

The terms of office of the Treasurer and the Secretary shall begin on such date subsequent to their election as the Board of Directors may appoint.

6. Duties of Officers. The President shall have general supervision of the affairs of the Society. He shall preside at the meetings of the Society and of the Board of Directors and of the Executive Committee herinafter provided. He shall be ex-officio a member of all committees and of all sub-committees thereof. In his absence his duties shall devolve upon the Vice Presidents in succession and in their absence upon the senior director.

7. The President, or in his absence the Vice President or other senior director, and the Secretary shall sign all written contracts and obligations of the Society. They shall jointly sign securities belonging to the Society and indorse financial papers necessary for the use of the Society.

8. The Treasurer shall have charge of the funds of the Society; under the direction of the Board of Directors he shall make collections and disbursements and render an annual report and such special reports as may be called for by said Board; his accounts shall be audited annually by an auditing committee of three members to be appointed by the President at least thirty days prior to the annual meeting in each year and the committee shall report the result of its audit at such annual meeting. In anticipation of the absence of the Treasurer and on his recommendation, or in the event of his disability, the executive committee shall designate a director or other officer of the Society to serve as Acting Treasurer and to discharge for the necessary period the duties devolving upon the Treasurer.

9. The Secretary shall give timely notice of all meetings of the Society, of the Board of Directors and of the Executive Committee; he shall record their respective proceedings and shall submit an annual report to the Board for presentation to the Society at its annual meeting. He shall furnish the Treasurer and the Editor with the names of all persons elected to membership, shall keep the roll thereof and shall be the keeper of the seal of the Society and shall conduct and have custody of such correspondence as does not relate directly to the duties of the Treasurer, or the duties of the Editor. He shall be responsible that suitable arrangements are made for the annual and other meetings of the Society, of the Board of Directors, and of the Executive Committee.

ARTICLE III.

COMMITTEES.

1. The standing committees of the Society shall be as follows, to-wit: An Executive Committee, a Committee on Membership, and a Committee on Service Relations and Military Policy.

2. *Executive Committee.* The Executive Committee shall consist of the President, the two Vice Presidents, the Treasurer, the Secretary and three others to be elected by the Board of Directors from its own number at its first meeting after the annual election.

3. The Executive Committee shall, during the intervals between the meetings of the Board of Directors, possess and exercise all the powers and functions of said Board except for consideration of matters which may have been specifically prohibited by said Board: *Provided*, That full report of its proceedings shall be made to the Board at its next succeeding regular or special meeting.

4. The committee shall have final jurisdiction on all questions concerning the eligibility of applicants for membership and shall be charged with the election of members of all classes.

5. The Executive Committee shall have supervisory charge of all publications of the Society and, for the discharge of its duties in connection therewith, may appoint sub-committees, boards of review and other assistants as hereinafter provided for. This committee shall also make arrangements for lectures under the auspices of this Society.

6. *Committee on Membership.* The Committee on Membership shall consist of not less than three active members appointed by the Executive Committee and it shall be the duty of said committee to inquire as to the character and qualifications of all candidates for membership and to report thereon to the Executive Committee for its final action.

7. *Committee on Service Relations and Military Policy.* The Committee on Service Relations and Military Policy shall consist of not less than five members so appointed as to equitably represent the entire membership of the Society. It shall be charged with the consideration of all matters which may be properly brought before the Society or may originate within the committee itself involving the relations between the military engineers and other arms of the military service and between the military engineers and the engineering profession in civil life, including all questions relating to the tentative military organization of the latter and other measures of military preparedness affecting such engineers. *Provided*, That the proceedings of this committee shall be confidential, and that its recommendations shall be advisory only and subject to review and final action by the Board of Directors. Said committee may appoint such assistants or sub-committees from amongst the members of the Society as it may deem necessary, subject to the prior approval of the Executive Committee.

8. In addition to the foregoing standing committees, the Board of Directors may appoint other standing and special committees with such duties as the Board may assign. Such committees shall report to the Board and take only such responsibilities as the Board may specifically authorize.

ARTICLE IV.

SUBSIDIARY OR LOCAL SECTIONS.

Subsidiary or local sections may be formed of members within any given geographical jurisdiction, or composing any military unit or organization heretofore existing or hereafter organized. Each such subsidiary or local section shall have power to select its own designation and draft its own constitution and by-laws: *Provided*, That the same shall be in harmony with the constitution of this Society and in furtherance of its objects, and *Provided further*, That prior to their final adoption the constitution and by-laws so drafted and all subsequent amendments thereto shall have been submitted to and formally approved by the Board of Directors of the Society of American Military Engineers.

ARTICLE V.

FINANCES.

1. The fiscal year of the Society shall begin on the 1st day of January.

2. The annual dues of members, which shall entitle them to all regular periodical publications and to all privileges of the Society, except as otherwise specifically provided herein, shall be fixed each year by a majority vote of the Board of Directors at not to exceed $5.00 per annum, payable at the beginning of each year of membership: *Provided*, That under exceptional circumstances said dues may be fixed by a three-fourths vote of the entire Board at not to exceed $10.00 per annum: *Provided further*, That applicants elected to membership after July 1 in any year shall pay not to exceed fifty per cent of the fees and dues for that year.

3. Any active or associate member not in arrears may, on the payment of $85.00, become a Life Active or Life Associate Member and shall not be liable thereafter to the payment of annual dues: *Provided*, That if the annual dues be increased, the Board of Directors shall be empowered to increase the cost of life membership in proportion: *Provided further*, That all moneys received from life memberships shall be invested and the income thereof only shall be used for current expenses of the Society.

4. *Budget.* The Treasurer shall prepare annually about December 1, a statement showing the probable income and the probable ex-

Digitized by Google

penditures for the ensuing calendar year on account of publications, and a similar separate estimate covering expenditures for other activities of the Society. The Board of Directors shall then determine the amount of available funds to be applied to each of the various activities, naming in each case the maximum amount that may be expended. It shall be the duty of the Treasurer to report to the Board whenever there appears to be a probability that the income will not be sufficient to meet the several allotments.

ARTICLE VI.

PUBLICATIONS.

1 The Society shall issue a periodical entitled "The Military Engineer" and such other publications as the Board of Directors may prescribe.

2. The Executive Committee shall appoint an Editor from the active membership of the Society who shall serve for a term of two years and who shall be eligible for reappointment: *Provided*, That the Editor shall be an officer of the Corps of Engineers on the active or retired list of the United States Army.

3. Under the direction of the Executive Committee, the Editor shall have charge of the publication of the periodical and other literature issued by the Society. He shall receive moneys accruing from subscribers, advertisers and other sources pertaining to the periodical and other publications and shall be responsible for all details relating to the editorial and business management connected therewith. The Executive Committee may authorize him to engage clerks, proof readers and such other assistants as it may deem necessary and said committee may appoint such Associate or Corresponding Editors, Boards of Review, or other business and editorial assistants as in its judgment shall serve the best interests of the Society: *Provided*, That no such appointments shall be for a term of more than two years.

4. With the advice and consent of the Executive Committee, the Editor shall pass on the fitness of all articles and communications submitted for publication. The Executive Committee may appoint from amongst the members of the Society a Committee on Papers and Publications which shall act in an advisory capacity and assist the Editor in all matters connected with publications of the Society.

5. To help defray the costs of publishing "The Military Engineer" funds of the Society may be allotted in accordance with an annual budget to be prepared by the Editor and submitted to the Treasurer on or before December 1st of each year: *Provided*, That the business of publishing said periodical shall be conducted under accounts separate and distinct from all other business activities of the Society.

ARTICLE VII.

SEAL AND INSIGNIA.

The Board of Directors shall have authority to design and adopt a seal and insignia for the Society.

ARTICLE VIII.

MEETINGS AND ELECTIONS.

1. The annual meeting for the election of officers and for the transaction of other business of the Society shall be held in the City of Washington, D. C., on the Friday preceding the third Wednesday in January.

2. Special meetings for the transaction of business or for other purposes of the Society may be held at such time and place as the Board of Directors may appoint: *Provided*, That a notice of not less than twenty (20) days stating the object of the meeting shall be sent to all members.

3. The President, the two Vice Presidents and two directors in each group of six representing the three sub-classes of the active membership, to wit: the Regular Army, the other military forces of the United States and the membership at large exclusive of the fore going two sub-classes, shall be elected by a written ballot at each annual meeting of the Society to serve for the appointed term of office or until their successors shall be elected: *Provided*, That a plurality of all votes cast shall be necessary for election, and *Provided further*, That at the first meeting of the Board of Directors after the first election held under the provisions of this constitution, two directors of each group shall be selected by lot to serve for one year only, two others of each group to serve for two years only and the remaining six to serve for the full term of three years.

4. *Nominating Committee.* On or before the first day of October of each year the Executive Committee shall appoint a Nominating Committee of five members so distributed as to equitably represent the three groups of active members: *Provided*, That not more than two members of said committee shall be members of the Board of Directors. It shall be the duty of said committee to make nominations for President, for First and Second Vice Presidents and for places vacant or due to become vacant in the Board of Directors. The list of nominations shall be transmitted to the Secretary of the Society not later than the twenty-fifth day of October. A list of nominations so made shall be printed in "The Military Engineer" for November or in the discretion of the Executive Committee shall be otherwise published to the members not less than sixty days before the date of the annual meeting.

5. In addition to the nomination so made by the committee, nominations may be made by a "nominating letter" signed by not less than ten active members: *Provided*, That such nominating letter shall be received by the Secretary not later than the first day of December. The Executive Committee shall verify the eligibility of all nominees and their acceptance of nominations, and all nominees found eligible for election shall be included in the printed election ballot which shall be mailed to all active members between the first and fifteenth days of December. The names of candidates for each vacancy shall be arranged in alphabetical order with such data as to place of residence, civil and military record of each candidate, as the Board may deem pertinent or desirable: *Provided*, That no person shall at any one election be a candidate for more than one office or position.

6. The ballot shall also contain statements of any proposals which require determination by vote of the members and the voter's decision shall be indicated in each case in accordance with instructions furnished with the ballot as to the manner of voting. The ballot unsigned shall be transmitted to the Secretary in a sealed envelope on which the voter shall legibly write his name. The polls shall close at the hour fixed for the first session of the annual meeting, at which meeting all ballots shall be canvassed by three election tellers appointed by the President.

7. Prior to such canvass the Secretary shall mark all envelopes from persons not entitled to vote and shall furnish the tellers with a correct check list of all members entitled to vote.

8. The envelopes containing the ballots shall be delivered unopened to the tellers who shall carefully scrutinize the ballots, count the same and prepare a written report thereon. All votes shall be counted for those candidates for whom the voter has plainly indicated his choice and those candidates receiving a plurality of votes cast shall be declared elected to their respective offices or positions: *Provided*, That all votes not definitely identified by the names of voters on the mailing envelopes shall be rejected. In case of a tie vote between two or more candidates for the same office the members present at the annual meeting shall decide by ballot between the candidates thus tied.

9. The terms of all officers and directors shall begin upon the ajournment of the annual meeting at which such officer or director is elected.

ARTICLE IX.

GENERAL POLICY AND PROCEDURE.

1. The Society as a body shall take no action and make no recommendation which shall be or shall appear to be detrimental to any class or group of its membership or not in accordance with the purposes and aims of the Society as expressed in its constitution and by-laws.

2. In the event that any action is proterests of any such class or group or which is not clearly in harmony with the objects of the Society, the proposal shall be submitted to the Executive Committee in writing signed by not less than twenty active members. The Executive Committee shall canvass the entire Board of Directors and shall inform the original proposers of the opinion of the Board in reference to the proposal, whereupon the proposers may withdraw the same, may accept changes suggested by the Board or may adhere to the original form: *Provided*, That the declaration of such adherence shall be signed by thirty active members, of whom not less than fifteen shall have signed the original proposal.

3. The proposal, whether approved or disapproved by the Board of Directors, shall be brought before the Society for determination at its next annual meeting: *Provided*, That the proposal with full and fair statements for and against the action proposed shall have been published to all members not less than sixty days before the annual meeting. The original form, if adhered to, and the form preferred by the Board shall be mailed to all members with the annual election ballots in the shape of a ballot which shall permit the voter to accept one or the other form or to reject both: *Provided*, That any vote not clearly indicating a choice in favor of one or the other form shall be counted as a rejection of the proposal in both forms.

ARTICLE X.

QUORUM.

Twenty-five voting members present in person or represented by proxies shall constitute a quorum for the transaction of business at the annual or any special meeting of the Society. Five members of the Board of Directors shall constitute a quorum for the transaction of business except as otherwise specifically directed herein. Four members of the Executive Committee shall constitute a quorum for the transaction of business except as otherwise specifically directed herein: *Provided*, That in all cases a number smaller than that

Digitized by Google

fixed for a quorum may adjourn to a future date to be determined by such number.

ARTICLE XI.

ORDER OF BUSINESS.

At the annual meeting the order of business shall be as follows:

(1) Reading of minutes of preceding meeting.
(2) Report of Board of Directors.
(3) Reports of officers.
(4) Election of officers and directors.
(5) Reports of standing committees.
(6) Reports of special committees.
(7) Miscellaneous business.
(8) Reports of election tellers.
(9) Announcement of election of new officers and directors.
(10) Literary and Social Program.
(11) Adjournment.

This order of business may be changed at any meeting by a majority vote of the members present.

Robert's Rules of Order shall be the parliamentary guide and shall govern the proceedings at all meetings of the Society.

ARTICLE XII.

AMENDMENTS.

1. Proposed amendments to the constitution shall be reduced to writing and shall be signed by not less than twelve directors or by not less than thirty active members. The procedure for the submission of such amendments to the Society for final determination shall be similar to that prescribed in Article IX of these by-laws in respect of proposals affecting the interests of any class or group of the members: *Provided*, That the declaration of adherence to the original form of the amendment shall be signed by not less than forty-five active members, of whom not less than twenty-four shall have signed said original form.

2. Amendments to the By-laws may be made at any regular or special meeting of the Board of Directors by an affirmative vote of two-thirds of the total number of ballots cast by the members of the Board voting in person, by written proxy or by letter-ballot: *Provided*, That the following procedure shall have been observed, to-wit: The proposed amendment shall have been presented to the Secretary in writing signed by not less than four directors or by not less than ten active members; copies thereof shall have been submitted to all directors at least sixty days prior to the meeting of the Board at which the amendment is to be voted upon and shall have been published in THE MILITARY ENGINEER or otherwise communicated to the members of the Society in ample time to permit them to express their opinions to the Board.

In its discretion the Board may refer a proposed amendment to the by-laws to the Society for determination in the manner hereinbefore prescribed for amendments to the Constitution.

ARTICLE XIII.

ADOPTION.

1. The constitution and by-laws shall be considered as adopted and shall be in full effect when they shall have been accepted by not less than seventy-five persons having the qualifications herein prescribed for active members, and these persons shall then and thereafter be known as charter members of this Society: *Provided*, That all subscribers to THE MILITARY ENGINEER (formerly PROFESSIONAL MEMOIRS, Corps of Engineers and Engineer Department at Large), whose subscriptions are paid in full to December 31, 1920, and who are otherwise eligible to membership in any class under the provisions of this constitution may on their own application become charter members of appropriate class without payment of further dues for the current year. Non-members may enter or renew subscriptions to the journal at their option.

2. As soon as practicable after such adoption of the constitution and by-laws the charter members shall proceed to the election of permanent officers and directors in accordance with methods hereinbefore prescribed: *Provided*, That for officers and directors so elected the first year of office shall terminate with the adjournment of the next annual meeting of the Society in January, 1921: *Provided, further*, That pending such election and induction into office of the officers-elect and the Directors-Elect, the temporary Board of Directors shall discharge the duties herein prescribed for the permanent Board.

The Field Artillery Journal

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bimonthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

Address—

The Secretary
United States Field Artillery Association
War Department, Washington, D. C.

Harnessing the tide in the Bay of Fundy. The essential requirements for a tidal power development, according to a Canadian engineer are:

1. Sufficient tidal range to produce a good head.
2. *Two* reservoirs to insure continuous power.
3. Power plant centrally located in district to be served.

These essential conditions are found at the confluence of the Petitcodiac and Memoramcook Rivers when they empty into Shepody Bay, an arm of the Bay of Fundy, and lead to the hope that the first great tidal power development in the world will be installed at the village of Hopewell, New Brunswick.

It is well known that the Bay of Fundy exhibits the greatest tidal range of any locality in the world. At Hopewell the ranges of spring and neap tides are 45 and 38 feet, respectively. Two great reservoirs, almost completed by nature, exist in the lower reaches of the two rivers, and the development would serve a population of 250,000.

Shepody Bay and the two rivers form a large letter Y of which the stem is Shepody Bay, designated as S, and the branches are the two rivers, designated L and R (left and right). These three are to be separated by dams, according to the project, the dams forming an inverted T at the confluence of the two rivers.

Water is to be admitted and discharged by sluice-gates in the dams, and the cycle of flow will be from S to L, from L to R, from L to S and finally from R to S. Thus L is evidently a high level reservoir and R a low level.

The high level basin L is filled at high tide. At the next low tide water passes through turbines from L to S and also from R to S. As the tide rises R is cut off from S, and water flows through turbines from L to R. When the tide reaches the level of L the power flow from L and S, of course, ceases, and the tide replenishes the storage in L, the power developed by flow from L to R continuing meantime until the tide has half ebbed, when a power flow from both L and R to S is again possible. This cycle is continually repeated.

The mean area of the high level basin (L) is 330,000,000 sq. ft., but that of the low level (R) is only 60,000,000. Thus while L is lowered 6 inches R is raised 33 inches. This condition limits the available power, but by enlarging the low level basin by dredging an output of 200,000 H. P. may be obtained, which is the untmost possible under existing natural conditions.

The average head on the turbines would be 22¼ ft. The estimated cost of the first 100,000 H. P. is $11,000,000; the next 100,000 would cost much less. The average charge to consumers per horse-power year would be $45, which would cover all costs and returns on the investment and at the same time furnish electric power at about half the present cost.

FLORY

Contractors' Hoisting Engines

are built to a high standard of perfection, guaranteeing maximum length of service and elimination of hoist troubles that would naturally develop were our standard lower.

On hundreds of operations throughout the country Flory Hoists are performing their duty with speed and precision, indicating perfect construction, accurate finish and the finest mechanical equipment that can be built into a hoist.

Standard Contractors Engines

Our illustration shows a Flory Double Cylinder, Double-Friction Drum Engine, complete with boiler and fixtures, ratchets, pawls, winches and foot-brakes. It is especially adapted for pile-driving, docks, bridge building, operating derricks and for other general hoisting purposes.
From 6 to 70 h. p. hoisting on single-line rope 1,200 pounds to 16,000 pounds. Powerful, easy to handle, it will hold the load with positive safety.
The Flory Catalogue gives complete details and may be obtained from the nearest office.

The Society of American Military Engineers

What It Is

The Society of American Military Engineers is an organization composed primarily of engineers—civil, electrical, mechanical, mining and others—who have served at any time as officers, soldiers or civilians in any arm or department of the military forces of the United States, including the National Guard, the volunteers, the Reserve Corps and other contingents. Its ranks are open also to persons other than engineers who may be interested in the national defense. The society was organized by officers of the Corps of Engineers and by prominent engineers now in civil life who served as officers during the World War. The formation of the society has been approved by the Chief of Engineers and the Chief of Staff, U. S. Army.

Purpose

The constitution of the Society provides that, "The objects of the Society shall be in the interests of the national defense to promote the efficiency of the military engineer service of the United States; to maintain its best standards and traditions; to disseminate professional knowledge concerning developments in engineering with special reference to their application to military purposes; to develop between the military engineers and other arms of the service a spirit of cooperation and a mutual understanding of their respective duties, powers and limitations, and to foster relations of helpful interest and friendship between the engineering profession in civil life and that in the military service."

Membership

The following persons are eligible to active membership, with power to vote and to hold office, viz,

(*a*) All persons who at any time have been commissioned as officers in the engineer service of the United States, in the Regular Army, the National Guard, the Reserve Corps, the volunteers or in the selective service forces.

(*b*) All technical engineers, or others of equivalent technical education and experience who have served or are serving in any capacity whatsoever, whether as officers, soldiers, or civilians in any arm or staff department of the military forces of the United States above mentioned, but civilians must have rendered at least six months' continuous service.

Associate membership is open to all officers of the military forces of the nation, other than engineers; the Navy, including the Marine Corps, the Coast Guard, the members of technical units of the R. O. T. C., and to all soldiers serving in technical engineering units of the military forces, including Engineers, Ordnance, Signal Corps, Chemical Warfare Service and other technical arms or branches.

Government

The Society is governed by a Board of Directors consisting of a President, two Vice Presidents and eighteen other active members. These are all elected by vote of the active members. The three officers first named serve for one year and the 18 directors serve for three years each. Six directors are chosen from the Regular Army, six from the National Guard, the Reserve Corps and other contingents subject to active military duty, and the remaining six are from the membership at large not including the foregoing two groups; that is to say, from former officers, soldiers and others who are not now subject to active military duty.

Local Sections

Local sections may be formed of members within any given geographical jurisdiction or composing any military unit or organizaton heretofore existing or hereafter organized. This permits regimental associations to be formed as branches of the main Society and also permits sections to be formed in any city or state.

Journal of the Society

The Society publishes a bi-monthly journal called THE MILITARY ENGINEER which contains articles bearing on engineering in both war and peace, as well as articles of a general military nature. It contains news of the work done by the Corps of Engineers and other technical services of the Army, items of interest concerning the engineer regiments of the Regular Army and the National Guard, news of the local sections of the Society and the individual members, and of the activities of the Reserve Corps and R. O. T. C.

This journal is the medium through which you may keep in touch with engineering developments bearing on the national defense, and with other engineers both in the service and in civil life, who are interested in this important matter.

The journal is sent without additional cost to all members of the Society. For non-members the price of subscription is $4.50 per annum.

Dues

No entrance fee is charged and the annual dues are fixed each year by majority vote of the Board of Directors and normally will not exceed $5.00 per year. Under exceptional circumstances, however, the dues may be fixed by three-fourths vote of the entire Board at not to exceed $10.00 per year. For the year 1920 the dues are $4.50, and this includes subscription to THE MILITARY ENGINEER.

Further Information and Applications

For further information and for application blanks for membership address The Secretary, The Society of American Military Engineers, Washington Barracks, D. C. If you desire to receive THE MILITARY ENGINEER beginning with the first number, send $4.50 at once, with address. You will promptly receive the journal and your name will be entered for membership subject to examination as to eligibility.

The Officer's Library

Here is the answer to your questions—How can I keep in touch with the Service? How can I get ready for examination for promotion?

Get your military library started—Devote your spare time to studying and reading Military Books. Here is a list that we recommend to you.

COMPANY ADMINISTRATION. Based on War Department Regulations No. 57. All blank forms used in the Administration of a Company Troop and Battery made out. Text explains all details ---------- $2.50

PLATOON TRAINING. Waldron. Published in two handy volumes. A complete Training Manual for the instruction of all foot troops. All subjects fully illustrated. The one book that should be included in the library of every Reserve Officer ---------- 2.50

THIRTY-MINUTE-TALKS. Stewart-Waldron. A collection of twenty essays on Military subjects. Invaluable to an officer who may be called upon to address an audience on a Military Subject. Will keep you brushed up on the Military Game ---------- 2.50

TACTICAL WALKS. Waldron. The details of the up-to-date method of training in Minor Tactics. The system that will be employed in Training Camps and in determining qualifications for promotion ---------- 1.50

ARMY PHYSICAL TRAINING. Waldron. The System of Physical Training in the Army systematized. Exercises all arranged in logical sequence and each fully illustrated ---------- 1.50

SCOUTING AND PATROLLING. Waldron. A little book that tells all about how the individual scout goes about his work and how the operation of a patrol are conducted ---------- .75

INFANTRY DRILL REGULATIONS. (Provisional), 1919. The Infantry Association Edition. Illustrated and Annotated. Original text preserved intact. Cloth bound ---------- .75

INFANTRY SCORE BOOK. U. S. Infantry Association. If you are going to take advantage of the opportunity for target practice this summer this is the book you will need. Detailed instruction for the individual marksman. Score sheets for all classes of Fire ---------- .35

MILITARY SKETCHING AND MAP READING. Grieves. The best and most complete book on the subject that has been produced. All that you need to know about it ---------- 1.00

TECHNIQUE OF MODERN TACTICS. Bond-McDonough. The standard American work on modern tactics and troop leading methods. Used by students at all service schools and by all officers preparing for examination ---------- 2.65

USE THE ORDER BLANK BELOW.

THE MILITARY ENGINEER,
WASHINGTON BARRACKS, D. C.

GENTLEMEN:

Inclosed please find ---------- for $---------- Please forward the books checked to the address below: Company Administration. Platoon Training. Thirty Minute Talks. Tactical Walks. Army Physical Training. Scouting and Patrolling. Infantry Drill Regulations. Infantry Score Book. Military Sketching and Map Reading. Technique of Modern Tactics.

ADDRESS----------

Write address plainly.

Some Practical Points on the Training of Troops

By

H. A. Finch

Colonel, Engineers; formerly Commanding the 6th Engineers and Division Engineer, 3rd Division, A. E. F.

ALL engineer regiments in the regular service are now at a very low strength. In some cases the entire enrollment of the regiment totals only about 100 men.

This means that should these organizations be finally recruited to full strength, the situation as regards training the large draft of new men will closely approximate the condition which existed throughout the summer and autumn of 1917, when 90 per cent of the men were recruits and the burden of the training was borne by a small nucleus of the personnel that had seen service.

The difference is that, while in 1917 the prospects for immediate war service acted as a wonderful inspiration, the training nowadays lacks that great stimulus and consequently the burden thrown upon the instructor will in many respects be heavier.

In view of this situation, a few notes on the practical training of Engineer troops should not be amiss.

The writer's excuse for putting down these notes is not that he believes that he knows more about the subject than anyone else but because through the fortunes of war he was associated with eight different regiments during the period March, 1917–March, 1919, and having worked with six of these regiments during their training for overseas service, it is hoped that the points emphasized by this rather varied experience may be of interest or assistance to other officers of the service.

So far as the actual theoretical training itself is concerned, there is an ample supply of literature available to act as a guide. Part VIII of the Engineer Training Manual, 1917, dealing with "Intensive Training and Mobilization for War" contains some excellent advice and some thoroughly practicable schedules of instruction. It is evident that a great deal of work was devoted to the preparation of this Manual. Morrison's "Training Infantry" is full of meat for those who have to teach infantry tactics; an excellent guide for Engineer instruction is the "Training Circular No. 1," and its appendices issued by the office of the Chief of Engineers beginning in October, 1918. It is regrettable that this last Manual (particularly Appendix No. 2 dealing with recruit training) could not have been published earlier, for it would have been very timely and would have met a real need.

The three manuals mentioned above and some of the A. E. F. notes were found to be most helpful as guides to the hours for instruction and the subjects to be taught, but certain useful and practical methods are developed by all trainers of troops and these are not always fully treated in published manuals.

The following pointers are submitted for what they are worth. They at least have the merit of having been used with success in actual practice.

Recruit Training

(*a*) Follow some such schedule as that set forth in Appendix 1, Training Circular No. 1, which makes the drills short, snappy and progressive.

(*b*) As soon as possible separate the men into two groups according to progress shown, so as to avoid having the bright men held back by the "slow" ones.

(*c*) Select the non-com. instructors very carefully and have them on duty as *specialists*. Recharge their batteries every day. Give them special privileges as a recognition of fact that their duty is extremely important.

(*d*) On no account allow profanity to be used, also encourage the instructors to strive to avoid impatience, and to establish a friendly spirit in dealing with their men.

(*e*) Encourage the officers concerned (including yourself) to give the recruits a friendly word from time to time. Some men get very homesick and the habit of "passing the time of day" does no harm.

(*f*) *Tell the recruits why they are required to do things and invite question.* (Very important.)

(*g*) When the time comes for the recruits to take up special Engineer training, make them talk about the lines open to them for instruction and let them choose what they would like to take up first. It will be found that every line will have sufficient volunteers to provide a class, but some little shifting may be necessary. The great point is that the majority of the men have the opportunity of choosing a congenial line of work.

(*h*) Be sure to insist on having credit given for good work whenever done. This helps a great deal, for all of us appreciate commendation.

Digitized by Google

Recruits are human beings, sometimes a little too human, but they are responsive and are eager to find out what the Army has to offer. It has been found to be an excellent practice to give them frequent talks during the afternoons or, better still, in the evenings when they have idle time to "kill." These talks can be made on a large variety of subjects including the news of the day and the part that our Army might be called upon to play in the world's events.

Target Practice

The value of efficient shooting in keeping up the morale of an organization is admitted on all sides.

During the eight months' period following the armistice when the writer's regiment "roosted on the Rhine," about the only courses of instruction that aroused great interest were those in gas engine operation and in rifle and machine-gun practice. All men like the idea of being able to shoot; the marksmanship badges are popular and the extra pay helps. It is thoroughly practicable to have 80 per cent of the regiment qualified as Marksmen or better. The Fifth and Sixth Marines in the spring of 1919 averaged 75 per cent qualified. The Engineer Regiment above referred to qualified slightly less than 50 per cent and should have done better.

The McNab system of instruction is excellent. This demands nothing more than thorough and progressive individual training to be given by patient, interested and painstaking instructors. The pamphlet on this system is obtainable from the War Department.

During the last two target seasons, the writer followed this method for preliminary training, and on the range he used the system of coaching which has been employed by Colonel V. L. Peterson, C. E., and others with marked success. Non-coms are carefully selected for duty as coaches. Each coach is assigned to a definite target, which assignment is permanent for all firing points throughout the season. The men are likewise assigned to definite targets and shoot at the same target throughout the season. In this manner each coach deals with a definite group of men and soon becomes acquainted with the weak points that he must work on in each individual.

As a time and labor saver, the Belgian Aiming Device will prove of great assistance.

Trade Schools

Great stress is now being laid upon the advantages given the young man entering the Army in the way of vocational training. This the writer firmly believes in. One of the strongest appeals that the Engineer branch has always made is that the man enlisting for our service is taught a trade that otherwise in all probability he could not hope to learn.

Except for good food and decent treatment nothing promotes contentment and pride in an organization more than an opportunity given men to follow their trade or to learn one.

As set forth in Training Circular No. 1, it is believed that general pioneer training should be given to the entire personnel, leaving the special training to be given to selected men from each platoon who do not take any other course until they have completed the special one to which they are assigned.

Another point which is brought out in the Circular No. 1, but which should be emphasized is that the instructor should also be specialized, *i. e.*, be assigned to a definite subject and teach that subject day after day.

This has been objected to on the ground that, with special instructors handling his men, the captain of a company will lose touch with them. However the captain loses touch with his men to a great extent anyway when the company is divided into working platoons, and the field of engineering instruction is so wide at present that it is almost impossible for a captain to do justice to all subjects.

The method of assigning special instructors to supervise courses of training was followed with great success by Colonel E. I. Brown, C. E., during the spring of 1918 and by the writer with two different regiments in the United States and in France. Doubtless many others have followed this system; the writer was told by an inspecting officer that at Camp Taylor, the engineers operated what was in effect a vocational college.

It has been found practicable to qualify men in one or more courses following the completion of the first course assigned them and this plan has even been followed in bayonet training, each platoon being assigned a daily period for instruction under commissioned and noncommissioned experts.

It has also been demonstrated that certificates of proficiency, signed, and countersigned by the instructor and the regimental commander, are eagerly sought after. These serve to stimulate interest in all subjects, particularly the less popular ones, such as trench and dugout construction.

Guard House Administration

Some ten years observation of the manner in which guard houses are administered in our Army has convinced the writer that not only do most of our guard house sentences fall far short of the purpose for which they are intended but many of these sentences are total failures.

The chief difficulty appears to lie in the fact that, due to the daily shifting of the officers and non-coms of the guard, there is no one man charged with the definite and continuous duty of seeing that the prisoners are properly looked after and are worked or drilled for reasonable periods each day. In some

Digitized by Google

regiments there is a provost sergeant whose duty it is to supervise the work of the prisoners but this method at best is unsatisfactory unless by some great good fortune the sergeant is very wise in the handling of men and is interested and impartial in the discharge of his duty.

Another difficulty in securing better results from guard house sentences is the fact that all of the regimental officers are usually too much occupied with their work to give the prisoners any attention except perhaps for a brief time during their tour of duty as officer of the day. The company and battalion commanders, the adjutant and supply officers are all so fully occupied in their respective spheres that ordinarily these officers are willing enough to leave the handling of the prisoners to anyone designated by the colonel.

The number of prisoners in the guard house is a good barometer to consult on the state of discipline in the command. These men are a sore spot in the organization. Dealing with them is too important a matter to be left to the discretion of anyone but a carefully selected officer, who should be detailed by the regimental commander and provided with one or two assistants.

It should be the duty of this officer and his assistants to see that the work required of the prisoners is neither degrading nor too easy. The prisoners should turn out for drill with their companies. Ordinarily this is not done and as a consequence a guard house sentence is often a restful and agreeable change from the routine of company drills.

If the prisoners are drilled daily and in addition if they are required to work during certain periods that are devoted by the other men to recreation, the effect of the guard house sentence will not be lost but if the work be made degrading or useless or if the provost officer fails to take advantage of every opportunity to help the individual much good that might be done will be missed.

Many of us make the mistake of assuming that a man is incorrigible because he is frequently in trouble. The writer has made his errors along this line but he has learned that there are extremely few incorrigibles among the men who appear for trial before our Summary Courts. By far the greater part of them will respond to individual treatment accorded them by a wise commanding officer.

The great thing to work for in any organization is an empty guard house. This point is an excellent one for captains to bring out at their company gatherings and for the colonel to present at the periodic meetings of his officers and the non-coms.

Much may be accomplished by extending special privileges to the companies which run for a month or more without having a man in the guard house. While this may prove somewhat of a temptation to the non-coms to conceal breaches of discipline the result on the whole has been found to be very beneficial since it has the effect of causing, to a certain extent, the men in the ranks to discipline one another.

In the writer's experience by far the best method that he has seen tried of encouraging good behavior and keeping an empty guard house consists in organizing a disciplinary squad or platoon from the guard house habitués. This organization not only receives the direct personal attention of the provost officer but of the colonel, the chaplain, the medical and dental officers and in fact every officer of the regiment except perhaps the veterinary whose services unfortunately can hardly be utilized along such sociological lines!

This expedient never fails to work. The last time the writer tried it the disciplinary platoon consisted of some 18 "hard boiled" drinkers and "bad actors" who apparently couldn't stay out of the guard house. All sentences were suspended, the prisoners were removed from the guard house and were quartered in a single large room to themselves. They had no guards posted over them and were not allowed to do any work around the stables or latrines that might be called in any way degrading.

A group of selected officers and sergeants was detailed to supervise the schedule for "J" Company (as the platoon soon became known) and one or more of these drillmasters was present with them at all times from reveille until well after taps. The daily schedule consisted of drills of every kind that fall to the lot of a soldier. These were short, snappy and followed each other at five and ten minute intervals throughout the entire day with the different drill masters relieving one another at certain intervals. The point was made to the men that due to their shiftlessness and indifference they had become poor soldiers and that consequently (since they had shown that the guard house did them no good) a special drill schedule had been prepared for the purpose of placing them on a par with the other men of the regiment. The men were advised that they were not prisoners, that there were no guards over them and that nothing degrading would be required of them. Furthermore, they were told that all sentences were suspended and would be remitted upon a satisfactory showing during the course of training prepared for them but that any indifference on their part, any failure to meet the snappy standard set for them, would result in their having an extended period of the intensive training.

A system of daily demerits was started and the men were urged to work up to their limit in order to avoid demerits and thereby secure a prompt return in good standing to their company. The point was made that none of the men detailed for duty over

Digitized by Google

them welcomed the hardships which such duty imposed but that everyone was actuated by a sense of duty that the schedule would be maintained until every former prisoner showed by his actions that he met the standard required.

In carrying this plan into actual practice the men were handled with the utmost fairness and patience, no profanity nor rough methods were permitted but the greatest precision and snap were insisted upon. When a man did not know, he was taught and was thereafter required to remember what he had been shown.

Whenever the platoon was dismissed from drill the men were not allowed to break ranks but were marched in a body first to the lavatory and then to their quarters to prepare for the next drill or for a meal. They were marched to their meals by an officer or sergeant and they were served together in one mess hall after the main organization had eaten.

During the few brief periods throughout the day and throughout the evening when the men were resting in their quarters they were allowed to smoke or read but no loud talking and no games were permitted. An officer was always present in the room, seated at a table and engaged on any work that demanded his attention. If a man desired to leave the room he was required to state his business and, if allowed to leave, the officer checked him out and he departed and returned on the run. About every second evening night exercises were given; on other evenings the officer in charge gave a talk to such as could keep awake.

The schedule was exceedingly strenuous and made heavy demands upon the nervous and physical force of the instructors, but the results were more than worth the energy expended.

The point that appeared to make the deepest impression on the men was the fact that they were not left to themselves for a moment during the 16 hours or more covered by the daily schedule. They could stand the work, they didn't mind the drill more than soldiers usually do but they hated the idea of not being able to relax and "rough house" or "shoot craps."

Three days of such a régime is believed to be equivalent to a sentence of several weeks in the average guard house. The best men can safely be released within three days; the worst will hardly require more than a week or ten days before they "see the light." It has also been found after several experiments that the repeaters for this form of disciplining are extraordinarily rare.

As stated, all agencies throughout the regiment were brought to bear on the men in the disciplinary platoon in the endeavor to bring these men back to a normally good standard of behavior. It was noted first that nearly all of them were untidy in their appearance and wore disreputable looking uniforms. The supply officer was thereupon required to outfit them completely with the best clothing and equipment available. Once equipped the men were required to take care of the property entrusted to them and with this end in view there was held a daily inspection of arms and uniforms.

Acting on the well established theory that a man's poor physical condition is often the cause of misconduct, the medical officer was urged to find out what was wrong with the physical mechanism of the individuals in "J" Company. This also applied in the case of dental treatment—the dental officer being given to understand that if pulling teeth would make a good soldier, there were several candidates in the "J" Company group who could afford to lose their entire dental equipment!

Laying all levity aside, the writer submits that the question of the proper handling of delinquents is one of the most important that can be presented to an officer in command of troops. The system of treatment described herein has been proven in actual practice but its administration requires patience and tact and makes heavy demands upon the physical strength and nervous energy of all men charged with this duty.

Many soldiers find the montony of the normal drill schedule very irksome and as a consequence they are discontented or indifferent. A tour in "J" Company serves to show such men how much harder their lot might be made on strictly military lines.

This plan is a great remedy for an epidemic of summary court cases and for an overtaxed guard house.

Discussion

Lytle Brown
Lieutenant Colonel, Corps of Engineers
formerly Brigadier General, Chief of War Plans Division

The author has indicated that the training of troops in the immediate future will not have the stimulus of war conditions as was the case in 1917. All who direct or are responsible for training should realize the difference and act accordingly. The work will not be done with as much spirit, and the identical measures used in 1917 will not serve now. The men cannot be held to the work as closely as was the case during the war. There must be more recreation and amusement, less severity; better judgment on the part of instructors, and more tact on the part of all concerned.

Superiors must concentrate attention on the unit schools for the preparation of competent instructors—commissioned and non-commissioned—to prepare them for their duties, as proper vehicle for carrying the instruction to the men.

In order to foster and promote organization spirit and emulation, and place responsibility where it belongs, as well as to secure initiative, as much instruction as possible in strictly military duties should be conducted within the company. In the recent experience the tendency was otherwise for obvious and good reasons, which now do not

Digitized by Google

or should not long exist. Trust the company commander to train his men; if that can not be done there is something the matter with one authority or the other. The inspection for results may be as detailed and as vigorous as desired. Before drawing men out of their companies for instruction by special instructors be sure that there are the strongest reasons for so doing. It is as a practice not conducive to the best general results in the long run.

The guard house, nor any special arrangement, is not good for discipline of minor offenses; that should be a company affair—but the company should handle it thoroughly, *more as a matter of instruction* than for punishment. I concur in general with the author, but do not favor a special company nor a large number of offenders gathered together either in the guard house or elsewhere. The treatment is good, but I prefer it in the company and administered by the captain and his subordinates who are always present and who are best informed and most interested.

Often before the war I have seen the responsibility of subordinates usurped by those in higher authority; have been guilty of it myself to my own discomfiture, but believe that it was often done in training, with reason, during the war. The temptation to do so should be strongly resisted; but the determination to fix that responsibility and hold it fast where it belongs as well as to constantly verify the results can not be too strongly held.

I am led to these remarks by the author's reference to special instructors, and by what I know of my own tendency to make use of them. Present conviction is that the special instruction method is very easily abused, and tends toward unsound practice, based on the supposition of incompetency somewhere down the line.

M. J. McDonough
Colonel, Engineers
formerly Commanding the 114th Engineers, and Division Engineer, 39th Division

I heartily concur in keeping the guard house empty. This institution is the lowest in corrective value, its use properly is either punitive or preventive, but it often tends to harden young soldiers in evil ways. My experience for many years is that captains generally speaking are too prone to send a man to the guard house, lieutenants are even worse than captains. The average soldier is not vicious, the great majority of his sins are minor and even unintentional. Rather than put him in the guard house the captain should be encouraged and even compelled to exercise ingenuity in his corrective discipline. If space permitted I should like to write a brief memorandum on punishments other than guard house confinement. [Colonel, we would like to have this.—Ed.]

For instance, for mistakes in connection with guard duty let the offender be required to write out five pages of the guard manual each day, in all fifty pages. The writing should be handed in daily without fail to the commander. For drinking offenses it may be practicable to compel the culprit to send to his mother ten or fifteen dollars next pay day. [Some other method of giving money to mother must be provided for these dry times.—Ed.] For repeated lates the wood pile is excellent. For uncleanliness in the toilets or latrines let the culprit clean the same for a given period. Confinement to the tent or barrack only irritates all parties concerned; I find it a poor punishment, because it is too slow and negative. Where the culprit is truly penitent it is often wise to suspend all punishment for a month with the promise that if he sins again he will answer both charges and if he does not sin again within the month all will be forgiven. This is a common practice in civil life. Ridicule is a powerful corrective weapon, but should be used carefully. Except for desertion, theft, and grave cases of moral turpitude, the general court martial should be almost unknown. Punishment should be summary and as nearly practicable appropriate to the offense, having in view that "object all sublime to make the punishment fit the crime." For a vast number of minor offenses a severe "tongue-lashing" by the captain is better than anything, this implies that the culprit is truly sorry.

The use of "J" Company is very interesting and is new to me, I should think it would work very well; it requires good officers who are devoted to their duties.

Commanders are advised to obtain as much first hand information of their men as practicable; this can be done in an infinite variety of ways. It implies that the colonel or captain shall talk to the men a great deal—at inspection, on the drill field, in the office, on the march and so forth. Sometimes when the talent is low the captain may complain to the colonel that he hasn't one man who can be the company clerk or who can fill this or that job. The colonel may have noticed a 1st class private in the company who kept and owned a general store in his home town. The colonel then tells the captain to look over his talent more carefully, giving the captain only a hint as to the man. When the captain realizes that the colonel excels in certain detailed knowledge of his own company he usually wakes up. I have never countenanced the practice of requiring a soldier to obtain the 1st sergeant's permission in order to interview the captain. Each soldier should have free access to the captain without going through intermediaries. The captain gains in intimate knowledge and control of his men by close personal contact. Likewise, the adjutant should not act as insulation to the colonel. I allowed and invited an officer or soldier to see me at any time on any business without the use of the adjutant; thus the colonel gains greatly in detailed knowledge of what is going on under him. The confidence of the men is also gained.

Knowledge by the commander is gained in no way better than by frequent inspections of everything. The colonel should spend more for shoes than for trouser reinforcement.

To increase accuracy among officers, it is well that the colonel send officers to make inspections of all kinds and then frequently follow up himself. His immediate knowledge will then check the accuracy of his subordinates' reports as well as their powers of observation. He also freshens his own knowledge of what the regiment is doing.

In these days there is a tendency to enlist boys. These boys are incapable of performing full duty or of understanding discipline, they are wholly useless and if enlisted they ought to be discharged. It is impracticable to allow them to break discipline and yet it is sinful to punish these immature youths.

Night schools for all ranks are a powerful means of promoting efficiency. Lessons should usually be assigned in advance and the class held responsible. The recitation usually was followed by a brief written test of five or ten questions. The advantage of the questions is that it makes every individual express his opinion or his knowledge in writing, he cannot escape or bungle it. The papers can be marked by a detail of instructors; another quick way to mark is for each man to exchange his paper with his neighbor, each question is then marked according as the instructor announces the answer.

Proper execution of guard duty is the criterion for all other discipline, it should receive immediate and vigorous attention. If the guard detail be a platoon with its own lieutenant responsibility is well fixed and the regiment quickly reaches a high state of guard discipline. If the commander of the guard has his own men rather than a

Digitized by Google

mixed detail from the regiment, he can be held to high responsibility because he instructs his own men in guard duty at all times in connection with drills; he is thus not limited to guard instruction when on actual guard duty. Guard duty should be executed literally according to the manual and with the utmost snap. The usual theatrical variations of this duty which new troops introduce should be anticipated by the officers and vigorously routed.

J. L. Schley
Colonel, Engineers
formerly Commanding the 307th Engineers, Division Engineer 82nd Division, and Corps Engineer, 5th Corps, A. E. F.

Colonel Finch's remarks are very interesting and contain useful suggestions. The following points on troop training seem worthy of special emphasis:

The Engineer Training Manuals, 1917, served a very useful purpose during the training period of the draft forces. These manuals should be revised in the light of the experience of the war.

Special instruction, theoretical and practical, should be given to officers and non-commissioned officers regularly throughout the training period.

Short talks should be given to the men by the unit commander. In this way his spirit and ideas are transmitted directly to the men.

The present strength and equipment of the engineer regiment make it necessary that it be given enough infantry training to give a good account of itself when acting as infantry on the offense and defense.

I agree with Colonel Finch in emphasizing the recommendation that general pioneer training should be given to the entire personnel of a regiment, and that special training should be given to selected men. I assume, however, that these selected men for the more technical training would first receive the preliminary infantry training which the entire organization must be given at the outset for purposes of discipline, set-up, and the other rudimentary developments of a soldier. After the selected men have received their special training, the special training can be extended to other men.

The technical instruction should be conducted at first under specialists by battalion or regiment. When a certain degree of proficiency has been reached, the men should be returned to the company to apply what they have learned to practical drills under the company commander.

In assigning the specially trained men to companies and platoons, it must be remembered that platoons often operate independently, and each platoon may be called on to perform many different kinds of special work.

Careful thought is necessary at regimental headquarters in order to prescribe what is wanted without destroying the initiative of the battalion and company commanders in training their units. The latitude given to the commanders of the lower units should be increased as the training progresses. I think it advisable, even during the early days of training, to set aside a portion of the time for the battalion commanders and company commanders to have their units for such drills and exercises as they wish to prescribe.

This brings to mind the existence of a tendency on the part of regimental commanders to look on the regiment as a unit composed of six companies instead of a unit of two battalions of three companies each. In active operations, the battalion is an important unit.

Colonel Finch properly lays stress on the question of the proper handling of "delinquents." Instilling a high degree of discipline and maintaining it in an organization is undoubtedly one of the most important and difficult problems which confront a unit commander. It is believed that no standard procedure can be prescribed and that the individuality of the units and of their commanders must be studied carefully as the unit develops, in order that the most effective means to the end may be applied.

I can give further testimony to the successful use of disciplinary units. I can conceive of conditions under which it would be advisable to have disciplinary units in the smaller organizations of the regiment instead of a single unit for the regiment.

Colonel Finch's remarks on the relation of the guardhouse to this problem are undoubtedly along sound lines.

In adopting methods for maintaining discipline and in prescribing drill schedules, it is necessary to take into consideration the character and the spirit of the organization. By "character" is meant that deep-rooted quality of a unit which depends on such features as the kind of commissioned and enlisted personnel of which it is composed, their length of service and perfection in training and in discipline, and their sense of loyalty and service. By "spirit" is meant that more changeable quality of a unit which depends on such features as living conditions, weather conditions, the current training schedule, disciplinary treatment, and the type of men who assume what may be called the unofficial leadership among the enlisted men. Units are not alike. They have individuality. I feel that it cannot be too strongly emphasized that the characteristics of a unit must be studied at all times and the results of these studies should influence the drill schedules and the methods of maintaining discipline.

E. J. Atkisson
Colonel, Engineers
formerly Commanding 30th and 1st Engineers, A. E. F.

The absence of prospects for immediate war service should not be allowed to alter or change the spirit of instruction. From the day a recruit reports until the day he is discharged, he should feel and later know and understand that every duty and drill is better fitting him to meet the real tests of war. This point must not be camouflaged, whether in doing the many odd jobs which fall to the engineers in a division (similar work has to be done in time of war) or in vocational training. Men skilled in the trades are essential in war, train them accordingly, and consider it fortunate but of secondary importance that this training is also useful after the men cease to be soldiers.

Seven years ago, few of us really believed we would ever be called upon to train and probably lead troops against the veteran forces of Germany. This experience should make the spirit, the very foundation of our training, that of fitness for actual war service. It should not be implied, it should be a real living thing, which inspires the instructor and is transmitted to his men. It makes discipline mean something and furnishes the reason for exact performance of even the most trivial duties. If men can be made to do the "little things" right, and to realize their importance, the "big things" are provided for, since they are made up of little ones.

In the preparation of schedules there should be one, underlying the detailed schedules of the month or season, which is progressive throughout a period corresponding to the enlistment. Certainly each man can learn something new which will make him a better soldier, every day of his enlistment, if the instruction is progressive. This is certainly sufficient to justify the additional work necessitated by progressive instruction. It also emphasizes the importance of keeping the same officers on duty with units for a considerable period of time.

Digitized by Google

The use of enlisted specialists as instructors is desirable and undoubtedly must be resorted to in any case, due to shortage of officers. But it is considered of special importance that this work be closely supervised by officers, and that these officers be thoroughly competent to supervise. The troop commander's supervision and training of his officers will have much to do with the success of the training of the men. It is considered especially important that company and platoon commanders should have much experience in handling their men, both in routine and special work.

Engineers have much special work to do outside of routine instruction, such as road repairs and signs, bridge construction, athletic field construction, operation of utilities, and many other miscellaneous jobs. This is considered an advantage and should be solicited, provided it is handled as an important part of the training, and not turned over to some old reliable non-commissioned officer and a fatigue detail as a side issue which unfortunately must be attended to even though it interferes with regular instruction. When the request for a particular job comes to regimental headquarters, formulate the necessary work order, making the assignment to an officer or non-commissioned officer who will profit by the experience. Follow his work through his plan, estimates for men, material and transportation, handling of job, completed work and final report. Give the next job to a new man. In the operation of a utility requiring a continuous detail, rotate the men so that a particular man will remain in one position only long enough to thoroughly master its requirements. Use it as a training center.

In recruit instruction as well as in later instruction and work, I agree with Colonel Finch in giving the men definite reasons and clean-cut explanations of the methods to be used. Invite comment and questions. The training should develop a proper self-confidence and ability to assume responsibility.

In target practice, I have had an opportunity to observe a course of instruction given under the personal direction of Colonel A. J. ("Sandy") MacNab and to hear his comment on the subject generally. This course was given to the infantrymen from the last class graduating from the Military Academy. Every man qualified and the average of all scores was above the expert rifleman requirement. Several points with which I was not previously familiar are as follows:

(1) The sighting and aiming drill (triangle-exercise) was carried out at 200 yards, using an 8-inch disk. This gives the man a true conception of how the target will look when he goes on the range, does not require a readjustment, and having qualified in the triangle exercise, the indistinctness of the bull does not give him concern.

(2) Careful instruction was given in the manner of taking up the correct positions and the method of trigger squeeze. Further time is not spent on this work except during actual firing, when the coach makes the necessary corrections. Trigger-squeeze exercises are not used in preliminary instruction or on the range.

(3) Every shot in preliminary instruction is fired under the supervision of a coach and the men are required to coach each other. No men are allowed to idle around the firing point. With this class, pistol practice was carried on at the same time, and men not actually firing or coaching spent their time on the pistol range rigged up at the side of the particular firing point in use.

(4) Great use was made of dummy cartridges, in both slow and rapid fire. A special dummy made from service ammunition was used in rapid fire.

Colonel MacNab states, with reference to correcting trigger-squeeze and preventing flinching, that by this means alone men will average better scores at rapid fire than at slow fire. Firing in which the coach squeezes the trigger was also used.

One of Colonel MacNab's reasons for the differences between this system and previous systems is very pertinent and is as follows:

Any man who is physically able to walk to the firing point has all the strength necessary to make a score well over 40. If he is making very low scores it is because he is not aiming and squeezing the trigger properly. To give him push-and-pull exercises is no more beneficial than to have him take a trip in a balloon or ride in a sight-seeing automobile, or do any thing else except to learn to hold his aim while he squeezes the trigger in the right way. To take a man who is making a low score off the firing point and give him "push and pull" with a view to improving his score is about as sensible as to have him skip rope as a means of teaching him how to remove a tire from an automobile. Good physical condition is of course an asset to an excellent shot, and physical exercises may help him to raise his score from an average of 47 to an average of 47.5, but physical exercises will not help in the least degree a man who is averaging under 40. Each man undergoes all the necessary muscular training while he is being taught to aim, how to take the correct positions, how to squeeze the trigger, and in acquiring a habit of smooth and rapid bolt manipulation.

It is believed that group athletics, as developed by the War Department, should be included in all schedules of training. They can be made interesting and all the men are reached.

Special emphasis should be placed on the importance of the closest personal supervision and interest of all officers, in the mess, clothing and equipment, bathing, guard instruction and recreational features.

Colonel Finch's guard house administration is considered especially good where conditions, personnel and facilities exist to carry it out. I used the following system with considerable success. A special officer, the adjutant in this instance, made it his business to study each case, get at the bottom of the particular man's trouble, learn his weakness. He soon was ready to recommend that the man be put on probation in some particular job, or assigned to a company in which the company commander knew how to reach such men. One man who failed to respond to treatment I took as my personal orderly, had him properly outfitted and except for one slight relapse he continued to make good during the remainder of his service.

C. P. Gross
Captain, Engineers
formerly Colonel, Commanding the 318th Engineers, A. E. F.

I do not share Colonel Finch's hope that recruits will come to the regular army in such large numbers that the conditions of training will approximate those that obtained in 1917–1918. Under a system of universal military training, these conditions, however, would again prevail.

Colonel Finch's pointers are in the main concurred in. However, I am not inclined to be so kindly. I would not encourage my officers to "pass the time of day" to the men. Nor would I permit recruits to choose what they would do first where they have two or more things to do. It has been my experience that the familiarity of the recruit has to be curbed rather than encouraged. A recruit passed me one day coming from the post exchange, with cigarette in his mouth and hands in his pockets. I wheeled, calling, "You man, with the cigarette in your mouth." He

Digitized by Google

turned, and with an engaging smile, drew a package of Fatimas from his pocket, offering it with "Here, have one." It is difficult to teach the average American obedience. I do not believe it wise to permit him to have a choice other than in voluntary subjects, not required of him as a duty. I would not define any of the duties of a soldier as "degrading work" and exempt prisoners from performing it on that ground.

Colonel Finch's "Guard-House Administration" I think is excellent. While the number of prisoners in the guard-house is significant, there has been a tendency to regard it as indicative of the discipline of a command, and to call a regimental commander to account because his guard-house has more prisoners than that in another regiment held up as an example. If that is the view taken, how easy it is to secure a rating of 100 per cent on the discipline of a unit. (In truth, the fact that there are prisoners in the guard-house is a sign that discipline is exercised.) As in times past discipline is based on the hope of reward and the fear of punishment, and of the two, despite the wave of sociological effort, the latter seems to be the more effective.

The pioneer regiment in war always works and sometimes fights. It should be trained for both. Its excellence, either working or fighting, depends on its discipline, its organization for the duty in hand and its morale. Morale is dependent in part on the other two, on the knowledge of excellence, and is here not considered further.

Under intelligent drafting or assignment of recruits, engineer regiments receive the specialists they require. They can not make them. The task is to discipline them and to organize them. Vocational training, as far as the organization is concerned, is a liability. It will not produce specialists for the regiments in numbers to justify it on that ground. Artisans are not made in a school year. It merely provides a means to the individual soldier of utilizing his spare time by learning a trade from one of his fellows who acquired his skill generally before entering the army. To that extent, of course, vocational training is excellent.

Discipline can best be obtained by intensive infantry training. That is well recognized and provided for in the training manuals.

During this early infantry period, the trade qualifications of the recruits should be indexed, both in the company and in regimental headquarters, preparatory to the engineer training. Headquarters should know from that time on that they can turn out 60 carpenters and who they are by name, 44 truck drivers, 35 miners, etc. The company commanders should then use this information in organizing their platoons and in selecting men for special engineer training.

It is not believed that in the past our engineer training has been carried to completion. It has not provided training in organization for real work. The tendency has been to establish a school system—a "vocational college," as Colonel Finch calls it. That is excellent if we provide for a graduation from the school and have the unit plan and perform real work.

The 318th Engineers, after an uninterrupted period of training, following a school system in the states, arrived in France two months in advance of its division. During that period it was assigned to the Division of Construction and Forestry and worked at Gievres, Mehun, and at Montierchaume, laying railroad tracks, building wood and steel warehouses, constructing water tanks, laying concrete, building roads, etc. It was ideal training because it brought to the officers and men definitely the knowledge that they *could* perform. Officers were developed in planning work and organizing their men for it. The work showed up the skilled and reliable men of the regiment as nothing else had previously done. That training proved invaluable. The confidence gained by the officers in themselves and in their units led them to engage in tasks at the front from the start with dispatch and skill. Such work for a short period hurts the military courtesy shown by a command. However, it improves its real discipline, for it teaches the men to form for organization around their leaders and to perform work as a unit.

Now, in the normal training of our pioneers, no such instruction is given. Work as extensive as that mentioned above, of course, can not often be provided. Work of this nature in the past has been possible only in exceptional cases and then not encouraged. Its encouragement, it is believed, should be definitely made a matter of policy. Military mapping, logging in woods, building roads, constructing bridges like the one at Fort Riley, fortification construction, give the training that rounds out the unit. Funds are frequently necessary and should be allowed liberally for that purpose. It is appreciated that work of this character, if too long engaged in, is harmful, injuring the organization as a fighting unit. However, with such instruction for two or three months each year to try it out and complete its training, it is believed the engineer unit would render better service when facing its real duties in war.

E. C. Kelton
Major, Engineers

This article has many points which it is believed should be emphasized even more strongly than the author has done. One of these is the importance of training engineer troops in conjunction with infantry.

Fortunately for the good of the army as a whole, we at last are to have divisional camps, where will be located under one command troops of the infantry, artillery, signal corps, engineers, medical corps, etc. This permits the formation of a fighting unit, the elements of which, provided they are properly trained together in time of peace, will know what is expected of them in campaign and what they in turn can expect of the others. In time of war nothing is more important than that the different branches of the service understand exactly this point. Combined with it there must also be a spirit of co-operation and mutual esteem which can only be accomplished by establishing friendly social relations between the officers of the various units.

This friendly relation is especially necessary between the engineers and the infantry. Some engineers believe that it is not their function to help the infantry in special work; that it is not their place to help improve the camp of a neighboring infantry regiment, or even to send an officer or qualified non-com to the other camp to give technical advice on some minor engineering point. Such should not be the case. If there is a target range to be built for the division or even for one particular infantry regiment in the division, the work should come under the province of the division engineer. An officer of the engineer regiment should be in charge of the work. Sufficient engineer soldiers should be employed to care for the tools and perform any special work that may be required, such as carpentry work, sign painting, laying out of drainage systems and supervising the infantry working parties. The engineer regiment is thoroughly equipped to do this sort of thing and will be called upon to do it in time of war. Why, then, should not this necessary work be used as a basis for the instruction of the officers and soldiers of the

Digitized by Google

regiment? It is realized that there are some practical difficulties connected with the plan due to the shifting of personnel in order to give the whole regiment an equal amount of training in all subjects but it can be accomplished if the companies are rotated upon the tasks as they come up.

Considering the problem from the purely instructional side, much may be gained by having the engineers enter into all the maneuvers of the infantry. To do this it will be necessary for the regimental commander to know what is going on in the division and be ready with schemes by which the maneuver can be changed slightly as to time or location so as to include certain engineer problems. During several months at one of the large corps schools in France, I was fortunate enough to be able to put these principles into practise. Each month, several days were devoted to maneuvers which combined the functions of the infantry, the signal corps, air service, artillery and engineers. Arrangements were made by which the maneuver was made to take place over ground which required the bridging of a stream and the construction of a small piece of road. On the day before the maneuver, application was made to the aeronautical school for aerial photographs of the ground over which the advance was to be made. From these, sketches were prepared showing the exact location of the bridge. Engineer orders were issued, based on the general orders for the maneuver. At H hour the engineers started to put the bridges across the stream protected by the barrage of machine guns, 37 mm. guns, Stokes mortars and thermit bombs, the last being handled by the students of the gas school. As soon as the foot-bridges were across the stream, the infantry advanced to the attack. The foot-bridges were then replaced by heavy ponton bridges. There is no reason to believe that the same sort of instruction could not be carried on in the divisional regiments in this country, especially at the present time in the big camps where there is (or should be) engineer material ready for use.

Colonel Finch's remarks on the subject of recruit training are full and convincing. It is believed, however, that more stress should be laid on the importance of properly selecting the n.c.o. to train the new recruits. The first month of a recruit's life in the army is by far the most important. It is believed that he should be sent quickly to his regular organization and then receive instruction heretofore ordinarily given in the recruit depot. Having joined his own company and regiment the recruit is at once taught the traditions of that regiment, his thoughts are for the regiment and he works for the good of the regiment from the very first. *Esprit de corps* is thus instilled in him in the shortest possible time. This being the case it is seen how important is the task of the n.c.o. in charge of the recruits. The company officers can do their part, but it is really the non-commissioned officer who moulds the mind of the recruit at this impressionable period. He is with him on the drill field, at meals, when he is cleaning his equipment, his tent, or squad room, he is the one of whom the recruit asks questions concerning all the strange things that he is hourly learning or seeing. To him comes the recruit to ask the proper manner of approaching the captain, to ask what he is to do when an officer passes; what is the reason for the salute, etc. To answer all these questions tactfully, to gain the respect and at the same time the confidence of the recruit, to insure his absolute obedience and yet make him feel free to come and ask such questions is a difficult task. But that is what is required of the recruit instructor and he must be selected with these points in mind.

Too much cannot be said in favor of the plans suggested for reducing the guard house "population." The "J Company" plan referred to in the article was put into effect the day before I rejoined my regiment. Most of the officers never having seen the scheme in practise were most skeptical as to the results. However, in a very short time they were all enthusiastic in its support. On the other hand, it must not be forgotten that there are certain offenses which for the good of the regiment and discipline generally require the use of the court-martial and severe punishment.

R. G. Moses
Major, Engineers
formerly Commanding 601st Engineers, and Commandant, Engineer Candidates School, A. E. F.

This article, I am sure, will be welcomed by all officers and especially by those who have command of troops just at the present time. The suggestions herein will be thankfully received by those who are hard pressed for expedients to keep up the morale of the men in their organizations. Since, as Colonel Finch states, in the depleted organizations of to-day a large number of the personnel are recruits, and they will be brought up to full strength by recruits, pointers on recruit training are particularly valuable.

Short, snappy and progressive drills have clearly demonstrated their superiority. Ordinarily, drills of one hour or less enable the instructor to cover a complete section of the subject at hand. It should be left to the discretion of the instructor to dismiss his platoon ahead of time when the work for the period has been covered thoroughly and the men have done particularly well.

The two group system works well and the "slow ones" should be given extra work to bring them up to the standard. This system also appeals to the pride of the men.

Thorough preparation by the instructor for the next day's schedule is most important. Only by the careful selection of instructors and their assignment as specialists, as Colonel Finch says, can the best results be obtained. These instructors are able to develop the fine points of the work, are able to criticize more closely, and give more real help to the individual. It was clearly demonstrated at the Engineer Candidates School in France that the "specialist," or man who was particularly well qualified to teach a certain subject and who developed himself in it, accomplished far better results than the average or "general" instructor.

Every man wants to know why it is necessary for him to do certain things, and when he knows, he does them more efficiently and in a better spirit. This is a matter of the utmost importance. If the reasons for things are not explained the men too easily come to believe that everything is unnecessary and a waste of time. If they can be convinced during their period of training that they are never called upon to do anything that is not vitally necessary, they can then be depended upon to do their full duty at all times. In the stress of battle there may not always be an officer at hand to keep the men up to their work and they will not always understand the reasons for what they are told to do. But if they have been properly taught they will have faith that nothing unnecessary is ever demanded of them. They will say to themselves: "We cannot see the reason for doing this just now, but the captain told us to do it, and we know he never asks anything unnecessary." By establishing friendly relations with the men through "friendly words," better co-operation will be obtained; questions will be asked and answered, and interest aroused. Each man can easily be made to feel that the instructor has a personal interest in him, by the attitude of

Digitized by Google

that instructor. Short talks or conferences are particularly valuable.

A system of marking proficiency by the men themselves was used successfully where the men were officer candidates. The same system is of value with recruits, although it is not practicable to use it to so great an extent. The recruit should be taken out of his squad or section and told to give each man a rating after watching them drill for some time. This causes the recruit to look for mistakes and to see the small things which are essential to good performance. Most men involuntarily apply the things they have seen to themselves, and correct many faults in their own work.

As stated by Colonel Finch, efficient shooting on the range is very valuable in keeping up the morale of an organization. Thorough preparation of schedules and instructors before the season begins is extremely important. I have seen a company of engineers make the eighty per cent qualification said to be "thoroughly practicable." The obtaining of this result was clearly assisted by having "specialists" see that no man took the next step in the schedule without being checked as proficient in the preceding one. Patience and thoroughness in instruction are necessary for the instructor. It is particularly valuable in this instruction to show the recruit why he is required to hold the rifle and take the positions in prescribed ways.

Lake Erie-Ohio River Barge Canal

Governor Cox, of Ohio, approved on Feb. 20th the Bellew-Pearson bill, providing for the creation of a canal zone to aid the Federal government in constructing a barge canal between Lake Erie and the Ohio River.

The bill provides in detail for financing the undertaking and for all administrative matters, and for enforcing its provisions.

The gist of the bill is contained in Sec. 2, as follows:

SEC. 2. That whenever the Congress of the United States shall authorize (the construction, maintenance and operation of) a canal or waterway along a substantially definite route situate either wholly within the State of Ohio, or partly within the State of Ohio and partly in some other State or States for the purpose of connecting the Great Lakes with the Ohio River or its tributaries so as to provide a route for the passage of steamships, barges or other vessels from the Great Lakes to said Ohio River, and shall make an appropriation or appropriations for the construction, maintenance and operation of the same on condition that the State of Ohio or any part thereof shall contribute a certain part of such cost of construction, then the lands within the zone described in Sec. 3 hereof, all of which said lands will be specially benefited by the construction of said canal, and by the operation thereof, may be organized into a canal district in the manner hereinafter described, with all the rights, powers, liabilities, organization and administration as in this act set forth.

Northampton County Federal Road Project

This project is located in Northampton County, Pennsylvania, and is the generally recognized standard 18-foot, two-way traffic roadway, 5.45 miles in length. In general the location follows an old right of way but the original alignment has been improved, sharp curves eliminated, and reasonably long tangents introduced. In one of the relocations advantage was taken of a high railroad crossing over a small creek to eliminate a grade crossing. Savings in distance on relocation was also based on the comparison of the surfacing cost of $6 per linear foot and the excavation and right of way cost.

The salient features of the design are short uniform gradients, frequent breaks in grade, and long vertical curves. The adjustments of the grade line was also influenced by the fact that, generally speaking, hard surface pavements have given more trouble on deep fills and deep cuts than where the original ground surface has been slightly disturbed. Consideration was also given to the impression that the less cutting therein done the better both from the standpoint of the safety of the pavement and of the traffic passing over it. The ditchless cross section, advocated by those who consider a heavy ditch dangerous to fast moving traffic, was adopted: extensive tile drainage and careful maintenance provision control the effectiveness of this section. The surface is concrete with 8-inch center and is of 1-2-3 mix.

The contract was let for approximately $320,000. The maximum use is made of machinery and particular attention is paid to the accurate cutting of the road bed, rolling the fill in layers, and protection of the concrete until it is cured. Since the concreting began the mixing plant has worked 30 out of 31 working days and has averaged 240 feet of 1-2-3 concrete pavement 18 feet wide and an average of 7.33 inches thick per day with a force of 8 men on the mixer, 6 men on the material piles, and 4 men on the trains.

The above is taken from *Public Roads,* issued by the U. S. Department of Agriculture, Aug.-Sept., 1919.

De Havilland "Fours" Equipped with Eight Machine Guns

The Engineering Division of the Air Service at Dayton, Ohio, has remodeled four DeHavilland Four airplanes to carry a total of eight machine guns each. The DeHavilland 4's now carry two fixed synchronized guns, two fixed Marlin guns projecting through the floor of the pilot's cockpit, firing at an angle of about 45 degrees, two flexible guns on the upper gun mount, and two Lewis guns in the floor at the rear of the observer's cockpit. In several of these airplanes these lower rear Lewis guns are fixed while in others they are mounted on a sort of a floor turret which allows them to be directed by the observer.

In all of these airplanes the arrangements of the guns are such that the pilot can direct his airplane in such a way as to fire his synchronized guns directly at the object to be attacked. As he gets closer to the object and can no longer fly directly toward it he raises his nose slightly and flies horizontally, firing the lower forward guns at the target. After he passes over the target he brings his lower guns to bear and as he then begins to climb away from the ground the observer can fire his flexibly mounted Lewis guns at the target; thus the pilot and observer have four sets of guns shooting at the target at different times as the airplane passes over.

Suitable sights are provided so that by maneuvering the airplane the pilot is able to aim accurately all of the fixed guns while the observer is able to direct the fire of the flexible guns. The completed airplanes now at McCook Field are to be sent to the Border for service tests.—*War Dept. News Bureau.*

Pipe-line Dredging in the Open Gulf of Mexico

Atchafalaya Bay Ship Channel

By

T. E. L. Lipsey

U. S. Assistant Engineer

THE following is a description of the work done by the U. S. Dredge *H. S. Taber,* on the Atchafalaya Bay Ship Channel, under the direction of the U. S. Engineer Office, New Orleans, La., from December 2, 1918, to April 5, 1919.

The *Taber* is a 24-inch hydraulic dredge of the self-propelling, stern-wheel type, designed for work in the Arkansas River. The hull is of steel, 206 feet 9 inches long, 44 feet 4 inches wide, and 7 feet deep, with 3 feet 7 inches draft. It has one 24-inch centrifugal dredging pump, driven by a triple-expansion engine. The suction-pipe has what is known as a dust-pan head, with a system of water jets for agitating and disintegrating the material to be dredged. This dust-pan head is 20 feet wide, and can be lowered to a depth of 14 feet below the surface.

The dredge cannot be swung while in operation, but is pulled straight ahead, making a comparatively narrow cut. The discharge can be arranged so as to leave the dredge from either side a little forward of midship. The discharge line is a very heavy pipe, in 50-foot sections, each on a turntable on the center of a steel ponton. The connections between the pontons were rigid when the dredge arrived in this district, but were afterwards modified as herein described, to meet local conditions of exposure.

The dredge was transferred to this district from the Kansas City District, leaving there on August 20, 1918. The plant stopped at the mouth of White River en route to do some dredging, and arrived at Plaquemine, La., on September 28, 1919. As the dredge was to work on the Atchafalaya Bay Ship Channel in the open waters of the Gulf of Mexico, it was decided to modify the ponton pipe-line by removing the large rigid flange connections and providing rubber sleeves in lieu thereof. The result was a pipe-line 500 feet long in sections of about 50 feet, supported on small single steel pontons 12 feet wide, 47 feet long and 2 feet 10 inches deep, all connected in the usual manner. In operation, this line proved to be one of the best ever seen, and was capable of standing the most severe weather and seas.

The work to be done was the dredging of a channel 14 feet deep at mean low Gulf, and 200 feet wide on bottom, for a distance of 15¾ miles in the Gulf, the inner end being 4 miles from the mouth of the Atchafalaya River in Atchafalaya Bay. This is a very exposed locality and the work had to be done during the winter months, in order to prepare the channel for ships being constructed at Morgan City, La., by the Emergency Fleet Corporation. Fig. 1 shows the location of this channel. The winter of 1918-1919, proved to be one of the worst in years, and in consequence of bad weather, and other unfavorable conditions, about 27 per cent of the available time was lost, as will be seen from the records herewith.

This dredge is without spuds, and could not swing as is the usual case with a hydraulic dredge, hence a new scheme of anchoring and moving the dredge had to be devised. This was successfully done by a system of anchors arranged as shown in Fig. 2. A double drum hoisting engine was installed near the rear of the dredge, to operate the rear anchor lines. The forward anchor lines were operated from the main spool of the dredge winding engines. When the dredge was in place for work, the anchors were placed as shown, the dredge was slowly but continuously hauled forward about 1,000 feet, making a cut as wide as the suction head, namely, 20 feet. The dredge was then pulled back to the point of beginning, shifted sidewise the width of the first cut, and the operation repeated until the entire cut 200 feet wide had been made. To make this cut usually took five operations, as the material was very soft and flowed freely from the sides to the suction head. The material was also drawn upwards from the bottom of the cut, making the average cut 2 feet deeper than the 14-foot depth of the bottom of the suction head. In some places the overdepth was as much as 3 to 5 feet, depending upon the depth of the material dredged, being greater for the shallower cuts.

Digitized by Google

The pile sinker, which was a part of the dredging plant when received, was anchored in a similar manner to the dredge, and was used to hold the pipe-line straight out from the side of the dredge, the whole line being connected to the dredge by a wire cable which passed along the tops of the pontons. This enabled the ponton line to be held securely when heavy cross seas were running. During very calm weather the baffle-plate, which was placed on the extreme end ponton, was sufficient to hold the line straight. The method of holding and operating the ponton line is shown in Fig. 2. When the seas were so rough that dredging operations were suspended, the wire line holding pontons to dredge was turned loose, and the ponton line was allowed to swing around in lee of the pile sinker, so that it would ride the seas in safety. Due to the shoal water and the extreme depth of the soft mud, it was exceedingly difficult to handle the heavy anchors that were necessary to hold such a large plant in position against the prevailing high winds and rough seas. On several occasions these anchors sank 60 feet into the mud.

To handle the anchors readily, it was necessary to use a large shallow-draft snagboat (the *Denison*) and a 50-horse-power gasoline launch (the *Beaumont*). The powerful rigging for snagging on the *Denison* was very satisfactory for pulling these anchors out of the mud, although the large house combined with the shallow draft made the boat rather unhandy in the wind and sea. However, on the whole, it proved fairly satisfactory. An additional 40-horsepower launch was provided to carry the personnel, mails, and supplies to the dredge. The site of the work was from 30 to 45 miles from the base at Morgan City. All men, coal, and supplies had to be brought from this locality. The remainder of the equipment consisted of two coal barges and two water barges. It should be stated that this work was done during the period of the worst emergency of labor conditions, due to war and draft, and when it was almost impossible to secure men of experience or those who were even worth their hire. Ofttimes they would go to the plant, get something to eat, and return by the next trip of tender to Morgan City. Some trouble was also experienced with steam engineers who demanded the rates of pay adopted by the Steam Engineers' Association. This was overcome, however, by getting the chief engineer to stick, and by having all others rated as dredge engineers, as this designation did not require a license. In addition to this, the epidemic of influenza was at its height during this work, and the dredge at times was almost a hospital.

The plant usually was operated with three crews working eight hours each, but due to shortage of men, the average was not over two crews for continuous service.

The number of men and rates of pay on each plant are shown in the accompanying tables. The ordinary ration allowance was 60 cents per day per man.

The material handled was a very soft mud, mixed with shell in certain portions of the channel. A mechanical agitator was not found necessary, as the jets sufficiently disintegrated the material, and rendered it fluid enough to pass readily to the suction.

The tables herewith show the time lost from different causes, and also the time actually working and pumping.

The total cost of the work, from the date of arrival of the plant at the site, December 2, 1918, to the date of completion, April 5, 1919, including all lost time from all causes, was $59,815.64. The total yardage removed, figured on the theoretical cross-section of 14 feet deep at mean low Gulf and 200 feet wide on bottom, with side slopes 1 on 1 and 1 foot overcut, was 2,480,724, costing 2.4 cents per cubic yard. The actual number of cubic yards removed was 3,202,217, costing 1.9 cents per cubic yard. The above yardage was figured on actual cross-sections taken before and after dredging.

The total cost of bringing plant from the Kansas City District and altering it for work on the channel was $13,808.27. The total gross cost of the work, including all expenses to this district, was $73,623.91, or 3 cents per cubic yard on the theoretical cross-section and 2.3 cents on the actual section.

The largest day's work was on March 22, 1919, when the dredge excavated a channel of the above dimensions 2,000 feet long, removing 82,900 cubic yards at a field cost of $375.00, or 0.452 cents per cubic yard. During this 24-hour period, the dredge lost 3 hours and 40 minutes shifting anchors, and 4 hours "dropping back" to take up new cut and shift over." The pump was actually running 16 hours and 20 minutes. "Field cost" includes payroll, subsistence, fuel, engine room and miscellaneous supplies.

Distribution of time. December 2, 1918, to April 5, 1919.

Time at work.—	Hours	Minutes	Per cent
(*a*) Pumping	556	55	.185
(*b*) Handling pipe-line	10	22	.008
(*c*) Handling anchors	377	14	.126
(*d*) Placing dredge	112	26	.038
Total	1,056	57	.352
Time lost from work.—			
(*a*) Changing location of plant	6	50	.002
(*b*) Bad weather	811	00	.270

4	Deckhands	70
1	Cook	75

Note: Subsistence also furnished all hands.

In 1915 the hydraulic dredge *Gulfport* (20-inch pump) worked in this same channel, removing nearly 2,000,000 cubic yards at a field cost of 1.04 cents per cubic yard. The following is a comparison of the work of the two dredges. All figures are cubic yards.

	Taber	*Gulfport*
Average dredged per hour, pumping	5,750	2,620
Average dredged per hour, effective working time	3,030	1,875
Average dredged per working day	41,054	40,920
Maximum dredged in one month	892,312	1,062,030*

*July 1-29 only.

Record Dredging on the Mississippi River

[The following data concerning the performances of the dredges *Fort Gage* and *Fort Chartres*, furnished by the District Officer at St. Louis, will be of interest in comparison with that of the dredge *Taber* in Atchafalaya Bay.—Ed.]

These are self-propelling steel-hull suction-dredges, each 97 by 45 by 7½ feet, 4-foot draft, 815 tons, built in 1908 at a cost of about $177,000 each.

Complement (double crew, two 8-hour shifts) 9 officers, 39 men.

Boilers, six Mississippi River type, horizontal, externally fired, each 30 feet by 44 inches diameter, with three 10-inch and two 11-inch flues; 3,900 square feet, total heating, and 130 square feet, total grate surface; 160 pounds steam.

Propelling engines, two Mississippi River, 24 inches by 8 feet; 800 I. H. P.

Paddle wheel, stern, 26 inches by 21¾ feet diameter; 16 buckets, 35 inches wide, revolutions per minute 16; speed of boat, 7 miles per hour.

Pumping engines, 2 tandem compound condensing, 16½ inches and 30 inches by 24 inches; 140 to 150 R. P. M., 1,000 I. H. P.

Dredging pump, centrifugal, balanced type, volute lined, diameter of runner 84 inches; discharge overhead, either side of dredge.

Suction pipe, "dustpan" head 30 feet wide, 2 suctions, 24 inches diameter; average vacuum, 22 inches.

Discharge pipe, 32 inches diameter, 400 feet; maximum pressure, 5 pounds.

For a number of years these dredges have handled 500,000 to 2,000,000 cubic yards of river sand and silt per low water season, August to December.

The record monthly output thus far of these dredges is by the *Fort Chartres*, in August, 1919, when 344,000 cubic yards were dredged in 20 working days. The actual dredging time was 203 hours, with 111 hours consumed in handling pipeline and dredge, cleaning suctions, etc.; the effective hourly rate thus being 1,100 cubic yards.

The record day's work, however, is by the *Fort Gage*, August 6, 1919, when 32,439 cubic yards were dredged in 12¼ hours actual dredging time, with 3¾ hours for placing dredge and pipeline; giving a maximum hourly rate of 2,650 cubic yards, and an effective hourly rate of 2,000 cubic yards.

Unit costs, cents per cubic yard.

	Field	*Gross.*
For season 1919—		
Fort Gage (679,000 cubic yards)	7.9	11.9
Fort Chartres (654,000 cubic yard)	9.3	13.5
Average	8.6	12.7
For 10 years ending December 31, 1919.—		
Fort Gage (4,678,000 cubic yards)	6.6	12.1
Fort Chartres (5,864,000 cubic yards)	5.6	10.1
Average	6.0	11.0

Dredging in the Gulf of Mexico

In the month of January, 1914, the dredge *Texas*, belonging to the Atlantic, Gulf and Pacific Co., removed 1,246,000 cubic yards of material from the Houston (Texas) Ship Channel. Data furnished by U. S. Engr. Office, Galveston.)

Duties of Engineers

A Map Problem on the "Applicatory System"

By

L. M. Adams

Colonel, Engineers

Note: The "applicatory system" of tactical instruction was in vogue in most armies prior to the World War. Its highest development was found at the Service Schools of the U. S. Army, at Fort Leavenworth, Kansas. The usual means of instruction is the "map problem." The student is given an assumed military situation and a map. He is then required to make an "estimate" or appraisal of the "situation," to determine his "mission," and decide upon a plan of action for carrying it out. These constitute the "solution" of the problem, which the student is required to write out. Having completed his own solution (and not before) the student is permitted to read an "approved solution" by his instructor, and to note the things he has overlooked or the mistakes he has made. This system has been found to be the best substitute possible in time of peace for the actual experiences of war. It places upon the student the *responsibility* of making his own estimate and decision and formulating his own plans of action.

The following problem is an application of the "applicatory system" to the duties of the engineer in war, and illustrates the methods of instruction at the Engineer School, Camp Humphreys, Va.

This problem demands of the student fast original thinking along practical engineering and military lines. It will have, of course, little value for instruction purposes unless it be honestly and conscientiously solved before the "approved solution," which accompanies the problem, is read.

Officers of the regular service or of the Reserve Corps who desire to learn how the military art is best taught in time of peace are urged to essay the solution of this problem, and especially *not to read the approved solution until they have completed their own.*

For guidance in the solution of the problem the following suggestions are offered:

The "Estimate of the situation" should include the following considerations so far as they may influence Major A's actions:

(*a*) Major A's "mission"—what he aims to accomplish.
(*b*) The forces of both combatants.
(*c*) The existing conditions, both favorable and unfavorable.
(*d*) The terrain.
(*e*) The enemy's intentions—what he may be expected to do.

Having reviewed the "situation" Major A next considers the various courses open to him, from which he arrives at a "decision" as to the course which gives the greatest promise of fulfilling his mission. And finally he prepares in detail his adopted plan of action.—ED.

General Situation.—The U. S. and Mexico are at war. The U. S. is taking the offensive and has already launched four Divisional invading forces from LAREDO, EAGLE PASS, EL PASO and COLUMBUS. U. S. forces of all arms are also known to be concentrating opposite OJINAGA. MEXICO'S armed forces are scattered from DURANGO to TAMPICO and number some 75,000 poorly disciplined and poorly equipped troops of all arms. Those in the vicinity of CHIHUAHUA are known to be very capably led.

Special Situation (United States or BLUE):

You are Major A, the senior engineer officer on duty with a re-inforced brigade which has been concentrated under Brig. Gen. B near SHAFTER. The command consists of:

1st Inf. Brig. (1st and 2nd Infs.).
1st Reg. F. A. (75 mm. Rifles).
1st Sq. 1st Cav.
9th Engineers (Mounted).
1st Field Signal Battalion.
Trains: 1st Division Trains practically complete.

On January 19, war was declared and the four Divisions mentioned above each crossed the Border. On January 20 the 1st Sq. 1st Cav. forded the RIO GRANDE at OJINAGA and moved to SAN JUAN to cover the advance of the rest of Gen. B's Command. By 8 a.m. Jan. 21st the whole of Gen. B's Command was at or s. w. of SHAFTER. You are with the General and his staff at SHAFTER and at the first meeting of the C. G. and Staff the General reads the following:

HDQRS. SOUTH. DEPT.,
SAN ANTONIO, Jan. 21, 7 a.m.

To Gen. B., SHAFTER (by Wire)

MEX. NAT. R.R. from JUAREZ to CHIHUAHUA completely destroyed, and will take weeks to open up. I count on your command moving on CHIHUAHUA at once from your present position via RANCHOVIEJO and the K. C. Y. M. & O. R. R. It is intended to increase your force to two divisions just as soon as it becomes clear that you have established a line of communications for such a command to CHIHUAHUA. Unlimited funds and supplies are at your disposal. Your base will be SHAFTER, you are responsible for everything from SHAFTER (Exclusive) to your objective. Chief QM. this Department opens L. of C. MARFA to SHAFTER by tomorrow night. This will be followed by a branch R.R. very soon. Lose no time.

DICKMAN.

The General then turns to you and says:

"Major A, you are to be my Chief Engineer, a member of my staff, as well as commander of the engineer troops. We shall cross the RIO GRANDE immediately after dark tonight. Our cavalry have just reached ALAMO after considerable skirmishing, and report the road to that point unmetalled, but in very fair condition, with all bridges and culverts intact. There are no towns worthy of the name this side of CHIHUAHUA. I count on marching via SAN JUAN—ALAMO—FORTIN—COYAME—PUEBLITO—RANCHOVIEJO and then via the RR to CHIHUAHUA. Supply will be by motor transport (the divisional trains) until we reach RANCHOVIEJO. Submit to me not later than noon today, a full plan of the contemplated engineer operations to cover our march to RANCHOVIEJO. There is only one crossing of the RIO GRANDE between here and SAN JUAN suitable for military vehicles and that is the ford at OJINAGA, 700 feet wide. With RANCHOVIEJO once in our possession I expect to make it an advance section (line of communications) for the two division expedition. Our progress from thence onward will depend largely on the success of our cavalry and upon the capture of rolling stock. We are going to take CHIHUAHUA, but we must fight our way through the mountain passes to do it. Here is a copy of the best map available (handing Major A a copy of the map herewith). You will be furnished copies of the March Order for tonight, about 5 p.m. We now have both wire and wireless communication to MARFA and we expect to have this continue by wireless at least, no matter what happens. We will be joined by an air squadron tomorrow. I may be able to answer a few questions if you are not clear on the situation as we find it."

Digitized by Google

(The situation seems clear, and Maj. A asks no unnecessary questions.)

Note: Area concerned is on the "Tableland of Mexico" or "cold country" as Mexicans would call it in English. January and February are dry season months where we find only the larger streams, such as the RIO SAN PEDRO, flowing. The country is open rocky "mesa" with very limited wooded areas except on the steep mountain slopes and along the streams. The country is now practically barren of resources. The railroads are all standard gauge and are, or were, very well built with American and British capital. Chihuahua is a fine city with all modern improvements but the stores and factories are stripped.

Solutions will be turned in not later than 12 M.

All work will be in ink.

Where orders, messages, etc., are sent as part of the Solution, they will be written out in full, just as in the actual case they would be.

Fifteen minutes will be allowed after the issue of the Problem to the Class in which Student Officers may ask questions; thereafter no questions bearing on the Problem will be answered. A General Map of Mexico is posted on the front board, for anyone to consult if he so desires.

There will be a full discussion of this problem at a later conference period.

Required.—

1. Major A's estimate of the situation.
2. His actions and orders until noon January 21st.

An Approved Solution

REQUIREMENT NO. 1.

Mission.—Major A is to act as Chief Engineer of a small expedition as well as to command the mounted engineer battalion of the expedition. He is to rapidly prepare "a full plan of the contemplated engineer operations" to cover the first part of the march—that is 100 miles by dirt road to the beginning of the standard gauge railroad at RANCHOVIEJO.

Forces on both sides.—The U. S. forces are given in the problem and may be tabulated as follows:

	Officers and men	Animals	Horse-drawn vehicles	Motor vehicles
1st Infantry Brig.	8,417	854	370	11
1st Field Artillery	1,543	1,330	169	6
1st Squadron 1st Cav.	400	470	10	
9th Engineers (Mtd. Bn.)	387	465	12	
1st Field Signal Bn.	488	34	10	38
Aero Squadron	173			56
1st Div. Trns. Hdq. & MP	269	107	5	20
Ammunition Train	1,333	634	93	213
Supply Train (motor)	501			211
Engineer Train	84	110	26	15
Sanitary Train	951	205	35	123
	14,546	4,209	730	693

It thus appears that Brigadier General B has well over half of the equivalent of an infantry division at his disposal. They are well equipped, well disciplined and presumably seasoned regulars. The command is concentrated at its Base, SHAFTER, a small Texas town about 40 miles from the RAILHEAD at MARFA on the main line of the Southern Pacific. Four other widely scattered U. S. divisions are already across the BORDER but at points so distant that Gen. B probably expects no direct assistance from any of them. They are most probably already acting as magnets, however, to attract much of the original MEXICAN armed strength to them. However it is known that the enemy is already resisting our independent cavalry in its movement towards CHIHUAHUA, and with an alert commander at CHIHUAHUA, Gen. B probably expects a very well conducted resistance to develop soon. The Command is to move across the RIO GRANDE in a few hours, and thence force its way rapidly along the main road, some 100 miles to its first objective—the railroad at RANCHOVIEJO. Major A wishes that he had at least an Engineer Platoon with the Independent Cavalry now half way to RANCHOVIEJO. He plans to remedy this at once by despatching one of his mounted companies to catch up with this Cavalry Squadron. This will insure prompt and thorough Engineer Reconnaissance. The enemy's forces are inferior troops, poorly equipped but ably commanded by a Mexican Officer who operates in his own territory.

Conditions—favorable and unfavorable.—The most unfavorable conditions from the Americans' point of view are:

Territory almost unknown and unmapped.

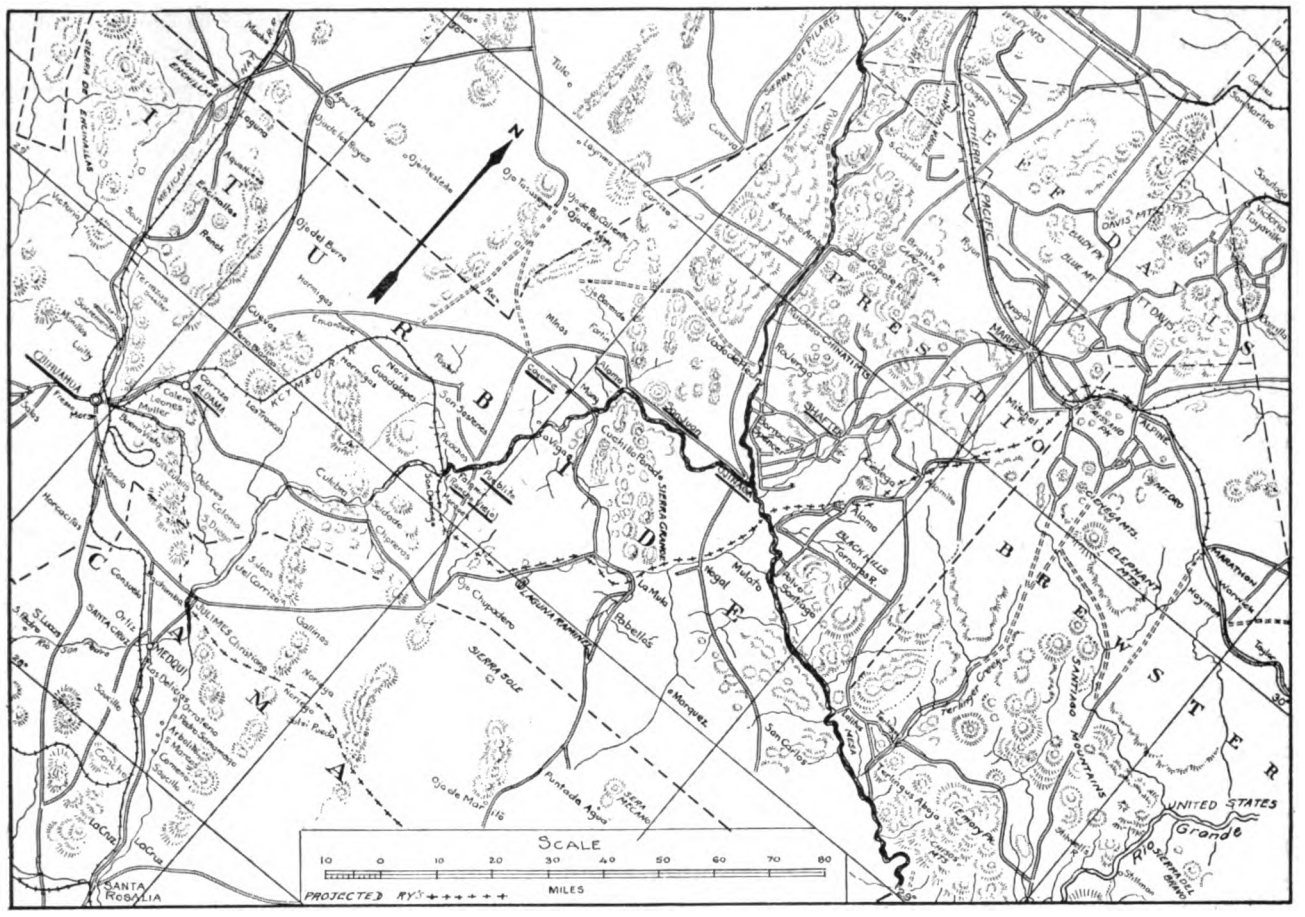
Poor roads probably for motor transport.

No rail line of communications.

No grazing for over 4,000 animals.

A very long line of communications to be opened and held open by a force that must be rapidly depleted by L. of C. Detachments as the advance progresses.

An advance section is to be established at RANCHOVIEJO, with depots, repair shops, corrals, stables, hospitals, etc., all to be built sooner or later. This means that hundreds and hundreds of tons of lumber, nails, roofing, ironwork, machinery and general supplies and equipment must be assembled and erected at RANCHOVIEJO, and this all done weeks and perhaps months before any branch standard gauge railroad could be put in service via either EL PASO or EAGLE PASS and CHIHUAHUA.



Assuming prompt success in reaching and taking CHIHUAHUA, it will become necessary almost at once to prepare for the arrival of another division and a half. The resulting Army Corps is expected apparently to be based on SHAFTER, which will soon be connected by rail (standard gauge) with the S. P. R. R. at MARFA. However, Major A is most concerned now with the plan of engineer operations to include the occupation of RANCHOVIEJO.

Most favorable conditions affecting the U. S. forces appear to be:

Well equipped and well disciplined troops.

The water situation (usually critical in Mexico) practically solved without effort by the proximity of the RIO SAN PEDRO. With the opening of the

will be a very weak link in the proposed line of communications.

Courses open to Major A.—Major A is primarily concerned with those engineer plans having to do with insuring a proper line of communications, first, for Gen. B's small force via motor transport to RANCHOVIEJO and thence via the repaired K. C. Y. M. & O. R. R. to CHIHUAHUA, and later for a largely augmented force of an Army Corps to be based on CHIHUAHUA—RANCHOVIEJO—OJINAGA—SHAFTER.

Major A must make a rough calculation of what the motor transport (Supply Train and possibly part of the Amm. Train, 1st Division), will be capable of in the way of supplying the column by dirt road.

He bases his general supply figures on:

14,000 men requiring 5 lbs. a day	70,000 lbs.
4,000 animals requiring 26 lbs. a day	104,000 lbs.
Minimum daily requirements	174,000 lbs.

Now there are 163 2-ton trucks available in the Divisional Supply Train, but it will not be safe to count on better than 1½ tons net capacity on dirt roads, or 3,000 pounds per truck.

It will also not be safe to count on the truck convoys making more than 5 miles per hour, for 10 hours per day. This means that 4 days will be required for the motor truck trains to make the round trip from SHAFTER to RANCHOVIEJO. Say there will be 160 supply train cargo trucks available — then we may count on an average daily delivery at RANCHOVIEJO of 40 by 3,000 or 120,000 pounds. This is 54,000 pounds less than the estimated daily minimum requirements. This difference will have to be made up by using a part of the 100 trucks of the ammunition train. This capacity of 110 ammunition trucks is based on the 3 regiment brigade, so its depletion to even one-third full strength would not be unreasonable, particularly as a large expenditure of ammunition will probably not be be required to brush aside the small hostile bodies that will be encountered. We do however wish to "get a bluff" on the enemy from the start, by making his first contact with American troops in force one to remember with fear thereafter. Major A will therefore assume that as many as 75 of the 2T. ammunition trucks will be available for regular supply cargo carrying when RANCHOVIEJO is reached. This will keep the expedition supplied with food and forage, while water and firewood will have to be obtained locally.

Major A carefully considers the possibility of running a narrow gauge railway, or even a standard gauge from SHAFTER, to reduce the truck haul. However he gives up this idea for the present when he considers that the branch line from MARFA is yet to be built, and at the rate of 1 mile per day will require over 40 days to build as far as the base at SHAFTER.

Major A decides at once on a temporary heavy ponton bridge crossing at OJINAGA, this to be replaced by a trestle structure at an early date.

Good maps of the country in general are very desirable, but mapping on a large scale is as slow as railroad building, so that Major A will be careful not to encourage Gen. B to think that fine maps will soon be made available for all. Active reconnaissance by the cavalry, mounted engineers and aeroplanes must furnish the necessary data for Gen. A to make his tactical decisions, instead of the almost perfect maps the U. S. forces became somewhat spoiled by in FRANCE.

Even with the hiring of large numbers of Mexicans for road work, Major A believes he will have his hands full to keep open a suitable road for heavy motor trucks for 100 miles. He also expects to have several destroyed stream crossings to replace, with skilled enlisted labor, and he does not forget that before many days he will have a project for an advance section at RANCHOVIEJO to begin work on; the searching out and seizure of every available article for such project in or anywhere near RANCHOVIEJO will warrant Major A in sending forward a large mounted engineer party at once to join the independent cavalry.

To accumulate the necessary quantities of lumber, iron, roofing, nails, machinery, etc., at RANCHOVIEJO an additional system of supply columns of the line of communication must be organized at the BASE for the heavy extra hauling by truck involved.

Major A's plans will be laid with the object of insuring the successful advance of Gen. B to RANCHOVIEJO, and he will carefully avoid trying to do the impossible with the small force at present at his disposal. A series of small, safe, successfully executed engineer projects, will secure Gen. A in the rapid accomplishment of his very important mission, whereas to plan for and attempt the impossible will result in hopeless delay and eventual failure.

Decision.—Major A therefore decides to send forward at once to join the independent cavalry, one company of engineers (less the combat wagon and the platoon that operates with such wagon). The captain of this company is to be principally concerned with engineer reconnaissance and the advising of the cavalry commander of those points on the projected line of communications whose early seizure is vital. He will ask the General for orders to cover this at once.

He further decides: To leave one company (less its pack train and the platoon that operates with such pack train) at SHAFTER. This company to have orders to take charge of the vital matter of promptly erecting a heavy ponton bridge and then a pile

Digitized by Google

trestle bridge at OJINAGA, then to take charge of all road building and maintenance from SHAFTER (exclusive) to SAN JUAN (inclusive).

To accompany the advance guard of the Command with the rest of his battalion—that is, bn. headquarters plus 1 mounted company plus 1 extra combat wagon plus 1 extra pack train plus two extra platoons. Major A expects to assign a definite section of the road (depending on condition in which it is found) to the company commander with most of his company available to oversee the work on such section.

To use the rest of his command, that is 2 platoons and the 1st Engineer Train, on the last section of the road to include starting work on an Advance Section at RANCHOVIEJO. It is evident that more line of communication troops must be detailed before Major A can plan the engineer operations beyond RANCHOVIEJO.

Major A will urgently demand the assignment of 3 Southern Dept. National Guard Infantry regiments to act as L. of C. troops in the near future on the road from SHAFTER (excl.) to RANCHOVIEJO (excl.) These troops should be available in a very few days, and will soon be competent to guard and maintain the road and stream crossings to RANCHOVIEJO. They will thus release most of Major A's command for duty again with the advanced elements of Ge force. The expedition is doomed to failure unless some such assignment of additional L. of C. units is made, and made promptly.

REQUIREMENT NO. 2.

Major A returns to his own headquarters and orders all officers, master engineers and 1st sergts. of his battalion and the engineer train, to assemble. On arrival the situation is explained from the map as given in the problem. He then tells Capt. D of B Company, "Get your company ready to leave at once. Your orders to join the independent cavalry under Major E, will be asked for immediately." Major A then asks if there are any questions. Answers such as he can and dismisses those assembled so as to get to work on his "plan of engineer operations." This takes about the same form as the "decision" given above. It will be presented by Major A in person at noon, and will be resolutely backed up by more detailed explanation as exemplified in the estimate of the situation above.

Message from Major A to the Dept. Engineer, Southern Dept., San Antonio, Tex., a copy being sent to Gen. A at once:

"I am Chief Engineer of Gen. B's column here. We move tonight by the road OJINAGA—ALAMO—FORTIN—COYAME to RANCHOVIEJO, to carry out GEN. DICKMAN'S orders of this date. Only engineers are my mounted battalion. Will leave part of my command to build heavy ponton bridge over RIO GRANDE at OJINAGA, this to be replaced soon by a pile trestle good for military highway traffic. Rush 4 heavy divisions ponton equipage to MARFA. Follow this with 2 portable pile drivers and all lumber, spikes, etc., necessary for pile trestle bridge 800 feet long and 20 feet above river bed at center, further details later. Also send MARFA all road machinery necessary to maintain 100 miles dirt road dry season, use figures based on COLUMBUS—COLONIA DUBLAN road. Mail me rough plans and estimates of all necessary for the advance section, RANCHOVIEJO. I am going to demand 3 SOUTHERN DEPT. NATIONAL GUARD INFTY. REGIMENTS to relieve me of L. of C. maintenance as soon as we get the line opened to RANCHOVIEJO. Send me all available data of RAILROAD, RANCHO to CHIHUAHUA. Hire an American engineer familiar with that road and send to me. Send also $10,000 gold and $10,000 MEX. silver for requisitioning materials and labor for cash. I leave Capt. C with A Company at SHAFTER to build bridges OJINAGA and look out for things as far as SAN JUAN. I send one company ahead to join our cavalry now at ALAMO, while I march with GEN. B with the remainder."

Draft of an order for Gen. B to sign:—

Company B 9th Engineers (Capt. D) is assigned to the independent cavalry (Major E). It will join at once. Captain D will acquaint Major E with the new developments in the situation, and keep him informed as to all points along the proposed line of communications which engineer reconnaissance indicates it vitally necessary to seize and hold.

Topographic Survey of the City of Flint, Mich.

A topographic survey of the City of Flint, Mich., now in progress, was undertaken for city planning purposes. The survey covers the 30 square miles to which the city limits are soon to be extended, the adjacent areas expected to fall in the city limits by 1960, and certain small additional tracts included to secure complete drainage data. The total area to be covered is approximately 60 square miles. The scale is 1 inch, equals 200 feet, with a contour interval of 1 foot. Horizontal control is established by primary traverses in which direction is measured to 30 seconds and distance to hundredths of a foot. The average error of closure in a representative traverse is 1 in 24,150. About 3 miles per day is the average progress of each traversing party. Vertical control is established from existing precise level bench marks by level lines with an error of closure less than $.05\sqrt{M}$, M being the distance between bench marks (presumably in miles.—ED.).

All mapping is done in the field by plane table. Secondary control is obtained by the plane table traverse with stadia and magnetic needle. The area involved embraces a small river and varying topographical forms, including drift plains, irregular glacial forms, and the rugged river valley. The average day's work of a single mapping party is about 28 acres. The accuracy of the map is established by test profiles run with the plane table and compared with profiles scaled from the map. The average error of 130 test points in a profile 6,423 feet in length, amounted to 0.26 foot and only 0.03 per cent of the test points on the profile disagreed with the contours by more than 1 foot.

In the finished map topography is shown in blue, culture and lettering in black, and hydrography in blue.—*Eng. News-Rec.*

Army Essay Winners

The three prize winners in the Army National School Essay Contest on the subject "What are the Benefits of an Enlistment in the United States Army," are:

1st—Donald L. Campbell (age 15),
Junior Class, Clinton High School,
Clinton, Iowa.

2nd—Marjorie Sheetz (age 14),
Chillicothe High School,
Chillicothe, Missouri.

3rd—Bettie Bowen Eason (age 16),
De Soto County High School,
Olive Branch, Mississippi.

This decision was announced April 17 by the Board of National Judges consisting of the Secretary of War, General John J. Pershing, and General Peyton C. March, Chief of Staff, U. S. Army. The judges themselves did not know the identity of the winners, nor the states from which they came until after their decision had been made, as no markings whatever were permitted on the copies of the essays submitted to the Board.

The three winners of this National Essay Contest in which about ten million school children took part received a gold, silver and bronze medal according to their standing in first, second or third place. They also were given a free trip accompanied by their parents or guardians to Washington where Secretary Baker presented the medals and also a large silver loving cup to each of the schools they represent. The competitors who receive an honorable mention are the recipients of engraved certificates signed by Secretary Baker, General March and General Pershing, also each of the fifty-six District competitors will receive an autograph letter from the Secretary of War.

A total of more than one million dollars in local prizes was offered throughout the country to the winners in the various cities of the Recruiting Districts. This essay contest has aroused unusual interest among the school children throughout the nation. It has been suggested that this School Essay Contest be made an annual event in the Army.

The essay of Donald L. Campbell, Clinton, Iowa, deemed the most expressive, original and sincere by the judges, and which was awarded first prize, is as follows:

As Horace Greeley once said, "Young man, go west!" we now say, "Young man, join the Army!" Why? It is the big opportunity of the age.

Are you physically weak?

"Health is the first wealth," and the Army is a health-builder. It provides wholesome food, clean, comfortable surroundings, proper clothing, and medical attention when necessary. Physical exercise is compulsory and every encouragement is given athletics. These, with out-door life, make men straight, strong, and healthy.

Do you seek an education?

You can attend school at any Army Post and study grammar and high-school subjects.

Would you learn a trade?

The government has recently appropriated two million dollars for the establishment and maintenance of vocational schools where you can learn to be a mechanic, auto repairman, electrician, telegraph operator, chemist or almost anything else you wish. These courses prepare you for a return to civil life or continued service in the Army.

Do you long for travel and adventure?

Join the Army. You can be an engineer at the Panama Canal, a wireless operator in the Philippines, a lineman in Alaska, or an aviator flying in the clouds. Whenever possible, the government gives you a choice of station.

In the Army you can travel, learn and earn at the same time.

You may think Army pay low. In addition to the $30.00 a month, Uncle Sam pays for your food, clothing, rent, light and fuel. With the present High Cost of Living, why not leave all the worries to Uncle Sam? After thirty years service, you can retire on three-fourths pay plus $15.75 a month. The Army is not all work and drilling. There are movies, libraries, games, music and dances; furloughs whenever conditions permit.

Do you admire courage, honesty, square-dealing, resolution, and tenacity of purpose? You will find these qualities in men like Washington, Grant, Sherman, Roosevelt and Pershing—men developed in our Army.

This training of body, mind, and soul, and these opportunities for education, travel and adventure are more than sufficient reasons for joining the Army; but there is another and greater motive for donning the "olive drab." Do you *love* your country and would you be worthy of her? You must be willing to serve her both in War and Peace.

Have you, like Nathan Hale, "one life to give for your country? If so, join the Army!"

It would seem that the school girls are better writers on military subjects than their brothers. Of the 56 District essays, 33 were written by girls and 23 by boys. Of the three prizes two were won by girls and one by a boy. Of the ten who received honorable mention, 7 were girls and 3 were boys.

The contest was conducted under the auspices of the War Department, but the prizes were purchased by the "Come-Back," the official newspaper organ published for the benefit of wounded soldiers at Walter Reed General Hospital, Washington, D. C. The essays were written in the school class-rooms on February 20th last, and the principal of each school selected one essay as the best product of his institution. The District Recruiting Officer then appointed a Board of three judges to pass on the essays submitted by the schools of his District, and those selected were sent to the National Board of Judges in Washington, whose decision was announced to-day.—*War Dept. News Bureau.*

Reinforced concrete freight car.—A concrete gondola is an innovation in railway equipment. The frame is of steel and the walls and floor of light-weight concrete with burned clay aggregate. The capacity is 100,000 pounds, and the weight 53,600. The car has now been in service 9 months.—*Concrete and Const. Eng.*

Governmental Investigation of River and Harbor Improvements

By

A. H. Ritter

Chief Clerk, Board of Engineers for Rivers and Harbors

Introductory Remarks

From time to time in recent years articles have appeared in periodicals of the country purposing to expose a wanton waste of public funds in connection with the improvement of our rivers and harbors. Quite frequently these articles are by professional magazine writers whose lack of knowledge concerning the conduct of this important work is exceeded only by their desire to create a sensation and their reckless indifference to the truth.

Those who really know the subject and who have undertaken to present it in the proper light have experienced difficulty in finding a medium through which to reach the public. The publications that lend themselves to "muckraking" attacks are in general unavailable for the presentation of the sober and non-sensational truth. It is with a sense of propriety, therefore, that THE MILITARY ENGINEER furnishes space for an article concerning one phase of the duties of the Board of Engineers for Rivers and Harbors, written by its chief clerk, Mr. A. H. Ritter, who having been with the Board practically from the date of its organization in 1902, may be credited with a knowledge of the subject whereof he speaks. His paper was inspired by certain articles in a well-known weekly periodical, containing references of a derogatory nature in regard to the work of the Board, and to these Mr. Ritter's account may be accepted as an adequate reply. The article is followed by a discussion by Col. Charles Keller, Corps of Engineers, who, since his return from France, has been resident member of the Board, of which he was also a member prior to his assignment to duty abroad.

The Board is constituted under authority of Section 3 of the Rivers and Harbors Act of June 13, 1902. Authorship of this piece of legislation is generally accredited, and it is believed rightfully, to the Hon. Theodore E. Burton, late chairman of the Committee on Rivers and Harbors of the House of Representatives, at that time accepted as a real friend, and one of the most influential, while also cautious and economical, advocates of waterway improvement.

Prior to 1902, preliminary examination and survey reports were prepared by the district engineers, except in the comparatively limited number of cases where special boards were appointed. The recommendations submitted varied not only with the importance of the project involved, but also with the individual judgment of the reporting officers, for, strange as it may seem, engineer officers under the same system of education and training, in common with people of all classes, do, did, and will differ in their views. Similar arrays of facts with respect to physical conditions, cost, traffic, and commercial prospects, may naturally be expected to appeal to the young and the optimistic while appearing doubtful to the mature and the conservative, and absolutely without merit to the superannuated, pessimistic or dyspeptic. It was with a view to eliminating these temperamental inequalities and standardizing the conditions precedent to a favorable recommendation for improvement, that the idea of the creation of this Board of Review was conceived.

As originally constituted the Board was composed of Col. A. Mackenzie, Maj. Harry F. Hodges, Maj. Edward Burr, Capt. C. H. McKinstry, and Capt. W. V. Judson. The list of officers later detailed for duty with it includes such names as Rossell, Kingman, Black, Beach, Abbot, Newcomer, Winslow, Flagler, and Harding. The present membership is—Col. W. C. Langfitt, Col. J. C. Sanford, Col. Harry Taylor, Col. Charles Keller, Lieut. Col. Jas. P. Jervey, Lieut. Col. John C. Oakes, and Maj. Max C. Tyler. It seems almost incredible that anyone with knowledge of the professional qualifications, character and reputation of such men as these and their associates, would intentionally call in question their motives as members of this Board.

At this time, when there is a strong agitation throughout the country in favor of economy in governmental construction, it should be of interest to the nation, and especially to the engineering profession, to learn that governmental expenditures on rivers and harbors are not made with reckless disregard of the taxpayers' rights, as certain ill-informed persons would have us believe.

This article indicates that there is a tendency on the part of Congress to gradually enlarge the advisory powers of the Corps of Engineers, and to repose greater and greater confidence in its judgment and advice. This is a confidence which the Corps has earned in over a hundred years of faithful service, strict observance of the law and the expressed wishes of Congress.

The Corps of Engineers is well qualified by its long and varied experience to study and formulate comprehensive plans for waterway improvement and development. While, as stated by Col. Keller, the final determination of our waterway policy is a function of statesmanship, the Corps of Engineers is prepared to conduct the necessary studies and investigations and to make intelligent recommendations on the whole policy or any phase of it, to the extent the Congress may decree. There would appear to be every reason why its powers to do so should be enlarged, it being borne in mind that these powers are advisory only. Congress is not bound to accept any recommendation of any corps or department unless the evidence presented is indisputable and convincing, and the recommendations based upon the evidence and sound and practicable in themselves.—ED.

Erroneous accounts in current periodicals

IN the recent past, certain writers for the daily press and current periodicals have attempted to explain the procedure of the investigations made to determine the advisability of proposed river and harbor improvements. It is a commentary on the knowledge or the candor of these writers to note that they seldom, if ever, correctly state the facts. To those familiar with the subject, it is not difficult to trace the source of much of the misinformation given in articles appearing in the popular magazines, and while it is not claimed that the writers intentionally deceive, yet they certainly make no effort to verify information furnished by opponents of river and harbor improvements, and it is not right to make statements one does not know to be true. The public appetite for sensation, even for scandal, is keen, and muck-raking is more interesting than prosaic truth. So far as is known, complete and accurate accounts of the procedure in determining the advisability of river and harbor improvements have never been published, and it seems opportune to present some information on this subject for the benefit of those who prefer facts to fiction.

Procedure in river and harbor legislation

Legislation pertaining to river and harbor improvements is under the jurisdiction of the Committee on Rivers and Harbors of the House of Representatives, and the Committee on Commerce of the Senate. In common with other appropriation acts, the river and harbor bill originates in the House of Representatives.

Digitized by Google

The first section of the bill is always devoted to appropriations for improvements, and a separate section contains a list of localities to be examined with a view to determining the advisability of improvement. This list of localities is made up by the Committee from the many requests received by it from members of Congress and others interested. The investigations are called "Preliminary examinations," and it is expressly provided by law "That no preliminary examination, survey, project, or estimate for new works other than those designated in this or some prior Act or joint resolution shall be made." The procedure also requires that, "In all cases where preliminary examinations and surveys are authorized, a preliminary examination of the river, harbor, or other proposed improvement mentioned shall first be made and a report as to the advisability of its improvement shall be submitted, unless a survey or estimate is expressly directed. If, upon such preliminary examination the proposed improvement is not deemed advisable, no further action shall be taken thereon without the further direction of Congress; but in case the report shall be favorable to such proposed improvement, or recommends that a survey and estimate should be made to determine the advisability of improvement, the Secretary of War is authorized, in his discretion, to cause surveys to be made, and the cost and advisability of the project to be reported to Congress."

After the bill is passed by the House, it goes to the Senate and is referred to the Committee on Commerce, which usually includes additional preliminary examinations.

As is well known, the work of improving our rivers and harbors is under the jurisdiction of the Chief of Engineers, United States Army. It is carried on through some fifty district offices located chiefly in the larger cities, each district being normally in charge of an officer of the Corps of Engineers, who is known as the District Engineer. In addition to duties connected with the actual construction work involved, this officer is charged with making investigations specifically called for by Congress with a view to determining the advisability of undertaking new improvements, or of extending or modifying those already in progress.

For many years, the District Engineer sent his reports on examinations and surveys directly to the Chief of Engineers, who, in accordance with the law as it then stood, frequently forwarded them to Congress without recommendation. This condition is now changed and reports on examinations and surveys are now required to include specific recommendations as to worthiness or advisability which, in turn, are based upon commercial benefits or economies likely to result from the proposed work.

There are now, however, a number of Division Engineers, through whom all these reports in each corresponding geographical division must be forwarded. These Division Engineers are generally officers of high rank and are selected because of their particular qualifications for the supervision of the District Engineers.

The present policy of having "preliminary examinations" precede surveys was inaugurated by Congress in the river and harbor act of 1890, but prior to that date the making of examinations, surveys, or both, at localities designated by the different acts was, as a rule, left to the discretion of the Secretary of War, and where an examination made prior to 1890 sufficed for the preparation of a project and estimate the survey was omitted as unnecessary.

Creation of the Board of Engineers for Rivers and Harbors

Section 3 of the river and harbor act of June 13, 1902, provides for the organization in the office of the Chief of Engineers, by detail from time to time from the Corps of Engineers, of a board of five engineer officers (later increased to seven) whose duties shall be fixed by the Chief of Engineers, and to whom shall be referred for consideration and recommendation, in addition to any other duties assigned, so far as in the opinion of the Chief of Engineers may be necessary, all reports upon examinations and surveys provided for by Congress, and all projects or changes in projects for works of river and harbor improvements theretofore or thereafter provided for. And in the consideration of such works and projects the board shall have in view the amount and character of commerce existing or reasonably prospective which will be benefited by the improvement, and the relation of the ultimate cost of such work, both as to cost of construction and maintenance, to the public commercial interests involved, and the public necessity for the work and propriety of its construction, continuance, or maintenance at the expense of the United States. It is further the duty of the board, upon request to the Chief of Engineers by the Committee on Commerce of the Senate or the Committee on Rivers and Harbors of the House of Representatives, in the same manner to examine and report through the Chief of Engineers upon any projects heretofore adopted by the Government or upon which appropriations have been made as to the desirability of continuing the same or upon any modifications thereof which may be deemed desirable. This provision of the law was extended by act of March 3, 1905, to require the board upon request of the committees of Congress specified above to examine and review surveys as well as projects provided for by acts or resolutions prior to the river and harbor act of June 13, 1902, and it was further modified by the act of March 2, 1907, to include consideration of any examination or sur-

Digitized by Google

vey made pursuant to any act or resolution of Congress.

Increase in scope of duties

Section 13 of the act of March 3, 1909, increased the scope of preliminary examinations and surveys by providing that every report therein ordered shall contain such data as it may be practicable to secure regarding (first) the establishment of terminal and transfer facilities, (second) the development and utilization of water power for industrial and commercial purposes, and (third) such other subjects as may be properly connected with such projects. It further provided that the investigation and study of these questions may, upon review by the board, "when called for as now provided by law, be extended to any work of improvement now under way and to any locality the examination and survey of which has heretofore been, or may hereafter be, authorized by Congress." Section 6 of the same act requires the board to pass upon all modifications in plan and location involved in the reconstruction of any lock, canal, canalized river, or other work for the use and benefit of navigation, for which expenditures are authorized by that section.

The provisions relating to terminal and transfer facilities, water power, etc., were renewed in the act of June 25, 1910, and extended to apply to all examination and survey reports hereafter provided for. The required investigation of these questions was considerably amplified by the act of July 25, 1912.

Outline of procedure. Publicity

From the above, it will be seen that Congress initiates each investigation by including in a river and harbor act direction for the making of a preliminary examination. The duty of making this examination is assigned to the proper District Engineer, who undertakes a study of the physical and commercial situation. He obtains as much definite information as possible regarding the character, scope, and alleged advantages of the desired improvements as the commercials interests, at whose solicitation the examination has usually been ordered, are able to furnish, and he holds amply advertised public hearings to enable the views of all persons advocating or opposing the improvement to be ascertained. In accordance with law, no estimates of cost are included in the report on preliminary examination, but the field examination of the physical conditions is sufficiently thorough to enable him to judge whether the cost will be reasonable in comparison with the money value of the probable benefits of the improvement. If the conclusions of the District Engineer are favorable, he recommends that a survey or estimate be authorized, and similar recommendation is permissible if he considers that a survey is necessary in order to reach a decision. If his conclusions are unfavorable, he notifies by letter all persons known to be interested, giving briefly the reasons for his conclusions, and invites them to submit statements and arguments, or within four weeks, to apply for a hearing to the Board of Engineers for Rivers and Harbors. His report is then transmitted to the Chief of Engineers, through the Division Engineer, who also gives his views on the matter.

Upon receipt of a report on a preliminary examination by the Chief of Engineers, it is referred to the Board of Engineers for Rivers and Harbors. The Board then makes a detailed study of the engineering, commercial, and economic questions involved, and if the report of the District Engineer is unfavorable, before submitting its report, it awaits the expiration of the four weeks allowed for appeal by interested parties. In case the report of the District Engineer is favorable, but the Board is unable to concur in his findings, it causes notices to be sent to all interested parties, advising them of this fact, and giving them an opportunity to be heard. If the Board concurs in a favorable recommendation of the District Engineer, it recommends the authorization of a survey, or a plan and estimate of cost, if a survey is not required, as a basis for formulating a project. In case of an unfavorable report on the survey, the same procedure as to notification of interested parties is followed. It will thus be seen that at every step the interests concerned are given ample opportunity to establish the merits of the improvement desired.

At this point, it is appropriate to remark that the object of the public hearings given by the Board is to secure facts, and that mere expressions of interest or general commendations of proposed improvements unsupported by facts, have little weight. The questions involved are susceptible of solution only by consideration of definite evidence. The most valuable evidence is usually given by men directly connected with the use of the improvements. Thus, in the case of the channel at Pollock Rip, Massachusetts, the testimony which served to finally convince the Board of the desirability of undertaking certain work at this locality, was furnished by a vessel captain who knew very little about politics, but a great deal about navigation. In contrast with this case, there are others in which strong delegations of influential citizens backed by their Senators and Members of Congress, have failed to produce the evidence necessary to secure a favorable decision. As many persons who have been before the Board can testify, there is no judicial body more conscientious in its decisions, and more immune from political influence than is the Board of Engineers for Rivers and Harbors. Those of us who are familiar with the work of the Board can recall more than a few instances in which the Board has reversed the findings of one of its own members, who, as District or Division Engineer, had reported in favor of a proposed improvement.

Digitized by Google

Decisions based on economics, not politics

It is obvious to all students of commercial and economic problems that there may be honest differences of opinion regarding the best solution in any given case, and it is not to be expected that in all instances the solution will meet universal approval. There is no objection to honest criticism as to the wisdom of a recommendation, and in fact such criticism is desirable, but there is clearly a rightful objection to expressions designed to impugn the integrity of those responsible for the execution of the processes laid down by law. It has been alleged, in effect, that the Board is unduly influenced by the desires of Congress. In contradiction of this charge, it may be stated that the Board gives no consideration whatever to the distribution of improvements according to their geographical location, nor does it takes any notice of the theory, occasionally heard, that governmental assistance should be apportioned in proportion to the local contributions to the national treasury (the "Pork Barrel" policy). Each proposition is considered on its merits and the verdict is favorable only when the evidence shows that the return to the public in general, and not merely to the locality, will be adequate.

Number of unfavorable reports

In a recent issue of a well-known weekly magaz ne, it was stated that "some five or six hundred projects for waterway improvements, each and all duly approved and recommended by the expert engineers, have been held up at the Capitol." Here is a plain statement easily susceptible of corroboration or refutation, so as to give some hint as to the dependence which can be placed upon other statements appearing in the same article.

From its organization in 1902 to January 1, 1920, the Board submitted a total of 1,986 reports on investigations ordered by Congress, of which 679 were favorable and 1,285 were unfavorable. In 22 cases, there were no recommendations as to worthiness. The details are as follows:

Authority for investigation. Acts of—	Investigations ordered.	Reported on to Jan. 1, 1920.	Favorable.	Unfavorable.	Per ct. of favorable reports.
June 13, 1902	170	170	52	118	30.6
Mar. 3, 1905	176	176	74	102	42.0
June 28, 1906	2	2	1	1	----
Mar. 2, 1907	200	200	108	92	54.0
May 28, 1908	1	1	1	------	----
Mar. 3, 1909	274	274	120	154	43.8
June 25, 1910	187	187	62	125	33.7
Feb. 27, 1911	90	90	28	62	31.1
July 25, 1912	226	226	70	156	31.0
Mar. 4, 1913	122	119	43	76	36.1
Mar. 4, 1915	219	210	42	168	20.0
July 27, 1916	128	112	15	97	13.4
Aug. 8, 1917	84	59	5	54	8.4
Mar. 2, 1919	53	6	----	6	----
Resolutions	*157	154	58	74	----
Total	2,089	1,986	679	1,285	34.2

*No recommendation as to worthiness in 22 cases.

Of the 679 cases favorably recommended, Congress has appropriated for 541, leaving 138 not adopted. From the latter figure must be deducted, however, those rendered obsolete by later recommendations. In explanation of this necessary deduction, several typical cases may be cited. In 1902, the Board recommended the improvement of Wrangell Narrows, Alaska. Subsequently, an examination of Dry Straits, Alaska, was authorized, and upon investigation it appeared that Dry Straits afforded a more desirable passage than Wrangell Narrows, and it was accordingly recommended *in lieu* of the latter. There are also many cases of investigations ordered by Congress at localities which the Board had previously reported as worthy of improvement, and the adoption of the second recommendation frequently rendered the first one obsolete. An example of this kind is the Hackensack River, for which the Board recommended an improvement to cost $60,000 but after a later investigation recommended a more extensive improvement costing $171,018. The latter project was adopted by Congress. In this case, the restriction of the law made it impracticable for the Board to report on a project of adequate scope on the first investigation.

There are also a number of cases where favorable recommendations were later superseded by unfavorable recommendations because of changed conditions since the first report was rendered. Examples of this kind are Wickford Harbor, R. I., Manchester Harbor, Mass., and Cohasset Harbor, Mass.

Of the 138 cases not adopted by Congress, 54 have been superseded by reports which have had the effect of revoking the first recommendations, leaving before Congress at present only 84 favorable reports which could be made the basis of action. The details are shown in the following table:

Authority for investigation.	Favorable reports.	Adopted by Congress.	Superseded and obsolete.	Not adopted by Congress.	Estimated costs of improvements recommended but not adopted.
June 13, 1902	52	30	17	5	$2,154,980.00
Mar. 3, 1905	74	67	5	2	136,750.80
June 28, 1906	1	1	--	0	----------
Mar. 2, 1907	108	96	6	6	479,048.00
May 28, 1908	1	1	--	--	----------
Mar. 3, 1909	120	102	16	2	34,300.00
June 25, 1910	62	55	--	7	5,837,700.00
Feb. 27, 1911	28	24	2	2	42,468.00
July 25, 1912	70	44	4	22	7,862,820.00
Mar. 4, 1913	43	23	2	18	5,780,720.00
Mar. 4, 1915	42	28	2	12	13,351,145.00
July 27, 1916	15	11	--	4	526,800.00
Aug. 8, 1917	5	3	--	2	150,000.00
Resolutions	58	56	--	2	111,800.00
	679	541	54	84	$36,468,531.80

Due to the great increase in cost of labor and materials during the last two years, the estimates contained in many reports submitted prior to 1916 are inapplicable, and there are now only a very few

Co-operation of Aeroplane Searchlights in Anti-Aircraft Defense

By

W. F. Tompkins

Major, Engineers

NOTE:—The Engineers had charge of all searchlights operated by the American Expeditionary Forces, and of training, supply and development in the United States and in France. The searchlight organization consisted of the 56th Engineers, ten companies of 250 men each, under command of Lt. Col. J. C. Gotwals, Engineers, who directed all searchlight operations of the American Army in France. The entire 56th Engineers was in France at the time of the armistice. Three companies were with the American 1st Army, operating 42 searchlights, and two with the 2nd Army, operating 16 searchlights. In addition they manned the searchlight defenses around Is-sur-Tille and Colombey-les-Belles. The remainder of the regiment, not thus employed, was in training. Many of our searchlight troops had received previous training and had seen service with the French and British armies in the operation of searchlights.

The Engineers in the U. S. Army are charged with the development and supply of searchlights for all purposes and with the operation of mobile units. They accordingly operate all searchlights except those at permanent (sea-coast) fortifications, or semi-permanent land defenses of important cities, railroad or industrial centers. It is regarded as desirable that the same service should operate all the correlated equipment of a semi-fixed searchlight installation.—ED.

Bombing and bombing machines

THE importance of bombing in warfare is now well recognized by all of the leading nations. During the past war bombing machines were constantly increasing in size, and cruising ranges were continually extended. The size of the projectiles and the quantity of explosive carried were similarly increasing. It became more and more difficult to withdraw troops to billets where they could rest and recuperate in safety. Large dumps, rail heads, bridges and other items of military value were not only most seriously and constantly threatened, but actually destroyed in vast quantities. The greatest cities, such as Paris and London, were subjected to bombardment from the air, and thus the civilian population found itself in closer contact with the enemy and more or less open to demoralization, with its consequent tendency to weaken the resistance of the allied nations against the common enemy. Smaller cities, such as Amiens, Nancy, Peronne, Bapaume, Abbeville, Bar le Duc, were greatly damaged or nearly wiped out by aerial bombardment. The fact that the enemy received similar punishment was satisfying, but did not prevent the destruction visited on Allied territory.

As defenses against aerial bombardment became stronger, day bombing gradually decreased and more reliance was placed upon night operations. The advantage of the day bombing machine is that routes may be easily followed and objectives clearly seen. However, defending aircraft, having much greater power of maneuver and being very much faster, soon demonstrated their ability to prevent bombers from crossing the lines during daylight. The bombing machine, heavily loaded, must always fly at a comparatively low altitude and thus is constantly exposed to attack by pursuit planes, the fire of anti-aircraft artillery, and even machine gun and rifle fire. The greatest difficulty for bombing machines at night is the darkness, which is, in turn, also their greatest security. Routes of approach are hard to locate and follow and it is extremely difficult to see even a large objective. They have the great advantage of being hidden in darkness, so that the defending forces find it extremely difficult to locate and attack their targets. So far as airplanes are concerned, the most dangerous natural objection to night operations is in landing. Here the slow flying bombing machine finds another advantage over the fast pursuit planes which must combat it, since it lands without great difficulty. There is one other advantage of note in night bombing, and that is the far greater demoralizing effect upon troops and especially civilians.

Searchlights against aircraft

In order to locate the night bomber and successfully attack him, past experience has shown that he must be artificially illuminated. This not only renders him open to attack, but the searchlight beams dazzle and confuse the aviators, and, by contrast, hide objectives. The pilot and his companions are flying at night, necessarily at a comparatively low altitude, in a slow machine very difficult to maneuver. As soon as a bomber is illuminated, the realization that he forms a large target, especially unprotected in the rear, open to attack by fast pursuit planes, anti-aircraft artillery and machine guns, possesses him. The psychological effect on the aviator is very important.

Digitized by Google

Seeing nothing himself and yet seen, he soon loses hope of a successful mission. If he flies higher, the risk of losing his way correspondingly increases, and he can never rise above a certain level which is always within easy range of illumination and attack. If an attempt is made to circle the lighted area, the distances to be traveled become very much greater, with correspondingly greater chances of becoming lost or meeting with some accident which necessitates a landing in hostile territory. It is thus seen that the use of searchlights with pursuit planes and anti aircraft artillery constitute a defense against night bombing operations.

Searchlight tactics

In order to avoid becoming lost, and to find objectives, night bombing machines must follow certain clearly defined natural features, such as large rivers and river valleys, edges of great forests, coast lines, railway tracks with trains moving over them, canals, clearly defined highways and railroads. Consequently, searchlights in defense should be placed in bands along the entire front, but especially defending, by more concentration and additional depth of the lighted area, the prominent routes leading to the important objectives in the rear. The closest liaison and coöperation with other branches is essential. When hostile planes have been illuminated, they must be attacked by pursuit planes or by well-placed bursts of anti-aircraft fire. Excellent telephonic communication between searchlights, pursuit squadrons and anti-aircraft batteries is necessary. Wherever possible, listening posts should be established along the front to report back by wireless or telephone whenever hostile planes cross the line, giving their direction and other important information.

The band of lights must be continuous along the entire front, in order to avoid the encircling of flanks by bombing squadrons. If a dark gap is left in the lighted area it will soon be found and passed through by hostile aviators. The searchlights are placed in lines, and the lights in each line are staggered with respect to those in adjacent lines. Wherever there is sufficient equipment, there should be a depth of at least four searchlights. It has been found best to locate the emplacements so that targets may always be held by three beams, and this is done by placing the searchlights in quincunx order. In addition, more material should be placed so as to protect especially vulnerable objectives in the rear, in case hostile planes should penetrate the primary defenses or circle around the flanks. All positions must be selected so as to have excellent coöperation between adjacent lights, while covering as great an area as possible. It is of interest to note that, as a rule, bombing planes strike a lighted area nearly perpendicular to its length and therefore, when turning to the right or left to avoid the nearest beam, must pass obliquely through a greater distance in which they are subject to illumination.

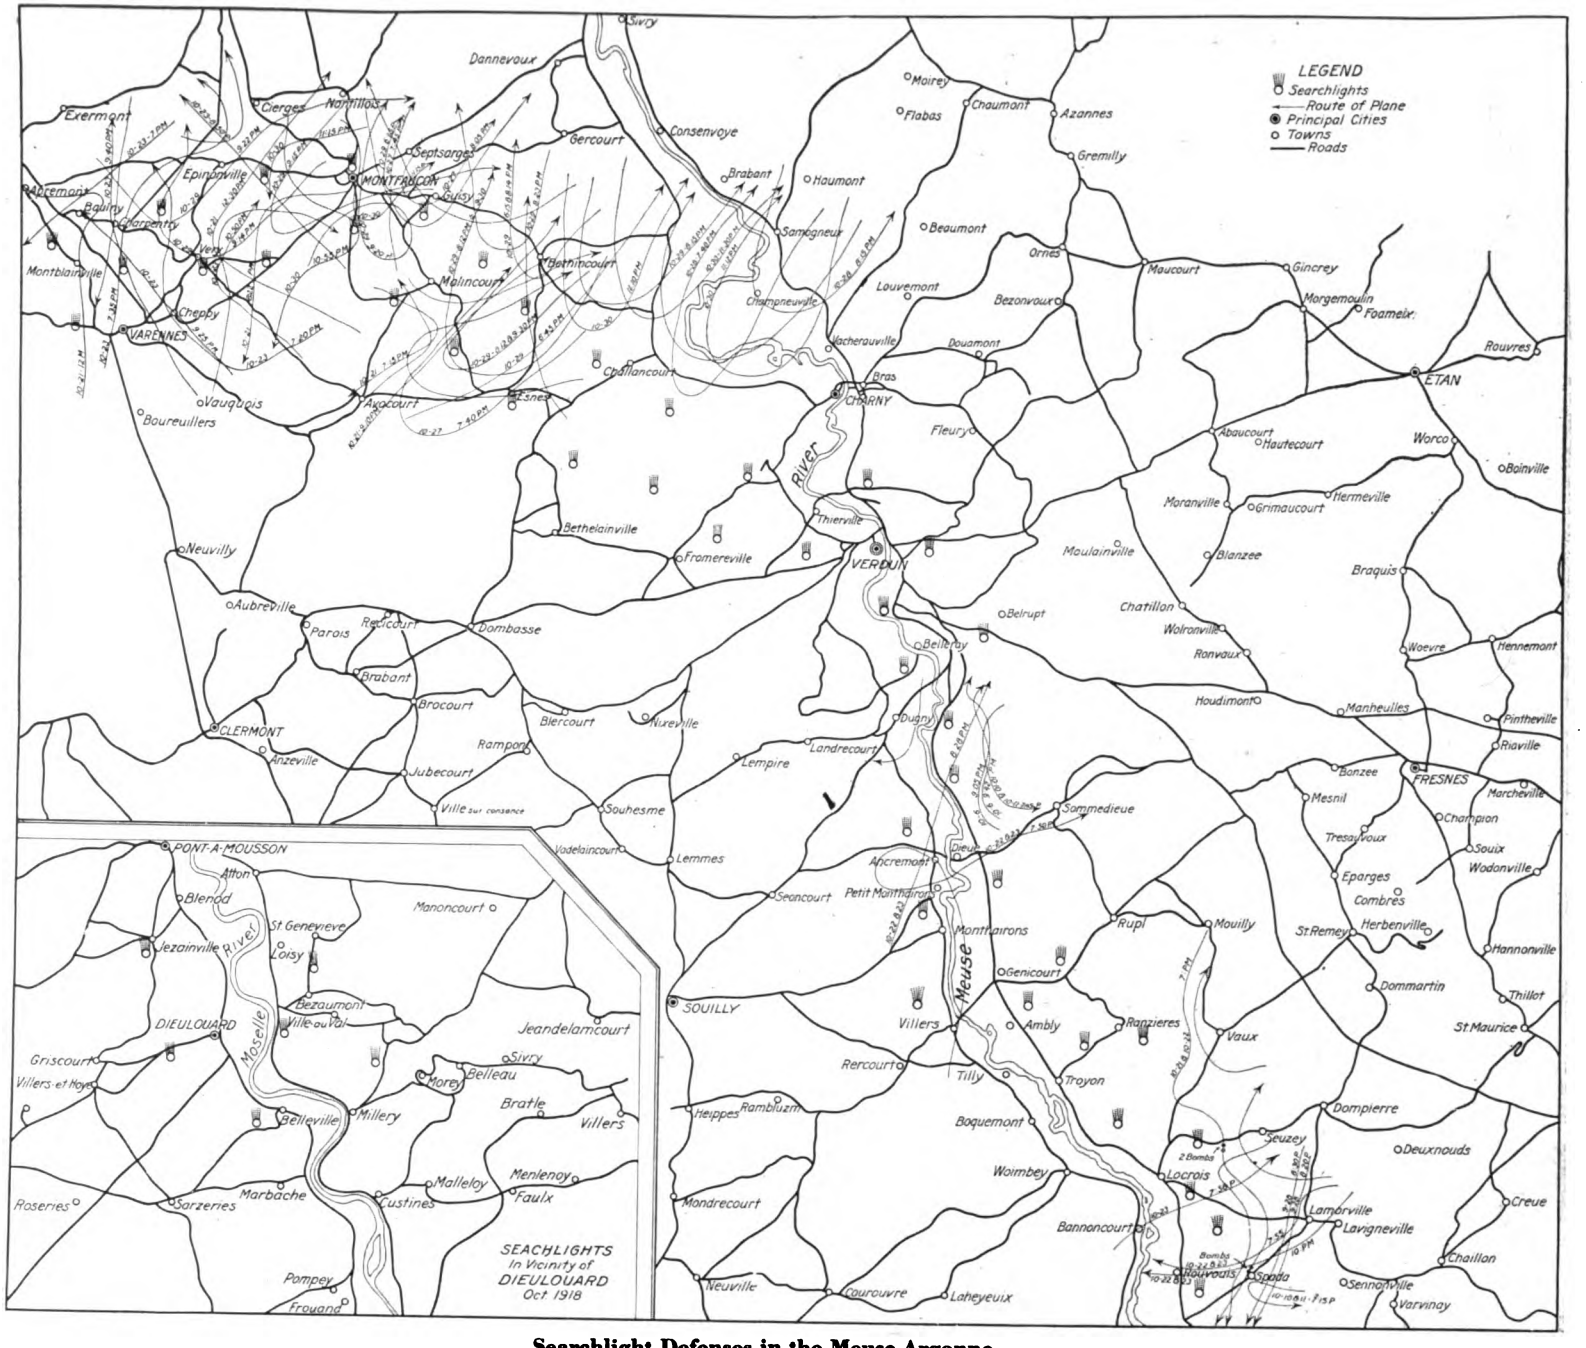
The individual locations should be on high ground to obtain a good field of view and to avoid ground mists. They should be near good roads, but preferably not main roads, since continuous traffic interferes with listening, which is essential for determining the general location of the plane before searching commences.

The map herewith shows the locations of searchlight defenses during the Meuse-Argonne offensive. This gives an example of searchlight defense, as outlined above. It is unfortunate that the contour lines are missing, as they would show why the final location was selected. The traces of hostile planes can be seen, which in general, show the effectiveness of the defenses. At the time of the armistice, searchlight equipment was becoming available in huge quantities, and searchlight troops were being rapidly trained, so that soon a closer concentration of lights would have been assured and the lighted area doubled in width. It is confidently believed that the defenses would have been nearly impregnable.

Night pursuit squadrons

During the early part of October, 1918, at a conference at First Army Headquarters, it was decided to utilize a squadron of pursuit planes in coöperation with searchlights and anti-aircraft batteries for defense against hostile night bombing machines, and by the middle of that month the general plans and details had been drawn up. It should be noted that the British, employing only one squadron, the 151st Squadron, Royal Air Force, had already met with marked success in night air defense, bringing down 25 bombing planes after illumination by searchlight beams during the month of August, with the loss of not a single plane or aviator. American searchlight units had coöperated with British searchlights during this remarkable period of successful defense against night raiders, at a time when strategical considerations and exceptional weather conditions called for great activity by the enemy's bombing squadrons.

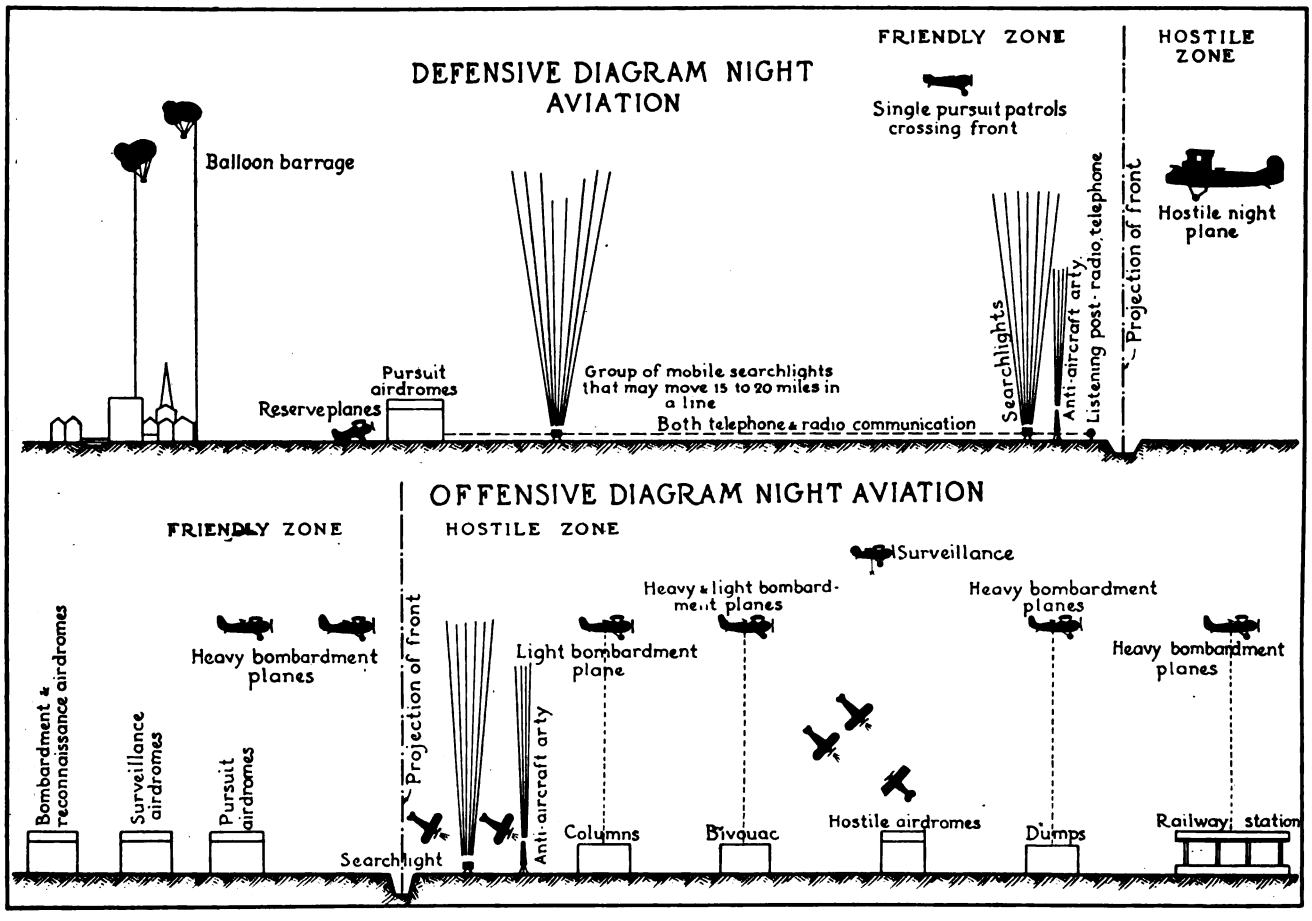
The adoption of this policy had had great advantages in that the anti-aircraft defenses were made more effective, and were greatly increased. In order to clearly illustrate how these advantages resulted, the actual plan adopted will be detailed briefly.



The pursuit planes defended the following areas:

(1) From La Croix-sur-Meuse to Verdun.
(2) From Verdun to Varennes.

The anti-aircraft batteries defended the following areas:



(1) The area south of a line running east and west through La Croix-sur-Meuse.
(2) The area northeast of Verdun, between the

Digitized by Google

Searchlight Defenses in the Meuse-Argonne

Digitized by Google

Meuse River and the Verdun-Metz Highway, including Verdun.

(3) The area west of the eastern edge of the forest of Argonne and south of the lighted area.

A brief outline of the principal details of this coöperation follows:

(1) Sopwith-Camel planes with Monosoupape motors were employed. These planes were very suitable, since they were comparatively easy to land at night, easy to maneuver, climbed quickly and had rotating motors which could be shut off for quite a length of time, thus enabling the searchlight personnel (and the aviators) to listen and detect the location of the hostile plane. It is worth noting that the fastest pursuit planes, which are most suitable for day work, are not as desirable for night operations, due to the increased difficulty in landing. The night pursuit plane need only be faster than the slow-flying bombing machine.

(2) On such nights as were suitable for attack, pursuit planes patrolled over the lighted areas which were defended by planes. They flew at a very high altitude and in rear of the searchlights. Rising to about 10,000 feet, the motors were shut off, and they slowly glided to about 5,000 feet, thus leaving sufficient time for the searchlight personnel to listen and direct their beams on the target. Sound locators aided the searchlights by giving a general direction in both azimuth and elevation, thus limiting the field of search. Additional planes stood by at the airdrome ready to start as soon as an alarm was received.

(3) A searchlight officer with sufficient personnel was stationed at the airdrome to insure thorough liaison, and to operate an additional searchlight placed near the airdrome. This searchlight, by directing its beam at certain prescribed angles in the air, acted as a guide for the patrolling pursuit planes, so that they would locate their landing field without difficulty. When a patrol was completed, the pilot easily recognized his guiding beam, and when he neared that beam, the ground lights could be seen and the landing signals observed.

(4) Practice was carried on by day and by night to familiarize the pursuit aviators, gunners and searchlight personnel with the details of operation, so as to avoid challenging or searching for friendly planes or firing in areas which were patrolled by pursuit planes, and similarly, to prevent pursuit planes from entering areas which were defended by anti-aircraft batteries. The night fliers became familiar with the areas to be patrolled, routes to and from the airdrome, the best positions for attack, etc.

(5) Wireless stations were installed, so that prompt signals of "alertes" (alarms) could be sent from the front line to the searchlight command post and to the airdrome. Excellent telephonic communication was also established between the searchlight command post and the airdrome; and the searchlight emplacements were connected to central switchboards at platoon, company, and searchlight headquarters.

(6) Experience has shown that a plane may land on a suitable field with the aid of the searchlight beam and no other illumination. The beam is directed across the ground and the aviator thus judges the ground line and makes his landing across the beam

Digitized by Google

away from the mirror so as to avoid being blinded by the brilliant light. On a given emergency signal from a friendly plane, all searchlights near suitable fields illuminate those fields, thus aiding the pursuit plane in making a forced landing. By this method many widely scattered locations where friendly fliers could land, when forced to, were established, and the greatest danger in night flying was materially decreased. This use of searchlights was extended so that friendly bombing planes could also take advantage of the safer means of landing at night when necessity demanded it.

(7) The illuminated hostile planes were carried near the edge of the searchlight beams and then were attacked by pursuit planes close in, from underneath and behind. Due to its greater speed and maneuvering ability, the small pursuit plane can avoid attack, and, concealed by the darkness, it suddenly attacks an illuminated large target, from a dead angle where

Sopwith-Camel British pursuit plane

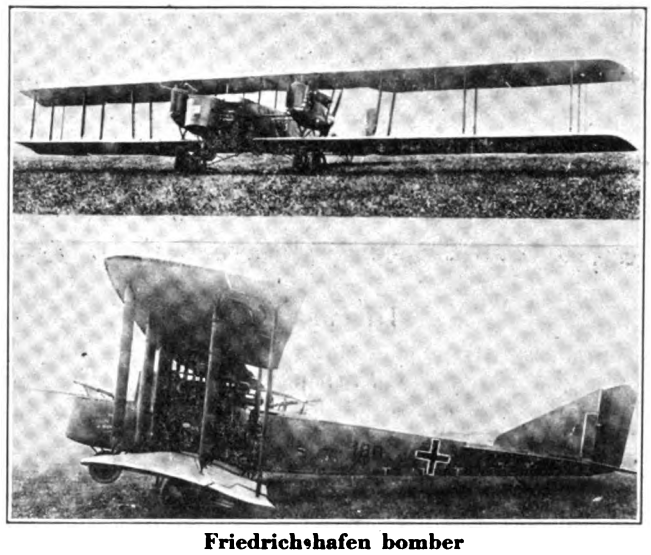
no defensive fire can be brought to bear on it. It is believed that it is not even necessary to illuminate a hostile plane, for if three searchlight beams are searching for a target and the pursuit plane flies toward the approximate intersection of these sharply defined pencils of light, there is enough twilight and reflected light from the beams themselves to enable the aviator to see his target and attack it.

(8) The anti-aircraft batteries were to put up a heavy barrage at the extremities of each patrolled area for the purpose of forcing the enemy plane into the lighted area where it could be attacked by the pursuit plane. The anti-aircraft batteries were thus concentrated much more than ever before, and if a bombing machine flew over their area, the chances of bringing it down were correspondingly increased.

(9) At the limits of the patrols the personnel at the searchlights fired a stream of tracer bullets when the friendly plane approached. This indicated that the end of a patrol was reached, so that the plane would turn back over the proper course and avoid being lost or getting into gun-defended zones.

Combined air defense tactics

The general principles for combined air defense tactics may now be enunciated:



Territory. An area must be set aside for the operations. In this area there must be thorough liaison between pursuit planes, anti-aircraft batteries and searchlights. The area should cover a natural and usual approach of enemy bombing planes.

Anti-aircraft batteries. The anti-aircraft guns must not fire over the portions allotted to defense by pursuit planes. The guns should be grouped beyond the limits of the area, in order to insure a greater length of front being protected against enemy bombing planes, and to drive enemy machines into the zone defended by pursuit planes.

Pursuit planes. They should be flying at a suitable height to quickly attack any plane when illuminated. They should fly just in rear of the lighted area in order to prevent enemy listening posts from being aware of them, to avoid preventing the searchlight personnel from listening for the enemy planes, which is essential in order to illuminate them, and to be in a better position for observing the lighted area. The airdrome of the pursuit planes should be located just in rear of the center of the lighted area which is defended by them. This gives the following important advantages:

(*a*) Greater efficiency, since it will not take the planes as long to reach the proper point in the lighted area.

(*b*) Economy of planes and pilots, since here it would not be necessary to have a plane flying over the area except when the alerte was given, or definitely expected. No continuous patrol need be maintained when bombing operations are possible but not probable. If the field is suitably located, there is still sufficient time when an alerte is given for the plane

Friedrichshafen bomber

to rise to the proper height and reach the place for attack.

(*c*) Less chance of accident to machine and pilot, since the distances to be traveled to and from the landing field are greatly shortened, while the number and length of flights will be correspondingly decreased. When an alerte is finished, the aviator may land immediately, but if the airdrome is a great distance away, the patrol must be continued in order that the pilot may be ready for a second alarm.

Searchlights. They should cover as great a length of front as is consistent with making the defenses ef-

Digitized by Google

fective. When resources are sufficient and a continuous band of light has been placed across the front allotted to the army, the remaining searchlights should be used to broaden the lighted area. The searchlights must illuminate enemy bombing planes for a length of time sufficient to allow the friendly pursuit plane to attack them successfully. The searchlight beams must not be exposed until the hostile machine is well into the lighted area. If beams are exposed too soon the bomber will turn back from the zone, while if searching is commenced only after the target is well into the area, the chances of illuminating him no matter how he flies, are excellent.

General. It is believed that, in the future, the principal use of army searchlights will be in conjunction

90 cm. Harley searchlight with paraboloid

with the air service to combat night bombers. The economy, as well as the efficiency, of this method of air defense is apparent after even a casual study. One pursuit plane can patrol an immense area. Two or three others, all manned by skilled pilots such as America has shown herself capable of developing, located at a convenient field to furnish reinforcement and relief, are all that is necessary.

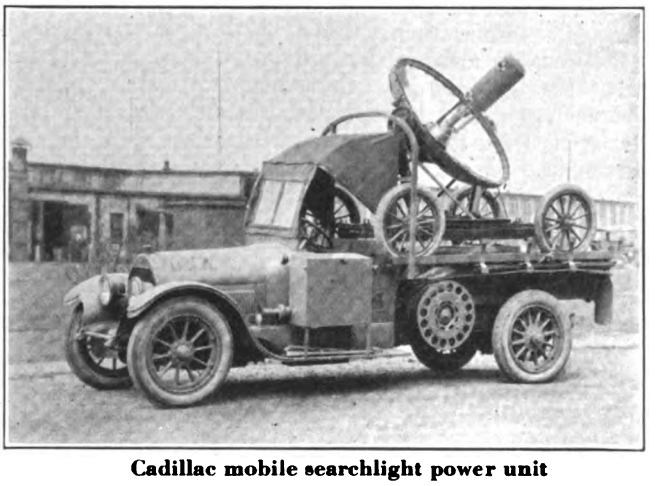
Discussion

J. P. Hopkins

Colonel, C. A. C.; formerly Chief of Anti-Aircraft Service, A. E. F.

The author of this article was one of the searchlight officers in the Anti-Aircraft Service in the A. E. F., and knows his subject thoroughly. Whatever can be added has probably been considered by the author and deleted. With this warning to the reader and with apology to the author, the following remarks are submitted.

The gasoline engine for running the searchlight can be started and the light put in operation very quickly, but the beam is kept covered by a shutter until the proper instant for its exposure. A listening apparatus (supposed to be available) mounted near the searchlight, determines the direction to the plane. Of course the plane is always ahead of the direction in which it is heard and proper allowance is made for travel of the plane during the time of transmission of its sound. The direction to the plane is continually communicated to the searchlight so that the axis of the light can be made to follow the plane continuously. The shutter is opened at any desired instant after the light has received proper setting.



As soon as the light is flashed, an observer with field glasses can usually spot the plane. If the plane is not already covered, the observer directs the light on to the plane. If this fails, the light is continually directed from the listening apparatus so that the beam is always approximately on the plane.

Illumination which makes the plane visible from the ground is ideal but not essential. In addition to the "twilight" illumination it was found in the London defenses that the beam would penetrate a fog or mist so as to be effective for the pursuit plane even when observation from the ground was impossible.

The light is never flashed except when directed toward a hostile plane, so that the pursuit patrol knows there is always a hostile plane near a beam. Two intersecting beams locate a plane with fair accuracy.

A plane has less than one chance in ten of getting through a searchlight area without being illuminated. If the patrol can get sight of the bomber, the chance is ten to one that the enemy will be brought down. The difficulty is in having the patrol near enough to catch the bomber as he passes. Organization in depth of searchlight area, so that illumination can be continued by successive lights, adds to the pursuit patrol's chances of overtaking the bomber. A patrol may follow a bomber into gun area by giving a prearranged signal flare or light to prevent the guns from opening fire.

The defense of back areas is greatly strengthened by the use of protective balloons. These are simply obstacles which are effective because of the danger to the plane if it strikes the balloon or its holding cable. The British devised and used wire streamers suspended from wires connecting three successive balloons and kept taut with weights. The British, French, and Italians all found protective bal-

Cadillac mobile searchlight power unit

loons to be a complete success in that no bomber would knowingly take a path through them, and in an area where they were known to be used, would always remain at such a height as to insure safety. This reduced greatly the vertical space in which patrols would have to search for bombers in a beam. Incidentally it kept the bombers at such height that accurate bombing was impossible. The British overheard a German commander reporting upon his return from a raid over London that the route he took was "ballooned" and that he could not follow that route again.

There were two distinct plans for defense against night bombing. The plan adopted by the British and American

Digitized by Google

anti-aircraft services was to use listening apparatus as a means for directing search lights; then to attack the illuminated target with anti-aircraft guns or with pursuit planes.

The French plan was in general to determine the path of the plane and its height by means of listening apparatus and plotting boards from two or more stations, and with data thus obtained, to place a barrage or successive barrages in the immediate path of the plane with all guns within reach. American anti-aircraft artillery was instructed in the French system as a supplementary means of defense. The French had developed the search-light system previous to the first raid on Paris in 1918. They changed to the other system immediately thereafter, and continued "fire by sound" to the end. In subsequent raids on Paris, only 26 planes out of an aggregate of 453 sent over, actually reached Paris. In the absence of anti-aircraft defense, each hostile plane might have reached its objective and delivered its load of bombs with fair accuracy, so it is fair to credit the anti-aircraft defense of Paris with being at least 94 per cent efficient. In addition, hardly a German plane returned from Paris unwounded; twelve were brought down: either shot down or forced to land in French territory from wounds received from the Paris defenses.

As for the other system, 34 German planes took part in the last raid on London on the night of May 19-20, 1918. Three of these were shot down by anti-aircraft artillery; three were brought down in England by pursuit planes; one crashed in England as result of engine failure possibly caused by anti-aircraft fire; and three were lost in Belgium in returning. Of the thirty-four planes in the raid, thirteen actually arrived over London, but eleven, or 30 per cent, were destroyed.

John C. Gotwals

Lieutenant Colonel, Engineers; formerly Commanding 56th Engineers, Searchlight, A. E. F.

Major Tompkins presents a phase of warfare which was seen for the first time in the World War, and one which was under development when the war ended. It is unfortunate that a deeper and more general impression could not have been made upon our army as to the efficacy of the methods described. Major Tompkins has performed an important duty in describing in this clear way, the really remarkable work done in France. There is no thought of looking backward in so doing, and reward has already been given in the consciousness of difficult work honestly and zealously performed, but we must look forward.

An aeroplane carrying twenty passengers has operated uninterruptedly between London and Paris daily for five months. Nor is this alone in the post-war aeroplane achievements. Lord Fisher recently said that floating battleships were obsolete in view of the possibility of attack by bombing planes. We must realize the amazing change which the present development of aeroplanes has brought about in warfare and the possibilities of the same in the future. We must realize now the power of the bomber and prepare a defense against him rather than wait until thousand pound bombs dropped from night bombers crossing the lines by hundreds in the next war, give us the dangerous proof of his power. The night bomber will cross the lines in such numbers and will drop bombs of such size in the next war. We may prepare for it now if we wish. The tactical, as well as the economic advantage of delivering explosives to the enemy in cheaply fabricated bombs, carried by a night bomber, is obvious. To combat the night bomber, we have the various means of defense, pursuit planes, searchlights, artillery, machine guns, smokes and camouflage. Experience in this defense has confirmed the following:

Combating the night bomber calls for an organization for carrying on war In the air at night.

This seems self evident, but the belated use of the pursuit plane against the night bomber in France, showed that this simple principle was not promptly recognized.

A word in reference to searchlight material seems worth while. The material for searchlights, while it should be brought to the highest possible state of perfection by electrical engineers, must not be such that only an expert electrical engineer can obtain service from the same. The more or less humorous picture still left of the operation of searchlights placed in the hands of troops before this war must never be seen again. Such a searchlight after protracted labor, much to the surprise of all observers, would finally strike the arc and thereafter promptly sputter away into darkness by virtue of the ingenious and cumbersome "automatic" control which had been so cruelly inserted between the entirely innocent power plant and the arc. The simple mechanisms and power plant with a simple, dependable mechanical pipe control developed in France, must continue in use or be improved upon in the direction of simplicity.

As to personnel, intelligent, well disciplined soldiers only are necessary. High technical attainments in electricity and physics are all worth while, but not indispensable.

A correct picture of the mobility demanded of searchlight units must be given. The method developed in 1918 and prosecuted in the closing months of the war of moving the searchlights forward with the advancing line will prevent an enormous amount of bombing. The demands made upon every one in the searchlight units to secure mobility are very great. Light and power plant must be dug in, movements made over crowded roads, searchlight positions selected, telephone lines and wireless set up and constant co-operation with the neighboring flyers and artillery secured. The conditions of service for searchlight units operating continually behind the lines are very similar to those of pioneer engineer regiments with combat divisions. The service of one searchlight company in France which was continually in advanced positions in very active sectors from May 1st until the armistice, has left a very distinct impression upon me of the demands made upon searchlight personnel. For this reason, searchlight troops operating just behind the lines must be relieved at intervals for rest and refitting. To make this possible the British army plans to attach searchlight troops to divisions and thus rest these troops with the division.

Finally it is desired to present the following, which I believe now to be axioms of procedure in combating the night bomber.

(*a*) The night bomber operates with comparative security until caught and held in the searchlight beam.

(*b*) The night bomber is a good target for the artillery when held in the searchlight beam.

(*c*) The night bomber is helpless if attacked by pursuit planes after being caught and held in the searchlight beam.

Major Tompkins has presented the successful use of searchlights and pursuit planes in a very clear manner and it is thought that this paper deserves careful study. His conclusion in regard to the future use of searchlights in war, that they will be used chiefly in conjunction with the air service to combat night bombers, is entirely sound.

Tank Tactics

Extracts from an article, in "The Infantry Journal,"

By

S. D. Rockenbach

Brigadier General, Chief of Tank Corps, A. E. F.

I. History and organization

The present organization and doctrine of the American Tank Corps was developed during the late war, utilizing the experience of the French and British, and modifying their organization to suit our own needs and experience. Immediately after the arrival of General Pershing in France in 1917, a careful study was made of the Tank organization of the Allied Armies. The French at this time were using two types, the Schneider and the St. Chamond. These were artillery carriers rather than tanks, each carrying a 75 and two machine guns. As a matter of doctrine the French had, however, abandoned the idea of the tank as primarily an artillery carrier. The American Army concurred in this view, believing that the moment the tank goes into the artillery business it loses its idea, and must greatly increase its personnel for observation, special reconnaissance, indirect firing and other purely artillery functions. The French also believed a separate Tank Corps was necessary in order to maintain esprit and to insure proper training. They did not consider it practicable to have tank units an organic part of divisions, since only about 40 per cent of the Western Front was suitable for tank operations, and since further the limited supply of tanks made it impossible for them to be assigned permanently to divisions.

The British had developed a separate tank corps, and on account of the peculiarities of the terrain along their front were working with heavy tanks. They considered these tanks as belonging to the strategic reserve. Their theory of operation was that the tanks should be sent forward in a series of waves; the first going to the enemy's third lines, the second to the enemy's second lines, etc. Experience at the battle of Cambrai in 1917 showed that this method of attack was practicable, but that tanks could not hold the ground which they had captured and therefore the infantry must follow closely to take possession.

As a result of the study made by our officers, a definite organization for an American Tank Corps was recommended, and it was decided to adopt two types of tank—the Renault for a light tank, and a new model Anglo-American heavy tank. Two Renaults were sent to the United States as copies. For the heavy tanks it was decided to construct twelve hundred, England and America to cooperate in supplying the material, and the tanks to be assembled at Chateauroux and distributed among the American, British, and French Armies. Arrangements were also made for training tank personnel with the British, and for developing tank training centers in the A. E. F.

American tank units were present at St. Mihiel, using one hundred and fifty Renault tanks bought from the French. They also fought through the Argonne. During the latter part of October the effective American tank organizations had been reduced to one company, but by October 30 the Second Tank Brigade was prepared to enter the fight with one hundred and fifty light tanks.

As a result of A. E. F. experience, the proper tank organization was considered to be the following: General Headquarters of the Tank Corps at G. H. Q.; Tank Corps Headquarters with each army; tank centers for training and replacement; and ten tank brigades. Such an organization includes personnel of 21,800; 730 heavy tanks; 1,520 light tanks; 1,460 6-pounder guns (2.28″); 600 37-mm. guns. In connection with these figures the point should be noted of the great economy in personnel for a given amount of armament in the Tank Corps. The personnel to man the above artillery and machine guns, on the basis of personnel allowance in the field artillery and machine gun battalions, would be 145,000, simply for serving the guns. It must, however, be understood that a tank is not a substitute for artillery, and must have artillery support.

II. General combat principles

The tank is purely an offensive weapon, and if used during a defensive combat must be used for counter-attack only.

The tank is primarily an aid to the advance of infantry engaged in a vigorous offensive, either in the assault of semi-permanent works or in open warfare.

Tanks should never be used in operations where the other arms can advance without their aid. One reason is that what disables tanks is not so much the fire of the enemy as the wear and tear of operation. Another is that when infantry habitually attacks behind tanks it loses its initiative and morale—just as it does when it attacks habitually behind a barrage—and becomes a scavenger for the tanks or artillery.

Tanks can take anything, but can hold nothing, and there must therefore be the closest liaison between tanks and infantry, both before and during combat.

Tanks should be placed well in front of the most advanced line of the infantry, but in open warfare should be preceded by infantry scouts to locate machine guns and centers of resistance. They must, however, regulate their pace on the infantry skirmish line.

Tanks in an attack must be disposed in depth, the support tanks following the infantry support and the reserve tanks following the support tanks. This is essential to maintain the strength of an attack by the feeding in of supports and reserves; at the same time the support and reserve tanks can destroy centers of resistance overlooked by the first wave, and assist in resisting flank counter-attacks or in exploiting the success on the flanks.

The assault position should be arrived at if possible under cover of darkness. A tank attack should be launched at dawn and be a surprise attack. Otherwise, the enemy will place isolated guns to break up the attack.

Tanks should have supporting batteries to fire on anti-tank guns, in the ratio of one battery per one thousand yards of front, and should have airplanes detailed to assist them in the ratio of one per 1.000 yards of front.

Tanks must direct their fire on the elements most dangerous to the infantry, except that where anti-tank guns are located they must concentrate on these. Continuous fire should be used only in attacking batteries, as these are the

Digitized by Google

most dangerous foe of tanks. Batteries should if possible be taken in the flank or reverse, never frontally except in great emergency. In a frontal attack on a battery a tank should follow a zigzag course and use smoke screens. Movement is the best defense of tanks and smoke the next best. If they halt to make repairs they must take cover.

Even if out of ammunition, tanks should advance as long as the infantry does, for the moral effect and to attract fire. Reconnaissance during combat should be made at every halt by tank personnel with the special purpose of avoiding surprise by hostile batteries.

Infantry operating with tanks must fight their way forward in all respects as if no tanks were present. If this is understood, tanks will be called on only when strong resistance is encountered. They should be used in large numbers or not at all. Demands for tanks to do trivial things must be invariably refused. A few tanks will destroy the independence of infantry without being able to make substantial gains. Large tank units should be held intact for major operations.

III. Tactical employment of light tanks

Light and heavy tanks, as a rule, will both be in an operation. The heavy tanks precede the light tanks and infantry, especially in the first stages of an attack on works, in order to insure passage and to cover the infantry and light tanks while they clean up. *The function of the light tanks* is then to fight in immediate touch with the infantry, destroying machine guns, cutting wire and breaking up other resistance which is retarding the infantry.

The light tank combat unit is a *platoon* consisting of five tanks, which habitually attacks in line on a front of 300 to 600 yards. A platoon follows the barrage by about 75 yards and precedes the infantry by about 50 yards. In the first stages of the assault the light tanks open fire on the enemy as the barrage lifts, and thus keep them down until the arrival of the infantry. Their next function is to cut the wire. On reaching the trenches they should not attempt to cross unless the trench is narrow, but should deluge the trench with fire, and prevent the use of front-line machine guns by patrolling the front of the trenches. At this stage they should also neutralize the fire of the enemy support trenches. The first trench having been occupied by the infantry, the accompanying engineers (half a platoon for each tank platoon) at once prepare one crossing per tank platoon. The platoon then passes over in column and deploys to continue attack.

In assaulting villages, light tanks avoid the main streets and attack by flank and rear, and after taking the village pass beyond to avoid the fire of the enemy artillery.

Platoon exploitation. In a platoon sector not exceeding 600 yards, the light tanks precede the infantry, and are preceded at 150 yards by infantry scouts, whose function is to locate centers of resistance. When a scout signals that one is located, the two nearest tanks converge on it. The infantry following the tanks at once initiates attacks on any centers of resistance attacked by the tanks. If the center of resistance contains field guns or anti-tanks guns, all tanks of the platoon converge on it, attacking by flank or rear where possible, and using smoke screens and a zigzag course. The supporting infantry should at the same time open fire on the center of resistance.

A light tank company consists of three platoons and additional units. In assault two platoons attack as described above, usually separately and the third platoon acts as support for one or both, either to supply replacements or to mop up defensive centers which have been overpassed.

Company exploitation. The two platoons remaining in the front line will here usually be more than the normal interval apart. The function of the support platoon in exploitation is primarily not for replacement but as a tactical support. The support platoon should accordingly advance from cover to cover, approximating normal distance only. The radio tanks remain with the company commander, and take every advantage of cover. Of the eight reserve and training tanks, one is a repair tank and should follow the support platoon at 500 yards. The others follow at about 1,000 yards, and are normally used as replacements at the end of the first day's fighting.

A light tank battalion consists of a radio tank and three companies. The battalion attacks with one company in reserve, at 1,000 yards behind the support platoon of one of the attacking companies.

IV. Tactical employment of heavy tanks

The principal function of heavy tanks is the reduction and destruction of works in trench warfare. They are seldom used in exploitation, advance, or rear or flank guards, due to their vulnerability and rapid depreciation.

The combat unit is a *platoon* of three tanks. It attacks in a wedge-shaped formation with center tank 50 yards in advance. Each tank must have a definite route, and regulate on the infantry and barrage, but action in attack is more or less independent. Platoon attack orders specify points where tanks are to cross trenches, and also the flank to which they will patrol, so that a definite sector of trench may be neutralized by each tank. After accomplishing their mission of reducing works, tanks push forward into enemy territory.

In attacking villages, heavy tanks attack by flank or rear to avoid obstacles. An attack on a village should be started in time to neutralize or reduce it before it becomes harmful to the approaching infantry. As soon as the tanks have reduced resistance offered to the infantry, they proceed to the rear of the village to prevent the escape of the enemy.

A heavy tank company consists of three platoons, six reserve tanks and the company commander's tank. Nine tanks are employed in a company operation, the remainder as replacements. In an attack the company puts two platoons in the front line and one in support at 200 yards.

The heavy tank battalion operates along the same principles as the light tank battalion.

A tank brigade consists of one heavy and two light battalions and a repair and salvage company. It is an administrative rather than a tactical unit.

V. Tanks in special operations

Pursuit. Tanks are very effective to pursue a broken enemy. Here they will attack without immediate support of infantry, being launched in small groups along roads, and across country where possible. Their object is to break up organized bodies of the enemy, obstruct roads by killing horses or wrecking trucks, and delay the retreat. In such an operation tanks act for the most part individually.

Light tanks may be used for *advance guard work,* but only in pursuit or in a reconnaissance in force. Two tanks precede the point of the advance guard and attack centers of resistance, the remaining tanks of the platoon accompanying the reserve of the advance guard.

The use of tanks in *rear guard actions* is not permissible unless the retreating force is demoralized. When used, they should be dropped behind at critical points, and as the enemy approaches should attack vigorously, and then retreat after doing as much damage as possible.

Night operations can be conducted by tanks with infantry

Digitized by Google

support, under favorable conditions, but require very careful training of both tanks and infantry.

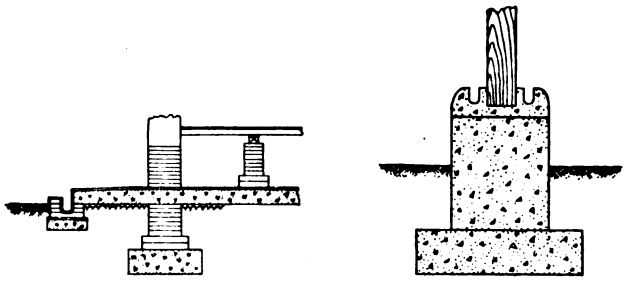
In stationary warfare, *tactical raids without a barrage* may be assisted by two tanks with the infantry. This will require a moonlight night, and the use of airplanes to drown out the sound of the tank motors. Tanks attack at 100 yards interval, cut wire and then move along the trench toward each other, clearing it of hostile troops. When they meet they return through the wire, and then cover the withdrawal of the infantry.

Tanks may be used in conjunction with *cavalry* on *strategical raids.* In this case each tank pulls a trailer wagon loaded with forage, etc., allowing the cavalry to travel with stripped saddles. The tanks are used where necessary to break up opposition to the cavalry.

Circumventing the white ant in building construction

Every race and every clime has its own difficulties. Manifestly it is part of the Creator's scheme of things that we should have them.

In our country the troubles of the engineer are due in large measure to Jack Frost and the teredo. In Formosa they are due chiefly to the termite or white ant.



The Philippine Journal of Science devotes an issue to an account of this destructive creature and his stimulating effect on man's ingenuity—from which the following statements are culled:

Because of his subterranean and aerial habits it is very difficult to destroy the termite, or to guard against his insidious attack. Also he is highly civilized, very intelligent, has an excellent system of autocratic government, including universal training for all males and females of military age.

Wooden buildings fall an easy prey to the termite. It also attacks the lime mortar in the joints of brick buildings. If the building be protected by a layer of concrete covering the entire foundation, subterranean attack is of course prevented. In this case the termite builds a tunnel of mud over the concrete foundation to reach the superstructure. Railway ties are, of course, wide open to attack. Even ships are not immune, as the ants, who are winged at certain periods of their career, fly out to the ships in the harbor.

As it is impossible to eliminate all non-resistant timbers from a building, some method of excluding the termite is necessary. The first step is to treat the site of the foundation with a heavy crude oil. All footings must be of concrete, and a layer or shield of concrete must extend over the entire area of the foundation. Around the entire outer edge of this concrete base extends a channel or drain which is kept filled with water or non-volatile oil. Thus the termite is excluded from beneath. Should the drain go dry and he be able to cross it, his tunnel is easily detected. It is essential that the concrete shield be a monolith, otherwise the termite will penetrate the joints In the Philippine Islands the concrete shield is often dispensed with, buildings being erected on concrete posts, extending well above the ground, each protected by a continuous oil channel.

But even these precautions are not enough. Unable to attack under or over ground, the termite has recourse to the air, entering the upper portions of the building.

Termite-proof building construction

A very exhaustive test of many varieties of wood was conducted and only four were found to be entirely immune from damage. These were the Philippine woods, ipil and molave, and cypress and teak. These were hardly sufficient to meet the needs, and experiments were made in the treatment of timber with various chemicals. Camphor green oil was found the most satisfactory, rendering many other woods in large measure immune from attack.

Our Motto

Editor of THE MILITARY ENGINEER:

I note with interest your discussion of the motto "Essayons" in the Jan.-Feb. number of the MILITARY ENGINEER. I agree with you that "let us try" does not meet the requirements of a present-day motto either for military or civil engineers, and I would venture to suggest a more free translation which I believe would more nearly satisfy the requirements. Instead of "Let us try" why not translate "Let us go," which when used on the march or on any kind of engineering work is usually abbreviated to "Let's go," and really means "We go to accomplish regardless of what the task may be."

To illustrate the above I give the following: My brother was with the 23rd Inf., 2nd Div., near Belleau Wood, in June, 1918, before the German drive had been turned. He was badly wounded and taken a distance to the rear and placed in an emergency hospital in a French village. After he returned here I visited him and asked him what impressed him most while in the fighting zone and his reply was about as follows: The passing of thousands of truck loads of American soldiers going towards the front from which he had just returned, with the ever sounding call "Let's go" echoing down the streets. This cry meant more than "Let us try" or even "They shall not pass," it meant to the villagers and the wounded American soldiers "They shall go back," and they did. The young Frenchmen of the village got orders to mobilize for immediate active service and they took up the American's call "Let's go" which sounded more like "Lees go" as they rushed along the street, full of excitement and desire to accomplish.

I believe that the free translation of "Essayons" to mean "Let's go" would meet the requirements of a present day motto for engineers. "Let's go" carries with it the implied meaning "We go to accomplish."

ENGINEER RESERVE OFFICER.

[We like the spirit which our correspondent breathes. It is the spirit the engineers have, and which their motto should convey. "Essayons" appears to be an elastic motto as interpreted. In the foregoing it is equivalent to "Allons!"—"Let us go." It has also been interpreted as "Asseyons!" ("Let us sit down")—expressing quite a different mood.—ED.]

Ranging Equipment of the U. S. Army

By

J. B. Cress

Lieutenant Colonel, Engineers

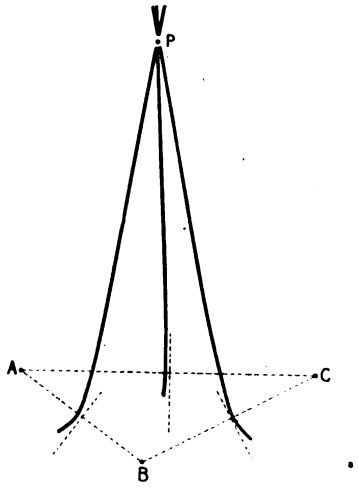
RANGING by sound and flash, to determine the location of hostile batteries and for other purposes, was one of the picturesque developments of the World War. It seemed to interest the average officer of another branch of the service as much as anything the Engineers were doing.

When the United States entered the contest, over two years of position warfare in Europe had brought about the development of remarkable ranging instruments. This development can be traced: first, to the advances of science; and, second, to the static conditions of the fighting fronts, which permitted the laying out of exact base lines and the use of complicated and delicate devices. It was, therefore, necessary, that if American forces were to use the ranging instruments of the Allies, a determination be made as to whether we should use foreign equipment of foreign manufacture, or adapt these instruments to American manufacture and develop improvements. The latter course was adopted with provision to utilize the instruments of our Allies until we should be able to put our own into production. The difference between our manufacturing methods and those of France or Great Britain involved difficulties in reproducing European matériel, appreciated by those who have encountered them. Further, any equipment to be produced in quantity in the United States should, as far as possible, be made up of American standard articles.

Ranging equipment may be divided into two general classes: the first, that which utilizes *sight*; second, that which utilizes *sound*. Sight ranging, or as it is usually called, "flash" ranging, has been used during the war both for the location of enemy guns and for the purpose of ranging for our own batteries by locating bursts. The theory of flash ranging is very simple: the methods used are based on the well-known principles of triangulation. The outfit consists of a central switchboard connected electrically to as many as six field observer stations. When an observer sees a flash, he presses a button which flashes a small electric light on the central switchboard. The observer then reads the azimuth and phones in his readings. Lights appearing simultaneously on the central switchboard indicate that the observers are on the same flash. Knowing the positions of the observers, a simple calculation gives the location of the flash.

The development of equipment for this work consisted principally of designing a telescope and a portable switchboard, American made. The problem was one of production rather than development.

Sound ranging is of several types: that which utilizes vibrations of the earth; aerial ranging, or that used with searchlights, for determining the location of aeroplanes; and, most important of all, what is commonly known as sound ranging, for locating enemy battery positions. Earth ranging is used almost entirely in mining operations. Our Allies developed a small instrument known as a geophone, which, if placed upon a rock, or solid earth, at the head of a mine, greatly increased the powers of the listener to determine what mining operations the enemy was carrying on. The American instrument, as developed and manufactured in the United States, is about 30 per cent more acute than any of the European instruments. In its improvement, special emphasis was given to making it *selective*, so that sounds, such as those produced by hammering, picking, shoveling or scraping, were distinguishable one from another.



An electrical and mechanical development of the geophone, manufactured both by our Allies and ourselves, is known as the microphone listening set. In this instrument, the listening devices are electrically connected to a switchboard and battery box, provided with a telephone head set, which may be placed in a dugout a mile or so to the rear. The observer can then listen to sounds which are received at the head of the mine galleries, or from points in No Man's Land, while he, himself, is in a position of safety. Thus it is possible for one man to listen at six places instead of one. In the American microphone, the listening device is so designed that, if buried about 3 inches under the surface of the ground, it will register both earth waves and air waves, so that the sounds of mining, or countermining, footsteps, or even conversation in the vicinity, can be picked up by the listener, far in rear.

Reports from France indicate that the geophone was in a measure responsible for the abandonment of mining operations. Microphones were used to a

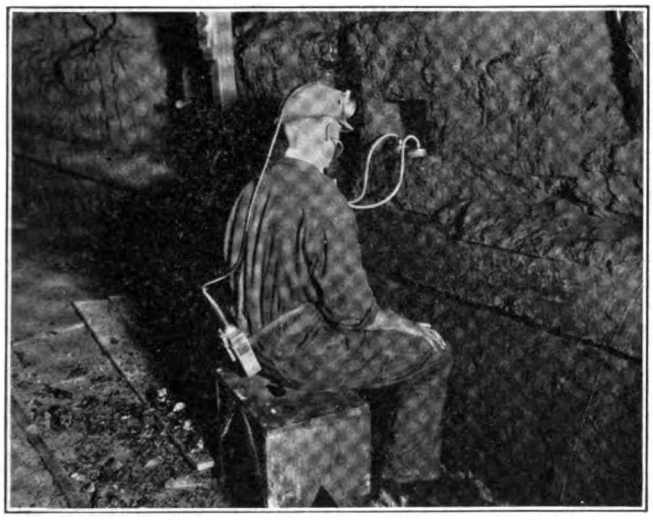
Digitized by Google

certain extent during the war, but it is believed that they are suited to much broader utilization, particularly for determining what is happening in front of outposts or strong points when no patrols are out.

The increase in night bombing operations at about the time the United States declared war brought about the serious investigation of sound ranging devices for determining the position of aeroplanes at night. It was once thought that these devices might be of practical use in connection with anti-aircraft artillery fire, but their accuracy is not sufficient to give more than an approximate direction. However,

in the case of anti-craft searchlights, a successful listening device is of great advantage. Several types of these instruments have been developed by the British and the French. The American instrument, developed from a European design, consists primarily of a paraboloid, which reflects sound to its focus, where are placed a number of listening trumpets. These trumpets are connected for two listeners: the horizontal listener directs the paraboloid so that it has apparently the same azimuth as the source of sound (when he hears the sound equally with each ear); the vertical listener, similarly, moves the paraboloid until it has the same elevation as the sound.

The principal problem of development in the United States was the production of an instrument of greater portability, and, if practicable, of greater accuracy than those used abroad. The latest 9-foot American paraboloid weighs about 1,300 pounds as against 6,000 pounds for the French instrument of the same diameter. Its cost is about one-fifth and its accuracy equal to or greater than that of the French paraboloid. It is mounted on Ford axles and wheels, and can be readily run into place and set up. For shipment, it can be knocked down and boxed in a small space. All these are improvements over the French instrument, which is heavy and bulky and requires at least a day to set up.



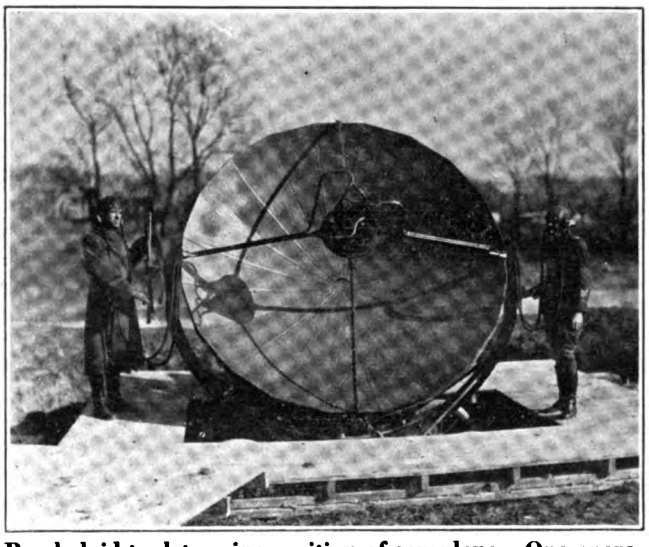
Developments in the so-called "long horns" which are shown in the illustration (page 279) have also been extensively carried on by the Army and Navy in the United States. These instruments have the advantage of an accuracy within 1 degree as compared to from 3 to 5 degrees for the paraboloid, but because of their great weight and size they are suitable only for fixed positions in rear areas.

Since the signing of the armistice, certain German listening apparatus has been secured which shows that while the Germans were not as far advanced as were the Allies in this development, it had not been neglected by them. The German listening device has one great advantage in that it is extremely light and portable.

By far the most important form of sound ranging, however—the one which has received the greatest attention and yielded the greatest return—is sound ranging for enemy battery positions. The theory of this method of location is not particularly complex. Suppose that a gun fires at some position, which may be called P (see figure), and that, at known positions A, B and C there are devices which will accurately register the *time* of arrival at A, B and C of the report of the gun fired at P. From the records obtained at A, B and C, we do not know the distance to the point P, nor its direction, but we do know the times at which the sound arrived at these points, and from these times of arrival we can determine the interval which elapsed between the arrival of the sound at A and its arrival at B. Similarly for the intervals between the arrival of the sound at A and C, and B and C. As sound travels some 1,090 feet a second, knowing the time interval we can compute how much further A is from the gun at P than is B; similarly how much further B is from the gun than C, and similarly for A and C. Turning to our analytical geometry or conic sections, we find that the locus of all points, the *difference* of whose distances from two fixed points is constant, is a hyperbola. The data obtained at A and B, that is the difference in the distance of the gun from the two stations, enables us to construt a hyperbola on A and B as foci, with the given fixed difference, and we know that the gun lies somewhere on this hyperbola. In the same way a hyperbola is constructed on A and C as foci, on which the gun also lies. Manifestly then, the location of the gun is the intersection of the two hyperbolæ. As a check on this location a hyperbola constructed on B and C as foci, should pass through the point of intersection of the other two. In practice, and to save time in plotting it is assumed that, except very close to the foci, a hyperbola coincides with its asymptotes, which assumption is sufficiently close for practical purposes. The asymptotes pass through the centre of the hyperbola, or the point midway between the two stations. From this point as a centre a circle is struck on the edge of the plotting board, and on this circle are graduations in seconds and fractions, corresponding to the time

Digitized by Google

differences at the two stations concerned. A circle is made for each pair of stations, each circle having a distinguishing color for identification. A thread of the same color is fastened at the mid-point between the stations. When the time difference is known the thread is drawn taut across the proper division on the time scale of the circle. It then coincides with the asymptote of the proper hyperbola, and the asymptote itself need not be drawn. The intersections of two or more strings determine the location of the sound on the plat. In practice, in order to determine the interval between the arrival of the report at several points—A, B, C, etc.—electrical devices are set at these points, which, when disturbed by the sound waves, cause a chronograph record to be made by an instrument at a central station. In other words, each indicates the time of arrival of the sound on a central recorder; time intervals can then be readily determined at the station where the recording mechanism is located.



The Geophone in action

There were four types of the latter class of sound ranging equipment in use by our Allies when we entered the war. The British set, known as the "Bull-Tucker," was considered the best by the A. E F., chiefly because of its adaptability to work in periods of considerable artillery activity, and was, therefore, adopted for manufacture and use by the American forces. A survey of production and development facilities in the United States was then made, as a result of which a laboratory was installed at Princeton University for the manufacture of special cameras, by means of which photographic record of the sound arrivals is made; and designs were developed for the commercial manufacture of the remainder of the equipment. At the same time, the Bureau of Standards was requested to assist in the development of the French system, known as the "Telegraphe-Militaire." By the end of the war, American-made "Bull-Tucker" sets, capable of covering 80 km. of front, were in France, and other sets were ready for shipment.

About a month prior to the signing of the armistice, an American development of the French "Telegraphe-Militaire" was sent to France for comparative tests with the French, and "Bull-Tucker" instruments. This instrument arrived at the front too late for actual war test, but reports received indicate that it has many desirable qualities. It is more portable, costs less, and is more robust than the "Bull-Tucker."

The accuracy of sound ranging is entirely sufficient for directing artillery fire. A survey made in the A. E. F., after the cessation of hostilities, to determine German battery positions which had already been located by sound ranging devices, indicated that, while the individual locations in many cases were in error from 20 to 60 meters, the mean of six or seven locations could be counted on for an accuracy of within 10 meters. On the other hand, where an enemy gun fired and we immediately replied, the chronograph record from our bursts, if the latter were accurately placed, would be identical with that of the report of the enemy's gun. In this case, uncertain conditions, such as temperature, wind velocity, etc., were the same, and identity of record indicated a hit within 25 meters of the target.

The use of sound ranging had become very extensive before the fighting stopped. Reports state that some 80 per cent of all battery locations were made by this method. The number of locations which could be made in a given time depended upon the amount of firing on the front, but one section operating a single "Bull-Tucker" set located as many as 117 enemy guns in 24 hours.

Paraboloid to determine position of aeroplane. One operator controls the azimuth, the other the elevation

The sound ranging facilities of the Germans were far inferior to those of the Allies. It seems that they had succeeded in capturing two English "Bull-Tuck-

Digitized by Google

er'' sets, which, after the armistice, were found at a school not far from the front. Apparently, however, the use of these instruments had not been developed by the Germans, and no other instruments of even comparable accuracy or speed had been put into service by them.

Discussion

R. G. Alexander
Major, Engineers; formerly Colonel, Chief of G-2-C (Intelligence Section, Topography), A. E. F.

As shown in the foregoing article very satisfactory progress was made during the war, in the United States The main difficulty arose from the great distance from the scene of operations. With the constantly increasing participation of American troops in the fighting, experienced officers were needed for new sections at the front and could not be spared for return to the United States. As a result developments in *material* were not always co-ordinated with front line conditions. Thus at one time sensitivity of sound ranging apparatus was so developed in the comparative quiet of the proving ground as to make the instrument almost useless in the greater sound activity of the battle field. Again the switchboard was equipped with conveniences and labor saving devices until it was so large and heavy it had to be taken apart and reassembled in France to accommodate it to the dugouts and other restricted quarters at the front. In the future all interested parties must work for better co-ordination.

The Bull-Tucker apparatus proved the best for sound ranging of any equipment available during the war. Its greatest defect lay not in the apparatus itself but in the fact that it required for its satisfactory use a double metallic circuit of high grade insulated copper wire. In addition to the cost the weight of wire was a great handicap. The wire for a section required two-thirds of all its transportation. The maintenance of the double circuit over shell-swept areas added greatly to the labor and danger of the wiring parties.

The most needed development was something to do away with the double circuit and permit of the use of a single line of light, cheap wire with ground return. The first T. M. set produced by the Bureau of Standards and sent to France effected this, but at the expense of other desirable qualities. The latest set sent arrived too late for field use, but offered much promise.

Although this article is on the subject of equipment it would seem of interest to add a few words as to the operating methods of sections at the front.

For quickly computing the location of a hostile gun when a record of its firing had been made by sound ranging, recourse was had to the use of a plotting board. On the board was stretched an accurate detailed or skeleton map of the sector in question on a scale of 1:20,000, divided into the customary kilometer squares. The positions of the microphones were carefully plotted. There were usually six microphones composing a section base, each two adjacent microphones constituting a sub-base. No personnel was stationed at the microphones.

In the earlier French plotting boards a set of hyperbolæ for each sub-base was plotted for regular successive time intervals of 0.1, 0.2, etc., seconds, up to 4 seconds (adjacent microphones were usually about 1,340 meters or 4 sound seconds apart). Each set of hyperbolæ was drawn for convenience in a distinctive color of ink. When a record was received the location of the gun firing was determined by approximating between the proper hyperbolæ already drawn on the board.

Later a simpler, but equally effective method was adopted, using the asymptotes instead of the hyperbolæ themselves. This could be done with sufficient accuracy, since the hostile guns were relatively much further from the microphones than the latter were apart, hence in the portion of the map where the hostile batteries lay, the hyperbolæ and the corresponding asymptotes were practically coincident.

Under this system the curves themselves were not drawn on the board, but the mid-point of each sub-base (intersection of all asymptotes for hyprebolæ on that sub-base) was made a pivot point for a plotting arm or string. The position of the string when coincident with the perpendicular bisector of the sub-base was marked as zero on the edge of the board. From this point as zero, a scale was extended round the edge of the board in both directions and graduated in units of time; that is, fractional parts of a second. The scale for each sub-base had a distinctive color corresponding to its string.

In practice, when a record was received, it was only necessary to lay the strings on their proper marginal scales to the readings corresponding to the recorded time intervals for the proper sub-base. Three or more strings intersected in a point for an exact location. For a poor location the failure to intersect or triangle of errror, indicated the degree of accuracy and represented the errors from wind, temperature, poor recording or reading of the film record, etc.

With American Sections in the field it was possible to telephone a new location within from three to five minutes after the hostile gun had fired. It was possible in less time to identify as firing a gun which had been previously located. In addition to the telephone report to counter-battery, a daily written report of all locations was submitted to the Artillery Information Service.

This report contained a great deal of useful information in addition to battery locations. A careful study of the film records disclosed at once the class of battery, that is whether howitzer or gun. With practice it also became possible for the reader to determine the caliber of the piece with reasonable precision. Since bursts of hostile shells were often recorded it was possible to gather much useful data as to targets selected by the enemy and batteries told off to fire on them. Forward observers stationed in advance and to the flanks of the microphone base for the purpose of starting the apparatus when wanted (thus saving film when there was nothing to record) also telephoned in much useful data as to kinds, calibers, and habits of the enemy artillery, and collected shell fragments, duds, portions of fuzes, etc.

These daily reports were studied by the Artillery Information Service and compared with information from the Air Service, statements of prisoners, captured documents, air photographs, and all other available sources. A location by sound was always verified when possible by study of the photographs and was often the first clue for finding the battery on the photo.

In one case this desire to corroborate the sound location was known to have saved a German battery from shelling. This battery was in the edge of a small clump of woods back of Mont Sec and was often located by Sound Ranging Section No. 1, and reported. It was very active up to the night of the Battle of St. Mihiel, when the guns were dragged out and stores of ammunition ready for firing left in place. Fresh wads and other signs told the story. A study of the ground showed that this battery had never been touched by an American or French shell. However

Digitized by Google

just to the right and less than two hundred meters to the front was an old decrepit battery emplacement unoccupied for at least two years, but bearing all the evidences of having received a plentiful and accurate fire from our guns. This old battery was in the open and showed upon the air photographs. The locations of the sound rangers had always been considered as in error for this case and the true location never accepted because it could not be verified from the air photograph.

It is always a matter of general interest to know in how great a degree of artillery activity sound rangers can successfully work and whether it is not possible for the enemy to evade location by firing several guns simultaneously.

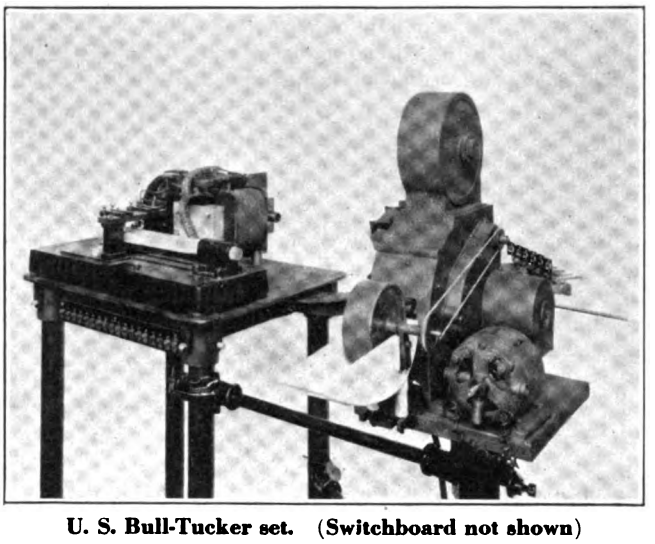
American sections have taken readable films in an activ-

Long horns to determine position of aeroplane

ity of six guns per second though, as a rule, little can be expected when the density of fire exceeds two guns per second.

As to masking fire, this can successfully be done only by increasing the general density of fire. Unless the two guns fired simultaneously are very close together, they cannot be equally distant from all microphones though they may be from any one or two. If very close together they form one joint target for our artillery. If apart, the record may show coincidence for possibly two microphones but sufficient interval on the others to enable the two locations to be distinguished.

The ability to pick out the proper breaks on a confused film is the result of considerable ability coupled with good training and much practice. The problem is greatly facilitated by placing the microphones in a straight line or preferably on the arc of a circle of large radius with center about the center of enemy artillery activity opposite the front in question. This results in the sound of a hostile gun reaching the microphones in a regular succession and the corresponding breaks on the film being placed in a more or less regular pattern, the shape of the pattern assuming certain well known forms. In a confused film it is thus possible to identify the corresponding breaks, when it would be impossible were the microphones placed indiscriminately in the sector.



The life of the sound rangers was varied and seldom monotonous. In quiet times there would be dull days with the apparatus idle because the enemy artillery was apparently taking a holiday, or because an unfavorable wind swept all sound away from the microphones. During such times ranging shots were arranged for our own artillery if conditions were favorable. Nights were often hectic. Harassing fire would bring repeated calls from counter battery to locate or identify the offending batteries so they could be silenced. At such times the central force worked steadily and continuously while wiring parties mended broken lines and dodged shells throughout the night.

One section near St. Benoit became too ambitious and advanced its central to the line of microphones to save wire with the result that a large caliber gas shell struck the central building squarely and seriously wounded seven members of the section.

Prior to an attack or general forward movement the sections worked hard in order that the "hostile battery map" might be as complete and accurate as possible on the day of attack, thus increasing the effectiveness of our own artillery plan and thereby lessening the task for all attacking troops.

Meanwhile the flash rangers were equally active, working on enemy batteries at night when the flashes were clear and distinct and in the day time also searching the sector every minute to discover working parties or other transitory human targets. These sections were the eyes of the artillery and in general the only means of reporting a temporary target with sufficient accuracy to enable the artillery to open immediate fire by the map with a good prospect of hitting. The Germans opposite the Chateau Thierry sector may well remember the keenness of the American flash rangers and the accurate shooting of the Second Division's artillery. This combination scattered death and confusion in many an indiscreet working party or group of reinforcements moving without due regard for cover.

Flash Section No. 1 moved from Chateau Thierry to the Vesle, operating all the way. At times too zealous members in search of good observation posts found themselves in

U. S. Bull-Tucker set. (Switchboard not shown)

advance of our infantry and forced to take shelter from hostile rifle and machine gun fire.

While at times the flash and sound sections duplicated each other's work, in general their work was mutually supplementary. In times of fog or rain, all too common in France, the sound rangers had excellent working conditions and constituted the main source of information. At such times visual observation was impossible, as were also airplane reconnaissance and aerial photography. On the other hand, on bright clear days and nights, accompanied all too often by high winds, the sound rangers could do little while the flash rangers had excellent working conditions. The latter were also the main reliance in war of

Digitized by Google

movement, since the enemy batteries were then on the move and occupying only transient positions.

One must not overlook the necessity for extreme accuracy in location of microphones and flash ranging observation posts with reference to the triangulation system of the map. On such careful tying in to the triangulation points, depended the accuracy of all battery locations. The work could not be done by rough and ready field methods but required careful instrumental work by skilled men capable of quick but accurate results under the unusual conditions prevailing in a sector under fire. The close union of Engineer map and ranging troops in France was a great advantage.

A staff officer of G-2-c, G. H. Q., in company with an experienced British ranging officer, visited a green American flash ranging section just installed, about a month before the armistice, on the heights overlooking the Woevre. The night was clear and the horizon illumined at intervals by flashes from the German artillery busy at harassing fire. The young section commander was in despair as his intersections on the plotting board were uniformly poor. On the advice of his visitors he telephoned his observation posts to each set the telescope on a certain low lying bright star and mark the reading as a new zero for further work. Upon resuming work with the new zeros the intersections on the plotting board at once became good, showing that the directing lines of the posts had not been parallel and probably the posts themselves poorly surveyed. A re-survey confirmed both errors and good results were thereafter obtained.

While good instruments for both sound and flash ranging are essential, it must not be forgotten that the best of apparatus is valueless if inefficiently operated in the field. Experiments should be conducted from time to time to improve equipment, keeping in mind that refinements carried beyond the degree in keeping with the allowable error in the field are useless. Efforts should be directed toward making equipment compact, robust, and fool-proof.

It is even more essential to secure a nucleus of trained and experienced men. In the A. E. F. green men were always fed into experienced sections for actual front line training before becoming themselves members of new sections.

In time of peace a limited personnel should be maintained for the service. In addition to study of equipment and technical methods of operating, including problems of computation, plotting, and survey, there should be frequent field practice, not on a proving ground, but at an artillery firing ground. It is essential that the artillery know and appreciate the possibilities of the ranging service in order to fully utilize it.

Commercial Use of the Geophone

[The engines of war find their application in peace. The following notes on the commercial development and possibilities of the geophone were prepared by Alan Leighton, Assistant Chemist of the U. S. Bureau of Mines. They will be of interest to all engineers.—Ed.]

The geophone, a listening instrument invented by the French during the war to detect enemy sapping and underground mining operations and for the location of enemy artillery, is now being used by the U. S. Bureau of Mines as an aid in locating miners who have been entombed by accident and for other purposes in mining and tunneling. The instrument was developed by United States engineers during the war and is now used by the Bureau according to plans drawn by these engineers. It is manufactured by the Globe Earphone Co., Reading, Mass.

The instrument, though small, is essentially a seismograph, since it works on the same principle as the ponderous apparatus with which earthquake tremors are recorded.

It consists of an iron ring about three and a half inches in diameter, in the center of which is suspended a lead disc which is fastened by a single bolt through two mica discs, covering the top and bottom of the ring. There are two brass cap pieces, one having an opening in its center to which is fastened a rubber tube, leading to a stethoscopic ear piece. These cap pieces are fastened with bolts to the iron ring and serve also to hold the mica discs in place.

The instrument is thus essentially a lead weight suspended between two mica discs cutting across a small air-tight box. If placed on the ground when there is pounding or digging in the vicinity, energy is transmitted as wave motion to the earth, and the earth-waves shake the geophone case. The lead weight, on account of its mass and because it is suspended between the micas, remains comparatively motionless. There is thus produced a relative motion between the instrument case and the lead weight. The result is a compression and rarefication of the air in the instrument. Since the rubber tube leading to the stethoscopic ear piece is connected with this space in the geophone, this rarefication and compression is carried to the ear drum.

When two instruments are used, one for each ear, as is usual, the sound is apparently louder from the instrument nearer the source. It is evident then that by moving the instrument a point can be found where the sound will be of the same apparent intensity in both ears. The direction of the sound is then on a perpendicular to the line connecting the centers of the two instruments either in front of or behind the observer, further observation will show which. Direction is quite accurately determined in this way. The sound is not actually louder in one ear than in the other, but the ear is capable of distinguishing the difference in time at which the sound arrives in the two instruments. Accordingly, even persons who are slightly deaf in one ear are still able to determine direction.

During the period of the War, engineers of the Bureau of Mines were engaged in determining the distance that different mining machines could be heard through the clay, shale, coal and the mine cover. Measurements were made also of the energy required in blows that they be heard definite distances through clay, shale and coal, as well as the distances at which the shock waves resulting from the discharge of various explosives could be heard. A brief investigation of the factors influencing the transfer of energy from a mining tool to the clay and coal was also made in

Digitized by Google

order that recommendations could be made as to the type of mining machine which could be used to accomplish the most work with the least noise.

In this connection it was found that sounds were transmitted only about half as far in clay as in shale strata, and about one quarter as far in clay as in coal. To give some idea of the sensitiveness of the instrument it may be said that the pounding of a pick on bituminous coal can be detected at 900 feet, and the direction determined, and that the pounding of a sledge can be heard at 1,150 feet. The explosion of a one-ounce charge of dynamite was detected at a distance of over 2,000 feet through the shale strata. One interesting feature of the instrument is that the sound as transmitted to the ear is very characteristic of the instrument producing the sound. To illustrate: Twelve mining and carpentering operations were carried out on the coal rib. An engineer of the Bureau who had never used the geophones and who did not know what tools were to be operated was able to recognize and name nine of the instruments at a distance of several hundred feet through the strata. The other three sounds were accurately described, but the machines were not identified.

Now that the War is over the Bureau work has turned to the development of the instruments for peace-time uses. In this connection, it is thought they may be of great value to mine rescue crews who may be entering mines for exploration and to locate miners who may have been entombed after a disaster. The tests so far made in the vicinity of Pittsburgh show that a man pounding on the coal rib with a pick, piece of timber, or a sledge can be detected and located from a point 600 to 1,200 feet distant. This distance depends greatly on the character of the coal but intervening open spaces seem to have surprisingly little effect upon the distance or the determination of direction.

Pounding with a sledge can be heard from two to three hundred feet through the mine cover, depending upon the quietness of the day outside, since any wind greatly interferes with the successful operation of the instruments. It will at once be seen that when mines are not too deep they can be "explored" from the surface and it will thus be possible to find and locate a miner who is pounding. At the Experimental Mine in Bruceton, Pa., a man has frequently been located through one hundred and forty feet of cover within fifty feet of his actual position. A study is being made of the distance that pounding on rails and pipes can be heard.

In metal mines expensive surveys have sometimes to be made in order that approaching tunnel headings may be brought accurately together. Since direction can be determined so well with the geophones, they can be used to guide such work. It would only be necessary to enter each heading and locate the direction of pounding in the other heading.

It is also thought that they will be of value to prevent accidents from explosions when breaking through. In this connection an interesting incident happened recently. Observations were being made at a tunnel heading. The pit boss happened along and asked to be allowed to listen. He put the ear pieces in his ears and remarked: "Mac is tamping in a charge, we had better move away." He spoke as naturally as if watching "Mac," and it is quite evident that he did not realize the sound was 300 feet distant.

Observations were made recently of a mine fire burning from twenty to forty feet below the surface. A low rumbling noise could be heard as if air were being drawn in along crevices, and occasionally sounds could be heard from the snapping and falling of pieces of coal or rock. It is believed the fire area was accurately located, but since the fire cannot be approached from the inside this cannot be verified. It is interesting to note that similar sounds could be heard from only one point inside of the mine and this point was the one nearest the area as located on the surface.

It has been found also that the instruments can be employed quite advantageously in locating knocks in automobile valves and cylinders, not only the cylinder but even the trouble area. For this purpose it is well to mount the instruments on a short iron rod that can be easily inserted in and around the machinery.

After the experimental work has been completed a course of instruction in the use of the geophones will be developed and recommendations will be made as to the proper procedure for a rescuer carrying their instruments, as well as for the entombed miner.

Longest concrete arch span.—A 400-ft. concrete arch constitutes the main channel span of the Franklin Avenue bridge over the Mississippi at Minneapolis. The arch is elliptical, with a rise of 88 ft. It consists of two ribs having a thickness of 8 ft. at the crown.—*Eng. News-Record.*

World's production of petroleum, 1918, and visible supply.—The total production of petroleum in 1918 was 514 million barrels of 42 gallons each, of which the U. S. produced 356 million, or nearly 70 per cent. The Geological Survey estimates that in our western states there are oil-bearing shales sufficient to produce at least 75 billion barrels.

The channel tunnel.—Military and naval authorities are reported to be in favor of the Channel Tunnel Project, connecting England and France.

It will take five years to complete the work at an expense of approximately $150,000,000.

The value of the proposed tunnel to industrial development has been recognized by all branches of the British government.

The project was first suggested in 1802, but due to political difficulties, it never received serious consideration until now.—*Jour. West. Soc. of Engrs.*

Progress in Society organization

IN conducting a campaign it is a military maxim and in all human endeavors it is ordinary common sense, to recognize the main issues and devote one's energies thereto, avoiding the temptation to fritter them away in too much attention to details.

A society cannot accomplish the purposes for which it was organized until it possesses a strong and influential membership. Accordingly, the main issue for the Society of American Military Engineers at this time is to build up its membership, and our energies have thus far been devoted almost exclusively to this end. The results attained have been gratifying, and applications for membership are steadily flowing in.

During the months of April and May there has been a steady and very encouraging increase in the rate of growth, and ultimate success seems assured. The aims of the Society, as set forth in its constitution, have received unanimous approval, and this journal has proved interesting to its subscribers.

The labors incident to the readjustment of our military establishment to new conditions are very arduous, and as a consequence the temporary Board of Directors, most of whom are officers on duty in the War Department, have not thus far been able to take action on the large number of applications for membership which have been received. An examination of the applications, however, indicates that all applicants thus far are eligible for membership.

Steps are being taken to effect a better working arrangement, pending the permanent organization of the Society following the first regular election of officers.

It is hoped that all applications will receive final action soon. In the meantime charter membership in the Society remains open, and it is hoped that many new members will avail themselves of the opportunity thus afforded.

All charter members are urged, at this vital epoch in the Society's existence, to lend their best efforts to the accomplishment of the main purpose now before us: that of building up a strong membership as rapidly as possible. Each of our members has many acquaintances, even close friends, who are also eligible for membership. Tell them of our society and its aims, show them this magazine (it will interest them), and invite them to join us without delay. Membership application blanks and copies of the constitution will be sent on request to any member who desires to give them to eligible friends. It is hoped that every charter member will secure at least one additional charter member before the permanent organization is effected, probably early in July, 1920.

Organization of local posts. Article IV of the By-Laws of the Society provides for the organization of local sections or posts. These local posts, in bringing our members into close personal touch with each other, are believed to be essential to the realization of our fullest usefulness. The number of members is now such as to warrant the organization of these posts. Preliminary plans and arrangements have been completed and the actual organization will be undertaken in the very near future. Dates for local meetings will be duly announced, and all members in each locality are urged to attend these meetings and to invite all friends who are eligible to membership to do likewise.

Society emblem. Our Board of Directors is considering a number of designs for an appropriate emblem for our Society. It is expected that this will be fixed upon very shortly, and orders for its fabrication will be placed at once.

National defense still a live issue

AN esteemed but not too thoughtful contemporary, in an editorial comment, commends the purposes of THE MILITARY ENGINEER, and we were mightily encouraged as we read the opening lines. But it promptly deals a heavy blow to our high hopes and aspirations in recommending that engineers who took part in the war make our journal the repository or crypt in which to bury their grievances and disappointments and the priceless military lessons they learned during the conflict, thus keeping them out of the live current periodicals where they are merely an irritation to the engineering profession. Twenty years hence, says our contemporary, these experiences may be dug up again, presumably when we find ourselves entering once more unprepared into a great war on which our existence as a nation may depend.

We are extremely desirous of receiving the contributions referred to, but we are very sorry to see this fresh manifestation of indifference, even of impatience towards the national defense, which should be a matter of chief concern, of lively and current interest to every patriotic citizen. It is this very spirit of indifference which is responsible for our having entered every war unprepared. It is responsible for the waste of billions of dollars and thousands of precious human lives.

This journal is dedicated to the national defense, and it is our mission to make it a *living issue* in the mind and heart of every engineer, a vital part of his everyday existence. It is our aim to keep constantly in his mind the relation of his peace-time activities to the duties he will surely be called upon to perform in the next war, which is sure to come. Whether that war will be twenty years hence, ten years hence or *two* years hence, we do not know. But we *do know* that in putting all thoughts of the relation of engineering to national defense out of his mind until war is actually upon us, the engineer is deliberately evading his patriotic duty.

The Daughters of the American Revolution, in convention assembled, recently passed resolutions favoring a system of universal military training as a measure of national defense. These ladies, whose principal purpose is to "keep the home fires burning" in peace and happiness, have shown a keen appreciation of our national needs and the ways in which they may be met. With them patriotism is a living issue, fresh and vigorous. We hope their splendid spirit may pervade to some extent those more faint-hearted patriots who, "fed up" on the war and reacting badly to the efforts of those who seek to promote the national defense, are too willing to drop back into indifference and apathy towards these things so vital to the welfare and safety of our country.

War promotes industrial and scientific development

IT has been said that there is no such thing as an unmitigated evil, that everything that *is* has its purpose. And this is true of war. As peace hath its victories so hath war its compensations, and they are many, varied and far-reaching.

The methods and inventions of peace find their application in the conduct of war. But the debt is not all on one side. Invention and development have received a powerful stimulus from war, and this is especially true of the late war. The aeroplane, for example, would not for years have reached its present stage of development and usefulness, except for the war. Aerial photography is exclusively a war-time development. High-speed construction and quantity production in manfacture have developed under the stimulus of war more rapidly than they ever developed during an equal period of peace. Transportation of all kinds has been given a great stimulus. War has contributed to the advancement of medicine, surgery and sanitation quite as much as peace.

Many of the devices developed for purely military purposes will find useful application in the gentle arts of peace. Amongst these is the geophone, described in this issue. Devised for the purpose of detecting the subterranean operations of the enemy it now finds a new field of usefulness in mining engineering.

Our service contemporaries

ONE of the encouraging proofs of the fact that the spirit of the army, though tried to the limit, is still strong, is given by the vigor of the journals representing the various branches of the service. All of them show renewed signs of life. Those representing the two branches of the artillery have broadened their scope and increased their helpfulness to the service. The *Military Surgeon* is better than before; the *Infantry Journal*, always a leader amongst service periodicals, is stronger and more aggressive than ever, and plainly intends to make sure that the infantry shall remain as heretofore, "the queen of battles."

During the war we heard little of the cavalry, because the peculiar conditions of the conflict allowed small scope for its time-honored activities. And so our cavalry officers turned their attention to other fields they were qualified to fill, such as exercising high command, performing important staff duties of all kinds, organizing the tank corps, commanding infantry and artillery units, etc., thus gracefully and efficiently filling into the situation as they found it. But now after a lapse of two years the *élan* of the cavalry reappears to the world in the rehabilitated *Cavalry Journal* whose first issue is dated April, 1920. It contains a large number of carefully selected up-

Digitized by Google

to-date articles and items, which, while of special interest to the cavalry, no doubt, are almost equally so to any soldier who aims to keep abreast of his profession. It is with pleasure we note that all these articles are short and very "snappy."

We have greatly missed our contemporary of late, and we welcome it back to life and service.

Civilian Engineers in the Army Engineering Corps

Employment in any department of the public service is unsatisfactory at best. But employment as a civilian engineer in the army engineer corps furnishes little satisfaction except that of having a job that is all work and no recompense. One cannot wonder at the dissatisfaction existing among the civilian engineers. The marvel is that any of them remain in the service. Their persistence in staying with the army organization is not that they cannot find employment elsewhere. As a matter of fact, most of them have opportunities to associate themselves with private organizations; all of them can find more remunerative employment outside of the government service, and some of them, discouraged over the prospect of receiving adequate recognition, are leaving the service after devoting many years to it.

More pay for these engineers is a necessity if the service is to maintain anything like an organization or is to function properly. To appeal to their patriotism as a means of retaining their services is at all times foolish, in these time idiotic. The government pays the market price for material commodities; it should pay likewise for engineering and all other service. It is reported that the commissioned personnel of the engineer corps is opposed to permitting salary increases for the civilian engineers because of the desire of the former to receive more remuneration than the men whose work they direct. This is a natural desire, but, since the direction is nominal only, it should not deprive the civilians of fair treatment. This they are not getting now.—*Eng. World.*

[We heartily indorse the views of our contemporary. There is no class of men in our country who perform more and better service and receive less pay for doing it than the civilian engineers of the U. S. E. D. Heretofore and up to now they have been men of the highest attainments, but such men can no longer be attracted to the service at the wages of a common laborer. The reason many of them remain in the service is because their work is varied and interesting, and their relations with the officers of the Corps of Engineers pleasant. From a knowledge of the facts, however, we wish to correct the impression that the Corps of Engineers is in any way responsible for the low wages paid its civilian assistants. This impression is the opposite of the truth, and this would be a most short-sighted policy even from a selfish point of view. The Corps of Engineers advocates better wages and the privilege of retirement on pension for civilian employees, especially the higher employees of the "educational" class. The "misery loves company" feeling has no place in the relations between the commissioned and civilian personnel of the Engineer Dept.—ED.]

The successful life

The following advice and suggestions to those who seek success in life, by an admittedly successful American, cannot fail to be helpful. They are extracts from a "talk" by Charles M. Schwab to the students of Princeton University. We say a "talk" because we believe Mr. Schwab himself would not wish to call it an "address."

Money is often a matter of chance or good fortune and is not the mark of a successful life.

If I were to say the most important thing that leads to a successful life, I should say that first of all was integrity—unimpeachable integrity—that is the foundation of a successful life.

You may think the opportunities of the past will not be the opportunities of the future. In that, boys, you are mistaken.

Boys, did you ever stop to think that a great man in life who has won great acclaim and great reputation is the very man who is willing to share and give the honor to the others in the doing of the things that made him great? You must learn to let others share with you in that which you are doing, and honor and credit will be reflected upon you for so doing.

Marshal Foch, the great commander, said to me a short time ago, when I congratulated him upon the wonderful work of the war: "This great military staff is like an orchestra, and each one fills his place. Each is equally important in the functioning of the whole. If the baton is in my hands it is merely the matter of chance, but we shall see to it that each man in the staff gets recognition for what is due."

If a man is of the character that you must find fault with him to get the best out of him, he is not a man to be desired in an organization.

A man to carry on a successful business must have imagination. He must see things as in a vision, a dream of the whole thing. You can cultivate this faculty only by an appreciation of the finer things in life; beauties of art, literature, and music will help any man in his career.

Let me give you a piece of advice. If you have any influence in the world to get you a start in life, do not use it. Start on your own merits, and start in some lowly position, no matter what it is. Be a laborer, if you will. I do not know but that is the best way to start.

You must make up your mind in advance whether you want a good time in life, or success; you cannot have both.

Concrete ships. In a committee report of the Concrete Institute on the construction of concrete ships, the following information is noted:

Speed of construction expected was not realized. Average time of constructing hulls, seven months; outfitting three to four months.

The boats have proved good sea boats. Vibration less than in steel ships. Period of roll in concrete ships much less. No leakage in any vessel has been reported.

The most serious defect in the concrete construction as affecting plant suitable for the work of the Corps of Engineers is its inability to stand the blows incident to handling. Impact which would not probably have damaged wooden or steel boats has produced a shattering of concrete. In case of nearly every barge constructed for the Railroad Administration the shell has been injured and repairs required. Should concrete barges and hulls be used for construction work adequate fender timbers appear necessary.

In cases of barges and canal boats the two obstacles to successful introduction are: cost and liability to injury by shock in handling.—*Eng. News-Record.*

Europe to India by Rail.—The project of effecting railway communication between Europe and India is now well on the way to fruition, owing to the construction and development of military railways in the Mesopotamian theatre of war. There are now approximately 1,000 miles of line in Mesopotamia.

In addition, a line is now operated between Bagdad and Quaritu on the Persian frontier, while construction is proceeding on an extension to Khermanshah. There appears to be every probability of considerable railway development in Persia in the near future. With the tendency of the Indian lines to extend into Persia, and the possibility of the completion of the channel tunnel in a few years, direct rail communication between England and her Far Eastern possessions would now appear to be well within the range of practical politics.—*Railway Age.*

Water Resources in Relation to Military Operations

By

Charles H. Lee

Captain, 26th Engineers (Water Supply), A. E. F.
M. Am. Soc. C. E.

The important relation which water supply bears to the successful execution of military operations has long been realized. Never before the World War, however, has specific provision been made, in technical personnel and material, for the supply of potable water to armies in the field. This innovation was not alone the result of the arid conditions under which it was attempted to carry on certain campaigns such as those of the British at Gallipoli and in Palestine and the Italians in Eastern Italy; an even greater reason for special provision for water supply was the inadequacy and often the pollution of local supplies in the humid regions of Northern France, where troop concentrations along the Western Front surpassed anything previously recorded in military history. Existing wells and developed springs were so inadequate in certain early operations on this front that the failure to attain success was often directly ascribed to the lack of sufficient water for the troops and animals engaged. In other instances the use of polluted water resulted in sickness and loss of morale among the troops. These experiences led to the organization, in the various allied armies, of specialized troops and technically experienced officers for water supply service.

In this connection, the military importance of regional water resources at once became apparent and geologists and hydraulic engineers were drawn into the service. The conditions, however, demanded a special type of experience, namely, that of a hydraulic engineer and a practical ground water geologist combined. This type of technical military service tended to develop a broadened type of hydraulic engineering, which, following the French practice, could be called "hydrologic engineering." Along with growth in the knowledge of hydrology in the United States there has been, during the past fifteen years, a growing need and demand in civil life for exactly this type of experience. The many public water supply, irrigation and water power projects, well designed structurally, but partial or complete failures because proper study was not given to the water supply, are eloquent examples of this need. It is believed that there will be a distinct gain in this branch of engineering as a result of the war and that with the increased investment of American capital in foreign countries, its field of usefulness will grow rapidly. The experience and practice along these lines during the war is therefore, like nearly all operations of military engineering, of great civil interest as well.

The writer was assigned to the 26th Engineers, but was later detached for service with the Water Supply organization of the American Expeditionary Forces in France where he handled matters involving water resources and choice of sources of water supply. From November, 1917, to June, 1918, he was attached to the Water Supply Section, Office of Chief Engineer, A. E. F., reporting to Col. F. F. Longley, Engineers, Chief of the Water Supply Service. In July, 1918, he was assigned to the First Army Water Supply Service, reporting to Lieut. Col. F. W. Scheidenhelm, Water Supply Officer, First Army, and continued on this duty until after the armistice.

Lieut. Col. Alfred H. Brooks, Engineers, was in charge of the Geologic Section, Office of Chief Engineer, A. E. F., and Maj. Edward H. Bowie, S. C. of the Meteorologic Division, Signal Corps, A. E. F.—Ed.

Military Water Supply Requirements

THE water supply requirements of an active army and its auxiliaries are varied. In France the important requirements of the American military forces were as follows:

1. Potable water for combat troops in the field.
2. Drinking water for animals accompanying combat troops in the field.
3. Water for drinking and general uses in relatively permanent camps, barracks, hospitals, depots, etc., in rear of the active armies.
4. Military railways, light and standard gauge.
5. Supplemental supplies for towns or cities extensively occupied by military forces in rear of an active army.

The consumption of water for these requirements varies widely both in quantity and regularity. For animals and combat troops in the field, where the practice is to establish water stations or "water points" at intervals of two to three miles, the demand at any station is mostly during the daylight hours and ordinarily varies from less than 5,000 to 30,000 gallons per day, although in cases of great horse concentrations away from open water it may be as great as 75,000 gallons per day. The stations supplying the greatest quantities are usually those at which motor truck tank trains are filled. The demand usually fluctuates widely from day to day, depending on troop movements. The per capita rate of daily consumption for men seldom exceeds three gallons, and for horses nine gallons. An essential feature of a source of supply in the army zones is immediate availability. This eliminates drilled wells except under highly stabilized conditions of warfare.

At permanent camps and hospitals in the rear the demand is more regular from day to day. Depending upon the size of the camp, the total consumption varies from a few thousand gallons daily up to 100,000 and even 250,000 gallons. The per capita rate of consumption varies from 5 to 10 gallons daily at ordinary barracks, depots, etc., up to 15 or 20 gallons daily at hospitals and may exceed 25 gallons daily where flush toilets and other conveniences are installed.

At light-railway filling stations the maximum total demand at terminals seldom exceeds 50,000 gallons per day and at stations along the line is very much less. For standard-gauge railways the demand is much the same as in civil practice on busy roads.

The demand for supplemental city supply depends entirely on local conditions and may require the development of a complete new source of several million gallons per day.

Digitized by Google

Problems Encountered

The following are indicative of the military problems whose solutions require a more or less detailed and comprehensive knowledge of regional water resources:

1. Preparation of general operation plans involving choice of the theatre of operations. This type of problem is important where great troop concentrations are contemplated or where either our own or the enemy's theatre of operations includes a poorly-watered region.
2. Preparation of special operation plans involving choice of line of march, camp sites or billeting areas for troops, positions for attack or defense, etc. Much hardship, delay, and unnecessary moving and labor can often be avoided among troops by the intelligent use of detailed water supply information.
3. Selection of camp, barrack, hospital, or other sites involving the erection of more or less permanent buildings or other construction. The saving in time, labor, and material which can be effected by considering water supply in the choice of a site is often very considerable.
4. Selection and development of a specific source of water supply for a camp, barrack, hospital or depot site previously chosen without regard to water supply. It frequently occurred, in all the Allied Armies that sites for important stations, such as large hospitals, training camps, depots, etc., were chosen by representatives of the branch of the service most interested and from consideration of the features most obvious to those concerned, but without particular attention being given to the question of water supply.
5. Selection of types, sizes and quantities of water supply materiel required by an army or smaller unit in a given theatre of operations. The water resources of a region are especially important in connection with the quantity and sizes of pipe and pumps needed and special equipment such as well-drilling machinery, filters, etc.

Data Required

The solution to these problems can seldom be reached merely by a superficial inspection of the ground made personally or from aerial photograph. Such an inspection must be supplemented by a broad knowledge of the hydrology of the region and the consideration of all possible local data. Hydrology, as here used is intended in its broadest sense, namely, as including both surface and underground waters. The two are so closely interrelated physically and their relative value as sources of supply often so difficult to judge, that it is absolutely essential to consider them as merely different phases of the same thing—the movement toward the ocean of water falling on the earth's surface as precipitation.

Viewed from this standpoint, the data required for the study of the water resources of a region is as follows:

1. Precipitation; its average depth for various periods of time and its monthly and annual variation from the average; also its geographic distribution and the form in which it occurs.
2. Evaporation; its depth as measured under specific conditions and its variation from month to month during the year.
3. The land surface; its topography, drainage basins, streams, vegetation, and permeability.
4. Geology; the material, thickness, sequence and exposure of the various local formations, the structural irregularities such as folding, faulting, etc., and especially the character, extent and position of saturated formations which are sufficiently porous and permeable to be considered "water bearing."
5. Stream and spring flow; its amount and variation at different times during the year and from year to year.
6. Lakes; their size, depth, and permanency.
7. Wells; their type, location, depth, size, formations penetrated, yield, water level, etc.

The American publications on practical hydrology emphasize surface water and give attention to the subjects of precipitation, evaporation, land surface, stream flow and lakes. The French, on the other hand, treat largely of underground water and devote much space to geology, springs and wells. The writer's experience which has extended to both phases of the subject leads clearly to the conclusion that the engineer assigned to the study of water resources and the selection of specific sources for military supply must have a practical familiarity with both surface and ground water hydrology in order to successfully solve the varied problems which arise.

Sources of Information

As a beginning for the study of water resources of any region there should be available as complete as possible a collection of published data relating to the region, together with topographic and geologic maps, geologic sections, and maps showing forests, streams, lakes and, if possible, springs and wells. The information thus obtained should as soon as practicable be visualized and supplemented by field observations. The latter must usually be done piece-meal in connection with specific problems, but if possible field trips for the purpose of general observations should be made. With the American Expeditionary Forces in France the Geologic Section, Office of Chief Engineer, and Meteorologic Division of the Signal Corps, coöperated with the Water Supply Section, Office of Chief Engineer, both in obtaining maps and data from French sources and in making mutually available all data secured. This procedure proved of value to all concerned.

The principal sources of published data in France are the various government services, such as the *Ministre des Travaux Public du Service de la Carte Geologique de France*, the *Service Geographique de l'Armee*, the *Bureau Central Meteorologique*, and the *Ministre de l'Agriculture;* geologic societies, especially the *Société Geologique de France* which has an unusually complete geologic library at Paris; and publishes books and reports of geographers, geologists and especially engineers. The whole of France is covered by detailed geologic maps of variable ac-

Digitized by Google

curacy on a scale of 1 to 80,000; but few geologic sections are available. Topographic maps of various scales are available which show accurately the locations of permanent springs, streams, and lakes. Precipitation data is very complete but there is little reliable evaporation data. Stream flow data is complete for only a very few streams and is of limited value on account of the short periods of record In general, water resource data is far from being as complete as in the United States, and geologic mapping although covering a larger proportionate area is not as accurate and comprehensive. There are but few countries of the world, however, in which available information of this sort is as complete as in France. In a region such as Northern Mexico, any one studying water resources should have had a broad practical hydrologic experience in both surface and underground water to enable him to form useful judgments based on hasty field observation and meagre general data.

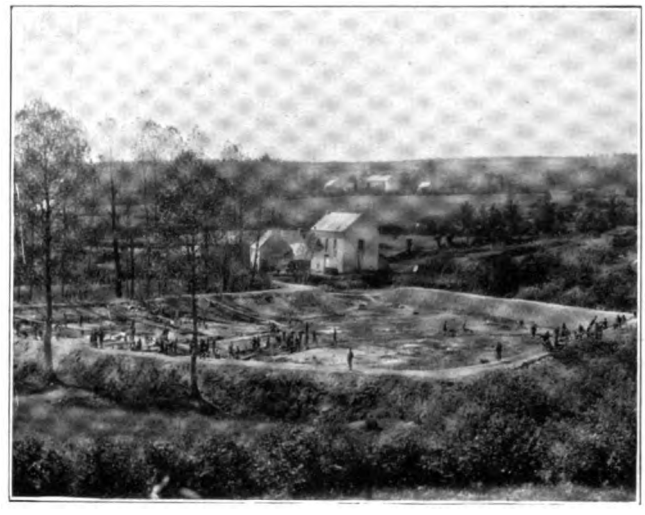
To facilitate the collection and preservation of data from the field, various blank forms were used by the Water Supply Service.

Hydrologic Provinces of France

The first step in studying water resources for a large region is to define the limits of areas with similar hydrologic characteristics. This done, a more detailed study of each district or province can be made to ascertain the typical sources of water therein, their characteristics and best methods for development. The details of such a study and its practical application are illustrated by work carried on as part of the activities of the American Water Supply Service in France. The Geologic Section coöperated more or less in this work.

There are three distinct types of hydrologic conditions in France, on the basis of which the country can be divided into several districts or hydrologic provinces.

The first type is represented by elevated igneous rock masses flanked or partially overlaid by metamorphic rocks and receiving an average annual precipitation of 35 to 60 inches.



The second type is similar to the first, being composed of elevated and highly tilted and folded sedimentary rocks and receiving about the same precipitation.

The third type comprises the geologic structural basins embracing the valley and plateau areas and receives an average annual precipitation of from 24 to 35 inches. These basins are filled with comparatively soft, regularly stratified sedimentary rocks (Secondary and Tertiary series) and are bordered by the upturned and exposed edges of the various strata.

Falling within the first type are; (1) the Brittany Peninsula; (2) the assembly of ranges in Central France, known as the Central Massif; (3) the Ardennes; (4) the Vosges Mts.; (5) the Pyrenees and (6) the main chain of the Alps. The second type is represented by (7) the Jura Mountains and (8) the Sub-Alpine chains, bordering the Rhône Valley on the east.

The principal rivers of France have their sources in these ranges. The igneous and metamorphic rocks are dense and unfissured, except very close to the surface, and below the surface have no stratification nor alternation of porous and impervious formations. The uplifted sedimentary rocks are more or less fissured and sometimes cavernous, but the rock is seldom porous. Portions of the American Line of Communication lay within the Brittany Peninsula and the western portion of the central Massif.

The Paris and Aquitaine Basins and the Rhône

A hastily constructed reservoir

Valley are the principal basins of France. They are traversed by the rivers from the highlands and contain the most highly developed industrial areas and most densely populated regions of France. The sedimentary formations of the Paris Basin apparently have the form of half a gigantic onion cut perpendicularly to the core. Paris lies at the center of the concentric rings and the outside ring lies against the surrounding highland areas. The extreme bottom of the onion is at great depth below the surface, possibly in the vicinity of Paris. The concentric layers are composed of all types of sedimentary rocks from late Tertiary alluvium at the center, in regular sequence down to the Carboniferous rocks of the upper Primary series. Certain layers are pervious and have water bearing capacity. Among these are fissured or jointed sandstone, fissured or jointed limestone, porous sandstones (lower Cretacious or Eocene), upper Cretacious chalks and quaternary river valley gravels and sands derived from the hard rocks of the highland areas. Interbedded with these are impervious non-

Digitized by Google

water bearing formations such as unfissured Triassic sandstone, unfissured limestone, shale (marnes), clay and most tertiary alluvium. The extreme northeastern and eastern portion of the Paris Basin included the army activities of the American Expeditionary Forces, while the line of communications lay within the southeast and southern borders. A portion of the latter also extended into the upper Rhône Valley.

The sedimentary formations of the Aquitaine Basin do not correspond in structure to those of the Paris Basin but are folded into a series of buried synclinal troughs and anticlinal ridges with a northwest-southeast direction. Along at least one of these troughs, represented by the line of the lower Gironde River and Garonne River immediately below the junction of Lot River, there has occurred faulting with marked depression of formation to the southwest and corresponding elevation of those to the northeast. The types and character of sedimentary rocks in the basin, however, correspond closely with those in the Paris Basin. The activities surrounding the American Base Port at Bordeaux lay in the Aquitaine Basin and certain of the important docks and terminals were situated just west of the line of faulting.

The Rhône Valley is underlaid by more or less porous alluvial débris deposited by streams flowing from the adjacent mountains.

Each of the eleven provinces thus described has certain typical sources of water supply which generally result from its distinctive hydrologic characteristics.

Sources of Water Supply

The important natural sources of water supply in France are as follows:

1. Flowing streams.
2. Shallow lakes.
3. Springs.
4. Water bearing river valley deposits.
5. Shattered limestone or chalk at margins of certain river valleys and bottoms of certain types of ravines.
6. Deep water bearing formations.

These included all classes of water supply developed for use by the American Expeditionary Forces.

Flowing streams occur throughout almost all of France and with certain exceptions have a dependable flow throughout the year. The exceptions are; first, a considerable portion of the Brittany Peninsula and the Central Massif where the rainfall is relatively light, the formation impervious and sloping, and vegetation limited; second, flat or gently sloping clay and shale areas of the Paris Basin; and third, tributaries and upper reaches of streams having their source in elevated limestone formations of the Paris Basin. Artificial storage is necessary to develop an important water supply from streams in the first two of these areas and was undertaken for the purpose of supplying the Base Port at St. Nazaire. River water was used for the supply of several large hospitals in Central France and also at certain points in the area covered by the Argonne-Meuse and St. Mihiel offensives.

Shallow lakes (*étangs*) occur in flat impervious formations of the Paris Basin, principally on the clay zone locally known as the Woevre (Toul Sector and northward to Stenay), and on late Tertiary alluviums (southeast of Tours). Many of these lakes have been increased in size and permanency by low earth dams for use as fish preserves. The water is more or less stagnant and often colored, but can easily be rendered potable. Water from such lakes was practically the only available supply during the St. Mihiel offensive for troops advancing northward from the vicinity of Xivray and Mont Sec.

Springs are widely distributed throughout France and many have a large flow and are reasonably dependable. The largest recorded has an average flow of 9,000 gallons per minute. Many permanent springs have average flows of 25 to 50 gallons per minute. The "contact" type of springs is a very important one in the northeastern portion of the Paris Basin. These issue from fissured limestone interbedded with layers of shale or clay, these latter serving as an impervious base upon which the water absorbed from precipitation may accumulate, occupying the fissures, cracks and joint planes of the overlying limestone. With the hydrostatic level in the limestone above a certain elevation, the water finds an outlet through some fissure, and issues as a spring at the contact plane, where the latter is above the level of the adjacent surface drainage channels. The "crevice" type of spring occurs where the contact plane is below the local drainage level. The latter type also occurs in fissured sandstone, which usually occurs without interbedding with impervious formations. Springs were the most generally used sources of water supply in the Argonne-Meuse offensive. They were also extensively used for small hospital and camp supply in rear of the Army Zone.

Water bearing river deposits consist of porous sand and gravel transported from the highland areas. They occur in shallow beds filling the bottoms of river valleys and usually yield water readily. The principal streams along which such gravels are found are the Moselle, the Upper Loire, the Cher, and the Rhône Rivers and their tributaries, and the tributaries of the Dordogne and Garonne Rivers. The French usually develop water from such deposits either by means of large dug wells or galleries. For military supply, however, the most practical method is by use of small dug, driven or drilled wells. This source of supply was used by the American forces at several hospitals and other permanent stations in

Digitized by Google

rear of the Army Zone. It could only form an important supply where the stream traversing the valley had a permanent flow not insulated from the gravels.

Shattered limestone at the margins of river valleys with water-bearing alluvial deposits, and occasionally in ravine bottoms where the water plane is shallow, sometimes yielded large quantities of water from dug wells. The success of such a well is somewhat a matter of chance. One such well at Sorcy Gare, the railhead for the Toul Sector, produced considerable water as did also the wells dug by the French in ravines in the vicinity of Verdun during their offensive of 1916.

Deep water-bearing formations consist of porous strata, lying at various depths below the surface exceeding 100 feet, from which water may be obtained in considerable quantity by means of drilled cased wells, either with pumping or by artesian flow. Deep water-bearing formations do not occur in the highland areas. There are important deep water-bearing formations, however, in each of the three basins. In the Paris Basin the fissured sandstone (*Gres Vogien*), whose intake area is along the western slope of the Vosges Mountains, is reached in the vicinity of Nancy and Lunéville at a depth of 2,500 to 3,000 feet and large artesian flows occur from wells located in the river valleys. Farther west in the same basin and, in fact, practically circling the whole inner basin is the intake of a porous lower Cretacious sandstone (*sable vests*). This formation has a depth of 1,500 feet near Paris and is progressively shallower toward the exposed edge of the stratum. Large artesian flows are obtained from wells in river valleys. The famous artesian wells furnishing part of the supply of Paris penetrate this formation. The upper chalks in the northern part of the Paris Basin are also an important water-bearing formation which the British Army extensively developed by means of drilled wells 200 to 300 feet in depth. In the Aquitaine Basin to the southwest of the line of faulting described above, the porous Eocene sandstones are locally depressed to a considerable depth and contain water under pressure. Large artesian flows occur from depths of 600 to 900 feet in wells drilled along the river valleys in the vicinity of Bordeaux and southwest of the line of faulting. Other less important deep water-bearing strata exist in both the Paris and Aquitaine Basins. The time required for drilling wells precludes the use of deep water-bearing strata as a source of supply in the Army Zone, particularly in a war of movement.

A number of successful deep wells were drilled by American forces in the vicinity of Bordeaux and also near Tours. These wells were drilled by American "oil country" drillers with American machines, and, much to the astonishment of the French, were completed in as many weeks as similar wells drilled by themselves had required months and even years to finish. These wells all penetrated recognized water-bearing strata. In other locations where wells were drilled without consideration of the geology and in unfavorable locations, either dry holes or very meagre yields were obtained. There was an idea prevalent even among engineers, that a well rig possessed a certain mysterious charm capable of curing all water supply ills, and that by drilling deep enough, water in abundance was bound to be reached at any nicely located camp, hospital, or depot. As a matter of fact, however, the highland areas and certain portions of the basins are not underlaid by water-bearing formations and efforts to drill wells in such areas were foredoomed to failure. By the application of the principles of ground water hydrology it is possible in many instances to predetermine the probability of success and so obviate the needless loss of effort and time. The practice of ground water hydrology has now passed beyond the stage of supposition and when judiciously applied is of much value in practical water development.

General Hines appointed Superintendent of Inland Waterway Transportation.—The Secretary of War has delegated to Brigadier General Frank T. Hines, Chief of the Transportation Service, U. S. Army, control of the inland waterway transportation systems which were transferred to the jurisdiction of the War Department under the Transportation Act which returned the railways to private control. General Hines has announced that the same service will be maintained for the present and that he will utilize the existing organization and personnel in administering the work.—*Railway Age.*

The English Channel tunnel.—In order to expedite decision respecting the construction of a tunnel under the English Channel, a deputation of the Channel Tunnel Committee of the House of Commons recently called upon the Prime Minister. His attention was called to the fact that no serious engineering difficulties were anticipated; that the time necessary for completion would be five years; and the total cost would be $155,728,000, or double the pre-war estimate. There was said to be great enthusiasm for the scheme in France.

The Prime Minister, in replying, stated that the problem would be carefully examined from the engineering, military, naval, and air points of view, and "if the military advice is favorable, the Ministry will certainly be prepared to support the plan on general grounds."—*Railway Age.*

New railroad line for Mexico.—The Rio Grande border town of Ojinaga, which has figured prominently in revolutionary affairs in Mexico in recent years, is to obtain a railroad outlet according to official announcements. It is stated that the Department of Communications and Public Works has authorized the construction of a railroad from Juarez to Ojinaga, 250 miles, and that the survey for the proposed line has been ordered. The route of the road will follow closely the course of the Rio Grande.—*Railway Age.*

Retirement of Engineer Officers

General Sibert

Major General Wm. L. Sibert, U. S. Army, whose portrait appears as our frontispiece in this issue, was at his own request placed upon the retired list April 3, 1920. By his retirement the service loses one of its ablest officers, to whose energy and skill as organizer, executive and engineer, the successful completion of many important public works is due.

He was born in Gadsden, Alabama, October 12, 1860, graduated from West Point in 1884, and was commissioned in the Corps of Engineers. Until 1907 he was engaged chiefly in river and harbor work in the United States, but served also in the Philippine Islands during the insurrection in 1899, where he achieved his usual success as Chief Engineer of the 8th Army Corps in an expedition against hostile natives. For this service Sibert (then a captain) was recommended for promotion to the grade of Brigadier General.

General Sibert's career has been characterized by sound judgment, great practical ability and resourcefulness, and a willingness to assume responsibility while giving his subordinates full power of action. An incident occurring during his tour of duty in charge of the important Pittsburgh district shows the nature of the man. During the construction of a dam in the Ohio River a flood occurred which, because of the obstructions in the river incident to the building of the dam, threatened to flood a large area and cause millions of dollars of damage. General Sibert on his own initiative, without any authority, unhesitatingly destroyed nearly $100,000 worth of construction, thereby releasing the flood waters and preventing the threatened disaster.

In 1907 the U. S. Government placed the construction work on the Panama Canal in the charge of the Corps of Engineers of the Army. General Sibert was then a major, but even at that time he was recognized as the peer of any construction engineer in the U. S. Accordingly, in March of that year he was ordered to Panama as a member of the Panama Canal Commission, construction engineer on the "Big Ditch," and second in command to Gen. G. W. Goethals.

At Panama Sibert was assigned the difficult tasks of damming the Chagres River, constructing the Gatun locks and dam and the breakwater at Toro Point. This was Sibert's great opportunity, and all the world now knows that he proved more than equal to it.

In 1914 his work on the canal was successfully finished, Sibert received the thanks of Congress, was promoted to Brigadier General, and later (in 1917) to Major General.

Sibert the soldier is the equal of Sibert the engineer. When America entered the World War, Major General Sibert was selected to organize, train and command the first American combatant troops sent to France, the famous 1st Division Regulars. That the fighting efficiency of the 1st Division was never exceeded by any other organization in any army was due in large measure to the training received at the hands of General Sibert and the spirit absorbed from him.

In the spring of 1918 our government was beginning to appreciate the great importance of a new combatant arm, chemical warfare. The spasmodic efforts to organize this service had produced no satisfactory results. To General Sibert was entrusted the grave responsibility of placing the new service on a basis of practical working efficiency. This he proceeded to do with his characteristic skill and energy, and his success in building up the Chemical Warfare Service is perhaps the best proof of his ability and force of character.

For his services in the Great War, General Sibert was awarded the Distinguished Service Medal and was made Commander of the Legion of Honor of France.

He has five sons, all of whom, like their father, served in the armed forces during the war in grades from corporal to lieutenant colonel.

General Sibert's last active command was the 5th Division at Camp Gordon, Ga. He retires from the government service in order to devote his attention to private business affairs, including the development of oil resources on his estate in Kentucky.

To few men still in the bloom of health, is vouchsafed the privilege of looking back upon a life so full of varied achievements. The name of Sibert is justly honored in the history of the Corps of Engineers and in the annals of the engineering profession, not in his native land alone, but throughout the world.

Colonel Shunk

Col. Francis R. Shunk, Corps of Engineers, was, at his own request, placed upon the retired list March 6, 1920.

Col. Shunk was born in Pennsylvania, November 25, 1862. He graduated from West Point at the head of his class in 1887, and was commissioned in the Corps of Engineers, rising through the various grades to that of Colonel in 1917.

Colonel Shunk's career is an excellent example of the versatility demanded of the engineer in these days, and the wide territorial range of his activities. Few engineers have been able to perform with consistent success such a wide variety of duties as fell to his lot in so many different places. He has served his country with conspicuous fidelity and ability from Maine to Porto Rico, and from the At-

Digitized by Google

lantic Seaboard to the Philippine Islands. He has been an active member of Boards for the consideration of a great variety of engineering projects, including membership on the Board of Engineers for Rivers and Harbors; he has improved rivers, built locks and dams, harbors, lighthouses and fortifications. He has been instructor at West Point,

Photo by Harris & Ewing

Francis R. Shunk
Colonel, Corps of Engineers, U. S. Army

and Department Engineer officer, and has commanded engineer troops at home and abroad.

His last assignment on active duty was as District Engineer in charge of the important district of Boston, Mass.

Colonel Harding

Col. Chester Harding, Corps of Engineers, Governor of the Panama Canal Zone, was retired from active service March 31, 1920, with the rank of Brigadier General, in recognition of his services as one of the builders of the Panama Canal. He will continue his duties as Governor of the Canal Zone.

General Harding was born in Mississippi, December 31, 1866, the son of Horace Harding. He is the descendent of a line of soldiers who served in the Indian and Revolutionary Wars. He graduated from West Point in 1889, number four in his class, and entered the Corps of Engineers, in which he rose to the grade of colonel, in 1917.

General Harding's career has been active, varied and successful. He served in the U. S. Engineer Districts in New York, Chicago, Newport, St. Louis and Grand Rapids, as instructor at the Military Academy, and Commissioner of the District of Columbia.

His chief claim to fame, however, is as a builder of the Panama Canal, where he was for two years engineer of the Gatun Locks division. He subsequently held the important posts of Engineer of Maintenance of the Panama Canal, President of the Panama Railway, and Governor of the Canal Zone. For his services as a builder of the

Photo by Harris & Ewing

Chester Harding
Brigadier General, U. S. Army

Panama Canal, General Harding received the thanks of Congress.

General Harding, who is but 54 years of age, and in vigorous health, will continue his work as a professional engineer upon the completion of his term as Governor at Panama.

The Chief of Engineers, U. S. Army, and the railways.—The Chief of Engineers, U. S. Army, exerts a most profound influence on certain matters of real importance to the railroads. Through the authority of the War Department over navigable waters, the decision of the Chief of Engineers must be obtained to plans for bridges, docks, and other engineering work when the interests of the railroads are thrown in contact with those of the waterways. He is thus in a position to require an expenditure of many thousands of dollars in excess of the amount which the railway officers may deem adequate at the inception of the undertaking merely to meet the railway requirements. In the establishment of dock lines, the determination of bridge span lengths for river channels, and regulations governing the design, maintenance and operation of movable bridges, the Chief of Engineers exercises control in the public interest of navigation.—*Railway Age.*

Possibilities of the Next War

From a lecture before the Royal United Service Institution

By

Maj. Gen. Sir Louis Jackson

Following the Great War, peoples cry aloud for disarmament and a reduction of expenditures for defense. The temptation to listen to them is very great. But should we do so we would presently be exposed to dangers even greater than those which confronted us in the late war.

As to the possibility of future war, Germany has frequently informed us, through many mouths, that she hopes for revenge some day. Let us recognize war as an inevitable accompaniment of human life. And if we are to prepare let us prepare thoroughly. We are on the eve of the most extensive changes in the art of war known to history, and the developments of the late conflict are only the beginning.

In these days nations take all possible advantage of secret preparations and attack suddenly without warning or without previous warning. This is an advantage a combatant is not likely to forego.

In the future wars, due to the development of the tractor, mechanical transport of artillery and supplies will be independent of the roads. Caterpillar tractors will be able to negotiate any terrain and surmount ordinary obstacles at a speed of 6 miles an hour. There will be no more congestion of roads and the entire transport of a division will follow it, deployed in open order. This will powerfully influence the tactics of the future. Roads will still be used for fast wheeled transport, but we will not be dependent upon them.

With regard to the use of gas in future wars, there is no more reason to forbid its use than to forbid the use of rifles. There were gases which killed painlessly, and it is easy to conceive cases in which it would be more humane to use gas than explosive shells. This is especially the case with punitive expeditions. It might be possible to come to some agreement that no gas would be used which would cause unnecessary suffering. Commercial progress and prosperity in the twentieth century will depend on chemistry, and chemical productions must have a great effect on all future warfare.

It is in the air that we are face to face with the problem of the future. It was in the air that we have made the most important advance in the art of war. We need not trouble ourselves yet with flying destroyers, or flying concrete forts, but in twenty years' time the air force estimates might be the most important part of our preparations for war. Bombing and reconnaissance machines will be developed commercially, for the machines used in commerce could easily be adapted to war purposes, and civilian pilots could be taken over with the machines. For fighting machines special types are required and highly specialized training is necessary for the personnel. For both machines and the men to man them, that side of flying must be developed by the government. One result of return to open warfare would probably be that bombers would not have the same targets near the front of the armies and would secure better results by going farther afield and bombing the centers where munitions were manufactured, stores were accumulated, and troops were trained.

There is room for great simplification of the means of communication, and the open warfare of 1918 led to the elimination of some forms of communication which had been used previously. Wireless telegraphy will be the principal means of communicating with aircraft. The development of the electrical listening posts used in trench warfare, and a ground wireless system will become the standard means of communication between advanced infantry and the headquarters controlling them. Smoke and light signals, a pillar of cloud by day and a pillar of fire by night, will be used by troops to show the positions they have reached.

There has never been a war in which such an extreme variety of weapons was employed. The long rifle has seen its day and should be replaced by a short carbine which would be accurate to 500 yards. Each man should also carry a good dagger which might be made attachable to the carbine like a bayonet. The automatic pistol will not survive, and the grenade may also go. It is doubtful, too, whether the Stokes mortar will survive. For our artillery we must be guided by the definite idea of the tactical possibilities of the future. If we assume the full exploitation of mechanical transport greater mobility in artillery would be required in order that the guns could keep up with the more rapid advance of the troops. The artillery must be of a character that it could be brought to the required position in the shortest possible time. Caterpillar traction should be employed, and for a daily advance of 12 miles the guns must be capable of an effective barrage up to 13,000 yards. A short 4.2-inch gun with an accurate range of 12,000 yards and a long 4.2-inch gun with an accurate range of 20,000 yards, might meet the requirements of the future.

The soldier of the future must be absolutely different from his predecessor. The days have gone when initiative was considered not only unnecessary, but dangerous In addition to his rifle, he should be able to handle a Lewis or machine-gun and to help the artillery. He should know something of explosives, have a general knowledge of fuses, understand signalling, and be capable of handling a ground wireless set. The soldier of the future must be a "handy man."

The question of invasion being primarily a naval question was outside the scope of this paper, though the possibilities of attacking transport by aircraft carrying torpedoes might come within it. Six months before the war the author was regarded as an alarmist because he spoke of the possibility of London being bombed. The Germans had made a mistake in using explosive instead of incendiary bombs. With the greater range of aircraft the position has become more dangerous for us, for we may be sure that every lesson has been learned from the failures as well as the successes of the last war. It is clearly impossible to provide anti-aircraft defenses for all the large towns in the country, and they would have to rely for protection upon our air forces. London could not rely solely upon our fighting machines and a large number of anti-aircraft guns with well-trained personnel would be required for the defense of London. The expense involved is a necessary insurance.

Railroad Trestle Building in Military Operations

By

Billings Wilson

Captain, Engineers

Note. In a presentation of this subject the writer realizes that most experienced engineers will see only a "rehash" of the existing fund of information, and this is necessarily true to a large extent. The main idea is to furnish a ready reference of actual working figures for the younger engineer officer of the army. Any civil engineering handbook will give various sizes and limiting dimensions for the timbers that go to make up a railroad trestle but the first time a young designer encounters these tables, he is apt to be at a loss as to the exact sizes to select. Frequently he will attempt to select values by rough computations of his own, using his cut and dried beam and column formulas—all of which is waste of time. The writer clearly remembers the time he was promoted from the "ranks" to be Assistant Resident Engineer and immediately called upon to make up designs and bills of material, in twenty-four hours, for about six grade crossing elimination projects, involving many underground "hazards" in the way of sewers, water and gas mains, electric light conduits, canals, etc. A knowledge of the standard market sizes of timber, combined with handbook information and a few leading questions saved the day. Senior engineers are apt to assign such problems, simple of solution with experience, to a new man to test his initiative and resourcefulness. It is hoped that these notes will be of some assistance, not only to the younger man, but perhaps at some time to the senior confronted with a problem of this kind who wishes to brush up hurriedly on such elementals and write down the answer.

The recommendations made herein are primarily for military engineering where *speed* in construction is the essential factor, and permanence with its *high factors of safety* is subordinate. In a rapid advance into enemy territory railway communications must be restored immediately. Wooden bridges will be burned and steel spans dynamited, and the timber trestle, with crib piers or frame and pile bents, is the quickest and often the only possible solution of emergency bridge problems. In such cases, for example, the one item of five-pile instead of six-pile bents, for ordinary heights, may save *hours* in effecting a crossing, and hours have a tactical equivalent value in mobile military operations. The value of *time* in war is so great that economies in money cost are of far less importance than in peace time operations, and if carried too far may actually defeat the aims in view.

FOR rapid emergency construction, if the material is at hand in each case, crib piers can be built more rapidly than trestles for heights of 15 feet or less (18 feet to base of rail). From 15 feet up to 25 feet frame bents are the fastest construction, and above 25 feet (28 feet to base of rail), pile-bents are almost invariably the quickest type of pier. In cases where rock bottom will not permit the driving of piles frame-bents should be built for all heights over 15 feet, unless running water is present; in which case crib-box piers should be built on shore, floated into position and sunk with one-man stone. It will be recognized that this latter method has its limitations and should only be used when other types of emergency piers are out of the question. Regarding "shooflies," it can be said that they are the fastest method of crossing wide, dry openings, but where and where not to use them must be determined for each case in the field, and the relative speed for effecting a crossing will, as in all cases, depend on the experience and judgment of the reconstruction engineer.

A combination pier, consisting of framed bents resting on cribs may often be employed to advantage.

Caps should always be 12 by 14 inches, laid on edge, for permanent operation. Twelve by 12 caps will do in an emergency, but should be replaced by 12 by 14 inch as soon as possible. Caps and sills should when possible extend beyond the outer posts (1 to 2 feet), to strengthen the "grip" of the sway bracing, which greatly increases the lateral stability of the bent.

Posts, sills and intermediate sills for frame bents should be 12 by 12 inches. (Ten by 12 inch and 10 by 10 inch posts may be used in an emergency, but have a factor of safety too low for continued operation.)

Sway braces, sash braces and longitudinal X-braces should all be at least 3 by 10 inches in section, and the sash braces preferably 3 by 12 inches. They should not be erected at a steeper angle than 55 degrees from the horizontal (the nearer 45 degrees the better). For sway bracing, *on pile bents,* this will mean:

No bracing required on bents less than 10 feet high;
Single-story bracing on bents from 10 to 17 feet high;
Two-story bracing on bents from 17 to 32 feet high;
Three-story bracing on bents 32 to 48 feet high;
Four-story bracing on bents from 48 to 64 feet high.

There is an exception to the recommendation for no bracing on bents less than 10 feet high. It quite frequently happens that piling will encounter an impenetrable stratum a few feet below the surface and the penetration will be insufficient to prevent the piling from spreading. The A. R. E. A. recommends in this case that the "strength should be determined as a column or beam; omitting the resistance, if any, due to skin friction." Stiff bracing is very important here and should always be used—particularly a heavy sash brace flush with the surface of the ground, or as near low water as possible. The depth of penetration required to give sufficient stiffness to the foot of a pile bearing on a hard stratum varies with the character

Digitized by Google

of the soil penetrated. Practical considerations, however, permit the recommendation that bracing, including a lower sash brace, should be used in all cases where the penetration is less than 8 feet.

For frame bents, the same holds true regarding the slope of the bracing, but another consideration enters. For heights over 24 feet high, it is better to build a second deck, and in all frame bents of more than one deck, providing materials are obtainable, the maximum economical height of each deck (that is, distance between intermediate sills) is about 24 feet. For this height of deck double-story sway bracing is necessary between intermediate sills. It is customary in multiple-deck frame trestles to make the height of the decks the same on all the bents, and each as nearly a factor of the total height as possible. This means:

Single-deck frame bents up to 24 feet high;
Double-deck frame bents 24 to 48 feet high;
Triple-deck frame bents 48 to 72 feet high, etc.

When longer timber is obtainable at a reasonable price, it is recommended that 30-foot posts be used as a maximum instead of the 24-foot lengths here listed. It is often possible, in certain sections of the country, to obtain 12 by 12 inch timber in 30-foot lengths at a small increase in cost, and the saving in time required to reopen a damaged line will almost invariably well repay the additional expenditure for the extra length. It is suggested, therefore, that a stock of these longer timbers be kept on hand for emergency repairs--but for reconstruction on a large scale, 24 feet is considered as the maximum economical length of post.

Sway bracing on each deck will be single or double story, as the distance between intermediate sills is less or greater than 16 feet.

Longitudinal X-bracing or "tower bracing" should be placed on every other span of trestles between the heights of 14 feet and 42 feet. For heights above 42 feet all spans should be tower-braced, but the bracing on every third span should extend down to within 6 feet of high-water mark only, to allow for passage of drift. This tower bracing is quite frequently slighted and the writer believes it to be a serious omission. The backward pressure of the driving wheels of a locomotive against the track, when working steam, or the forward pressure, when brakes are applied, creates a thrust force in the trestle deck perpendicular to the planes of all the bents and tending to overturn them. This thrust becomes dangerous in high trestles and for that reason tower braces are very necessary.

A sash brace must always be placed between each story of sway or longitudinal X-bracing.

Sway bracing should be through bolted at each intersection, including the outer ends of caps and sills.

Stringers should be 8 by 16 inches, placed on edge. For spans of 13 feet or less (center to center of caps), three-ply stringers under each rail should be used; four-ply for spans 13 to 16 feet; and steel stringers, or girders used on all spans over 16 feet. These spans may be exceeded by one foot in emergencies.

Longitudinal girts and guard timbers should be 6 by 8 inches, and dapped at least 1½ inches over each tie or sash brace. Girts are required on heights over 24 feet only.

Piling should be at least 12 inches in diameter at ¼ of the length from the butt and not over 20 inches diameter at the butt. The minimum diameter of the point should be not less than 9 inches for piles not over 30 feet long, 8 inches for piles from 30 to 50 feet long, 7 inches for piles over 50 feet long. A line drawn from the center of the butt to the center of the tip should lie wholly within the body of the pile.

Supporting power of bents is usually a function of the supporting power of the soil rather than of the timber. For 13-foot spans the maximum pier reaction of an E-60 locomotive is 74 tons under each rail or 148 tons total on the pier. For 16-foot spans, the maximum pier reaction under each rail is 86 tons or 172 tons total on the pier. The safe supporting power of a 4-post (12 by 12 inches) *frame bent* based on strength of timber, is 263 tons for Douglas fir, long or short leaf yellow pine and western hemlock of standard or standard heart grade. A *4-pile bent* has a safe supporting power, on the same basis of 172 tons total or 43 tons per pile. This means that 4-post bents are sufficient for any modern loading, so far as timber stresses are concerned. However, the supporting power of many soils is insufficient when only 4-piles are used. With the exception of stiff clay, hardpan and certain grades of sand, a pile penetration of over 25 feet is usually necessary to obtain a safe supporting power of 43 tons per pile. It is recommended, therefore, that 5-pile bents be used on main lines where heavy traffic prevails, and that 6-pile bents be used on these same lines where the height from ground to base of rail is over 30 feet. Four-pile bents are sufficient for heights under 30 feet in all emergency construction and in permanent work on branch lines, or on main lines with light traffic. Above 30 feet, 5-pile bents are recommended in these latter cases, but it is impossible to make rigid specifications for this class of work and the field engineer must determine the safe number of piles in all cases, by a judicious examination of subsoil conditions at the site of the work. Frame bents of one story require only 4 posts under all conditions, care being taken to provide ample bearing on mud sills. Frame bents of more than one story should preferably have 6 posts in the lower stories to increase the rigidity

Digitized by Google

of the structure. A summary of the foregoing in tabular form, is:

Frame bents, of one-story; 4 posts recommended.

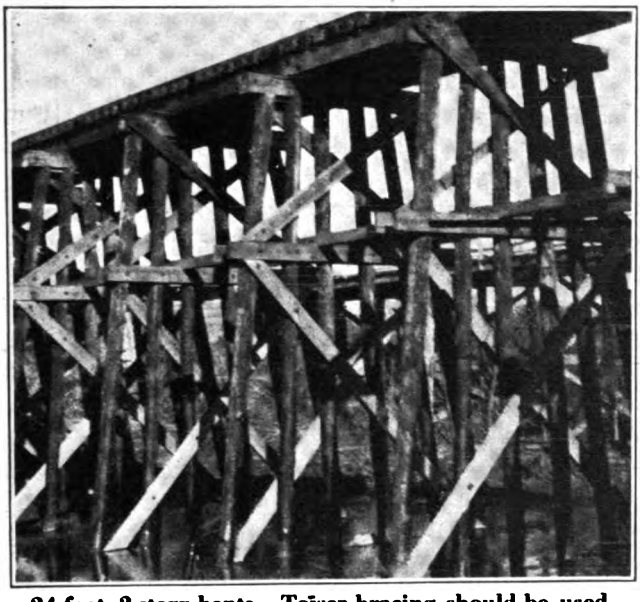
Frame bents, more than one-story—

4 posts in upper story.

6 posts in lower stories.

Very high frame bents require special designs in each case.

Pile bents; on main lines, height under 30 feet—



5 piles recommended.

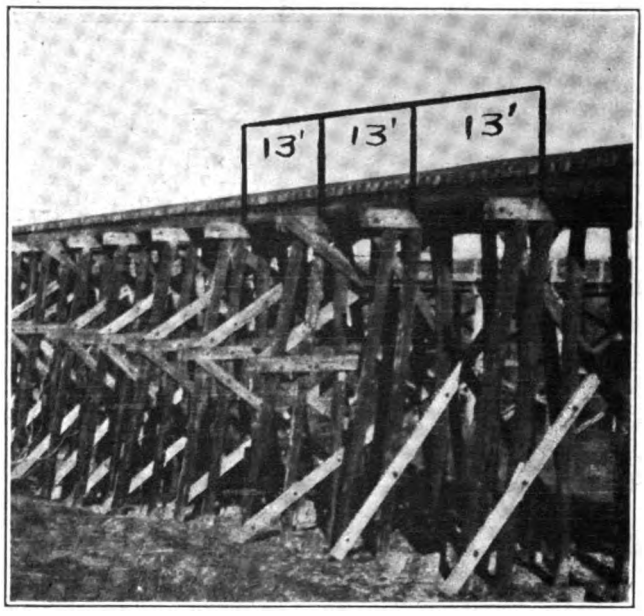
Pile bents; on main lines, height over 30 feet—

6 piles recommended.

Pile bents; emergency work, and branch lines, height under 30 feet—

4 piles recommended.

24-foot, 2-story bents. Tower bracing should be used on trestles of this height



Pile bents; emergency work, and branch lines, height over 30 feet—

5 piles recommended.

The following is a theoretical discussion of supporting reactions in pile foundations, and is submitted, not as an original study, but rather as a concise presentation of known conditions for the benefit of those engineers who have not previously considered the subject in detail.

The function of a pile is to transfer a concentrated load to the subsoil in a diminished unit concentration, or to carry the concentrated load through a soft strata to one capable of carrying the greater unit concentration. In doing this, skin friction exerts supporting power varying considerably with different kinds of soil, but apparently a variable function of the direct bearing value of the soil (the variable element being in most cases water content). As a pile is driven it creates a "cone of bearing" about itself, this cone diverging downward and its rate of divergence dependent on the relation of skin friction to bearing value in the particular soil. If piles are driven too close together, these cones overlap and consequently overload areas of subsoil and decrease the safe unit-pile supporting power. The writer recommends a minimum spacing of piles of 2 feet 6 inches on the ground surface and a batter sufficient to prevent extensive overlapping of these "cones of bearing."

Batter serves two purposes: (1) to stiffen the bent against side thrust, thus assisting the sway bracing, and (2) to spread the foundation over sufficient bearing area, and at the same time have the heads of the piles close enough together to keep down the size of cap necessary. (The first consideration is the more

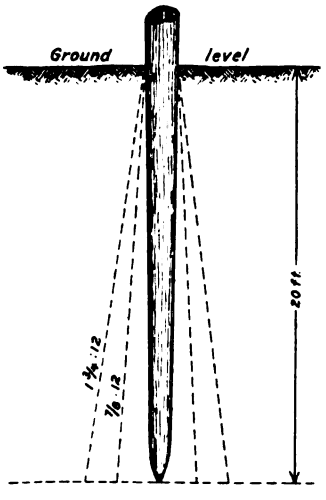
Change from single story to double story sway bracing when height reaches 24 feet

important in frame bents, and the second in pile bents.) A fair summary of observations and test reports at the writer's disposal, shows the following:

Table 1.

Nature of subsoil.	Direct bearing lb. sq. ft.	Skin friction lb. sq. ft.	Average Ratio DB to SF	Average Ratio SF to DB
Soft River Mud	400– 800	360	1.66	.602
Marsh	800– 1,800	600	2.16	.463
Alluvial Mud	1,600– 4,000	800	3.50	.286
Stiff Clay	8,000–12,000	1,800	5.55	.180
Sand, unstratified	4,000–12,000	1,000–3,000	4.00	.250
Sand, stratified "in situ"	12,000–18,000	2,000–5,000	4.80	.208

The last column represents the theoretical square feet of subsoil under load outside the perimeter of the pile, the load being transferred to this area by the skin friction on one square foot of pile surface.



Assume, for purposes of comparison, a pile with a

Digitized by Google

9-inch tip driven to 20 feet penetration, the diameter of the pile at the surface of the ground being 15 inches. The surface area of the pile in contact with the soil will then be 63 sq. ft. and by simple computations we obtain the following:

Table 2.

Nature of subsoil.	Area of indirect bearing sq. ft.	Area of direct bearing sq. ft.	Total area of bearing (base "cone of bearing") sq. ft.	Diameter of "cone of bearing".	Batter of cone surface per vertical ft.
				ft.–in.	
Soft River Mud	37.9	1.2	39.1	7 1	1¾ in.
Marsh	29.2	1.2	30.4	6 3	1½ in.
Alluvial Mud	18.0	1.2	19.2	5 0	1⅛ in.
Stiff Clay	11.4	1.2	12.6	4 0	⅞ in.
Sand, unstratified	15.8	1.2	17.0	4 8	1 in.
Sand, stratified	13.1	1.2	14.3	4 3	⅞ in.

In Table 2, column one represents the subsoil area in bearing as a result of transfer of load from the pile by skin friction. Column two is the subsoil area in direct bearing, being the vertical projection of the cross sectional area of the pile at the ground surface. Column three is the sum of columns one and two, and represents the area of "spread footing." Column four gives the diameter of the circles whose areas are given in column three. The last column is the slope of the surface of cones 20 feet high with base diameters those in column four. This last column represents the theoretical difference in batter required between any two adjacent piles to avoid overloading any portion of the subsoil. Since the load carried by a pile can only be transferred to soil *outside* of the perimeter of the pile by skin friction, it follows that the higher the supporting power of the subsoil the less the area of the cone of bearing required to support the load transferred away from the pile by skin friction. And conversely, in the softer and more fluid soils, where skin friction is a more important supporting factor, a larger cone of bearing is required to support the same load. These cones of bearing must not be confused with the truncated cones of direct bearing underneath, and inside the perimeter, of the pile. The divergence of the load in these latter cones is simply that of the ordinary reaction of a soil to a superimposed load and is a fairly well known function of the coefficient of friction of the individual particles in the soil.

In railroad trestles, or in any pile support where all the piles are driven in one plane and no other piles driven alongside within say 10 feet, it is permissible and better to allow the bases of the "cones of bearing" to overlap slightly. This will reduce the amount of batter required and diminish the spacing of the piles, making for more economical construction. Also the percentage of overlapping area in each cone base is relatively small when the combined middle ordinate does not exceed one foot (being about 14 per cent in stiff clay, and 6 per cent in soft mud).

In cases where very deep penetration is necessary to obtain a sufficiently large and, at the same time, safe supporting power for a pile, it is evident that the foregoing theory would demand abnormal batters or rather large pile spacings. (By "very deep penetration" is meant penetration over 70 feet.) In these cases, almost invariably, there is a great deal of water in the subsoil and the foregoing values for direct bearing and skin friction do not apply. It is probable in this class of foundation that there is little, if any, load transferred from the pile to the subsoil in the upper quarter of its length and that the rate of transfer in the lower three quarters is considerably less than any values derived hereinbefore. This would mean a steeper "cone of bearing" than any here worked out, with a consequently smaller allowable pile spacing and batter. Reliable data on pile supports in soil of this character being exceedingly limited, it is difficult to predict, in a purely theoretical discussion, the nature and amounts of the subsoil reactions. Test piles must be driven, not singly but preferably in groups of three or four, and loaded as a group, to derive a safe working figure for the foundation support as a whole.

Based on the foregoing theoretical discussion and certain practical considerations, the following batters are recommended for railway trestle bents in average soils—

4—Pile bents (spacing, 2½, 3, 2½ feet).
2 inside piles plumb.
2 outside piles battered 2½ inches; 12 inches.

5—Pile bents (spacing 2¼, 2½, 2½ feet).
Center pile plumb.
2 intermediate piles battered 1 inch; 12 inches.
2 outside piles battered 2½ inches; 12 inches.

6—Pile bents (spacing 2¼, 2½, 2½, 2½, 2¼ feet).
2 center piles plumb.
2 intermediate piles battered 1 inch; 12 inches.
2 outside piles battered 2½ inches; 12 inches.

Digitized by Google

The spacings here given are to be taken as a minimum.

It must be borne in mind that batter piles driven to the same depth as plumb piles have greater supporting power because of their greater penetration. In the foregoing discussion it is assumed that all piles are driven with the same penetration. In actual practice they are frequently driven to the same depth, but the difference in supporting power, because of this is neglected here, the error being on the side of safety, and less than 3 per cent.

Believing that many field engineers do not give sufficient attention and consideration to pile driving, the following principles of practice, as recommended by the American Railway Engineering Association, are quoted for guidance:

Pile spacing, 24 foot bent. Note absence of lower sash brace, not required if penetration is 8 feet or more

There is danger from overdriving when the hammer begins to bounce. Overdriving is also indicated by the bending, kicking or staggering of the pile.

The brooming of the head of the pile dissipates a part, and in some cases all, of the energy due to the fall of the hammer.

The use of a cap is advantageous in distributing the impact of the hammer more uniformly over the head of the pile, as well as in holding it in position during driving.

The steam hammer is usually more effective than the drop hammer in securing the penetration of a wooden pile without injury, because of the shorter interval between blows.

In general, the resistance of piles, penetrating soft material, depending solely upon skin friction, is materially increased after a period of rest. This period may be as short as fifteen minutes, and rarely exceeds twelve hours.

Before testing the penetration of a pile in soft material where its bearing power depends principally, or wholly, upon skin friction, the pile should be allowed to rest for 24 hours after driving.

Where the resistance of piles depends mainly upon skin friction it is possible to diminish the combined strength, or bearing capacity, of a group of piles by driving additional piles within the same area.

Where a pile penetrates muck or a soft yielding material and bears upon a hard stratum at its foot, its strength should be determined as a column or beam; omitting the resistance, if any, due to skin friction.

Where piles will foot in a hard stratum, investigation should be made to determine that this stratum is of sufficient depth and strength to carry the load.

Piles should not be pointed when driven into soft material.

Shoes should be provided for piles when the driving is very hard, especially in riprap or shale. These shoes should be so constructed as to form an integral part of the pile.

Piles should be driven to a firm bearing; or until five blows of a hammer weighing 3,000 lbs. falling 15 feet (or a hammer and fall producing the same mechanical effect), are required to cause an average penetration of ½ inch per blow, except in soft bottom where special instructions must be given. (Note: This rule will give a safe bearing value of about 30 tons per pile.)

Framing details, upper story. Note dap of longitudinal girt on sash brace

Batter piles should be driven to the specified inclination, and should require but slight bending before framing.

Table 3—Working Unit-Stresses for Structural Timber, Expressed in Pounds per Square Inch.

Note.—The working unit-stresses given in this table are intended for railroad bridges and trestles. For highway bridges and trestles the unit-stresses may be increased twenty-five (25) per cent. For buildings and similar structures, in which the timber is protected from the weather and practically free from impact, the unit-stresses may be increased fifty (50) per cent. To compute the deflection of a beam under long-continued loading instead of that when the load is first applied, only fifty (50) per cent of the corresponding modulus of elasticity given in the table is to be employed.

Kind of Timber	Bending			Shearing				Compression						
	Extreme Fiber Stress		Modulus of Elasticity	Parallel to the Grain		Longitudinal Shear in Beams		Perpendicular to the grain.		Parallel to the Grain.

Adopted, 1909, by American Railway Engineering Association.
These unit-stresses are for a green condition of timber and are to be used without increasing the live load stresses for impact.
*Partially air-dry.
L equal length in inches.
d equal least side in inches.

Results of Federal control of railroads.—There has been so much adverse criticism of government control of railroads, much of it unjust, that it should afford some relief to the average citizen to hear the other side of the story as related by those who know the facts. Federal control made practicable a War Transportation Service that could not have been otherwise obtained; its unification practices have increased the utilization of the inadequate supply of equipment so that an exceptionally large transportation service has been performed in the busy periods of 1919 with a minimum of congestion; it met the emergency of the unprecedented coal strike in a way which private control could not have done and absorbed a heavy financial loss on that account which would have proved highly disturbing to private control; it provided more additions and betterments and equipment than private control could have provided during the difficult financial period of 1918 and 1919; it dealt fairly with labor and gave it the benefit of improved and stabilized working conditions which were clearly right; it not only did not cost more than private control would have cost during the same period but cost considerably less on account of the economies growing out of unifications, and the total burden put upon the public (through rates and taxes) on account of railroad costs was substantially less than would have been necessary if the railroads had remained in private control and rates had been raised enough to preserve their credit; it protected the investment in railroad properties, whereas without federal control those investments would have been endangered; and it turns the railroads back to private control functioning effectively with a record of exceptional performance in an exceptionally difficult winter, despite the disruption caused by the coal strike, and in condition to function still more effectively with the normal improvement to be expected in the weather and in other conditions.—*Report of the Director General of Railways.*

Train Ferries for African Lakes.—A proposal to employ train ferries for the great lakes in the African continent, as part of the Cape to Cairo route, has been offered. The project is reported as especially desirable, for a considerable time must necessarily elapse before the Cape to Cairo Railway is an accomplished fact, and anything, therefore, that is practical and calculated to expedite transport in the regions to be traversed should be welcome. For the purpose of train-ferry service, the Nyasa, Tanganyika, and Victoria-Nyanza systems have the great advantage that they are not tidal—although this does not mean that provision need not be made at the dock for appreciable changes of level, which may be due either to rainfall or to long-continued winds.

The lake routes indicated run practically north and south and represent, in the aggregate, about 850 miles. At present prices, it would cost about $20,000,000 to construct railways over this distance, as against a cost of $6,000,000 for train ferries, a saving of $14,000,000.

The use of train ferries on Victoria Nyanza will not be restricted to north-to-south routes. It is expected that, in days to come, there will be quite a number of other ferry services, notably between Kisumu (Port Florence) and the ports on the northern and western shores, for the purpose of developing the valuable agricultural regions in the vicinity of the lake, and particularly those lying to the west, northwest and north, by giving them better communications with the shortest route to the east coast via the Uganda Railway.—*Geographical Journal.*

Professional Notes

of Military and Engineering Interest

Commissions in new army.—To fill vacancies in the Army which will be created by the Army reorganzation bill, the War Department requests that applications for such appointments be made without delay by all emergency officers, who, on the termination of their war services were recommended for reappointment in cases of vacancies. These applications should contain a brief summary of the officer's civil and military experience. Forms may be obtained from the War Department.

The reorganization bill provides for 17,000 officers and will call for appointments in nearly every grade in the Army. Owing to the present shortage of personnel the War Department will make every effort to fill these vacancies as quickly as possible, and it, therefore, behooves every emergency officer who desires to obtain an appointment in the Regular Army to submit his application at once.

The dangers of specialization.—Mr. Morley Roberts once delivered himself of the aphorism, "Few men know their own business, for it cannot be understood without knowledge of things outside it." The comment is worth some thought, because at a time when the world is specializing more and more we find the common-sense of specialists so frequently impugned. The question concerns engineers, they are experts—at least it may be hoped that they are, and considering the enormous range of their subjects, there is no reason why they should not specialize, but in specializing it is essential that they should preserve their sanity. As human beings we are endowed with many faculties, and if we bring into concentrated employment any one faculty to the exclusion of all others, we are liable to become incapable of sound judgment on any subject, and possibly least of all on the subject which is peculiarly our own. There is an obvious advantage in possessing an intimate knowledge of some one branch of work instead of a smattering of many, but we lose that advantage if we fail to understand our own business from ignorance of things outside it.—*Indian Engineering (Calcutta).*

Largest concrete blocks.—In his presidential address, read before the Institution of Civil Engineers on Nov. 4, Sir John Purser-Griffith referred to the complete success which had followed the use of what are claimed to be the largest concrete blocks ever used. These blocks each contained more than 5,000 cubic feet of masonry and weighed about 350 tons. They were used in the construction of the North Quay extension of the Port of Dublin. The blocks were built above high-water level and when sufficiently set were lifted by a floating shears or crane and deposited on a bed prepared by dredging; they were leveled by men working in a large diving bell, entered through a tube fitted with an air lock. The same floating plant was used for laying similar large blocks for breakwater protection, and for the foundation of one of the lighthouses at the entrance of the harbor. These great blocks proved a complete success, both from structural and economic point of view. By their use it was possible to build the extension quays without costly cofferdams or heavy pumping.—*Concrete and Constructional Engineering.*

How to blast hardwood stumps.—The great majority of the best grade of wild land in the northern part of this country is "hardwood land" and consequently, the great volume of stumps to be gotten rid of are hardwood stumps. By "hardwood stumps" we mean maple, beach, birch, hemlock, and basswood.

There are several reasons why the use of dynamite is prevalent, the main one of which is economy. And since economy is the object of blasting, it naturally follows that the economic use of blasting supplies is of paramount importance.

It has been found that in the blasting of hardwood stumps, detonation is the best, and cheapest, done with cap and fuse; occasion but rarely arises where a blasting machine is required.

The charge is placed under the center of the stump, or the point of greatest resistance. The ability to calculate this, and the amount of charge, correctly, is obtained only by practice. It will readily be seen that correct location and amount of charge is the secret of economy.

It is best to use a bar made from a piece of steel shafting, about five and a half feet long, and weighing 23 pounds. One end of this bar is drawn to a point, and the other flattened like a chisel. Use the pointed end to punch the holes for the charge, and the chisel end to cut off small roots that sometimes interfere. When a stump is to be blasted, the calculation of the amount of the charge is greatly facilitated by "sounding" it; this is done by swinging the bar endwise and striking the stump with the chisel end. It can readily be seen that, unless the stump is a solid one, it can be shaken more or less with a bar of this weight.

In blasting on heavy clay, when it is wet, the bar sometimes sticks so that it can not be used to advantage. In this case, it is better to have a one and a half inch auger, with a 4 or 5-foot shank, with which to bore the holes.

As a rule the proper dynamite for hardwood stumps is a medium slow powder of 40 per cent strength. In old stumps on clay soil the use of dynamite of twenty per cent strength is recommended and on lighter soil and fairly green stumps sixty per cent is better.—*The Excavating Engineer.*

Open mouth for Mississippi River.—Under this title there was a paper by Allen E. Washburn read at a recent meeting of the Louisiana Engineering Society. Mr. Washburn outlined in a very interesting manner the history of the various projects for the maintenance of a navigable channel at the mouth of the river from the time of the early French settlers of 200 years ago down to the present development of the Southwest Pass. A number of proposals were made to side-track the difficulties due to sedimentation of the natural channels and bar formations at the mouth of the river, as well as to shorten the distance to New Orleans, by the construction of a ship canal. During a vigorous discussion of various canal projects in the early seventies James B. Eads became interested in the problem, and finally in 1874 made a proposition to Congress to build jetties at the mouth of Southwest Pass at his own risk and cost, he to be paid as results were accomplished. A bill was passed in 1875 authorizing him to build his jetties in South Pass, and the result is known to all—for the past 40 years South Pass has been the navigable channel and entrance to the port of New Orleans.

New Orleans has shown a singular lack of gratitude in that it has never recognized the work of James B. Eads by any sort of memorial to him.

South Pass is still a very excellent channel with a depth of 32 feet but owing to the natural formation of the bar the approach from the gulf has been shifted so far to the eastward that vessels must make a rather difficult turn just at the mouth of the jetties. With the expiration of the Eads contract consideration was given the problem of providing a larger channel from gulf to river. It was then decided to make use of Southwest Pass and to provide it with jetties in order to have a channel with a width of 1,000 feet and 35 feet depth. Construction of these jetties was begun in 1905.

Mr. Washburn calls attention to the phenomenon of "sand waves" as a retarding factor in the improvement of Southwest Pass. The volume of material and the speed of advance of these sand waves is of such magnitude at times as to cause a shoaling of 20 feet in 24 hours. There is apparently need for considerable extension to the study of this problem of sand waves, for while some points were brought out in the discussion of the paper, there appears to be a lack of definite data as to the periodicity of the waves, which of course would be a very important item in the question of the control and maintenance of the depth in the channel. A paper upon this very interesting phenomenon of the Mississippi River would be of interest to many.—*Eng. World.*

Chateau-Thierry honored.—Chateau-Thierry, the little French town on the Marne, famous in the annals of the American Army in the World War, is to be awarded the French Legion of Honor.

Commercial uses of the geophone.—The geophone is of special value in locating the positions of tunnel headings coming together when ordinary survey methods are difficult. A determination should be made from each heading, and if they agree the result may be accepted. The human voice in ordinary tones can be detected through 150 feet of solid coal, and conversation understood through 50 feet.—*U. S. Bureau of Mines.*

Motorized terminals.—B. F. Fitch, in *Engineer World* describes the motorized terminals now being employed in Cincinnati. He opens with the startling statement that the joint terminal charge to the carriers alone for New York and Chicago, equals the cost of the main line haul between the two cities.

The transfer of freight between terminals of different roads has been generally accomplished by the shifting around of "traps",

Digitized by Google

"transfer" or "ferry" cars. This procedure is characterized by the vast amount of "switching" which is such a common sight in every large city, and the cost and delays incident to this switching are the reasons, according to Mr. Fitch, for excessive terminal charges.

The "motorized terminal" as employed in Cincinnati eliminates this switching of freight cars. Its essential feature is a demountable motor truck body.

At each freight station there is one or more of these demountable bodies on hand for each station to which freight is to be transferred. These demountable bodies are moved about by electric cranes and placed conveniently to receive the freight discharged from the incoming trains, or load into outgoing cars. As freight comes out of the cars it is trucked to and loaded in the demountable body tagged with the name of the station for which destined. As soon as the demountable body is filled it is picked up by a crane, carried to and placed upon the chassis of a motor truck, and proceeds at once to the station for which destined, instead of knocking about the rail yards for two or three days or more.

The author states that within a 10-mile radius the cost of the carriers of this interchange of freight between stations, is less than $1.00 per ton. The great advantage of the system is the simplicity of its application, there being no excessive real estate charges, no difficult engineering problems or large construction projects, and little need for the co-ordination of conflicting interests involved. In most large cities a union freight terminal is an appalling problem which grows more appalling each year. By the motor transfer system a number of widely separated stations may enjoy the benefits of the union terminal.

Mr. Fitch is very keen to apply his solution to the largest and most scandalous of freight terminals, New York, which he regards as a check on the industrial expansion of the nation, and as largely responsible for the H. C. of L., not only for New Yorkers (who deserve it) but for the rest of us as well. He outlines a plan for terminal freight handling at New York, and utters the threat that unless something is done about it a long suffering nation will abandon that too conservative city to its own follies and proceed to create new transshipment ports.

Flood protection for Winnipeg.—Though exposed to devastating floods of the Red River of the North, Winnipeg has been mercifully spared during her recent rapid growth and development. But river floods are as sure as taxes, and Winnipeg dreads a repetition of the great flood of 1852, whose visible effects still remain. On this occasion the site of the city was completely inundated, the nearest dry land was four miles away, and this condition persisted for two weeks. A like occurrence at this time would cause millions of dollars of damage.

The causes of the Red River floods are readily perceived: a wet fall followed by a freeze-up, heavy winter snows, and a sudden burst of warm weather in the spring, accompanied by melting snow and heavy rainfall. A contracted channel between Winnipeg and Lake Winnipeg, the outlet of the river some 40 miles below, is responsible for the sustained flood period in 1852.

Mr. Douglas McLean, a Canadian engineer, proposes a sane project for flood prevention, based on a combination of the now well recognized methods of flood abatement. These would include—

(*a*) Reservoirs in the upper reaches of the Red River valley and the valley of the Assiniboine.

(*b*) Enlarging the capacity of the river channel below the city.

(*c*) Local protection by means of levees or dikes.

The estimated cost of these precautions is not given, but the most expensive item, the reservoirs in the Red River valley, is placed at approximately $25,000,000—*Canadian Engineer.*

General Goethals replies to criticisms of the concrete block tunnel.—Replying to criticisms of the concrete block tunnel, Gen. Goethals submitted a memorandum to the joint tunnel commission of New York and New Jersey, on April 2. After discussing his connection with the project and the preliminary studies which led him to recommend the 42-foot double deck, concrete block design, direct replies were made to the conclusions of the chief engineer and chairman of the board of advisory engineers.

(1) The 22-foot 6-inch roadway on each deck, provides for two continuous lines of traffic and a third passing line, and its capacity is much greater than a two-line roadway.

(2) The stresses in the concrete of the block tunnel would not be excessive under the actual loads determined from pressure observations on the Pennsylvania tunnels; though under the loading assumed in the chief engineer's analysis, both the existing Pennsylvania tunnel and the proposed cast iron tunnels would be unsafe, with tensile stresses in the cast iron of more than 9,800 lbs. per square inch. The concrete blocks are bolted together longitudinally and the block type tunnel has greater longitudinal strength and resisting moment than the 29-foot cast iron tunnel or the Pennsylvania Tubes.

(3) Regarding the difficulty of securing water tightness and consequent danger of disintegration, the example is cited of the Christopher St. McAdoo Tube, 2,000 feet of which was constructed of brick laid in Rosendale cement 35 years ago, and which is still in service.

(4) The original cost estimates were based on 1917 prices and the experience of the O'Rourke Engineering Construction Co. in work of this character. The cost of real estate was omitted as not affected by the type of construction. The question of relative costs could have been settled in 1917 by carrying out Gen. Goethals' recommendations that bids be called for upon competitive designs to be submitted by the bidders.

(5) The estimate of three years for completion was based upon the data of an experienced prospective bidder.

Gen. Goethals concludes that a vehicular tunnel providing for less than three lines of traffic in each direction would be inadequate. Concrete, unassisted by cast iron, is suitable for tunnel construction, and the concrete block tunnel is sound in engineering principle, practicable, safe, will not float or sink, and is far more economical than cast iron.—*Eng. News-Rec.*

Reconstruction of the Poughkeepsie Cantilever bridge for heavy traffic.—This is the only bridge over the Hudson south of Albany. Built in 1882, its total length, including approach viaducts, is 6,767 feet 8 inches. The river spans constitute a deck cantilever system of two 525-foot fixed spans, three cantilever 546 and 548-foot spans, and two 201-foot anchor spans. It was originally designed to carry train loads of 3,000 lbs. per linear foot with engine axle loads of 24,000 lbs. on both of its two tracks. In 1907 it was strengthened to carry train loads of 3,600 lbs. per linear foot with engine axle loads of 45,000 lbs. on both tracks. That strengthening was accomplished by the addition of a third central truss in each span, similar in outline to the original trusses but about 50 per cent heavier. In the river spans these trusses were supported on their own towers which rested on steel cylinder piles driven through the old pier cores, the new portion forming almost an independent structure. In the viaduct approaches, the original latticed trussed spans were replaced by girders and the additional central girders were added without providing separate supports.

The second extensive reconstruction, recently completed, was required by the necessity of providing for train loads of 6,000 lbs. per linear foot with engine axle loads of 60,000 lbs. In the studies preparatory to the reconstruction, three plans were investigated: (1) Substituting single for double track and distributing the single track loading over the three trusses; (2) Reinforcing the trusses for the new loading on both tracks; (3) Rebuilding the bridge. In general, method (1) was adopted for the main spans and method (2) was adopted for the approaches, though a portion of the latter were single tracked.

For distributing the load over the trusses of the main spans stiff floor beams were adopted in preference to an articulated system for equalizing the truss deflections. To provide for observed irregularities in the elevations of the upper panel points, five different depths of floor beams and various bolsters or fillers were employed, so that the floor beams act as rigid cross girders assuring approximately equal deflections in the three trusses under all loads. In the new floor system, the floor beams are designed to carry double track loading when spanning the 30 feet width of a proposed future two-truss span. Only the inside stringers of the two future pairs are placed in the single track portions.

On both approaches double track was retained for the most part. In about one-third of the east approach and 600 ft. of the west approach, original latticed trusses had been replaced in the 1907 reconstruction by viaduct girders which, with slight changes, were adequate for the new loadings. In the bents, however, neither the king-post trussed caps nor their two supporting columns were sufficiently strong. To meet this difficulty, two stiff diagonals from the center of the cap to the feet of the columns were added to take the outer girder reactions, relieving both the cap and the columns of that load. In the westerly two-thirds of the east approach, center line columns had been added in 1907, and the only deficiency in strength was found in the side columns, which were stiffened by two angles riveted to the web of each column.

In the truss spans of the east approach, the single track of the main spans was continued eastward over the 800 feet of trussed spans, and the latter required only the remodeling of the floor system after the plan used in the main spans. In the two 145-foot truss spans of the west approach, the spacing of the tracks was reduced from 14 feet 8 in. to 13 ft. between centers. This reduced the load on the outer trusses to safe figures and reinforcement was required only in the center span. This reinforcement was effected by side plates on the top chords, by loop rods on the tension members, and by a complete riveted tension system built around the bottom chord. Initial stress was forced into the new tension members in order that dead load stresses in new and old material might be equalized. To accomplish this, the gusset plates at field splices had full sized holes while one end of each member connecting to them was left blank. After pulling the new steel firmly into place against the old pins, the blank end of the member was marked for drilling, and then drilled with full size holes sufficiently offset to give the desired elongation. The joints were temporarily bolted with a few undersized bolts, and finally drawn up into place by a number of drift pins driven by succes-

sive moderate blows on each pin, to avoid deforming any holes. The actual elongation was measured by an extensometer of local manufacture which remained clamped to the member while it was being drawn into place for final riveting.

This method was not applicable to the bottom chord reinforcement because of the difficulty in shifting the members for drilling after putting them in place. Instead, it was determined that the initial stresses desired should produce an elongation equivalent to that of a change of temperature of about 17° F. The members were lightly bolted in place and heated by small wood fires, distributed along the member, until the desired expansion was secured, when the joints were completed.

After the completion of the work, the behavior of several members in the different spans was checked by means of a Berry strain-gauge and also by an improvised gauge constructed locally. The results of the gauge readings were in close accord and showed that the assumptions as to load distributions in design were borne out in the remodeled bridge.

The work was begun in January 1917, but due largely to the difficulty of securing material during the war, it was not completed until August, 1918.—Clement E. Chase in *Eng. News-Rec.*

Resistance of Greenheart to marine borers.—Greenheart timbers immersed for six years in waters of the Gulf of Mexico, infested with xylotra, limnoria, and pholas, were not attacked by xylotra. One specimen was slightly attacked in the sapwood by limnoria, and all were attacked by pholas, the surface being covered with burrows ¾ inch or less in depth.—*Eng. News-Rec.*

"Plastic fill" method of embankment construction.—In building the section of the Taylorsville dam of the Miami Conservancy District, it was necessary to construct a cross dike to enclose one end of the core pool. This cross dike was built by the "plastic fill" process—a method apparently little used hitherto.

The material from a borrow pit was dumped by trains alongside the unloading track, then picked up by a drag-line bucket and dumped in a windrow along the west side of the cross dike site, but well inside the west limit of the dike. This windrow was built up dry to a height of 10 feet.

A 10-foot length of ¾-inch gas pipe, connected by hose to a steam pump, was then used like an hypodermic needle, piercing the windrow vertically in row of holes about 2 feet west of the top of the material and about 3 feet apart, and water thus introduced throughout the west half of the mass.

The water thus introduced made the dry material plastic, and, it flowed slowly in a westerly direction, as had been planned, as the western limit of the dike was beyond the reach of the dray line from its location near the unloading tracks.

By dropping fresh material on top of the windrow, the stiff dough in the west slope was kept moving very slowly till it reached the limit staked out for it—the west limit of the cross dam—thus transporting itself a maximum distance of over 40 feet. If the material slowed up too much, a fresh injection of water or a new load of earth on top started it again.

A word of caution needs to be said about this method, however. The material used was largely glacial fill, containing such a percentage of clay that the water could escape. A material which would hold on to the water would no doubt give trouble if used for plastic fill.—*Eng. and Const.*

Note: A method similar to the foregoing was used in 1910 at New Orleans, La., in enlarging the levee section on the land side from the usual 1 to 3 slope to a 1 to 10 slope. The material, taken from the river side by drag-line excavators, was dumped just back of the levee, and then by wetting with a hose it flowed out to the limit of the new land side slope, a distance of probably 100 feet.

Japan's submarine tunnel.—Several months ago announcement was made that the Imperial Government railways of Japan intended to build a tunnel under Shimonoseki Strait. This strait separates the main island of the Japanese group, Hondo, from the smaller island of Kiushu at the south. It is now crossed by a car ferry which is rapidly becoming unable to meet the demands made upon it. Two years are to be spent in studying the geological formation of the sea bed in the strait and in drafting the general plan of work in preparation of the actual undertaking of tunneling, so that the real work will not commence until 1921. Engineers and workmen will be sent to America and Europe to make a study of what has been achieved in these countries in the way of tunnel engineering. The line is to be seven miles long, one mile of which will be entirely under the sea. The approximate cost of the undertaking will be about $10,000,000 and the work is expected to be completed in 1928.—*Scientific American.*

Laying a long steel pipe under water.—An interesting piece of engineering work has been done at the point where the Jersey City water supply line crosses the Passaic River. A pipe with an internal diameter of six feet and measuring 452 feet in length has been laid in a single piece in 26 feet of water. The pipe is encased in three inches of wire-reinforced concrete, placed with a cement gun. The concrete-cased pipe weighs about a ton per foot. A launching way was laid in a trench dug on shore and the pipe as it was complete was supported on cars running down a track in the trench. In order to deposit the pipe without strain in the submarine trench which had been dredged across the river, two parallel trestles were built between which the pipe was slung from timbers that were carried by cars placed at 25-foot intervals, opposite cars being connected by each to each by means of cables and were moved out across the river as the pipe was being built, and when completed the pipe was sunk by admitting water into it. In order to hold it down it was weighted with castiron blocks at each end. A goose-neck rises from the submarine section at each end and connects with the shore sections.—*Scientific American.*

Gyro compasses and oxygen heaters for aeroplanes.—For the first time in the history of aviation a gyroscopic compass was used successfully as a navigating instrument in an airplane at McCook Field, Dayton, Ohio, recently. Gyroscopic compasses embodying practically the same principles have been used for several years on American and foreign war vessels as well as the merchant marine, and particularly on submarines which depend almost solely upon an instrument of this kind when submerged. The gyroscopic compasses as used upon water craft weigh 2,000 pounds, and are quite bulky.

The chief problem in adapting a gyroscopic compass for aerial navigation was to design a similar apparatus where weight and bulk commensurate to airplanes with the same accuracy and dependability of the marine type as a result of laborious experimentation that looked hopeless, a model was made weighing only 17 pounds, and in size was 14 by 13 inches. It was tested in flight. The chief advantages over all former types or magneto compasses are: compass card free from spinning; indicates a true geographic north; no magnetic effect.

The test was successful in every respect and has definitely proved that a gyro compass will be the compass used for future aerial navigation.

Tests are being conducted at Dayton, Ohio, of a new apparatus for heating oxygen at high altitudes to prevent a recurrence of failure at high altitudes, such as experienced by Maj. Rudolph Schroeder recently in his record climb at Dayton, which came so near to costing him his life.

Tests so far have proved the new invention to be of material value.—*War Dept. News Bureau.*

Liquidation of War Department contract and sale of surplus material.—The value of all contracts liquidated to the end of March, 1920, is approximately $2,800,000,000. These included 18,860 formal contracts in the amount of about 1,550,000,000 and 5,385 informal agreements in the amount of about $1,250,000,000. It has cost about $360,000,000 to liquidate these contracts.

The saving effected by liquidation to March 27 amounts to $2,425,011,000. Of this, $1,364,648,000 was saved on formal contracts and $1,060,363,000 on informal agreements.

Value of contracts suspended	$3,944,369,000
Value of contracts liquidated	2,779,973,000
Saving effected	2,425,011,000
Percent saving effected	87

There are 2,469 contracts remaining to be liquidated. The value of these so far as known is $1,164,396,000. Assuming that in the future liquidation can be effected at the same rate as has obtained in the past, the cost of liquidating the contracts of known value may be estimated at $123,000,000. This would make the total cost of liquidation $536,000,000.

Total sales of surplus material to the middle of April amounted to approximately $800,000,000. Of this about $42,000,000 was transferred to other government departments.—*War Dept. News Bureau.*

Long-life creosoted piles.—A pile trestle approach to the L. & N. R. R. bridge over the Ohio River at Henderson, Ky., built in 1884, had 177 bents of creosoted piles. It recently became necessary to rebuild the trestle, as about 15 per cent of the piles were in condition to require early removal, and, in addition, the trestle was becoming too light for the increased loads.

Only about 10 per cent of the piles requiring renewal showed serious rot at the ground line. The most serious cause of decay was due to the fact that in rebracing the bents in 1896 many of the old piles were deeply adzed, exposing the less heavily treated wood. The part of the trestle which was not constructed of creosoted piles had piles of red cedar which gave a life of 18 years. These were replaced by untreated pine piles, which have been renewed at least once, so that the creosoted piles have given at least twice the life of untreated wood.

The long life—35 years—of the creosoted piling is clearly the result of the use of good timber, correct treatment, and continuity of the shell of protected timber on the exterior of the pile.—*Eng. and Const.*

The new one-inch and quarter-inch maps of the British Ordnance Survey

The original 1-inch maps of the Ordnance Survey were commenced in 1791 and the first sheet was published in 1801.

In 1872 an entirely new series of engraved maps was commenced, based on a new survey. Until 1894 the ordnance survey had produced only maps in the engraved form, the aim being to produce the best engraved article possible; a prejudice existed at this period against extending the work of the survey to lithography, and the attitude was that the survey was a map-producing rather than a map-publishing establishment.

In 1912 the whole question of the 1-inch map again came into the melting pot, as great strides had been made in reproducing methods in the twenty years since the first lithographic maps of the survey had been begun. A committee of both military and civilian users of maps considered an improved road classification, with particular reference to motor traffic. During the Great War, all the resources of the ordnance survey were devoted to the production of war maps.

Now that affairs have begun to assume their normal course, it has been determined to publish the regular 1-inch series of the following types:

A. The 1-inch Popular Maps;
B. The 1-inch Outline Map;
C. The Tourist District Map.

On the new popular 1-inch map, the road classificaton stands out in a very marked degree, the contours are uniformly at 50 feet vertical intervals, rivers, streams, and the sea are printed in solid tint, and parish boundaries have been omitted.

The new type of outline map is from stone, is a combination of the outline, water, and contours of the "popular" edition, and is printed on stout paper in order to make it more useful for engineering purposes. The new tourist district map is not yet on sale. The chief points to note are:

(1) The increased size of the sheet;
(2) The adoption of a broad layer system, printed in very transparent colors;
(3) The small number of printings for the effects obtained.

The quarter-inch maps were commenced originally in 1859, discontinued, and resumed in 1884. In 1902, the revised quarter-inch was published in its fully colored form in small sheets, and in 1912 it was produced in large sheets, ten sheets covering England and Wales.

This map was never satisfactory. It was far too crowded in many parts, and in particular the roads were badly shown. The water has always given trouble. There were no contours and the hill shading was very generalized and misleading.

The chief points about the new series are:

The abolition of the hill shading and the substitution of contours;
The introduction of the "layer system;
The comparative clearness of the detail;
Only main roads colored;
No green wood symbol.

Water, being on a separate plate and not overprinted, is much clearer.—*Geographical Journal.*

Map-making bureaus co-ordinated.—The United States Board of Surveys and Maps, created on December 30, 1919, by an executive order of the President, has perfected a permanent organization and held its first public meeting in March. The object of this Board, as outlined in the President's order, is to co-ordinate the activities of the various map-making agencies of the executive departments of the government and avoid the unnecessary duplication of work which may come about very readily when maps and surveys are being made by independent branches of the government. The Board has established a map information office in the Interior Department Building, where it will collect and catalogue as rapidly as possible information concerning maps, surveys, etc., prepared under the direction of the federal government or other governmental and private agencies. The Board is composed of one representative each of the Corps of Engineers, the Coast and Geodetic Survey, the Geological Survey, the General Land Office, the Topography Branch of the Post Office Department, the Bureau of Soils of the Department of Agriculture, the Reclamation Service, the Bureau of Public Roads, the Bureau of Indian Affairs, The Mississippi River Commission, the U. S. Lake Surveys, International Boundary Commission, the Foresty Service the Hydrographic Office of the Navy.

Wanted! Back Numbers of "The Military Engineer"

Because of the great demand for No. 61 (Jan-Feb., 1920) of the MILITARY ENGINEER by our new members, the supply of this issue is exhausted, but the demand continues.

We will pay 40 cents plus postage for each copy of No. 61 returned to this office with the name of the sender.

EMERSON
STEAM PUMPS

Emerson Foot Valve and Quick-Cleaning Strainer

Adapted to All Pumps or Intakes

Emerson Standard
Made in Eight Sizes

The EMERSON is a steam vacuum pump designed and built to handle air, sand, mud and grit in percentages with the water impossible by any other kind or make of pump.

It is invaluable for all work in cofferdams, caissons, and for keeping excavations dry—continuously.

EMERSON PUMPS are in daily use by U. S. Engineers in River and Harbor Work, Reclamation, and on the Panama Canal, where 64 EMERSONS have been in service

The Latest Type EMERSON is built of steel pipe instead of cast iron, is increased in capacity 10 per cent, with a decrease of 35 per cent in weight, less parts and steam consumption.

Governmental Investigation of River and Harbor Improvements

Continued from Page 264

favorable reports before Congress which could properly serve as bases of appropriations.

The river and harbor Act of March 2, 1919, adopted 80 projects. Another bill containing a similar number of new projects would more than exhaust all pending recommendations of the Department, including some described above as obsolete. The facts show, therefore, that instead of there being from five hundred to six hundred projects before Congress recommended by the Department, there are actually less than one-fifth that number remaining to be acted on.

By reference to the table, it will be noted that the percentage of favorable reports was considerably greater prior to 1910 than since that time. This may be partially accounted for by the fact that in the earlier years proposed examinations were carefully scrutinized by the committees of Congress, and all clearly unworthy cases were rejected; while in recent years Congress has relied more and more upon the Board to eliminate the unworthy cases.

Recommendations for abandonment of unworthy projects

The Act of March 4, 1915, called for review of ten specified projects and directed the Chief of Engineers to report upon any other projects, river or harbor, the further improvements of which under present conditions is undesirable, or in which modifications of the plans or projects should be made. Under this act, the Board has recommended the modification of 34 projects, and the complete abandonment of 38 projects. It can scarcely be contended that the Board's recommendations in these cases were designed especially for the gratification of Congress or any of its members. While none of the recommendations for abandonment of projects have been adopted, the expenditures on some of these projects have been materially reduced.

Savings of public funds effected by Board of Engineers

It is appropriate here to present some information showing the importance of the service rendered by the Board of Engineers for Rivers and Harbors, and the savings made possible by its recommendations.

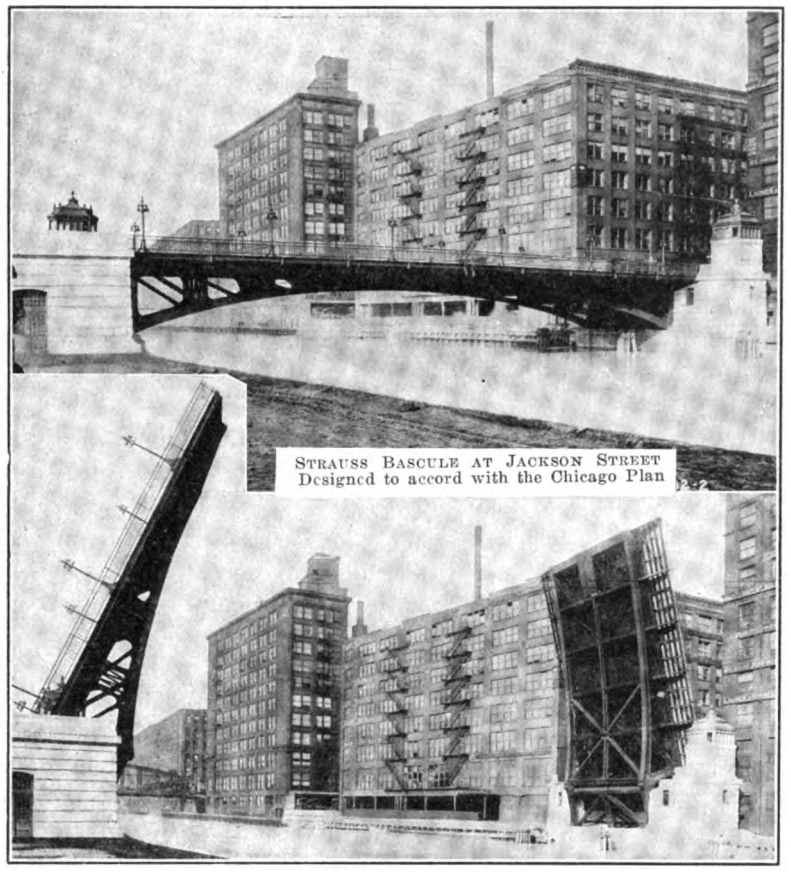
Notwithstanding the care exercised by District Engineers in their investigation, the Board is frequently unable to concur in their findings. These differences of opinion are largely due to the broader view that the Board is able to take because of its contact with commercial and transportation conditions in all parts of the country, and with other projects involving similar engineering or commercial problems.

From the organization of the Board in 1902 to the present time, the improvements recommended by District Engineers were estimated to cost $192,695,463.62 more than the final recommendations of the Board on these same projects. Deducting from this the sum of $4,476,358, being the estimated cost of work recommended by the Board, which had not been recommended by District Engineers, gives a net total of $188,219,105.62. This represents the saving in the estimates resulting from the review of the reports by the Board during a period of eighteen years, or $10,456,617 a year. The expenses of the Board during this period have averaged about $20,000 a year.

Other economies effected

Further important savings to the United States have resulted from the policy adopted by the Board of encouraging local coöperation. There are many cases where, in addition to the general public benefits to be derived from improvements, local interests will obtain substantial direct benefits from the proposed work, and in such cases the Board has felt that the interests immediately benefited should share in the expense involved. Its recommendations in cases of this kind have involved the contribution of over $11,000,000 in cash by local interests, donations of rights of way, participation in the construction work, and many other forms of coöperation which have made possible important savings to the Government.

In a number of cases the Board has recommended that the work be conditioned upon the establishment of adequate terminals by local interests, and this attitude has had the effect of materially improving terminal conditions.



Aid to local communities

In the river and harbor act of March 2, 1919, the following appears:

> It is hereby declared to be the policy of the Congress that water terminals are essential at all cities and towns located upon harbors or navigable waterways and that at least one public terminal should exist, constructed, owned, and regulated by the municipality, or other public agency of the State and open to the use of all on equal terms, and with the view of carrying out this policy to the fullest possible extent the Secretary of War is hereby vested with the discretion to withhold, unless the public interests would seriously suffer by delay, monies appropriated in this Act for new projects adopted herein, or for the further improvement of existing projects if, in his opinion, no water terminals exist adequate for the traffic and open to all on equal terms, or unless satisfactory assurances are received that local or other interests will provide such adequate terminal or terminals. The Secretary of War, through the Chief of Engineers, shall give full publicity, as far as may be practicable, to this provision.

In carrying out the requirements of the law, the Chief of Engineers has assigned to the Board the duty

of assisting local communities in the planning of their terminals, in order that they may prove adequate for the important uses for which they are intended. In connection with these duties, the Board has taken over part of the work and personnel of the former Port Facilities Commission of the Shipping Board. This work gives promise of meeting an important public need. From the first few cases referred to the Board, it is evident that purely local issues may often determine the character, extent, and location of facilities required for transacting the nation's business, and that there is a real need for an impartial study of these propositions by competent Federal authorities. The Board does not carry its work to the point where it might infringe upon the legitimate business activities of terminal engineers, but confines its advice to the general location, plan and layout of the terminal and its connections, leaving the details for determination and execution by local authorities.

Discussion

C. Keller
Colonel, Corps of Engineers; Resident Member, Board of Engineers for Rivers and Harbors

The preceding pages describe quite clearly the manner in which projects for river and harbor improvements arise and the laws and procedure under which the Board of Engineers for Rivers and Harbors, or as it is sometimes called, the Board of Review, operates.

The laws quoted by Mr. Ritter show the limitations of the authority confided to the Board. It is specifically authorized only to consider and report "upon examinations and surveys" provided for by Congress and "all projects or changes in projects for works of river and harbor improvements theretofore or thereafter provided for." It is also authorized and required to review prior reports on examination and surveys whenever called upon to do so by Congress.

The Board is therefore a creature of the law and its formal acts have hitherto been confined to those which it was affirmatively permitted to perform. It has generally been held that it could not, of its own motion, enlarge the scope of any inquiry, nor usually consider, in any given case, anything but the question that was immediately before it as expressed in the provision of law calling for the inquiry.

It is quite obvious that this rule must occasionally work badly, and that it may be in the interest of Congress and of the public to take a broader view. Particularly has this been felt to be the case since our entrance into the World War, which not only developed many acute transportation difficulties, but also witnessed the acquisition of an American mercantile fleet whose success must in great part depend upon the wisdom with which waterway facilities are provided and employed. Dispatch, or as it is now called, "turn-around," acquired to us a new and vital significance during the war, and our future as a commercial and manufacturing nation will largely depend on any special efficiency that we are able to develop in the operation of our vessels.

Quick "turn-around" may be promoted by many factors, such, for example, as the installation of apparatus for burning oil in place of coal, the better or more skillful handling of the ship, the provision of wharves conveniently arranged for the reception and temporary storage of cargo, and the application of efficient mechanical processes in loading and unloading; but an indispensable prerequisite is the provision of safe, adequate and convenient channels at a sufficient number of ports to enable freight to be assembled and distributed most economically and conveniently.

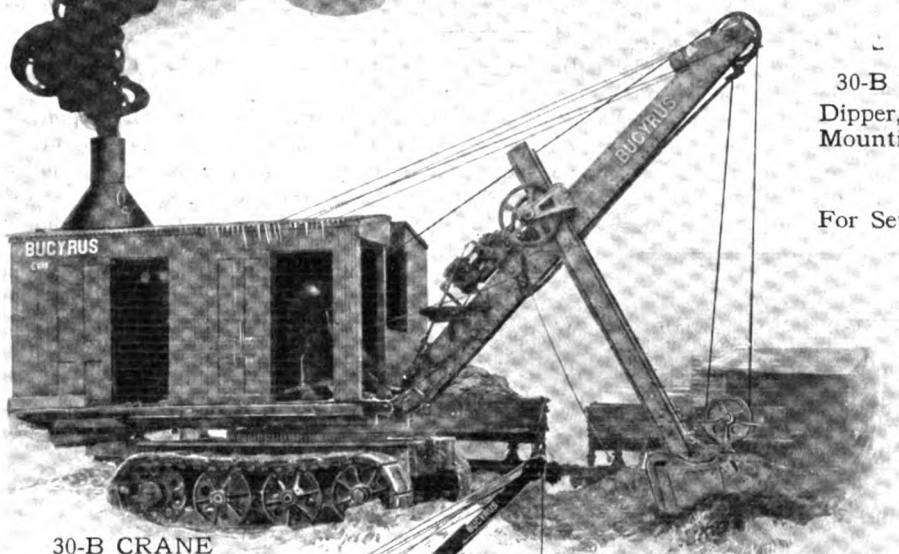
A proper general policy as to river and harbor improvements would be one which, visualizing the traffic of the nation as a whole, would provide for its transportation by land or water at a minimum cost, implying thereby the elimination of congestion, unnecessary transshipments, delay and needlessly long or difficult hauls.

It is obviously easier to state the principles upon which a correct general policy should be based than to formulate that policy definitely, since certain extraneous conditions, such as existing trade and financial practices and preferences, prevent an ideal solution. In any event, however, it is desirable and necessary to consider much more than the immediate locality and to endeavor to base decisions upon the broadest possible knowledge of the traffic of the country, its nature, volume, sources and destinations. In this way only can we provide wisely for our present prosperity and our future growth.

The study of this policy and its final determination is properly a function of statesmanship, and until recently the matter has not apparently received much thought. The Board of Engineers for Rivers and Harbors has, however, experienced so much difficulty in the performance of its functions that it has been forced to consider and to discuss this question and it has attempted to arrive at an agreement upon a general policy to guide its course. The question is at this very moment under consideration, certain proposals have been formulated, and eventually it is hoped to secure some expression on the subject from Congress, aided by such suggestions as the Chief of Engineers may approve.

What precedes leads to an attempt to describe the tests or criteria upon which the Board bases its judgment as to the worthiness or advisability of a proposed improvement. The ultimate test is usually the same as a railroad would apply in considering the construction of an extension into new territory, or the improvement of an existing line, namely, will it pay? In other words, will there be enough new traffic or will the economies in the carrying of the existing traffic justify the contemplated expenditure? In a few cases, the answer whether positive or negative, is plain. In most, however, the evidence is not conclusive, and the best that can be done is to exhaust all available sources of information and then to judge as experience and the preponderance of evidence may dictate. It should be observed, too, that in one respect the position of the Government may differ from that of a railroad in that often the traffic proposed to be accommodated by a new or a further improvement of navigation facilities may already be moving to market and the plan may be simply to change its routing.

The traffic data derived from the preliminary examination, together with such other similar information as the Board may have, will usually serve to show what would be the returns from an investment of funds in the improvement under discussion.



In many cases, of course, the information is inadequate or obviously unreliable, and then the Board is forced to originate new lines of investigation and to extend the scope of the original inquiry, always with the desire to protect and promote the interests of the United States and its citizens. Thus, in a certain case involving the proposal to construct a canal at a cost of about $2,000,000, it was urged

INTRODUCING

THE UNIVERSAL SHOVEL

THE BUCYRUS-30 B

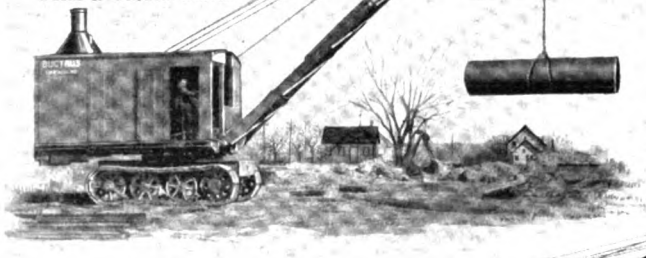
30-B REVOLVING SHOVEL

Dipper, 1 cu. yd.

Mounting, caterpillar traction, traction wheels, railroad trucks.

For Sewer Excavation

¾ yd. dipper, 30 ft. handle, max. ditch 20 feet.



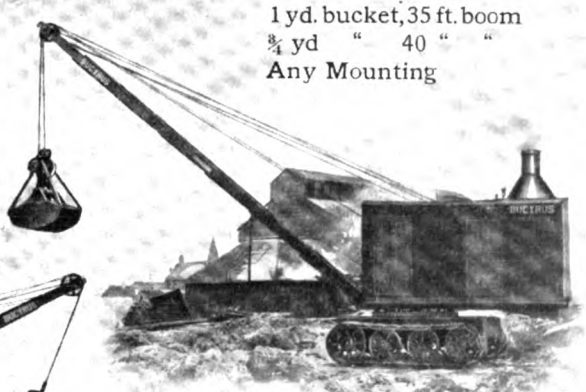
¾ yd. dipper, 24 ft. handle, max. ditch 14 feet.

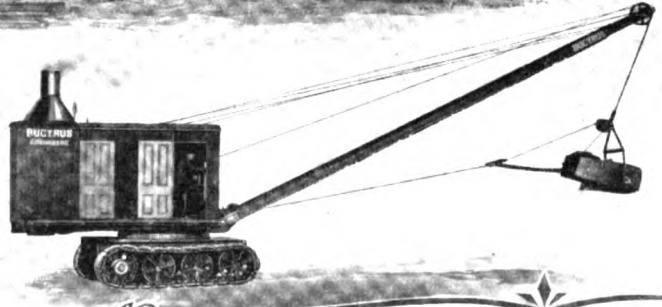
For High Lifts — Special combination.

30-B CRANE

Capacity 9¾ tons at 20 feet on caterpillars.

Capacity 9 tons at 20 feet, on railroad trucks or traction wheels.





30-B CLAM SHELL

1 yd. bucket, 35 ft. boom

¾ yd " 40 " "

Any Mounting

30-B
DRAGLINE EXCAVATOR

1 yd. bucket, 35 ft. boom

¾ " " 40 " "

Any Mounting

The Bucyrus 30-B is so designed that it may readily be changed in the field from any of the above combinations to the other.

It is the last word in excavating machinery. Nearly 40 years of Bucyrus sturdiness and reliability is built into it.

that the canal would afford an economical route for the transportation of oil in barges, and this was the principal traffic predicted. The report of the local officer left the Board in ignorance as to the probability or necessity of this traffic, the saving that would be rendered possible by the canal, and the relative advantage, or otherwise, of a pipe-line. Accordingly, the Board returned the report with the request that these matters be investigated.

In a recent case, the question to be decided was the advisability of constructing a 30-foot channel, giving access to a bay on which local interests and authorities proposed to construct extensive terminals. In this case, no doubt existed as to the necessity for additional modern terminal facilities to accommodate the large commerce of the port, but the investigation failed to show that the particular locality under consideration was the most desirable one for immediate improvement, or that the shore development and connections would be such as to insure the adequate utilization of the desired channels. The Board was constrained to withhold favorable recommendation and to suggest the desirability of an investigation covering the port as a whole, under which the relative importance of this improvement, as part of a comprehensive plan for the development of the port, might be determined and the execution of the work, if found advisable, might proceed in its proper order.

It will be seen from the above that while the activities of the Board have been considerably enlarged in recent years, the scope of its investigations so far as the improvement of channels is concerned is still limited to the language of the specific items of law calling for preliminary examinations and surveys, and hence, it is unable in certain cases to report upon the real needs of the locality. The investigation of terminal facilities, under the general authority of the Act of March 2, 1919, and the recent railroad act, obviously requires study of each port as a whole. The port problem includes not only the provision of a sufficient number of properly located terminals with adequate connections, storage and handling facilities, but also the provision of suitable channels to meet the requirements of the character of vessels which will use these terminals. Hence, the several facilities referred to as essential to a proper terminal development should be considered conjointly, without restrictions which might make it impracticable to formulate a complete and systematic plan. It would be helpful in this direction if the items calling for preliminary examinations were made sufficiently broad to permit consideration of each harbor as a whole, even in cases where report on a particular part of the harbor is especially desired. Perhaps the purpose in view could be attained more advantageously by the modification of existing laws to provide that in connection with the study of plans for terminal development at the ports of the United States, the Chief of Engineers is authorized to consider and report upon the channel improvements deemed requisite to the proper utilization of such terminals.

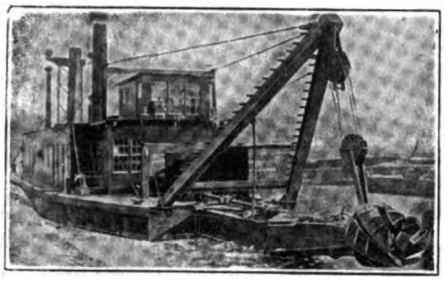
What is the Essence of Discipline?

Two correspondents contribute the following:

The first writes:

Lowell Thomas tells a story which has all the ear-marks of truth, if the many accounts we have heard of the lack of "discipline" among the Australian troops can be believed: General Birdwood who first commanded the Australians (know to them as "Birdie") was one day inspecting a regimental post under his command. He approached what was supposed to be a sentry post, but all he saw was a lone "Aussie" standing with his hands in his pockets and enjoying a cigarette. A rifle leaned against a wall some fifty yards away. Said the General to the soldier who hadn't moved, "Well, my man, who are you?" The Aussie replied with marked frankness, "I am a bit av a sentry, an' who may you be?" Said the general (who was by way of being a good sport), "Well, I am a bit of a General." Whereupon the Aussie looked him over and said casually, "So. Well if you will wait for a much as a minute till I get my rifle I'll turn you out a bit av a salute."

All reports go to indicate that this attitude towards military etiquette was characteristic of the Australians,—and yet as fighters were they not among the best? Good authorities say that they were. What is the answer? Would they have been better soldiers if extreme rigidity of military etiquette had been forced upon them? Some officers, perhaps many, think that they would have been harmed rather than benefited by such strait-jacket methods. Is not some of the hostility toward the Regular Army so plainly discernible in our country today easily traced to the ill-advised adoption of and the rigid insistence upon *non-essential details* of military etiquette so loved in continental countries and yet so utterly unsuited for our own?



The second correspondent, to whom the foregoing letter was submitted, has this to say:

In the early days of the A. E. F., General Pershing, than whom no man knows the American soldier better, announced: "The disciplinary standards of the A. E. F. will be those of West Point." These standards are rigid, even formal, yet they have produced results when men have remembered and understood the *end* in view, and not simply the *means* by which this end is supposed to be attained. The salute appears a foolish formality to those who do not understand its deep significance. It is useless, even harmful, to force men to salute when they do not understand what it means nor how important it is. Yet the initiated know that an organization whose members take a pride in rendering a snappy salute is always a good organization in all respects, one to be depended on in any emergency. There is perhaps no better test of the discipline of an organization than the manner in which its members render the salute—an apparently trivial formality.

Clean shoes seem an unnecessary refinement for a soldier in time of war. On a certain occasion Gen. Pershing was inspecting a number of enlisted candidates for commissions, in a school in France. One of them appeared with his shoes dirty. "Send him back to his organization," directed the C. in C. "A man who has not enough pride and self respect to clean his shoes when his general is to inspect him, is not fit to command American soldiers." Such was the importance placed upon an apparently trivial matter by one who knows what is trivial and what is not in matters of discipline and morale.

The writer once accompanied a British army commander in an inspection of a unit in the front line. After passing a few yards of trench we found two men on duty. "Let me see a clip of cartridges," said the general. Each produced a clip. The general examined the cartridges and passed them to me. They were bright and shiny. "You are good soldiers, boys," said the general, as he smiled and patted them on the back, "Britain is proud that her front line is held by men on whom she can depend." As we passed on he said to me: "Perhaps you think I give too much attention to minutiæ. But I have found by experience that minutiæ are the test. A man with clean cartridges is always a good soldier. The man who neglects the little things soon neglects the things not quite so little,

and he rapidly passes on to neglect of big and bigger things. Discipline consists of attention to a multitude of details, most of them of no great importance in themselves." This general knew discipline as Pershing knows it, and he knew the British "Tommy" as Pershing knows the "Yank."

The disciplinary methods of the American army are not the work of martinets. They represent the accumulated experience of all our greatest soldiers from Washington to Pershing. None of them are unnecessary.

If enlisted men do not understand the reasons for the things they are required to do they naturally regard many of them as unnecessary, and rapidly cultivate the *habit of neglect*. Officers who do not understand the fundamental principles of discipline naturally fail to secure real discipline, which in its essence is simply a fixed habit of *doing things right* under all circumstances. Such officers punish their men for neglecting apparently trivial matters instead of taking the time and exercising the patience necessary to convince their men that none of the things they are asked to do are either trivial or unnecessary. If the men are convinced that what they are asked to do is *necessary and important*—and it is very easy to convince most of them if one will only take the time—they can be depended upon to do it. An officer when training his men should convince them of the necessity for everything they do. This begets their confidence. When, in the stress of battle, such men are told to do things there is no time to explain, they *do* them, because they have learned by experience that their commander never asks them to do anything that is unnecessary or unimportant. Such is the essence of discipline.

There is little to be added to these two letters, so sharply in contrast. The first of our correspondents utterly fails to grasp the meaning of discipline, probbly because nobody who *knew* ever took the trougle to explain it to him. The story he relates is no doubt founded on fact, it may even be literally true. But every trained soldier will take exception to the statement that is was "characteristic" of the discipline of the Sustralians. Such a statement is an (unintentional) reflection on our splendid Allies. Soldiers *on duty*, who stand around with their hands in their pockets, smoking cigarettes, 50 yards away from their weapons, and who make flippant would-be humorous remarks to their superiors, are not the kind of men that Britain or any other country should be proud to have in the front line, where vigilant attention to duty is the price of victory.—Ed.

Strengthening a county bridge to carry motor truck traffic

Several highway bridges in Mercer County, New Jersey, on the Brunswick Pike, near the Middlesex County line, with original capacities of only 4 or 5 tons, recently required strengthening to accommodate practically continuous traffic of loaded motor trucks which were forced to detour from the main artery between New York and Trenton and Philadelphia during the improvement of the latter route. One of these bridges had a trussed span of 142 feet 6 inches, comprising 9 spans of 15 feet 10 inches each. The floor, approximately 17 feet 6 inches wide, was carried by a center and two outside channels all 6 inches deep, and eight 6-inch I-beams, equally spaced between the center and outside stringers. The flooring consisted of two layers of white oak totaling 5½ inches in thickness.

On examination, the trusses proved to be in good condition and capable of carrying the new loads under a stress of 23,000 pounds per square inch, which, in view of the temporary conditions imposing the increased loading, was considered safe. In one of the lower chord members a lateral deflection of 2½ inches was observed. Its cause was found in the insufficient length of the slotted holes for the anchor bolts in the expansion shoe and was corrected by lengthening these slots to permit further expansion.

The floor beams were found to be over-stressed and deflected laterally in some cases as much as 1½ inches. Each beam was reinforced by trussing with two 1⅜-inch rods with sleeve-nuts, passed under two 9-inch I-beam posts, 2 feet 10½ inches on either side of the center line of the bridge. The maximum depth of this trussing is 3 feet between center lines of the rods and the floor beams. The rods are fastened to the web of the beam under the outer stringers by clips. The lateral deflection of the floor beams was corrected by four tightly fitting 3 by 3-inch stiffener angles on each side of the web, at the ends and directly over the truss rod posts.

Examination of the stringers showed that they were already stressed beyond the elastic limit and had acquired permanent set. Two new outside stringers of 15-inch channels were placed against the old outer stringers, 8 feet 9⅞ inches from the center line, and two interior lines of 15-inch I-beam stringers, each 2 feet 10½ inches from the center line, were added. The old stringers were left in place as not worth using elsewhere, but they were neglected in calculating the capacities of the new floor.

The two layers of floor planking were thoroughly spiked together and fastened to the new stringers by ⅝-inch lag-screws and clips, producing the effect of a single layer continuous over the supports and of capacity equal to that of the stringers.

The reinforced bridge has a capacity of 12 tons at 16,000 pounds unit stress. All work was carried on without interference with traffic and the efficacy of the reinforcement is very evident in the almost complete elimination of noisy rattling formerly caused by the passage of vehicles.—*Eng. News-Record.*

Planning and progress on a big construction job

A writer in *Eng. News-Record* (Chas. Penrose, Progress Engr.) describes in interesting fashion the methods by which the operations of the building of the Philadelphia Army Base Depot were forecast, and recorded graphically for the administrative information of the directorate of the work. A progress department divided into graphical chart and statistical divisions was the organization which handled the work of progress and planning. The details of the methods by which data was collected, charted, recorded, and indexed are given. The size of the project and the special circumstances of construction are claimed to have warranted the elaborateness of the work. As a rule, the charts shown are curves platted on the rectangular co-ordinate system with time abscissæ and quantity ordinates, expected quantity and time element being shown on the same chart as the actual work or results accomplished. On a piece of work of the magnitude and importance of this, where war conditions required speed as a prime consideration, the detailed progress charts were essential. The reproduction of the charts is of course essential to a full discussion of the subject.

AUSTIN

"MOVES THE EARTH-MIXES THE CONCRETE"

TRADE MARK

For More Than a Quarter of a Century the name "AUSTIN" placed on a machine has stood as a sufficient guaranty that it was an absolutely perfect type of the kind of machine represented and would perform everything claimed for it.

For each of the many kinds of machines that we have designed, perfected and introduced we have demanded that it represent a distinct advancement in inventive achievement, that it be scientifically correct in principle, and the materials and construction of the highest quality.

U. S. Army Engineers have accepted CUBE CONCRETE as standard for many years. AUSTIN CUBE MIXERS (over 100 units) produced all of the concrete for the Panama Canal Locks. CUBE PAVERS are laying concrete on all of the great across-continent trails and highways.

AUSTIN TRENCH EXCAVATOR experience goes back to the days when there were no other trench excavators and Austin worked his own machine on a pay-for-work-done basis, thereby learning what every part had to be and to do to make money for the operator. Austin Trenching Machines dug the sewer and water pipe trenches for several of the largest U. S. Army Cantonments.

THE AUSTIN COMBINATION DRAG LINE has incorporated in its design and construction all of the developments that have taken place in recent years. The five combinations are easy to substitute and no drums have to be added.

THE AUSTIN WAGON LOADER with patented self-feeding device is a distinct advance in the multiple-bucket type of loader.

Lake Washington Ship Canal, Seattle, Wash.

By

A. W. Sargent

U. S. Assistant Engineer

History and location of the project

THE project for a canal to connect Puget Sound with Lakes Union and Washington is practically as old as the City of Seattle, the first federal recognition being contained in a report of a board of engineers for the Pacific Coast made December 9, 1867, recommending the lakes as sites for a naval station on Puget Sound. (See page 323.)

Seattle, the largest city of the State of Washington, has a magnificent harbor, perfectly protected from storms, and always accessible to the largest vessels afloat at all stages of the tide. In the immediate vicinity of Seattle are two lakes, Union and Washington, and also Salmon Bay, an estuary connecting through Shilshole Bay with Puget Sound.

Lake Union, the smaller of the two lakes, situated in the heart of Seattle, has an area of nearly 1,000 acres of which 500 acres has a depth exceeding 40 feet. The general elevation of Lake Union was originally 25.5 feet above extreme low tide in Puget Sound. Between Lake Union and Puget Sound is a high ridge, cut by a low valley at the extreme western end of the lake. Through this valley the natural drainage of the lake found its outlet to Salmon Bay.

To the south of this valley and of Salmon Bay are two high hills between which is a low narrow valley connecting the head of Salmon Bay with Smiths Cove, an indentation in the north end of Elliott Bay on which the City proper is situated, also the greater part of the present docking facilities.

Salmon Bay extends in a westerly direction to Shilshole Bay, an arm of Puget Sound. Salmon and Shilshole bays were originally navigable at high tide, but both bays were practically dry at extreme low tide. In these bays the tide has a mean range of 11 feet and an extreme range of 19 feet.

Lake Washington forms the eastern boundary of the City of Seattle, is 19 miles long, with an average width of 2 miles. The surface of the water in Lake Washington originally fluctuated between 33 feet and 37 feet above extreme low tide in Puget Sound. Lake Washington is separated from Lake Union and from Elliott Bay by a high ridge, extending along the western side of the lake. In this ridge is a low depression at a point where the shores of Lake Union and Lake Washington approach each other to within 2,000 feet. At this point known as "The Portage," a narrow channel was cut for the passage of logs. The natural outlet of Lake Washington was from the southern end through Black and Duwamish rivers to the waters of Puget Sound at the southern end of Elliott Bay. These rivers had sufficient capacity for the transportation of logs. Cedar River, which entered the Black River about ½ mile below the outlet of Lake Washington, is subject to annual floods, due to the melting of snow in the headwaters of the river in the Cascade Mountains. During the height of these floods the direction of the current in Black River between Lake Washington and the mouth of the Cedar River was reversed, and a large quantity of water emptied into the lake, which acted as a storage reservoir preventing excessive flooding of the Duwamish Valley.

The river and harbor act of 1890 contained the first appropriation for the canal, as a commercial waterway, and authorized a survey and selection of the most feasible location, together with an estimate of cost. A board of engineer officers, consisting of Col. G. H. Mendell, Maj. T. H. Handbury, and Capt. T. W. Symons was appointed to make the survey. Five possible routes were considered.

First. From Elliott Bay by way of the Duwamish and Black River valleys to Lake Washington, and across the Portage from Lake Washington to Lake Union.

Second and third. By way of the depressions between the southern end of Lake Union and Elliott Bay (known as the Mercer farm route and the tramway route) thence to Lake Washington by a canal through the Portage.

Fourth. By way of Shilshole Bay, Salmon Bay and the valley of the outlet of Lake Union, thence through Lake Union to the Portage, thence through the Portage and Union Bay to deep water in Lake Washington.

Fifth. By way of Smiths Cove to the upper end of Salmon Bay, thence as in the preceding route.

Digitized by Google

All of the routes except the last two were soon eliminated from serious consideration on account of their great cost and other disadvantages. The fourth and fifth routes were entirely feasible, and estimates of both routes were submitted. The two routes coincide in alignment from Lake Washington to Salmon Bay; they differ in that one route makes the connection with Puget Sound through a low valley to Smiths Cove and Elliott Bay, and the other (the present route) through Salmon Bay and Shilshole Bay.

In each of the projects, by Smiths Cove or Shilshole Bay, a masonry lock was to be built near the Sound, the waters of Salmon Bay being raised to the level of Lake Union and another lock was to be built at the Portage between Lake Union and Lake Washington with a lift of about 7½ feet to overcome the difference of level between these two lakes, the elevation of Lake Washington was to be held at approximately its lower water level. The Smiths Cove route required a dam to be placed at the westerly entrance to Salmon Bay to raise its level to the required height. The Shilshole Bay route, being less expensive, having a better alignment, and being more convenient for ships going from the lakes direct to sea and vice versa, was adopted by the Secretary of War in 1899.

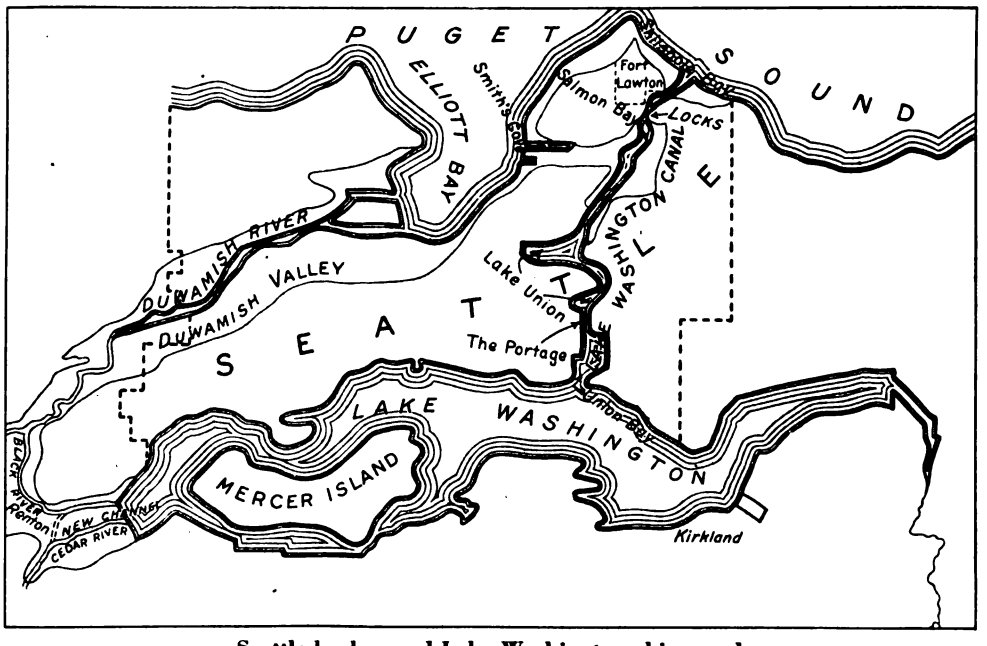
The rivers and harbors act of 1894 provided that no money should be expended on the improvement of the waterway until the entire right of way and release from all liability to adjacent property owners had been secured by the United States free of cost, and to the satisfaction of the Secretary of War. These requirements were satisfactorily complied with by King County, in which the canal is located, at a cost of $250,000.

During the following years Shilshole Bay and Salmon Bay were improved by dredging, and a narrow cut was excavated along the canal location between Salmon Bay and Lake Union for control of the water level of Lake Union. The cut between Lake Union and Lake Washington was enlarged to regulate the flow from Lake Washington. The flow of the water through these cuts was regulated by wooden gates.

The rivers and harbors act of March, 1907, ordered a new survey and estimate of cost. All projects prior to this date contemplated two locks, one between Salmon Bay and the Sound and the other between Lake Union and Lake Washington. In this report submitted by Maj. H. M. Chittenden, district engineer, the single lock plan was recommended, locating the lock at the westerly entrance to Salmon Bay, raising Salmon Bay and lowering Lake Washington to the level of Lake Union, with unobstructed channels uniting these bodies of water. Some modifications were made in the channel of the canal, the principal change being at the Portage, where a new route was adopted affording a better alignment. This changed right of way at Lake Washington is through the State University tract and was ceded by the State free of cost to the United States. Under this plan the County of King was required to do the excavating in the waterway above the lock, and to hold the United States free from any claims or damages on account of lowering the level of Lake Washington, raising the level of Salmon Bay or any other alterations of the levels of any part of the waterway. The cost of fulfilling these requirements was to King County $750,000; and to the State of Washington, $250,000.

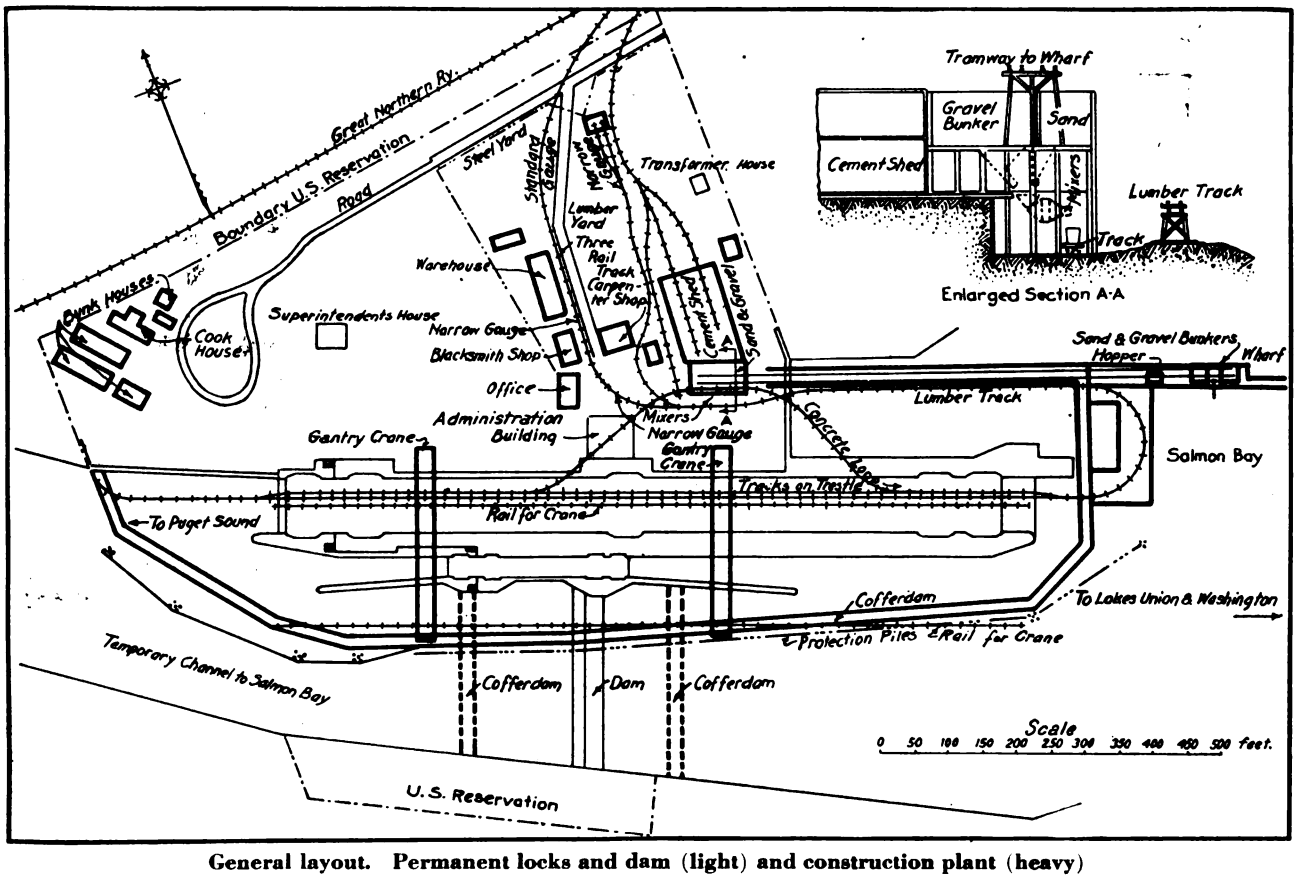
This report was approved by the Board of Engineers for rivers and harbors, and on June 25, 1910, the rivers and harbors act authorized the project. In September, 1911, construction work was actually begun under the direction of Maj. (now Colonel) James B. Cavanaugh, Corps of Engineers, the district engineer who was in charge of the entire project, both as to the federal and county expenditures, until the completion of the work.

General description of canal and results attained



The length of the canal between deep water in Puget Sound and deep water in Lake Washington, is 8 miles. The dredged channel below the locks is 150 feet wide at the bottom and 30 feet deep at low water; from the locks to Lake Union a channel 100 feet wide on the bottom and 36 feet deep has been dredged; from the easterly end of Lake Union to Lake Washington the channel is 75 feet wide and 26 feet deep. These dimensions will be increased to meet the needs of commerce.

The locks and dam are located in the narrows at the westerly entrance to Salmon Bay. The locks and spillway form a dam at this point, holding the waters of Salmon Bay 25 feet above extreme low tide in Puget Sound. They afford access from the Sound to Salmon Bay, and to the fresh-water lakes beyond.



The canal has added many miles to the water-front of Seattle and thus affords unlimited wharfage room as well as unlimited anchorage, perfectly protected from storms, and free from tidal fluctuation and currents. The construction and maintenance of wharves is much less expensive than in Elliott Bay where the depth of water is very great and where the teredo is very destructive. The economy of a fixed water level in loading and unloading vessels and the absence of the teredo is obvious.

The lowering of Lake Washington has helped to reduce the floods in the Duwamish valley, and the problems of the development of the Duwamish waterway have been greatly simplified. Swamps along the shores of Lake Washington have been converted into favorable sites for industries, especially at the north and south ends, where tracts have been made available for commercial purposes, as the shore is flat and

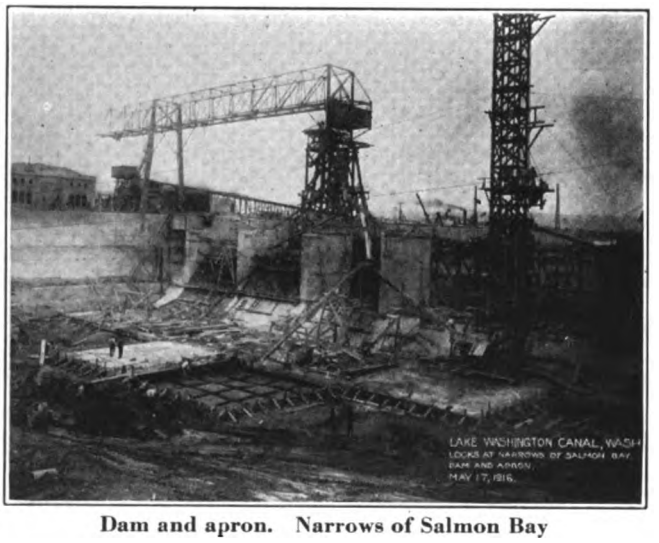
railroads may meet water transportation on an economical basis. In general there will be improvements of harbor facilities and increase of shipping and industries in an already developed city.

Foundations, excavation, cofferdams, etc.

The locks and dam are constructed by placing concrete directly on a clay foundation. Borings made with a 2-inch auger and carried to a depth of 50 feet below the foundations show the same character of ma-



Lock and guard gates

terial throughout. The tests of the bearing capacity of the foundations were made after the excavation within the cofferdam had been practically completed. The apparatus consisted of a 12 by 12-inch post 15 feet long shod at the lower end with a ½-inch steel-plate 12 inches square. A loading platform 4 feet square was built around the post, supported underneath by struts. The post projected about 2 feet below the loading platform and was held vertical by means of independent braces placed in such manner that the post was free to settle in its vertical position. The platform was weighted at first with a few tons of pig iron, and the load gradually increased until a maximum load of twelve tons had been applied. The settlement was carefully checked by levels, and allowed to cease before each increase of load.

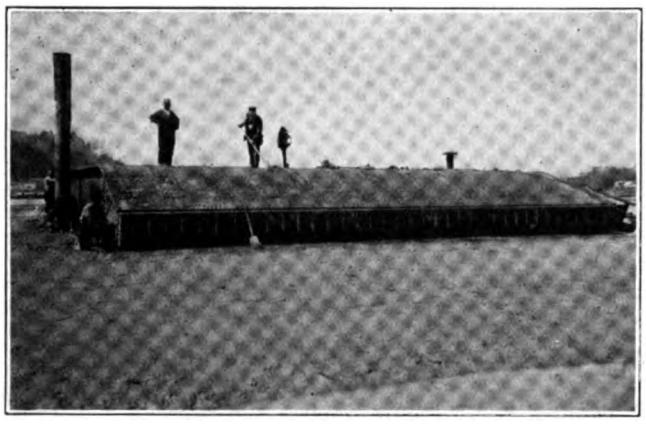
The material excavated from the lock-pit and the entire canal except at the Portage between Lake Union and Lake Washington, was removed by suction and dipper dredges, and deposited partly in deep water in the Sound and partly on adjacent lands. Excavation at the Portage was done in the dry by steam shovels and dump cars; the excavated material being used to fill the adjacent low land belonging to the State University. Before the excavation was commenced a cofferdam was constructed around the Lake Union entrance and a wooden dam with gates was constructed across the Lake Washington entrance. These head gates were later used to control the flow of water from Lake Washington during the lowering of that lake to the level of Lake Union.

The cut at the Portage is 96 feet deep at the highest point, the material mostly hard clay with some cemented gravel. The cut is 100 feet wide on the bottom with side slopes of 1½ on 1, up to an elevation 5 feet above the water surface, where there is a berm. Above this elevation the slope flattens to 1 on 1½ with another berm about midway of the slope. The cut is lined with concrete up to the first berm through a greater part of its length.

The cofferdams within which the locks and dam were constructed consisted of two walls of sheet piles, 17 feet apart, driven well into the hard bottom and supported by round piles and wales, the two walls being securely bolted together, the intervening space filled and the outside banked with clay. At high tide the bottom of the excavation in the lock pit was about 58 feet below water level, but very little difficulty was experienced from seepage. The cofferdam area was first unwatered by a pumping plant consisting of two 12-inch and one 8-inch electrically driven centrifugal pumps, after which a single 2-inch centrifugal pump was sufficient. The closure in the cofferdam was made at low tide after the required excavation inside was completed, and the entire cofferdam, except a gap

Dam and apron. Narrows of Salmon Bay

about 6 feet wide, had been completely filled and banked.



This gap extended down to low tide level and provision was made for sliding gates into recesses provided in each wall. These gates were made of the upper portion of the sheet piles which had been driven and sawed off at low tide. After these gates were placed, this section of the cofferdam was filled and banked as rapidly as possible by clam-shell buckets with material which had been deposited for this purpose in a convenient place near the cofferdam.

The excavation within the cofferdam enclosure was

Digitized by Google

carried to a depth of about 2 feet above the completed foundations with dipper dredges; the excavated material not required for filling and banking the cofferdam was placed on barges and dumped in Puget Sound.

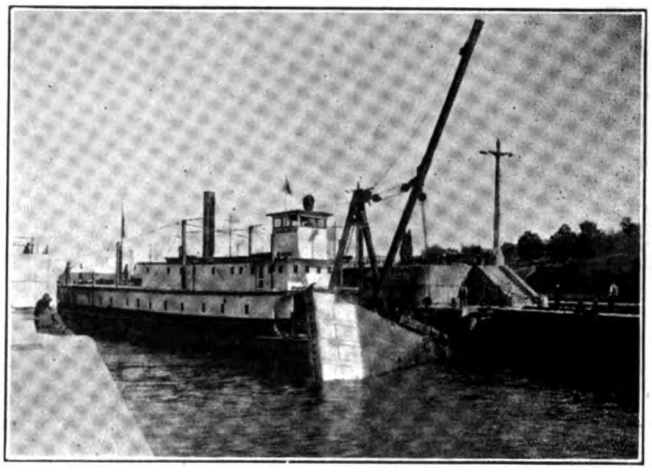
Provision was made for filling the coffer, when the work in the enclosure was completed, through three 4-foot diameter wood pipes, which were closed with wooden bulkheads. These were built into the coffer at low tide level. When the construction work on

Lower guard gate beached for painting

the locks was completed these bulkheads were broken and the coffer allowed to fill gradually.

General features of the locks and dam

The large lock is 80 feet wide and 825 feet long between upper and lower service gates; it is divided into two chambers 375 and 450 feet long, by an intermediate gate. Vessels up to 36 feet draft can pass through the large lock.



Alongside and south of the large lock is a much smaller one, suited to vessels up to 16 feet draft, its inside dimensions are 30 by 150 feet. The object of the small lock is to handle the great number of launches and small craft continually passing in and out of Salmon Bay. The spillway between the wall of the small lock and the south shore is 225 feet long, with six spillway openings of 32 feet, and a fish-way through which salmon can always find access to the fresh water in the lakes above. The spillway openings are closed by Taintor gates operated by means of a portable electric hoist on a track over the dam.

There are five gates in the larger and four in the smaller lock, all provided with a mitering device consisting of a jaw on one leaf which engages a post on the other as they swing together. The gates of the large lock are double sheathed so as to form an air chamber by means of which the buoyancy is increased and the pull on the anchorage reduced. The lower guard gate, which will be used only when the lock is unwatered for purposes of repair or inspection, will withstand a head of 43 feet. This is the heaviest gate, each leaf being 46 feet high, 47 feet long, and 5 feet thick. The lower service gate and intermediate gate are 56 feet high, to withstand 26-foot head. The upper service gate and upper guard gate are smaller, being 43 feet high, but the guard gate is subjected to a head of about 38 feet when the lock is unwatered.

In addition to the guard gates, emergency dams will be provided at the upper entrances to both locks. These dams will be used to stop the flow of water through the canal and locks in case the lock gates should be accidentally damaged. The dam for the large lock will be of the swing-bridge type, with rolling wickets, cutting off the flow of water in successive horizontal planes. The emergency dam for the small lock will be a series of wickets which drop into vertical recesses in the lock walls.

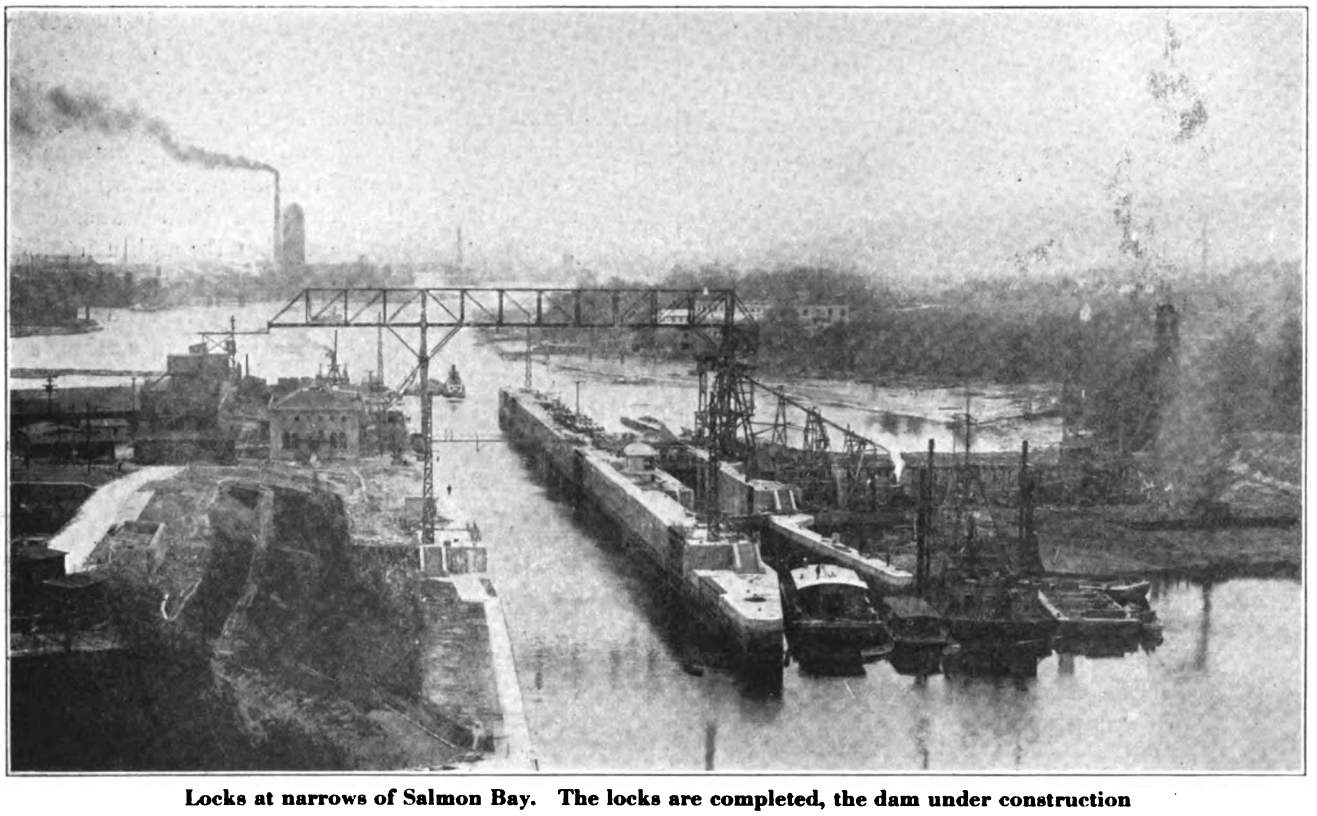
The large lock is filled and emptied by means of culverts 8½ by 14 feet in cross section, which extend almost the entire length of both walls, communicating with the lock chamber through a number of small openings at the floor level. The flow of water through the culverts is controlled by the Stoney gate valves. Similar culverts 4.3 by 6 feet in section, are provided for the small lock, the flow of water being controlled by cylindrical valves.

The Stoney gates are raised and lowered by means of two vertical screws revolving in fixed nuts in the

Replacing lower guard gate after painting

crosshead which is attached to the valve stem. The valve stem passes through a stuffing box in a watertight bulkhead closing the bottom of the machinery recess, which is about 22 feet below high water level in the lock. Roller trains are provided which are raised and lowered with the valve but at half the speed by means of a chain passing over pulleys, one end of the chain being fastened to the crosshead and the other end to the roller train stem which passes through a stuffing box in the bulkhead. Signal lights installed in the operating house, controlled by contacts with switch, indicate whether the valves are in

Digitized by Google



the open or closed position, and switches are provided for limiting the travel of the valves.

The cylindrical valves are raised and lowered by means of a screw passing through a stationary nut at the upper end of the shaft through which the stem passes. The travel of the valve is controlled by a limit switch, and signal lights indicate the open and closed positions.

Electric power purchased locally and delivered at the transformer station at the locks, at 13,000 volts, is used for the operation of the locks. The service gates and valves are controlled from operating stations on the lock walls. Three of these stations for the large lock are on the north wall, while a single station between the two serves the small lock. All operating machinery is placed in covered recesses in the tops of the lock walls. The gates are actuated by two cables attached near the outer edge of each leaf, the other end of the cables being attached to the spiral drum on the gate-operating machine. The drum spiral is so proportioned as to take up the slack due to change in cable lengths as the gate swings through its arc of revolution. The life of the steel cables used in the operation of the gates is from six months to one year. To replace broken cables and do other necessary repair work that can be accomplished without unwatering the lock, a diver is ordinarily employed as an operator or lineman on the lock force.

All of the gates and machinery in both locks except the bottom and back of the guard gates, are accessible when the locks are unwatered. To do necessary painting of these surfaces the guard gates of the small lock are hoisted onto the lock wall; and guard gates of the large lock are floated away and beached after the valves admitting water to the water chamber have been closed and the interior of the gate pumped out.

When the lower guard gate was removed for painting during July, 1919, it was found that the greenheart timber sill attached to the lower edge of the gate was completely honeycombed in places by the teredo. The sill was removed and replaced with iron bark.

Locks at narrows of Salmon Bay. The locks are completed, the dam under construction

A pumping plant of two 30-inch pumps, with a capacity of 4,000 gallons per minute, one 10-inch pump and a 3-inch sump pump, all electrically operated, has been provided for unwatering the locks when necessary for inspection and general repairs. The pumps are located in a well under the administration building, the intake being through the lock wall at the intermediate gate, while the discharge is carried in a concrete pipe supported on the back of the lock wall, and empties just below the guard gate of the large lock.

For the purpose of providing means of repairs, a combined machine shop, blacksmith and carpenter shop, has been constructed adjacent to the locks. There is also provided a concrete warehouse, administration building, and quarters for the superintendent.

The locks are well lighted by electricity.

The lock walls are mass concrete, approximately

Digitized by Google

62 feet high, and are constructed with stepped back and vertical face, except near the top and bottom, where the face is sloping. The top edge is rounded and the reinforced toe extends ten feet beyond the face of the wall, its top being at the floor level. Concrete cut-off walls were built under the heel of both walls, across the lock under the miter sill at both ends, and at the intermediate gate, and across under the entire length of the dam to the south bank.

Lead stopwaters were placed between all wall sections, a channel between Shilshole and Salmon Bays being always kept open for the passage of vessels; between the toe of the wall and the floor, across all floor sections and between the sections of dam. To relieve the pressure on the clay foundation a toe block 10 feet wide was built, on which the toe of the wall rested, the outer end of the toe being at the center of the block.

The bearing capacity, and the imperviousness of the material in the foundations, at the upper end of the large lock, beyond the guard gates, were less than over the rest of the lock area and cellular walls were built here, and the under side of the floor over this area was constructed in the form of a flat arch.

The walls, for the most part, were built up in sections thirty feet long, concrete being deposited in layers five feet thick. The top layers in adjoining sections were kept at approximately the same level and numerous key blocks were made projecting upward into the next layer formed. Key blocks were also built into the ends of each section, extending the full height.

The floor of the large lock is three feet thick and is constructed without valves of any kind to relieve the hydrostatic pressure, reliance being placed upon the cut-off walls to prevent leakage.

Locks and dam at narrows of Salmon Bay, after completion

The locks and dam were constructed as two separate units, a channel between Shilshole and Salmon Bays being always kept open for the passage of vessels. The cofferdam for the lock was 1,320 feet long, the two ends being tied into the high bank along the north side of the site, leaving a temporary channel between the cofferdam and the south shore. During the construction of the dam vessels passed to and from Salmon Bay through the large lock chamber, all of the lock gates being left open, providing an unobstructed channel.

Operation of the locks

The locks are operated 24 hours a day, 31 men being employed. Records of all lockages are kept and a statement as to the amount and kind of cargo car-

Digitized by Google

ried must be submitted by the masters of all boats. The information furnished is used for compiling commercial statistics of the canal.

The time of lockage varies with the stage of water and the vessel passing through. Tug-boats pass through the small lock in five minutes, but large vessels and barge traffic in the large lock require from 15 to 30 minutes and log rafts from 30 to 45 minutes.

During the three and one-half years of operation the traffic through the canal shows considerable increase, the principal traffic being logs, lumber and miscellaneous freight carried on barges.

During the calendar year 1919, 24,676 vessels, with total net registered tonnage of 1,104,688 and carrying 1,020,710 tons of freight with a value of $9,520,311, passed through the locks.

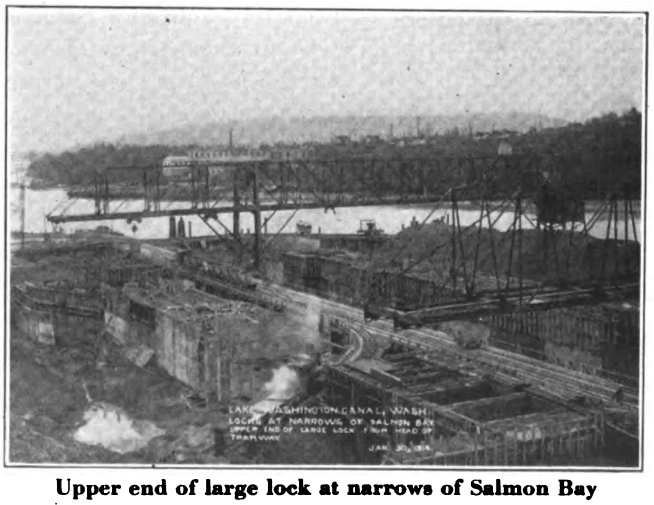
Since there was no navigable channel into either of the lakes prior to the completion of the canal, it will no doubt require several years before industrial and commercial lines of any great magnitude are established; although the opening of the canal has created a fresh water harbor absolutely beyond comparison and ample for the needs of the greatest commercial city in the world.

Salinity

When the lock has been filled, the water in the chamber is a mixture of fresh and salt water, the greatest salinity being always found at the bottom. The lower pool has practically full salinity and the upper pool contains mostly fresh water.

Since the water above is lighter than that in the lock, and the culverts through which the pressures on both sides of the gates are equalized, are at the floor level, the flow through the culverts ceases before the water in the lock has reached the same level as the water above. This difference in head is usually about 3 inches but sometimes is as high as 6 inches. When the difference in head is excessive the water in the lock is lowered by discharging into the pool below; and filled again with fresh water before the upper gates are opened.

At the lower end of the lock the outlets to the culverts were raised above the floor level and no difficulty has been experienced in opening the lower gates.



The difference in density of water in the lock when the gates are opened produces currents caused by the fresh water in the chamber flowing out on top of the salt water into the channel below; when the upper gates are opened the salt water in the lock rushes out into the upper pool, the fresh water flowing in on the surface. This flow of salt water into the upper pool would in time cause the water above the locks to become salt, but provision has been made for drawing the salt water back into the pool below the locks. A large sump or settling basin has been dredged in the channel above the locks, from which a concrete pipe with its intake near the bottom of this sump and its outlet over the spillway dam, is carrying a continuous flow of water from the bottom of the sump to the pool below. In addition to the salt water remaining in Salmon Bay when the water was raised by the closing of the dam and lock, the bottom of Lake Union contains large quantities of salt. In 1903 and again in 1914 the dam and gates controlling the outlet of Lake Union broke and the outflow lowered the lake to level of tide water and allowed salt water to enter the lake. It is not anticipated that all of the salt in the lake will be removed but it is hoped that all of the salt entering the upper pool due to the operation of the locks will find its way to the settling basin and be carried back through the pipe to the pool below. Salinity tests made during February, 1920, show that the salt remaining in the upper pool is confined principally in Lake Union at a depth greater than 32 feet, which is the controlling depth in the channel between Lake Union and the locks.

General

After completion of the locks and dam the lock gates were closed at low tide and Salmon Bay was filled with fresh water from Lake Union through the Lake Union outlet gates, after which the gates and dam were removed. The locks were then put in operation and the canal completed into Lake Union.

The lowering of the level of Lake Washington was accomplished through the head gates before mentioned. The lowering of this lake made a dry channel of the Black River and necessitates the conveyance of the entire run-off from the watershed of Lake Washington and Cedar River, 580 square miles, through the Canal to Puget Sound. The maximum known run-off from this drainage area is nearly 12,000 cubic feet per second for a period of 24 hours.

Owing to the fact that the waters of Salmon Bay were raised considerably above high tide elevation, a large proportion of the wharves, lumber and shingle mills in the bay had to be reconstructed. The same

Upper end of large lock at narrows of Salmon Bay

Digitized by Google

is true on Lake Washington where the water was lowered some 8 to 11 feet or to the level of Lake Union. The railroads and city bridges crossing the canal were all rebuilt with lift spans of the bascule type. The change by the Great Northern Railway required an entire relocation of its main line for several miles on either side of the canal, with heavy grading both north and south of Salmon Bay. There have been five new bridges erected, none of which has a horizontal clearance less than 150 feet.

The building of the locks was conducted entirely by hired labor and government plant. The gates and machinery were manufactured under contract from designs prepared by the Engineer Department.

The entire work was conducted under the direction of Major (now Colonel) James B. Cavanaugh, Corps of Engineers, the author being in local charge, and Mr. C. A. D. Young, Assistant Engineer, in charge of design of gates and machinery.

Questionnaire on battle experiences

With a view to profiting by the experiences of the war in our future training, the War Department is sending the following questionnaire to officers and N. C. officers who commanded troops in battle.

As this questionnaire has an instructive value in itself as indicating the things a commander will encounter, and what he should know and do, we reprint it in full.

1. Were you ever engaged in an active operation in a front-line organization and in immediate contact with the enemy? 2. In what major offensive, defensive, or local operation? 3. In what locality? 4. Date and time? 5. In what regiment and division?

6. What was your rank at the time and what command were you exercising? 7. What kind of orders did you receive governing the attack or defense? Written or verbal? Standing or special? Divisional, brigade, regimental, battalion, company or platoon? 8. At what time did you receive such orders, with reference to hour or other period of engagement? Where did you receive them? 9. Were your orders accompanied by a map? Kind of map? How marked? 10. Did you have a map, or the opportunity to consult one? What kind of map?

11. On receipt of orders, was your command in position for attack or defense? If so, where? 12. If not, did you have any opportunity to reconnoiter the ground? Were any guides furnished you? What reconnaissance, if any, was made? 13. If your command was not in position, where was it when orders were received? In what formation was it brought up? Under whose command? What were its relations on movement up to other units of the superior unit? What were the conditions of light or darkness, weather, roads, etc?

14. What was the physical condition of your command at the time orders were received? When had it last slept? Last eaten? Last eaten hot food? How far had it marched in the preceding twenty-four hours? 15. What was its mental condition, as to morale, briefly? 16. What was the condition of its clothing, equipment? What ammunition did it have? Where were packs left? 17. What was the strength of your command at this time? Officers? Men? 18. What, in brief, were the orders received?

19. In approach to attack or defense position, what changes in formation were made due to terrain or other conditions? 20. When and where did your command come under artillery fire? What changes were made, due to terrain or other conditions? 21. The same for small arms fire? 22. Once in position, when did your command start to fire? 23. At what time did Infantry attack or defense start? What was the condition of light and weather?

24. Who gave the order that actually started your command, if attacking? How was it given? Barrage, watches, word of mouth? 25. What was the conduct of your command? was it silent? Was there shouting? Singing? Grumbling? Swearing? Nervousness? Confusion? 26. What was the rate of advance? Did men halt to fire? Did men so doing resume the advance? 27. Was your command under your personal control? Were you in touch with your immediate superior? With units to your flank? How?

28. When and where did your command halt? What halted it? The barrage, orders, exhaustion, enemy fire, enemy hand to hand resistance, enemy counter-attack? 29. What was the strength of your command at the halt? Was there any check made of those present? Can you account for the absent? 30. What was the physical condition of your men at the halt? The mental condition? Were they silent? Noisy? Did they fire? 31. What was the formation of your command at the halt? Of the superior command? Were you in touch with adjoining commands? 32. Did you reorganize at the halt? How?

33. Was your command supported by artillery fire during the advance? At the halt? Were you in liaison with artillery? Was there any complaint of short firing? Was such complaint justified? 34. Same for fire of small arms and auxiliary weapons, including tanks. 35. When was the advance resumed? On whose orders? How given? 36. What was the strength of your command on resumption of advance? What was its formation? Was it in liaison to the flanks? With superior command?

37. Where was your command at nightfall? Did it remain there? What was its strength? Its formation? Did you reorganize it? Did you receive orders? When? What were they? Were you in liaison with any other command? 38. Did you receive reinforcements from the rear? Hot food? Ammunition? Did you have water? 39. What was the physical condition of your men? Mental condition?

40. What constituted the enemy's resistance? Artillery fire? Small arms fire? A hand to hand stand? Attack? Counter-attack? 41. Did the enemy die fighting? Did he surrender? Retreat? Stand to engage in bayonet fighting? Did an actual bayonet contest take place? 42. What constituted the most serious opposition of the enemy?

43. Was the advance of your command assisted by accompanying guns? By other artillery support? By auxiliary Infantry weapons? By machine guns attached? By overhead machine gun fire? By tanks? 44. Did you see your immediate commanding officer during advance or at a halt? Any other superior officer?

45. What were the losses of your command? Dead? Wounded? Gassed? Exhausted? Missing? Separated from the command but returned to it after the operation? Can you account for the absence of men so separated? 46. What kind of wounds were received? Shell? Bullet? Bayonet? Did you actually see bayonet wounds inflicted? 47. When did your command get to their packs after battle?

48. Who was your immediate commanding officer? 49. What other officers do you know with sufficient experience to speak authoritatively on front-line battle and with sufficient coolness to have observed in battle?

50. Submit a chronological report of the engagement. A sketch will be of value, and statements need not be restricted to cover only the points mentioned herein.

Plank surfacing for secondary highways.—A writer in *Eng. News-Record* suggests plank highways for the temporary relief of communities unable to invest in permanent construction. Generally the plank could be laid upon a well compacted sub-grade. A telford base should be used where the sub-grade is soft or badly drained. Sleepers should be laid on top of small trenches cut in the sub-grade and filled with crushed stone. The spaces between the sleepers should be brought to the level of their tops with crushed stone, and the whole thoroughly rolled. Two-inch plank are recommended for the wearing surface.

Counties constructing such roads should have their own portable sawmills and creosoting plants.

The writer estimates that such a road (exclusive of excavation, culverts, etc.) should be built for $12,500 per mile, on an 18-foot width. Seven years of good service may be expected.

Such a road would be specially applicable to military operations, except that the planking proposed (2 inches) is too thin. Three inches would be the minimum that would be satisfactory for the heavy motor traffic of an army, and 4 inches would be better. For military purposes creosoting of the timber would be unnecessary.

The Port of Seattle

(See plan with article on Lake Washington Ship Canal, page 321.)

Seattle is the only major port in the United States in which no dredging has to be done for ship channels. The ample depth in Puget Sound, minimum 156 feet, makes it possible for ships of the greatest draft to enter the port and berth, without the aid of a pilot.

The commerce of the Washington Customs District, of which Seattle is the chief port, has increased nearly 1,000 per cent in the last 10 years, and has risen from 22nd place in 1910 to 2nd place in 1918, amongst United States Ports of Entry.

The Port of Seattle Commission, an elective body, directly operates six terminal units. No exclusive leases are made, nor preferential assignments of an exclusive nature. The Commission is free to give berthage to all vessels and all lines, upon equal terms, and to keep every pier working.

The six terminals represent an investment of about $9,000,000 and a present value of $18,000,000. They include piers, transit sheds, warehouses, open storage, a grain elevator, oil storage tanks, and cold storage plants, and are equipped with mechanical handling devices with a range of capacity from a case of salmon, weighing 70 pounds, to a locomotive weighing 100 tons. The investment this equip- locomotive weighing 100 tons. The investment in this equipment amounts to three-fourths of a million dollars, more than any other port in the United States.

Seattle has led all other ports of the U. S. in the size and capacity of its ocean piers. It now owns and operates two piers, each over half a mile in length, one 310 feet and the other 365 feet wide, and representing the last word in terminal efficiency.

The six municipal terminals are equipped with about 15 miles of trackage, for loading and unloading cars: of this about 23,000 feet, with a capacity of 560 cars, are on the ship side of the piers, and 51,000 feet with a capacity of 1,280 cars, are on the land side. The berthing space is 16,700 linear feet.

The storage facilities in warehouse and transit sheds have a total net floor area of 1,635,000 square feet, of which 680,000 is covered.

The private commercial wharves have a total berthing space of 26,750 linear feet, a car capacity of 480, and a warehouse capacity of 290,000 tons. The private industrial wharves have a total berthing capacity of 10,000 linear feet; a car capacity of 270, and a warehouse capacity of 23,500 tons. The total grain storage amounts to 4,240,000 bushels.—*Port of Seattle Year Book, 1919-20.*

Metric System not to be perpetuated in the U. S. Army.—During the World War the U. S. Army, serving in France and largely equipped with French *materiel,* made much use of the metric system.

A recent order of the War Department prescribes that hereafter the customary British units of weight and measure will be used, as they were before the war.

All materiel and equipment graduated in metric units will, as soon as worn out, be replaced with articles graduated in British units.

Terminology for areas of military activity.—1. Hereafter the following terms will be used exclusively in describing the indicated areas of military activity:

Theater of operations.—The territory prescribed by the War Department as that within which military activities are controlled by the commander of the field forces.

Zone of the interior.—The territory within which military activities are controlled by the War Department acting through agencies other than the commanders of field forces.

Combat zone.—That portion of a theater of operations designated as such by the commander of the field forces operating in that theater. It includes division areas, corps areas, and army areas as hereinafter defined.

Communications zone.—That portion of a theater of operations designated as such by the commander of the field forces operating in that theater.

It includes all territory from and including the base to the rear line of the combat zone.

Supply zone.—A subdivision of the zone of the interior with boundaries prescribed by the War Department.

Army area.—That portion of the combat zone allotted to an army by the commander of the field forces or the commander of a group of armies. If but one army is operating, the combat zone and the army area are one and the same; hence in this case the use of the latter term is unnecessary.

Corps area.—That portion of an army area allotted to an army corps by the army commander or higher authority.

Division area.—That portion of a corps area allotted to a division by the corps commander or higher authority.

Advance section, communications zone—Intermediate section, communications zone—Base section, communications zone.—Subdivisions of the communications zone corresponding to similarly designated sections of the line of communications, as described in paragraph 369, Field Service Regulations.

Application of the cement gun.—Due to the pressure under which it is applied the strength of the mortar placed by the cement gun is much greater than by any other method, and accordingly very thin sections may be employed.

It is too slow and expensive for heavy mass work and should be used only in its proper field.

For coating steel structures to prevent deterioration it is ideal. No forms are required, and the very thin sections possible greatly reduce the dead load where this is important. The initial cost of the coating is greater than painting, but also far more effective and durable. Steel structures coated with gunite can be erected much more rapidly than reinforced concrete. For warehouses, etc., "mill construction" gunite coated may be quite as durable and much cheaper than reinforced concrete. While gunite coated structures are not strictly fire-proof, they are practically ignition proof, and thus greatly reduce fire risk. The reduction in insurance premiums more than offsets the cost of gunite coating.

Wherever steel must be protected from chemical action or wear, gunite is the most effective and economical covering.

For roof coverings and reservoir linings gunite is particularly useful because of its density and watertightness. It is equally applicable to tunnel and mine shaft linings, where it is easily applied and forms a fire-proof covering.

The application of gunite requires skilled operators, and usually a wire mesh reinforcement should be placed around the structure to be coated.—*Proceed. Eng. Soc. of W. Pa.*

Experiences of an Engineer Battalion Commander with the 2nd Division, A.E.F.

At the Second Battle of the Marne

By

M. P. Fox

Major, 2nd Engineers, A. E. F.

[*Note.*—Personal experiences of observant people are the most valuable and the most interesting source of information. There was no American division which saw more active front-line service than the 2nd Division. The author of this story commanded a battalion of the 2nd Engineers during that period of intense activity known as the 2nd Battle of the Marne. The account, enlivened by Major Fox's sharp perception and entertaining humor, is a word-picture of the experiences that fall to the lot of combat engineer troops during battle. In a highly entertaining fashion it presents a vast amount of information as to the difficulties that must be met and how things should and should not be done. Every engineer should read this entertaining and instructive account.—ED.]

I SHALL describe briefly the experiences of the 2nd Engineers near Chateau-Thierry and Soissons during the period from the last of May until their relief from the line in the latter part of July. The subject is taken up more from the standpoint of a battalion commander than from that of a divisional engineer, because my opportunities for observing at close range that portion of the work were much better. Attempt will be made to point out mistakes made during this period; show if possible how they may be avoided, and to explain in some detail the actual conditions under which the regiment worked and what it accomplished.

About the middle of May the 2nd Division was concentrated in a rest area about 50 K. N. W. of Paris. The division had previously served in a quiet sector near Verdun, American battalions being sandwiched in between French. In this rest area maneuvers were held, under French corps orders to fit the division for taking over a sector of their own, functioning as a division. The general understanding was that the first of June the division should be placed in line alongside the first division near Montdidier.

On the 27th of May, however, the Germans started their third big offensive of the year, over-running the Chemin des Dames ridge, crossing the Aisne and Vesle, and reaching the Marne. Accordingly, orders were received May 28th to be ready to move by truck at 10 that night. Movement by truck always means separation for an indefinite period from all animal-drawn transportation, including of course rolling kitchens and tool wagons. Consequently, all the available time between the receipt of orders to move, and the arrival of the trucks is usually employed in cooking up available rations. It is a pretty good idea to get rations into such shape that each man can carry his own rations on his person, since there is usually a march of several miles both to the embussing point, and from the debussing point. In this case the trucks were 12 hours late in arrival, about the usual amount. The entire regiment was loaded at 10:00 a. m. May 29th and unloaded at 3:00 a. m. May 30th at a point 35 kilometers approximately N.W. of Chateau-Thierry, about 10 kilometers in rear of the line and opposite a point half way between Soissons and Chateau-Thierry. From there the regiment was marched to Montreuil, about 10 kilometers west of Chateau-Thierry. Practically all the officers in one company and a large number of men were missing, due to several trucks having broken down on the way. It is like putting all your eggs in one basket to put only officers in a truck, for French trucks are uncertain to say the least.

At this time the front line was lightly held by French cavalry, about 150 men per kilometer of front. The divisional infantry had taken up a position in rear of the French outpost line, one regiment from each brigade being in line. Orders were issued that evening for assigning the engineers, one battalion to each brigade of infantry, an order which did not have the happiest possible results. The brigade commander to which my battalion was assigned in turn assigned two companies to the 9th Infantry in line, and one to the 23rd in reserve. At this time the engineers were in a far worse condition than the infantry for tools, since of course the wagons had not arrived, and the engineers had no intrenching tools. The division engineer was able, however, to secure from the French corps engineer enough shovels, picks, and axes to provide about 40 tools per company.

In leaving Montreuil to join the stations assigned,

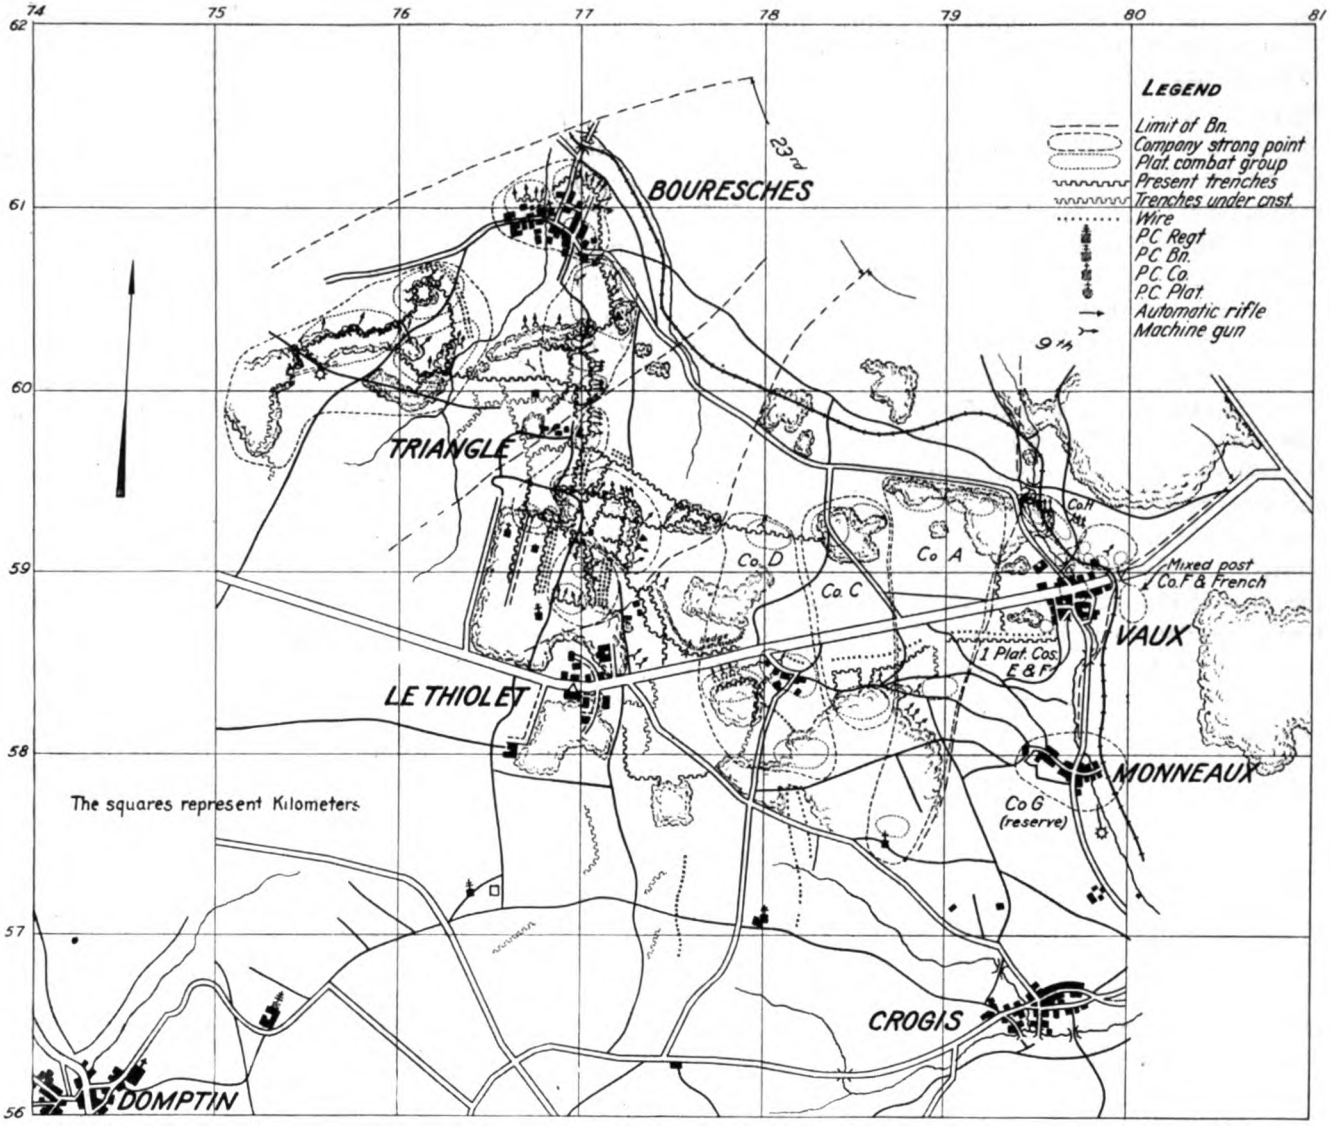
Digitized by Google

the companies took up formations designed to avoid loss in case of being shelled en route, and moved across fields instead of on the roads. This lost much time and proved entirely unnecessary, since the Germans had so far outrun their artillery that they did not have a single piece available. Upon reporting the two companies to the regimental commander, 9th infantry, he assigned one company to each of his two battalions in line. The result was that the battalion commander had no command and the only thing possible was to attempt to advise the infantry battalion commanders as to the choice of positions and the methods of preparing them for defense. With the limited number of tools very little work could be done, so one of the first steps necessary was to organize foraging parties, and collect all the tools in abandoned villages near the front. By these foraging methods, enough tools to equip all the men were secured, and enough kettles, pots and pans to provide each platoon with sufficient kitchen utensils to start a mess for each platoon. This made a very mobile organization.

Platoons could be sent anywhere, each man carrying in addition to his regular pack either some tools or a cooking utensil. The general distribution of engineers was, however, very unsatisfactory and no good results could be secured.

These arrangements lasted for about a week, until June 6. Life was very pleasant at first, due to the absence of German artillery, but about the third or fourth day their artillery started to arrive and by June 6th was practically all on hand. By June 3rd, the French had been driven through the American lines in some parts of the sector and on the balance the Americans had moved forward and taken over the front lines from the French.

On the 6th of June, about 3 p. m., the Americans started local counter-attacks with the idea of securing more advantageous positions. That company which had been with the brigade reserve was designated to take part in the attack. Two platoons were detailed with one infantry battalion. They were sandwiched in between the first wave and the support, given three tools per man and instructed to assist the infantry in entrenching as soon as the objective was reached.



The attack failed, with very heavy casualties, and the objective was never reached. The engineers were able to render valuable assistance to the infantry, both as engineers and infantry. But it was rather an unfortunate location for one of the two platoons especially, since it came out with one officer and four men. It is believed that in a small local attack of this kind the best place for engineers is at some distance in rear of the support, and it is usually preferable to wait until the objective is secured before moving out to consolidate it.

That evening about 9 p. m. orders were sent from Brigade Headquarters for the two companies attached to the 9th infantry to proceed to Lucy le Bocage. The two companies carrying tools and kitchens arrived there about midnight and found a dark, deserted town, under shell fire. The companies were halted outside and eventually a marine private was found who could give instructions on how to find the P. C. of one marine major. Two battalions of marines had attacked that afternoon, one succeeding in capturing the village of Bouresches, and the other securing a lodgment in Belleau woods. The engineers had apparently been sent to consolidate these two positions, and accordingly one company was sent into the village, the other two into the woods. The company in the woods could do very little. The woods were very thick, all fighting was very close and the engineers were valuable principally as so many infantry reinforcements. The company in the village had a better opportunity for engineer work. They fitted up all the cellars in town as secure dugouts. They prepared buildings and walls for machine gun and rifle fire, and laid out a few trenches near the town. Rations and supplies during this time were delivered at night principally, although during the second attack, which took place on the 8th, ammunition was delivered by truck.

The repulse of the second attack on the woods the 8th of June was the signal for the relief of all the units engaged in it. One day's rest was allowed, and then the engineers were ordered to resume work.

This time arrangements were made that proved more satisfactory. The orders governing the work were issued by the French corps to which the division was assigned. The outpost line or sector was placed entirely under the charge of the infantry occupying it. The main defense line was placed entirely under charge of the engineers, the corps engineer indicating where this line should run. It was, as a rule, placed about 2,000 m. in rear of the outpost line, the reason being of course that the French have a very healthy respect for the German *minenwerfer*. The conditions then existing demanded that the line selected be put in a defensible condition as rapidly as possible. The division engineer therefore decided to organize first a series of strong points on this line, capable of obstinate resistance, and at 400-800 meters in rear of these a similar system of supporting points. Each of these two lines was to hold four companies and numerous machine gun replacements. The strongpoints were to be dug to a depth of 3 feet with a 1-foot embankment. They were to be wired in, and the space between the strongpoints was covered with wire only, the wire to be swept with machine gun fire. After completion of this, fire and communicating trenches for a continuous system were to be dug to a depth of about 6 inches. This was done so that any infantry assigned to the positions would have a definite plan laid out, and the

Digitized by Google

works resulting from anything they might do would be part of a harmonious plan.

The construction of the works was divided evenly between the two battalions. One battalion was camped at La Croisette, the other about 2 k. east of Montreuil, or about 6 k. from the line. The battalion at Croisette was camped in a fairly large woods about 1 or 2 k. from the front, one large enough to make it too expensive for the Boche to try to cover the entire woods with artillery fire. Therefore so long as he was kept in ignorance of the exact location of the camp there was no danger from his shells. It made it very convenient to go to work making a long march to and from positions unnecessary. There were, however, several disadvantages. There was a more or less constant strain, since shells were continually passing overhead, and since the Boche used a cross road about 150 yards distant for a registration point. In case of an *alerte* this battalion was always assigned to a certain sector of trenches, and this of course interfered with work. There was also constant liability of a gas attack, always to be feared in camps located in woods.

The battalion camped further in rear, had a really more desirable camp site and selection of a position at this distance to the rear is to be recommended. They had, of course, to start to work earlier in the evening. But as they came nearer the front, it grew darker and they found they could just about march, so that the falling darkness would be sufficient to hide their movements from hostile observation. They lived, of course, under no strain and could have a much more comfortable camp than the battalion nearer the front.

In choosing camp sites it is of course necessary to secure concealment from aerial observation, which makes it necessary to choose either a woods or a village. While villages offer more protection due to their cellars, which can easily be gas-proofed, woods are less liable to shelling and to aerial bombardment, and in the summer are, in my opinion, more desirable.

The camp at Croisette consisted of a number of shallow pits, about 2 to 3 feet deep, laid out accurately in platoon streets. It is essential to have an accurate layout, since in case of gas men cannot be trusted to awaken by noise, but the gas sentinel must awaken

Digitized by Google

each man individually. Over each dugout was put about 1 to 2 feet of cover, dirt laid on short poles. This is a good plan in woods. The majority of shells landing in a wood are air bursts and even this slight protection will keep out fragments. Kitchens were placed about 300 yards from camp and so screened that cooking could be done at night, without light showing through. The location selected was on the road, to facilitate the delivery of rations.

Rations were delivered of course at night. Each battalion has a supply officer detailed with the regimental supply officer, whose duty was to look after supplying the battalion with rations and clothes. He was charged with distributing rations equally among the companies; a very serious proposition because of the extreme shortness of rations at that time. Food was brought up to the camp from the kitchen, and when there was any artillery fire going on served to the men at the entrances of their dugouts. One infantry company near by permitted their chow carriers to appear in the open one day, and this brought a salvo from the Boche about 15 seconds later that caused upwards of 30 casualties. Water was brought in at night. Water carriers had to work all night to supply enough for the kitchens and drinking purposes, so cleanliness was out of question. Hence cooties, the most constant companions of the soldier.

After the arrival of tool wagons, they were kept in camps near the kitchens, and intact as far as possible. Battalion engineer dumps were run by each battalion, these were located about 1 or 2 kilometers in rear of the outpost line. The material for these dumps came from the French and American corps engineers largely, since the division engineer tried to keep the supplies in the engineer train intact also, in case of emergency. The infantry could draw supplies and tools from the battalion dumps, or upon request, the division engineer would deliver engineer supplies to any spot desired. For this purpose an engineer supply officer was appointed who made deliveries nightly as requested, using trucks from the engineer train. Supplies consisted principally of barbed wire, intrenching tools, wire cutters, axes and mauls. There was little demand for dugout material, since the occupation of the sector was almost certain to be of short duration. During the period June 1 to July 8, there were lost by the division upward of 1,500 tools, mostly shovels. The only way to prevent this needless loss is to impress the infantry with the fact that tools cannot be replaced, for the principal loss was due to pure carelessness.

Work was of course done entirely at night, except in woods. Due to the shortness of the nights, hours were fixed from 10 to 4. It was found desirable in the battalion at Croisette to have each man keep his entrenching tools at his own dugout. This obviated getting a mass of men together for issuing tools and saved time; but from my observations of the infantry I doubt if the same rule could be successfully applied to them. Work in woods was done daytime, it was found impossible to work there at night. In isolated cases where it was necessary to go across open ground, working parties would be moved into the woods under cover of darkness and brought back the following night. Staking out was ordinarily done in the day. The size of the party was kept to the minimum, ordinarily the battalion commanders, the commander of the company which was to do the work, and one man to act later as guide for the working party. A party of this size usually failed to draw artillery fire. Care had to be taken to prevent the Germans learning where work was to be done. This could be accomplished by a staking out a few days ahead, or by staking out additional localities where no work was to be done at all.

Considerable difficulty was experienced in securing any infantry working parties. Eventually when it was seen how slow the work was going, the division engineer was given one battalion of the division reserve. The rules for working parties are well known, but too much stress cannot be laid on having them strictly followed. It is amazing how little work 1,000 infantry-men can do in one night on a poorly laid out job. An officer from each battalion of engineers was assigned to brigade headquarters as liaison agent. The importance of this officer's duty is very great. He must keep the brigade commander familiar with everything that the engineers do, since in an *alerte* the brigade commander is responsible for the defense of that sector. Also he is the division engineer's principal source of information as to what work the infantry is doing on the outpost line.

Lots of trouble was experienced in making reports of work done. Maps were so inaccurate, especially as regards woods, that considerable difficulty was found in showing accurately on a map the real location of work done.

During this period, instruction in wiring entanglements was given to some of the battalions of infantry in reserve. Excellent results were obtained and it is believed that considerable extension of this instruction in engineer work is possible and desirable.

Between June 8 and June 30 fighting continued in the famous Bois de Belleau, and the engineers were used to very large extent.

Serving with infantry as infantry, has two very considerable advantages. It gives the engineers more prestige than anything else they can do. After the infantry discovers that engineers can fight, they are usually much more willing to coöperate on engineer work, and line and staff officers are usually more willing to recognize the value of an engineer regiment. Furthermore, the effect on the morale of the men is excellent, it makes them easier to handle on any work

Digitized by Google

that has to be done under fire. But the practice must not be carried to such an extreme as to seriously interfere with the work the engineers must do.

On the evening of July 1st an attack was made by one battalion of the 23rd, one of the 9th, and one French, with the objectives of Bois de la Roche, Vaux, and Hill 204. This was an elaborately planned attack, very much on the order of trench warfare attacks. There was considerable time for reconnaissance, and for arrangements of details. Aeroplane maps were made, elaborate barrage charts, and tables worked out, and practice held over ground staked out to resemble the terrain to be attacked. One company of engineers was assigned to the 23rd infantry, and one to the 9th. The task of the first company was comparatively simple. They were to help the infantry dig in, and to wire the position when captured. The company with the 9th infantry going into Vaux was assigned the following duties by the infantry battalion commander:

To follow the support into Vaux at 400 meters.
To help mop up the town.
To spring tank traps on Monneaux-Vaux road and repair the road.
To examine all dugouts, box traps and label for use.
To inspect and label all water supply, whether fit for use or not.
To organize Vaux for resistance, loopholing walls and buildings and strengthening cellars.

Engineer dumps for these two companies were placed, one at Bourbelin and one at Monnieaux. The jumping off place was the north edge of Bois de la Marette, and both companies were moved into this wood before daylight of the first. The artillery preparation for this attack was very heavy, lasting over 12 hours. Naturally the Germans replied, firing back on the brigade sector, according to intelligence bulletin that day 21,000 shells, of which 12,000 were 105's or heavier. By keeping troops back 500 to 1,000 meters from the edge of the Bois de la Marette, however, very few casualties resulted, although most of the infantry and half of the engineers had no shelter whatever. Practically all the German shells fell within 100 meters of the edge of the woods, or in the village of Monnieaux. The attack was successful as far as the American end of it went. The company detailed to consolidate the woods waited until the German barrage placed on the north edge of the Bois de la Marette lifted, and then proceeded to their work. Two or three platoons finished their work and came out the same night. The third platoon was under a sergeant who became interested in teaching the infantry to operate German machine guns, and two nights later it was necessary to send back a platoon under an officer to finish up this work. The total casualties in this company were only four.

The other company moving into Vaux had more troubles. The artillery preparation had been so complete that it was in places hard to tell what had been street and what buildings. Careful examination of maps and distant reconnaissance of the ground had failed to show the relative heights of walls, buildings, etc. Therefore elaborately detailed plans for the consolidation of the town had to be abandoned, and new arrangements made on the spot. No tank traps nor booby traps were discovered. The company here remained in Vaux for several days, doing combined engineer and infantry work. This was necessitated by the failure of the French to capture Hill 204, leaving Vaux in a very uncomfortable position.

The Germans had been in these positions for a month, so they had made considerable preparations for defense. Their preparations as usually found were done in about this order: Preparing just trenches enough for the garrison assigned and wiring them in; preparing shelters, deep shelters for the men, and very fine ones for PC; making arrangements for obstructing roads to the rear. At this time the Germans seemed to have, and to be able to get to the front, all material including engineer supplies, they could use. This was probably due in large measure to their captures since March 21st.

Beginning the 8th of July, the division was relieved, and started for a rest area. Due to the discovery about this time of a heavy German attack impending, the division was held in reserve, about 8-12 km. in rear of their former position, and were engaged in working on the corps line, a position about 6 to 8 kilometers from the front.

On the morning of the 15th of July the German attack was delivered, the extreme western edge of the attack coming a few kilometers east of the divisions' position. That evening, as I learned considerably later, decision was made to counter-attack near Soissons. Work was called off on the 16th, and everyone held in readiness for movement. At 6 o'clock that evening orders were received to entruck at a point 6 kilometers away at 4 p. m. The trucks, however, did not show up until midnight, so the orders arrived early enough. As usual the engineers all carried tools in addition to their regular equipment. This has a certain advantage, since you can pick out your men at quite a distance. The trucks arrived at *their* destination (not *ours*) about 3 p. m., July 17th. For some reason French trucks never land you very near where you want to go. The entire country was filled with troops all marching east, both French and Americans. The division engineer had kept with division headquarters, and at this point issued maps and directions for the march to position. The greater part of the march was made at night and in the rain. Roads were badly crowded, four organizations of foot troops, and two columns of wheeled transportation abreast. Unfortunately, one of the engineer captains had not

Digitized by Google

been furnished with a map and in attempting to take a short cut lost his way. He had the 2nd company, so five companies did not reach their destination until nearly 7 the next morning. At that they did better than a large part of the infantry. The attack was scheduled for 4:35 a. m. of the 18th, and started off very successfully. The lateness of the engineers did not cut any figure, since they were in division reserve. As the attack progressed, the engineers moved forward, repairing the roads as they went. The main artery of traffic consisted of a road paved in the middle with Belgian block, and with a wide earth berm on each side. The Germans had ruined the road in several places, and had felled numerous trees across it. The work of removing these was very valuable, since the road in about four hours was made to carry three columns of traffic in place of one. One obstruction requiring much labor was a tank trap. Pits 8 feet deep and 15 feet long had been dug out on each side of the paving, and the paved sections ruined.

The first phase of the attack was completed by 8 p. m. the evening of the 18th, and the 2nd phase started immediately, with about 1,000 to 1,500 meters advance. This phase of the attack met with very severe opposition, and was stopped almost immediately.

The engineer regiment received orders to move out shortly after this phase of the attack had started, and consolidate the position to be taken that night. It was assumed, owing to the success of the previous attacks that this one would be successful, and assignments of sectors were made on the assumption that the objective would be reached. The attack, however, was stopped after about a 1,500 meter advance, and the lines were rather badly mixed and lacked some half a kilometer of connecting with the French on the right. The necessity for getting work done rapidly, the mingling of units, the difficulty of finding battalion and company commanders, and of trying to stake out positions at night made any satisfactory layout impossible. Lines were straightened as well as possible, and then the engineers dug in as supports and to fill gaps in the line. Carrying of tools was absolutely essential in this case. Practically all division maneuvers had been almost solely for testing out liaison agencies. But at 1 p. m. not a report had been sent back to brigade headquarters as to the location of the line, and so far as could be determined the only ones that ever did come back were sent by the engineers.

The value of insisting on prompt reports is of course evident.

Furthermore, it is believed that if engineers are to be used in consolidating positions in attacks of this kind, some liaison agents must be kept in touch with the infantry and be given every opportunity to make reconnaissance during daylight.

The next day the attack was scheduled for 7, but did not take place until 9. It was stopped completely by 11, partly due to the failure of the French to keep up, but principally because of a determined German resistance.

Orders were given for consolidating the ground gained that night. Arrangements were made by the division engineer for the delivery of wire, and additional tools at the front. By this time the engineer train was available, but most of the material had been secured from captured dumps. In this case it was possible to get a view of the ground by daylight and to find the location of troops and infantry unit commanders, and it is believed that work could have been done in a very advantageous and thorough fashion, lines rectified, and units properly placed. But by evening orders had come for the relief of the division, which took place that night.

Here endeth the first lesson.

Blasting a ditch when digging is impracticable.—A ditch 530 ft. long, 30 ft. deep and 6 ft. wide, through a tangle of underbrush in a soil of clay and quicksand, where digging was impossible, was successfully blasted.

Holes were bored in the soft sticky clay and dynamite cartridges pushed into them with a tamping stick. No tamping was necessary, as the water filled the holes.

In the quicksand the sticks of dynamite were encased in pointed tin tubes and then pushed down into the quicksand to the required depth.

The charges were spaced about 2 feet apart both in the quicksand and in the clay, at a depth of about 2½ feet. The charges were 1 or 1½ sticks of dynamite.—*The Excav. Engr.*

Gin pole aids in unloading trucks from open top cars.—A gin pole with block and tackle solved the problem of unloading a train load of trucks for the Iowa Highway Commission. The trucks were shipped by the War Department in open cars, of which neither ends nor sides could be lowered or removed.—*Eng. and Cont.*

Enemy planes brought down by anti-aircraft artillery and machine guns.—American anti-aircraft units, operating in France, brought down 59 enemy airplanes. The first plane was brought down by the 2nd A. A. Battery east of Verdun, May 18, 1918. This battery also fired the first shot against hostile aircraft, April 18, 1918. The other 58 enemy planes were brought down in the four months prior to the signing of the armistice; 17 by five batteries of anti-aircraft artillery and 41, which were low-flying planes, by two anti-aircraft machine-gun battalions of four companies each.—*War Dept. News Bureau.*

Winter work on Alaskan Railway.—The temperature in Alaska ranges from —70 to +100 degrees Fahrenheit. Construction is done during the short season of warm weather, but distribution of materials is accomplished during cold weather. Transportation by sled over the ice is easier than building corduroy roads over soft ground.

Peace-time and War-time Economics

By

P. S. Bond

Major, Corps of Engineers; M. Am. Soc. C. E.

[*Note.*—Economic principles are as applicable to war as to peace. The only difference is in the conditions to which these principles are applied. A knowledge of the fundamental economic principles which should govern the conduct of war is even more important to the military engineer than a knowledge of technical methods—which are simple in wartime. These economic principles are the basis of good practice, which is our excuse for presenting the arguments herein.—ED.]

IN the minds of many who are uninitiated the term "economics" finds no application whatever to warfare. War, they tell us, is unmitigated waste.

Now it is true that war is destructive, but it does not follow necessarily that it is uneconomical. The building of an empire by war was a fundamental economic principle of German politics, and Germany is by no means the only nation that has recognized the principle. When we look into the history of these things we find that all empires have been built up by war, including our own. To be sure the German empire was built up largely at the expense of other nations. But this was justified economically by the German publicists on the ground that, looking at the results as a whole, the economic progress of Germany more than compensated certain incidental temporary embarrassments to less worthy neighbors Germany's early successes in the practice of this particular form of economy ran away with her good judgment, and caused her to violate another fundamental economic principle, which is that anything, however wise in moderation, becomes bad when carried to excess. Germany carried her war economics to excess, and came to grief in consequence.

Those who have observed the processes of nature will have noted that she is prodigal in her expenditures. And if they have not thought deeply on the subject they may have come to the conclusion that she is inexcusably wasteful of matter, energy and life. But the scientists tell us that no atom of matter nor ounce of energy is, or can be, destroyed. They are not so positive as to life, but we may safely reason by analogy that life, in common with the matter and energy by means of which it manifests itself, is indestructible. Those who hope for a future existence *in propria persona*, if there really be anybody who desires eternally to combat the H. C. of L., can draw only a little comfort from the principle of the conservation of life. For while there is good evidence that life is indestructible, the same is not quite so true of conscious individuality.

But we are wandering from our proper domain into the dreamland of spiritualism and metaphysics. What we wish to point out is that prodigal expenditure is not necessarily the antithesis of economy. Nature is prodigal in her expenditure yet perfect in her economy. And in war a prodigal expenditure of money and life at the right time may be, and usually is, the means to victory, and the highest form of economy. The highest economy of war is victory, and the greatest waste is defeat. Assuming that we do not enter war for trivial purposes in a moment of inflamed passions, or without good and sufficient reasons of an economic nature, the value of victory is so great that it almost invariably justifies the expenditures *necessary* to win it, however great they be. Before entering the war we should carefully weigh the issues at stake, and consider all the probabilities. For it would manifestly be the height of folly to allow our passions to lead us into a war in which defeat was certain, and the end of which would find us worse off than if we had acceded to the demands of our opponents without resort to war. A settlement out of this court of last resort, whose charges are very high, may be and usually is the wisest and most economical procedure. And most cases are usually thus settled "out of court" by compromise. But if the compromise involves the sacrifice of national honor it may only lead to worse difficulties and greater sacrifices in the future, and even defeat may be preferable to this. There is a limit beyond which patience and compromise cease to be virtuous, wise and economical—especially economical. An example of this is afforded by our too pacific neighbor, China, whose history proves the economical principle heretofore referred to—to-wit, that anything carried to excess is bad, even the highly commendable desire to remain at peace with one's neighbors. Moreover, the fortunes of war are always uncertain, and we must reckon with the inclination to take "the fighting chance," which is characteristic of virile nations as it is of virile men though, fortunately for the peace of the world, to a much lesser degree.

All these are amongst the conditions that should be weighed by those in control of the destinies of the state before pitching the national hat into the ring. But having carefully estimated the situation and decided in sober judgment that war is the best solution, the highest economy usually demands that it be prosecuted as surely and rapidly as possible to decisive victory, freely paying the cost thereof. At least this is the wisest procedure for a nation so powerful as America. It might not be so in the case of a smaller nation, forced to hold a larger one at bay, while hopefully awaiting the intervention of allies. But even in this case, and when there is no hope of actual victory, expenditures should be made as freely as the resources of the state permit, to insure a strong defense. If a nation cannot win decisive victory it may at least evade crushing defeat, and that is worth much.

Accordingly a free and rapid expenditure, within proper limits and not reckless, is good economy in war. This is so because time is one of the important elements, probably the most important element of victory. And an expenditure which saves valuable time is always justifiable, even if it involves considerable incidental waste. War consumes our accumulated resources at an appalling rate, not only by reason of the direct expenditures, but in many incidental ways. When the war is over these expenditures cease, after a greater or less interval, depending chiefly upon the efficiency of the government administration at the time. Accordingly, if by doubling our direct expenditures of lives and money we can bring the war to a victorious conclusion

Digitized by Google

in one year, when otherwise we would spend two and, of course, run greater risks of defeat, economy invariably dictates such a procedure.

Another fundamental economic principle, not of war alone but of national policy, undoubtedly the most important principle of all, was enunciated by the Father of Our Country, the great Washington, when he pronounced that wise maxim: "In time of peace prepare for war." This maxim his people have never heeded, and perhaps it is useless to again call their attention to wise advice so persistently disregarded. This is sound economy, first because preparation in advance will frequently induce our neighbors to accede to our wishes or leave us alone, when otherwise they might have defied or attacked us; and second because preparation insures victory should war be forced upon us.

Important economic considerations are thus involved in the decision to make use of war as a means to our ends, and also in the manner of conducting the conflict itself. War is not always merely a necessary or unavoidable evil. It is usually a recognized means to an end. But in estimating the economics of the situation in order to decide whether we shall make use of war, we should, of course, consider *all* of them. And the decision will be made as in any other affair of life. If the probable profits are reasonably in excess of the probable costs, the war is wise and economical. But of course we must weigh *all* the profits and *all* the costs. These will include not merely the money outlay in prosecuting the war, and the territory and indemnity which victory will bring us, but matters of national honor, the effects on the spirit of our people and our future growth and prosperity in a multitude of direct and indirect ways. And we may go farther, and in an altruistic spirit consider also the effects of war or abstention from war on humanity generally, including even our enemy. As a wise and just people, we should use war as an economic instrument to accomplish a necessary purpose (when other instruments will not serve), and not at all as a means of revenge and destruction. The destruction is merely incidental to the purpose.

Of course extraneous conditions will have less weight with us than those which apparently touch our own welfare more closely. But it would be quite wrong to totally disregard them.

We may find it necessary during the war to cultivate in our people a spirit of hatred for the enemy. But this is solely for the purpose of insuring a vigorous and therefore economical prosecution of the war. Hatred of the enemy may be a necessary stimulus to our national effort, but should not be regarded as an end or purpose in itself.

It will certainly be quite apparent upon taking thought that the economic principles of which our industrial leaders tell us are quite as applicable, in fact more applicable to the affairs of nations and to war, than they are to the affairs of individuals and to peace. And serious mistakes in economic judgment are far more expensive and disastrous in war than they can possibly be in peace, because they involve the whole nation. And while there is usually opportunity at leisure to correct the mistakes of peace, those of war are generally irreparable.

All of the great nations, except China and the United States, are well versed in the economics of war. Especially do they realize the truth of the Washington maxim. The commanders of the armies of a nation, in fact all the officers of these armies, must appreciate and practice the economics of war. Otherwise they are not qualified to meet the great responsibilities placed upon them. A knowledge of these fundamental principles is more necessary in war than in peace. Economic blunders in peace-time may involve the waste of a few lives and a few millions of dollars. But in war they may involve the waste of hundreds of thousands of lives and billions of dollars, and perhaps also the loss of national freedom and independence. So we cannot afford to take chances, either in preparation for war or in the conduct thereof.

The expenditures of our government during two years of the World War were some 33 billions of dollars. This was a sum greater than all its expenditures in the 140 years of our previous history (including the cost of other wars), which were but 27 billions. An economic blunder in the conduct of such a war, a single wrong decision in an important matter, arrived at after a few days or even a few hours thought, by a military commander, a legislative body or an executive official, may involve a waste which could not be offset by a hundred years of the most rigid governmental economy during peace. And such important decisions must be made promptly on the information of the moment. There is never time for long reflection or exhaustive investigation after war is upon us.

It must be apparent then, that there is nothing which concerns our country that is so vitally important as that our army commanders and government executives, who direct the affairs of the nation, should be thoroughly versed by study and training, in the economic principles which find their application in the conduct of war.

The most important decision ever made by any legislative assembly was that of the American Congress in May, 1917, when they enacted the law providing for universal compulsory military service in the conduct of the great war. That fateful decision insured the victory of civilization and the downfall of Prussian militarism. Most of our legislators had but a few days in which to make up their minds in this important matter. Had Congress failed to enact this law they would have committed the most colossal economic blunder in all history. Yet considering the previous attitude of the American people towards compulsory service, it would not have been surprising had Congress committed this awful blunder, which would almost certainly have doubled, even trebled the cost of the war, besides uselessly sacrificing hundreds of thousands of precious lives, and probably bringing disastrous defeat to our armies and those of our allies.

A thorough understanding and a working knowledge of these fundamental economics of war is of the utmost importance to engineers who would fit themselves to perform the highest possible service to their country in times of armed conflict. It is well that they be carefully thought upon. The engineer does not escape from the practice of economics when he enters the war. On the contrary, the opportunities for tremendous profits or ruinous losses are far greater than will ever be presented in times of peace. The engineer must have that correct sense of proportion which will enable him to accurately determine the important matters to which he should devote his energies, and the less important and unimportant affairs to be temporarily neglected or permanently set aside. And having decided upon the really important tasks, he must be able to carry them out with vigor and courage, with the resources at his disposal, and in the manner and under the difficulties which war imposes.

The engineer in war must be constantly guided by his knowledge of the economic principles of warfare. These are easy to state, but their effective application in times of stress requires the highest judgment based on experience and study, and the greatest resourcefulness, determination and courage. The more important of these economic principles are briefly enunciated as follows:

(*a*) In war the principal considerations are *time* and

Digitized by Google

results. Cost, while not to be disregarded, is of far less importance than is usual in peace. This means that all works of military engineering must be conducted with feverish rapidity.

(*b*) The work of the engineer must be adapted to military needs. However excellent in themselves, his results are a waste unless they fulfill the tactical requirements of the army. Accordingly the military engineer must be a thorough tactician. It is not sufficient that his works be *technically* well executed.

(*c*) High technical skill will seldom be required of the engineer with the combatant forces, for works of military engineering are invarably simple, but his faculty of getting results will be constantly taxed to the utmost. Explanations or excuses for failure, however plausible or valid, are useless, and will receive no consideration. *Success* is the sole criterion by which the engineer will be judged. This is harsh but inevitable.

(*d*) While it is the duty of the engineer to see that suitable equipment and supplies are assembled for his works, yet results must be obtained with the facilities at hand, however inadequate they be.

(*e*) The works of the military engineer must be in nature and extent sufficient unto their purpose, and *no more* than sufficient. *Bare necessities* are all that *time* will allow. This means that the factors of safety and permanence are generally lower than in civil works. The rough-and-ready structures which serve their purpose are the triumphs of the military engineer's art. Any refinements beyond absolute necessities are evidence of incompetence. The civil engineer builds for posterity, and takes a just pride in the permanence of his work. The military engineer builds for the exigency of the moment, and may temporarily escape criticism if his work is ready when it is needed, or a little sooner.

(*f*) The engineer must be able to immediately perceive the principal requirements of any situation with which he is confronted. He must devote his energies to these, ruthlessly eliminating all but absolute necessities.

(*g*) Military engineering must be of the utmost simplicity both in plan and method. Only the simplest works can be successfully executed under war-time conditions. Complexity invites failure and is proof of incompetence.

(*h*) Ultimate completion and eventual utility of his work are not all that will be expected of the engineer. Work may be interrupted or the partial use of the structures demanded at any time. Accordingly they must be built so that at any instant prior to ultimate completion they will have the maximum utility that it is possible to secure up to that instant. For example, if the work consists of several units, each should be completed in its entirety, or to the point of utility, before the next is started, unless this start will not delay completion of previous units. This requirement is so at variance with that which usually obtains in time of peace that the civil engineer will find it difficult to adapt himself thereto.

(*i*) In military operations the engineer must be able to think in large numbers, and must have the foresight and courage to plan his work on a vast scale, even when the need is not at first apparent. For the demands of war increase at such a rate as to overwhelm us if we have not foreseen them. If, from motives of economy, we hesitate, we are very apt to be lost. This is closely related to (*j*).

(*j*) It is not sufficient that the engineer should promptly execute the works demanded of him. More than this will be expected. He should be so closely in touch with the military situation and the plans of his commander, that he can *foresee* the engineering needs before they arise, and take steps to meet them. Of course in doing this the engineer runs the risk of making mistakes and executing unnecessary works. It is a risk he must assume. If the staff perceive that the engineer is forehanded in his work, does the right thing on his own initiative before he is called in, they will have confidence in him and will be glad to give him a free hand in carrying on his operations. If on the contrary the engineer waits always for orders he will soon find that the staff will take over his proper functions and look upon himself as superfluous. Cordial relations between the engineer and all commanders and staff are essential to the success of engineering operations. These cordial relations depend chiefly upon the judgment, foresight, initiative and capacity of the engineer. If he is competent and universally recognized as such, he will enjoy the confidence of all, and be allowed full scope for the useful exercise of his talents.

To ponder upon these principles, to recognize the truth of them and accurately visualize to himself the effect of their application upon the conduct of his work, is the most important step in the engineer's preparation to efficiently perform his duties in war.

Controversy over concrete block tunnel for Hudson River

Sharply divergent views on subaqueous tunneling practice were brought out during the course of recent public hearings on the Hudson River vehicle tunnel project. Most of the controversy hinged upon the rejection of the 42-foot concrete block design in favor of twin 29-foot cast-iron tunnels. In reply to specific questions by the advocates of the former design, the chief engineer of the joint commissions advanced objections to that project.

(1) The 22-foot 6-inch roadway could accommodate but two instead of three lines of traffic as estimated.

(2) The concrete block tunnel does not provide sufficient strength at cross joints between adjacent segments.

(3) The great number of joints between the blocks makes it impossible to secure water tightness.

(4) The estimated cost of the concrete-block tunnel is too low; viz., (*a*) concrete blocks at $11 per cubic yard in place, instead of $33; (*b*) cost of excavation, estimated at $3,730,000, should be $9,700,000; (*c*) items of water proofing, tunnel ducts, etc., omitted from the estimate and quantities of steel and payment too low; (*d*) the cost of plant, $1,435,000, should be $2,658,000; (*e*) no item in the estimate covers the cost of real estate, about $2,500,000.

(5) The completion of the tunnel in the estimated time of three years would require more rapid progress than that attained in either the Pennsylvania tunnels or the recent rapid transit tunnels under the East River.

Col. W. J. Wilgus presented further objections of the Board of Consulting Engineers to the concrete-block design.

(1) The designer believes the material to be encountered is stiff clay, whereas it is a silt with specific gravity and moisture content classifying it among the softest clays.

(2) The unstable nature of this material would produce maximum stresses of 1,000-pound square inch compression, 400-pound square inch tension, and 1,192-pound square inch shear, in the concrete.

(3) The block tunnel with its many joints would be vulnerable to disintegrating attack by the acid-bearing underground waters encountered on the Jersey side.

(4) The proposed 42-foot shield with four horizontal air compartments, each carrying different air pressures, the face of each compartment three feet back of the one below it, ignores (*a*) the cracking in the material following each shove of the shield; (*b*) the probable obstructions, such as piles, boulders, sunken vessels, offering passage of the air between the compartments thereby raising the pressure of the top compartment to that of the bottom one and causing consequent blowouts in the former; (*c*) the unavoidable rotating of the shield, causing tipping of the floors of the compartments and also equalizing top and bottom air pressures; (*d*) the certainty of breaking many blocks under the enormous jack pressures.

To compare directly the cost of the two types of construction, J. F. O'Rourke presented estimates for a pair of 31-foot concrete-block tunnels and corresponding estimates for the pair of 29-foot cast-iron tunnels of the official plan. The totals of his estimates were:

Total cost of twin cast-iron tunnels	$30,240,000
Total cost of twin concrete-block tunnels	15,540,000
Estimated saving with concrete blocks	$14,700,000

Mr. O'Rourke's estimate of the cost of the twin cast-iron tunnels exceeds the estimate of the chief engineer of the joint commissions by $7,978,000.—*Eng. News-Rec.*

Ocean pier to be scrapped because of concrete disintegration

The municipal pier at Santa Monica, Cal., was closed to the public as unsafe in November, 1919. This reinforced concrete pier was built in 1908; it carries a large outfall sewer and serves as a public pleasure pier. It is 1,600 feet long, 35 feet 8 inches wide at the deck, with three platform spaces 89 feet wide located at the end and at two intermediate points. The floor is concrete on wooden stringers. It has concrete floor beams, on concrete bents, of posts cast in place, and supported by concrete piles which were jetted into place. The bents are spaced 20 feet center to center and the piles 13 feet 6 inches. The deck is from 21 to 50 feet above the ocean bottom, but the piles are not braced, either transversely or longitudinally, below the floor beam level. The piles are round with bulbs at the bottoms. They were cast on shore in a position inclined about 40° to the vertical.

The pier appeared to suffer no appreciable deterioration for some years; in 1912 it appeared to be in good condition. In 1916 it was again examined and serious deterioration was observed. Some piles near the outboard end had failed, supposedly because of damage inflicted by floating debris. An analysis of some of the disintegrating concrete showed the presence of 2.88 per cent MgO (magnesia), indicating that disintegration had been in progress for some time. Many of the piles, as well as the floor beams, were badly cracked, and some showed evidence of erosion and spalling. No examination was made of the outboard piles below the low water level at that time.

In August, 1919, a settlement of the outer end of the pier, occurring when it was crowded with people, led to an examination by a board of engineers from whose report the following comments are abstracted:

Forty-two bents, originally containing 150 piles, were examined. The following conditions below low-water mark were noted by a driver: 3 piles gone; 3 practically gone; 60 badly rusted, showing oxidation of steel had set in; 30 badly cracked, showing disruption was in an advanced stage; 54 still serviceable. The following conditions were observed above the low-water mark: 3 piles gone; 3 practically gone; 91 cracked in two or more places; 33 cracked in one place; 20 showed no serious deterioration.

The principal cause of the present condition of the pier was found to be permeable concrete permitting the penetration of sea water, producing: (1) chemical disintegration of the concrete, and (2) mechanical fracture of the concrete by expansion of the reinforcing steel due to corrosion. The chemical disintegration took place below the high-water line, while the cracking along the reinforcement was confined almost entirely to caps and struts above that level. Measurements with a milli-voltmeter showed a slight difference of potential between the sewer and the reinforcing steel of the pier. This difference fluctuated with the starting and stopping of electric cars on adjacent tracks. There are no signs of electrolysis at present, and the fact that similar disintegration has been observed in other concrete structures in these waters and even in lamp posts and fences exposed only to the salt air, indicates that electrolysis was not an important factor in producing the conditions under investigation. The life of the pier would have been prolonged had the reinforcement been more deeply embedded. Beach sand and gravel were used in the concrete. The uniform sizes of such materials increase the difficulty of securing impervious concrete, and the salts they contain facilitate the corrosion of the steel.

The Board finally concludes:

(1) The prime cause of this failure was permeable concrete due to poor workmanship and improper selection of materials.

(2) Contributing causes were two severe storms which cracked many members during construction.

(3) Electrolysis accelerated but did not cause disintegration.

(4) Blame does not attach to the designers nor builders, in view of the knowledge regarding the action of sea water on concrete existing when this pier was built, nor to the officials in charge of maintenance, who exercised reasonable care.

(5) Reconstruction of the pier in concrete is not recommended on account of the difficulty of securing concrete, particularly in substructural members, without removal of the deck.

As a consequence of this report, the pier has been closed by the City Commission and a new creosoted pile pier will be built.—*Eng. News-Record.*

Unique flood control project at Erie, Pa.—A mild little stream, called Mill Creek, flows through the city of Erie, Pa. At intervals of about 25 years this quiet stream goes on a rampage, and on the last occasion, in 1915, caused a loss of 34 lives, and millions of dollars of damage. And so Erie joined in the nation-wide movement for flood abatement.

A flood channel of sufficient capacity involved too much real estate, and so the engineers proposed the unique plan of sealing up the little creek in a tight concrete pipe, which it could not get out of. There was to be no more overflowing of banks as banks were to be eliminated, and Mill Creek degraded into a sewer.

The proposed plan included impounding or detaining dams, and a pipe large enough to carry the regulated flow. But having in mind the unfortunate experience of Johnstown in their native state, the good people of Erie decided they wanted no dam to get on their nerves. So an alternative plan of a tube large enough to carry the entire flow was adopted.

The tube is elliptical in cross section, 18 by 22 feet, and about 2 miles long, through the city. Wing walls at the intake and outlet regulate the velocity of flow.

The project was started in May, 1917, but due to the war extraordinary difficulties have been encountered. One contractor has gone bankrupt and the work is not yet completed.

The original contract called for completion at a cost of $812,000. The ultimate cost will be more than double this amount ($1,800,000).—*Eng. News-Rec.*

Growth of American merchant tonnage.—On June 30 the total gross tonnage of all sea-going vessels of 1,000 tons, or over, under the American flag, was 1,647,000. On May 1, 1920, it was 10,451,012. Of this increase 1,000,000 tons was obtained from foreign sources, and the remainder is new construction.—*Statistical Section, General Staff.*

Animal-Drawn Transport in War

By

A. A. Keesler

Captain, Engineers

[*Introductory note.*—At the entrance of the United States into the World War, A. A. Keesler resigned from the Presidency of the Watson Wagon Works, Canastota, New York, to accept a commission as Captain in the Corps of Engineers, U. S. Army. He was assigned to the General Engineer Depot and placed in charge of the procurement of road machinery. Later he was assigned to the work of developing a tool wagon for combat engineers which would overcome the defects in the type that was then being issued. In the spring of 1919 he was directed to take the wagon which he had developed to France for test and criticism by various engineer organizations that had seen actual service. After returning in the fall of 1919, he was charged with the design and construction of a wagon based on the criticisms he had received. On the completion of this work, he left the Service and resumed his former position as President of the Watson Wagon Works.—ED.]

IN all previous wars armies have placed their chief reliance on animal-drawn transport. The opening of the Great War, however, found motor transportation already well developed, and instant and far reaching use was made of it. Without it no such great armies could have been put in the field, supplied and munitioned, even under the favorable circumstances of fighting in civilized and well-developed countries, well cleared and gridironed with roads. Nor could the great strategic concentrations characteristic of the struggle have been so quickly effected. The splendid road systems of France, Belgium and Germany answered instantly the question as to what kind of transportation to use. The first great thrust of the Germans was parried by the taxicabs and motor busses of Paris. The two vital elements were there—the motor transportation and the roads. They were used most effectively and they won. Much has been and could be said of the miraculous performances of the gasoline motor in every moving machine from airplanes to tanks, and the vivid pictures in the minds of officers and men of the great problems solved and the decisive results accomplished by motor transport, have tended to obscure the still great importance of the slow moving but reliable wagon train.

Could transportation problems have been solved and the war fought and won without the aid of the horse and mule?

Perhaps it could. Given plenty, a great plenty, of all kinds of motor vehicles, it might have been done, and the general result would have been the same. Animals, like men, were resources ready to hand. They needed only to be mobilized. The "hay motors" were ready and prepared to function in the old familiar way, as in previous wars.

A horse and wagon are a simple and effective machine, with few things to get out of order. There is no delicately adjusted engine, with a thousand things to go wrong, no tires to puncture or blow. They are slow, perhaps, but sure. When you set out for a place you usually arrive.

Motor transport, certainly so far as now developed, demands good, or at least reasonably good roads for effective use. Where the roads are not of this class, the horse-drawn vehicle is both more economical and more reliable. For the purposes of the light artillery in battle the horse (not the mule) is still required. Of course the future development of caterpillar traction may change all this—we are speaking of conditions as they actually existed during the late war.

A war might be conducted without the aid of our dumb allies. It might even be done without the rifle, provided *neither* side had it. There is little point in such speculations.

The motor cannot be dispensed with and the horse and wagon must not be abandoned until every country where the army might be called upon to operate has adopted the motor and built the roads it calls for. All wars are life and death struggles for the nations, as for the men engaged, and no thoughtful and efficient staff would fail to use all available resources. So long as the horse and wagon remain a factor in civilian life and commercial transportation, they are bound to remain as a factor in military operations, and possibly that may be their last and final great use. If this is true, then it is obvious that the carrying capacity of the vehicle as a chief means of transportation should receive careful attention.

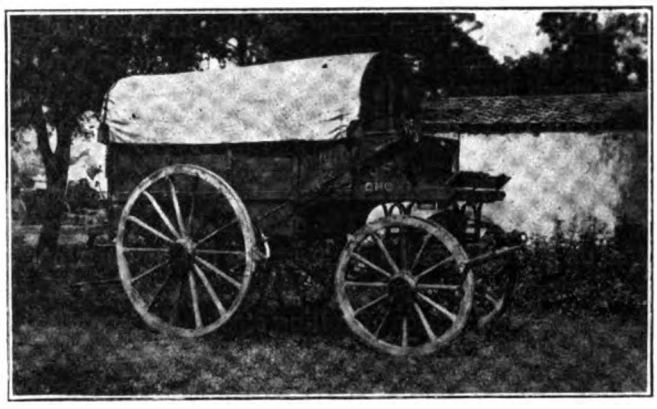
For a long time prior to our entry into the World War, very little attention had been given by our government to the development of animal-drawn transport and the proper equipment of our army therewith. In fact, except for the efforts of a few individuals, there had been little improvement since the Civil War. To say that we were unprepared in this important particular is only to repeat what has been said, and is so well known, of all our machinery of war. The people through their representatives had provided no money for either development or personnel. Our vehicles were obsolete. Yet we needed vehicles. There was neither time nor skilled personnel to improve and bring them up to the present requirements, or make

Digitized by Google

them more efficient. There was no time to study the relation of pay load to dead weight of vehicle and other important questions. There was no time to design, draft and build more suitable vehicles. There was no time to test out the improvements suggested by army officers or patriotic manufacturers. There was no time to study the relation between the loaded vehicle and the tractive power of the animal. Vehicles must be had in undreamed of numbers Everyone was busy, and prodding jaded brains and nerves to do more and still more. The forces "over there" with mountains to move from seaport to battle area, with grim determination moved supplies with whatever equipment they had, from where they were to where they were wanted. *Time* was indeed "the essence of the contract," and none of that precious "essence" could be used for deliberative study of the problems of horse-drawn vehicles. We used what vehicles we had. We won. It is hoped that a kindly recording angel omitted most of our remarks on the lines of communication, and gave us full credit for delivering the goods. May no inquisitive official ever investigate further the wrecks by the roadside, nor attempt to compute the cost in animals and other wastage. It would be useless, for we started at scratch and we crossed the tape a jump ahead, and ultimate success covers as with a blanket a multitude of sins. Had we given as much advance attention to these problems as the Germans, it would not have been so long a race. Give the American inventor a little time, a little money, and back him up with the engineering skill and plant facilities, and his transportation, as well as other war machinery, will have to be copied by any nation that goes to war with us.

One of the most brilliant of our regular army officers, being faced with the necessity of producing tool wagons for a certain number of divisions in a much shorter time than he should properly have taken for design alone, and with nothing to start from save an utterly obsolete model used for another purpose, in another war performed his task with the assistance of a civilian engineer in government employ, in about 5 days. He used an ordnance wheel and a searchlight frame, and concentrated on evolving a compartment body that would hold the tools as specified in the equipment tables. Was it satisfactory? No. Neither would it have been satisfactory to have taken the time for design, drafting, construction of model, testing, specifying, awarding contract, mobilizing material and building. The Kaiser would have been at Brest to prevent his landing with his carefully designed and efficient vehicle. The above is only an instance, but it is typical of America's neglect of all items of preparation for war. It is obvious that this is not the way to equip an army with transportation. Officers in the field will have plenty of handicaps to overcome, even when they are given carefully designed and well balanced vehicles suitable for bringing up their supplies and doing their other work.

It is not enough to have a vehicle that never breaks down. It is easy enough, but it is crude designing, to construct a wagon that cannot be broken, no matter what the loads piled on it or the roads traversed. It is also easy to go to the other extreme and construct your wagon too light, so that it fails shortly under normal load, and lies down utterly under the overload which an emergency will put on it. To overlook in design the factor of effect on animal tractive effort, or the important relation of dead weight to "pay load," is to produce an inefficient vehicle, and a rapidly growing "boneyard." Dead animals and broken-down vehicles are wastage that can be greatly reduced by intelligent design. Animals are like battleships, in that you have so many when you go to war, and every loss is a net decrease. Wars seldom last long enough to grow an animal to working age. Your vehicle and your road may be modified or improved to double and treble his transport capacity, but when you have overloaded and killed him your "horsepower" is decreased by so much for that war. There is no replacement available.



The spectre of broken-down wagons stands at the elbow of every designer of army vehicles, and he is surrounded by unknown factors which (in our country) he has not had time to investigate or funds to test. If he lacks experience as to the effect of road shock and vibration at various speeds, he increases the weight to offset uncertainty. It is easy to gain strength by weight. It is difficult and requires skill to decrease weight and still retain strength. Does a part break, weight is added. Does it need standardization, weight is added to utilize parts of other vehicles. The ideal is minimum weight with maximum strength. To gain it or come near it, it is necessary to have experience both as an army officer and a designer of vehicles. The designer must know the needs—how an army moves and fights and of what and how its vehicles should be constructed. It will make a vital difference whether we are at war with a first or a third-class power; whether we are moving over the paved chaussées of France or the undeveloped trails of Mexico. A wagon must be and can be had and used that will be suitable for both extremes.

Animal-drawn transportation for an army can be divided into three classes of vehicles, the stiff-reach wagon, the limbered wagon, and the two-wheeled cart. The first type was used largely by all armies in the field. It varied much in design, weight, construction and cubic and load capacity, but its function, that of hauling general supplies, was the same. Much might be written on the comparative established efficiencies of the French, British, German and American types.

British general service wagon

French Fourgon—general service wagon

Proposed American general service limbered wagon

German general service wagon

British general service limbered wagon

Digitized by Google

The American army used them all, but seldom if ever did the same regiment or unit have occasion to compare their respective merits. A discussion of the different models by regimental and company officers who actually had foreign-made vehicles in their trains, would be valuable and illuminating. Our own type of stiff-reach, known as the "escort wagon," is a familiar sight to every officer and man who served in the army. Undoubtedly, it has faults of design and construction which could and should be eliminated before it is called into service for another heroic campaign, but its strength and sturdiness can not be questioned, and it is generally spoken of by officers and men as the one satisfactory piece of rolling stock. The number of its friends fall only a few short of our total personnel. Those who say that it is too heavy and cumbersome, with too large a turning radius, admit at the same time that it came through every time with its load or overload. Its faults weigh more heavily on the animals than on the men, and the general opinion concerning it was that well enough should be let alone. An attempt was made during the war to transform this wagon into a full cut-under type similar to the French Fourgon. The designer, evidently having in mind the disturbance of standardization as little as possible, used as many of the original parts of the escort wagon as he could. The new type was not generally used and it has yet to prove itself. One serious objection to it is the raising of the center of gravity.

Next to the American "escort" the most generally satisfactory wagon was the British general service wagon. This wagon in design and construction is more nearly like the light farm and lumber wagons used in the United States than it is like the escort wagon, which latter has been developed for purely military purposes.

Its essential specifications are as follows:

Wheel-base	6′	10″
Over-all length	11′	10″
Height of wheels (front)	3′	7″
(rear)	4′	7″
Weight, lbs.		1800
Load distribution, proportionate—		
Front axle		35
Rear axle		65
Capacity, cu. ft.		41
Weight, per cubic foot of capacity, lbs.		44
Turning radius, ft.		30

Bed, removable.
Reach, extension.
Brake, operated by screw in rear and lever at right front.

The French Fourgon or general service wagon had undoubtedly received the close and careful attention of competent designers. Such of them as were used in the American Forces did not meet with universal favor, notwithstanding a full cutunder, but the sturdiness and capacity were generally admitted. This wagon has a canvas cover mounted on bows without extension to cover driver's seat. It is the only general service wagon mounted on springs.

Its essential specifications are as follows:

Wheel-base	6′	10″
Over-all length	18′	2″
Height of wheels (front)	3′	5″
(rear)	5′	2″
Height, ground to box bottom	3′	4″
Weight, lbs.		1960
Load capacity, cu. ft.		52.5
Weight, per cu. ft. of capacity, lbs.		37.2
Load distribution, proportionate—		
Front axle		0
Rear axle		100

Turning radius, own length.
Bed, non-removable.
Reach, none; connection by means of body side members.
Brake, screw; operated right side front.

The German general service wagon differs materially from either our own or our allies, but it would be more nearly comparable to the French than to the British or the American. It has quite evidently received careful and thoughtful attention from the designer, and from experienced officers. I believe an attempt has been made to standardize on the same type in several sizes, but this is not certain. It was of such design that use could also be made of it for peace-time purposes, and it is understood that each German farmer who provided himself with one of these wagons received from the government a subsidy in the form of a discount on the purchase price, which is characteristic of German thoroughness in "preparedness." Great attention had been paid to standardization in design, but in construction it was quite evident that much more hand work had been done than is customary in other countries. It is much the lightest in total weight and also in weight per cubic foot of capacity of all the general service wagons.

The essential specifications are as follows:

Wheel-base	6′	9″
Over-all length	12′	1″
Height of wheels (front)	4′	0″
(rear)	4′	0″
Height, ground to box bottom	2′	7″
Weight, lbs.		1210
Load capacity, cu. ft.		46.6
Weight, per cu. ft. of capacity, lbs.		26
Load distribution, proportionate—		
Front axle		23
Rear axle		77
Turning radus, feet		25

Bed, non-removable.
Reach, none; connection by means of body side members.
Brake, screw, operated right side front.

There has been much discussion regarding the relative usefulness of limbered and stiff reach wagons for army purposes. The limbered wagon is in the nature of special equipment. It can be dispensed with, but we cannot do away with the stiff reach general service wagon while animals are used in the tram. Anything that can be handled in a wagon can be transported in such a type as the escort, but undoubtedly there would be a great lack of efficiency. It would be like assigning one size of gun to all artillery.

Digitized by Google

There are engineer officers who made brilliant records in the hardest campaigns, who are of the opinion that the escort is a good enough engineer tool wagon, and others who believe it would easily take the place of the ammunition or combat wagon. Are they right? I believe not, and the great weight of opinion is against them. It is generally true that to do a special task most efficiently, you must have a special tool therefor. The task may be done with a general purpose tool, but it can be done quicker, better and with immensely more satisfaction to one's self and one's superiors with the proper tool designed for that particular work. On the other hand there is, of course, danger in having too much "special" equipment or too many different types.

The limbered wagon has one great advantage over any other. On extremely bad roads or if there are no roads, it can be instantly divided. Dividing the load is equivalent to doubling the horsepower. Its turning radius is so short that nothing exceeds it but a cart, and a properly designed and constructed limbered wagon can be put into service as two carts in less than three minutes. It is practically impossible to upset it, as it is swiveled in the middle. Limber and caisson may stand at sharply opposing angles without strain. An ordinary road ditch must be bridged or filled in before you may turn from the road to bivouac in the field with an escort, but the limbered wagon follows easily over the roughest terrain which the animals can negotiate.

The most successful, and practically the only successful, limbered wagon used in the Great War was the British type. Its lightness, its capacity and its mobility made it an immediate and strong favorite with many American officers who served with or near British troops. Some able officers believe that we should adopt it *in toto*. Probably it would be better to naturalize it first; that is, to adapt it to American uses and methods of manufacture. This wagon can be instantly divided, but it cannot be put into service as two carts. There is no way of loading the limber and caisson with different supplies, dividing the four-line team and sending them to serve different platoons. One may not retain the limber with its ammunition or tools, and send the caisson back for subsistence forage or more tools. One of the greatest advantages of this design is its low center of gravity, making it almost impossible to upset the two parts and causing them to ride steadily with the least possible sway. This feature is obtained by the use of a cranked axle, of a very costly and complicated design. The axle alone would cost as much to manufacture as the balance of the cart. The slight lowering of the center of gravity and the consequent steadying effect would not compensate for the cost and delay in procurement in quantities in times of emergency. The unit as a whole is also too light to stand the almost universal practice of overloading in the American army.

A limbered wagon so designed that it may be instantly put into service as carts; with open bodies, both limber and caisson being identical units, will probably come nearest to meeting requirements. It will embody the lessons learned in recent experiences, and will be capable of such a variety of uses that it should find a place in the wagon train in almost as great numbers as the escort wagon. It will be suitable for engineer tools, for small arms ammunition, and for other general and special uses. By substituting a tank for the body it would serve as a water cart. It should be light enough to be handled over the worst roads, and heavy enough to carry a conservative load for the animals. It should undoubtedly be postilion driven, using artillery harness instead of reins as shown in the illustration.

A comparison of steam and electric motive power.—Mr. A. H. Armstrong, of the General Electric Co., recently delivered an address with the above title before the Schenectady section of the American Institute of Electrical Engineers, from which the following is taken:

During the winter of 1917-18 our railways fell down badly when the need was the greatest in their history. It is true that the cold weather conditions were unprecedented and the volume of traffic abnormal, but the weakness of steam engine haulage was disclosed in a startling manner.

In marked contrast to adjoining steam-engine divisions, the 440 miles of electrified section of the Chicago, Milwaukee and St. Paul R. R. continued to do business as usual throughout the trying winter of 1917-18. Freight and passenger trains were brought over the electrified tracks on schedule time or better; in fact, it was quite customary to make up on the 440-mile electric run fully two hours of the time lost by passenger trains on adjoining steam engine divisions.

The author, in discussing other advantages of electrification, points out that a large reduction in non-revenue producing ton mileage would be made by eliminating locomotive tenders and locomotive coal, and also in the reduction of railway coal, by reason of the great savings that could be made in burning fuel in large modern power stations under the most efficient conditions possible, rather than under the boilers of 63,000 locomotives now in service throughout the country.

Without considering water power as a means for generating electricity, he estimates that the electrification of our railroads would in 1918 have saved more than two-thirds of the fuel consumed by the railroads that year.—*Eng. & Cont.*

Progress of the National Guard.—During April the National Guard of the U. S. a little more than held its own. Forty-three additional units (companies) were extended Federal recognition, and there was a gain of 2,666 in enlisted strength. The total authorized enlisted strength of the Guard is 178,920, and its actual strength May 1 was 45,272, or a little over 25 per cent. The individual states show great variation, from 2 per cent in Pennsylvania to 69 in Maine.—*War Dept. News Bureau.*

VOL. XII JULY-AUGUST, 1920 NO. 64

Formal organization of Society completed

THE temporary Board of Directors of the Society of American Military Engineers consisting of nine Engineer officers, which was appointed on November 1, 1919, to effect the preliminary organization, decided to fill the vacancies on the Temporary Board in accordance with Art. II, Par. 1 of the By-Laws, and accordingly called a meeting for June 2, 1920, which a number of representative members of the Society resident in the east were invited to attend.

At this meeting, the temporary organization was perfected, and, due to the lateness of the season, and to the fact that it requires at least 60 days to call a meeting of the Society, it was decided, upon motion by Colonel F. A. Molitor, to continue to function until after the first annual meeting, which is scheduled for the Friday preceding the third Wednesday in January.

The following officers and directors of the Society were elected and committees appointed; all to serve until the 1st Annual Meeting. The names are a sufficient indication of the calibre of the men who are directing the affairs of our Society.

Maj. Gen. William M. Black, *President*
Col. William Barclay Parsons, *1st Vice-President*
Col. Charles Keller, *2nd Vice-President*
Capt. D. L. Weart, *Secretary*
Maj. William O. Tufts, *Treasurer*

DIRECTORS

Col. F. V. Abbot	Lieut. Col. Glenn Smith
Col. F. A. Molitor	Lieut. Col. Evarts Tracy
Col. George D. Snyder	Lieut. Col. G. A. Youngberg
Lieut. Col. C. H. Birdseye	Maj. Percy E. Barbour
Lieut. Col. A. H. Brooks	Maj. P. S. Bond
Lieut. Col. J. H. Finney	Maj. J. J. Kingman
Lieut. Col. H. S. Graves	Maj. Max C Tyler
Lieut. Col. W. W. Kirby	Maj. William O. Tufts
Lieut. Col. Geo. B. Pillsbury	Capt. D. McCoach

EXECUTIVE COMMITTEE

Maj. Gen. William M. Black	Lieut. Col. A. H. Brooks
Col. William Barclay Parsons	Lieut. Col. H. S. Graves
Col. Charles Keller	Maj. William O. Tufts
Col. F. A. Molitor	Capt. D. L. Weart

COMMITTEE ON DEVELOPMENT

Maj. P. S. Bond, *Chairman*	Lieut. Col. J. H. Finney
Col. F. A. Molitor	Maj. Percy E. Barbour

COMMITTEE ON MEMBERSHIP

Lieut. Col. G. A. Youngberg	Maj. William J. Shea
Maj. Edwin H. Marks	Capt. Thomas H. Messer.

Let us get together

IT is a most natural human trait to distrust, or perhaps we should say to lack confidence in people and things we do not know. We are apt to mistrust the most honest man, if he is a stranger to us, and on the other hand, to have a considerable amount of confidence in one with whom we are well acquainted, even while knowing that he is more or less of a knave.

One cannot learn to play a game by reading the rules, nor to practice a trade by studying text-books. If one wishes to become a blacksmith, for example, he must go in amongst the blacksmiths. He might read all that was ever written on the subject of horseshoeing, yet he would have an awkward time of it on the first occasion when he attempted to shoe a mule. All trades and professions have developed efficient working methods which can be learned only by association with the trade. On the other hand, the professional man or artisan who never "rubs against" men of other trades becomes so narrow and one-sided in his development that he does not attain high proficiency even in his own calling.

Digitized by Google

These facts, which we think none will deny, have their application to the principal function of the Society of American Military Engineers, and this journal, which is the promotion of the practical efficiency of the engineering profession in the service of the nation in time of war.

The engineer in civil life can learn the practical side of military engineering only by contact and association with those engineers, both civil and military, who have learned the game by actual practice in war or peace. And the engineer in the regular service can avoid the narrow development, which so greatly restricts his usefulness, only by contact with engineers in civil life. Mutual confidence and efficient coöperation are possible only if we are all well acquainted. Therefore let us make an effort, a continuous effort, to "get together."

It was this "get together" idea that gave birth to our Society, and the next logical step was the formation of local posts in the larger communities. This was undertaken during the month of June in most of the important cities of the U. S., and everywhere the response was most enthusiastic. These posts will furnish the medium for personal contact and association between our members, without which our Society cannot be a virile, living organization. You will want to meet your fellow patriots—they are the best of good fellows—and so you should join the local post, if there is one in your locality.

THE MILITARY ENGINEER is a professional journal. And the usefulness of a professional journal lies in the fact that it brings the members of the profession in contact with the ideas, aims and experiences of a larger number of their professional brethren than is possible by personal acquaintance alone. Our columns include contributions from both military and civilian engineers.

When the next war is upon us, and it will surely come, the American engineering profession must work together with a friendliness, a mutual confidence and a practical knowledge of the game, which will achieve even greater results than we attained in the late conflict.

To insure such efficient service is the purpose of the Engineer Officers' Reserve Corps, the Society of American Military Engineers, its local posts, and its journal, THE MILITARY ENGINEER. But to these should be added the continuous personal effort of every member of the profession, both in and out of the regular service. The record of the profession in the late war is second to none. But we must not rest on our laurels. That record should be regarded as merely the point of departure for still better service in the future.

1st Division to erect memorial

THE following letter, which we are glad to present to our readers, has been received from the commanding general of the First Division:

The First Division will erect a monument in Washington or Arlington in memory of the 209 officers and 4,690 soldiers who were killed or died of wounds on the battlefields of France. We feel that the officers of the army would like to help us in honoring the sacrifices of the brave men who made the success of our arms possible and in preserving to our country, the inspiration of their spirit and their example.

The First Division endeavored to uphold before the world the standards of the Regular Army. You know its story. If it has earned your sympathy and approval, will you not join in this worthy task? Twenty dollars will make it possible to place one name in perpetual memory.

Should you be unable to contribute at once, will you not subscribe to a series of payments? If you have already contributed, please disregard this appeal.

It is requested that all contributions and subscriptions be sent to Major General C. P. Summerall, Camp Zachary Taylor, Ky.

C. P. SUMMERALL,
Major General, U. S. Army.

Emblem of the Society of American Military Engineers

FROM the earliest times and in all parts of the world it has been the custom for individuals and organizations to display distinguishing symbols. Ancient literature—both secular and sacred—describes the devices worn on the shields of heroes and antique sculptures and ceramics depict these badges of identification. In the Old World the Egyptian and the Greek, the Phœnician and the Roman, the Chinese and the Hindu, all had their emblems; and when the European first saw America he found the Aztec chiefs with shields and banners bearing their personal devices. Even the Alaskan tribes had their totems.

In the days of chivalry, the design of armorial bearings and coats of arms became a veritable science circumscribed by many meticulous conventions. Though "days of old when knights were bold" have faded into the background of medieval history, the value of the badge has in no sense diminished. The late war demonstrated its value and the idea blossomed forth to an extent never before exceeded from the standpoint of mere numbers. The divisional "shoulder patch," in its various forms, took its place in the military sign manual, and succeeded in a measure to the post of honor not long since occupied by the regimental insignia or the special uniform of various organizations. After much serious consideration certain of these insignia have been authorized by the War Department as part of the peace-time uniform.

Throughout the ages the effort has been to embody in these signs some manifestation of the wearer's individuality, some indication of his qualities of heart and mind. In conformity with this world-old practice, the Society of American Military Engineers has adopted an emblem which seeks to visualize the under-

Digitized by Google

lying principles of the organization. Formed in the interests of military preparedness as a rational measure of national defense, the Society has taken the national shield as symbolic of its reason for existence and as a token that the scope of the Society is nation-wide and that it serves no party or clique. On this shield is the figure which has been adopted for the World War medal. Its presence serves to indicate that the Society is an outgrowth of this greatest war of mankind, in which the engineering profession played so important a rôle. This winged being represents primarily the spirit of Victory, and it is an easy step to conceive it as "Liberty Victorious," which, in spite of the victory achieved, has not been lulled into a false sense of security and has not laid aside its armor or its weapons; it stands as the incarnation of Military Preparedness, equipped and ready to fight again,

if need be, that "government by the people may not perish from the earth." At its feet is the cogged wheel — the symbol of mechanical engineering, which has its application in war in a myriad of forms ranging from the production of the bombing plane to the manufacture of shoe-pegs for the footwear of the doughboy. Electrical engineering, too, plays its part and is represented by its characteristic symbol—the thunderbolt of Jove grasped in the talons of the eagle, which has ever been likewise the symbol of independent Americanism.

Beneath and underlying all is a bastioned fort—the strong point in military defense, representing the constructive skill of the civil engineer applied to military purposes. These three great branches of engineering — civil, electrical and mechanical — coupled with a sound knowledge of military history, strategy and tactics, are the fundamentals of military engineering. Though they by no means cover the entire field of military science and though the ranks of the Society are open to all engineers of suitable military qualifications, it is entirely appropriate that these three great divisions of engineering should be represented in the emblem of this Society, and their presence carries no implication of the exclusion of the miner or the metallurgist, the chemist or the physicist or other technicians, for war diverts to its own purposes all the arts of peace, with an intensity far exceeding their usual industrial application. Surrounding all is a laurel wreath indicative of achievement and representative not merely of past successes, but emblematic as well of aspirations and determination for the future.

The device as a whole is believed to be a fitting emblem of the Society and to present in dignified symbolic form a concept of the obligations and the responsibilities which rest upon every loyal American engineer to hold himself at all times efficient and ready to aid in his country's defense.

The Society is indebted to Mr. C. A. Houston of the Bureau of Engraving and Printing of the United States Treasury Department for the development in a well-balanced and artistic form of the ideas which we have attempted to present. Arrangements are under way for the production of this emblem to be worn as a lapel button, as a pin or as a charm, and announcement will be made at a future date as to prices and conditions under which this badge of the Society may be made available to its members.

We must "dig in" and hold our gains

One of our members writes:

A democracy is proof against the lessons of war. It nevers learns. The only way we can hold our gains in military experience is by means of such a Society as you have organized. I trust the censor may be conspicuous by his absence. Nothing can be accomplished if the *status quo* is considered perfect. We must not conceal our mistakes if we are to profit by them. There must be no camouflage. Good men learn more from their failures than from the successes.

Capitalize your "callings-down"—build on your "bawlings-out."—The resourceful man will turn any circumstance, however discouraging it may appear, to advantage. Such a man, in applying for membership in our Society, writes as below. We need more such men, and we recommend his methods to the attention of all. His desire to join us is further convincing proof of his initiative and resource.

I owe a large measure of my present success to a "balling out" administered by a Colonel of Engineers, while I was serving on the border in 1917. That deserved rebuke has resulted in an increase of 1,000 per cent in my income, and the further satisfaction that results from successful effort. I feel kindly towards the Engineers. Please send me information concerning the Society.

General officers serving in the World War.—During the World War there were 489 general officers, i. e., generals, lieutenant generals, major generals, and brigadier generals, who served in the American Army. Pennsylvania furnished the largest number, 51, with New York a close second with 46, 31 joined from the state of Ohio, 29 from Illinois, 25 from Missouri, 21 from Michigan, and 20 from Massachusetts. Colorado and Delaware furnished one each, while there were none from Nevada, Montana, Idaho and Wyoming.

The average age of the general officers was 49 years. 52 were born in New York, 45 in Pennsysvania, 35 in Illinois, and 29 in Ohio; the remainder being natives of the other states except 7, who were foreign born.

Congress Investigates Army Construction

By

H. A. Finch

Colonel, Engineers

BUILDING contractors and engineers generally throughout our country's civil and military circles, who are concerned with construction work will find very interesting, if curious, reading in the government document listed as No. 190 on the House calendar (Report No. 816, H. of R.). The document includes the majority and minority reports of the House Investigating Committee on the cost and construction methods of our army cantonments erected to meet the needs of the war.

As the document itself is rather long, containing some 175 pages devoted to a compilation of the voluble testimony of many witnesses, as well as the widely divergent conclusions of the two factions of the Committee itself, this digest may save the busy man some valuable time. The subject is of such importance to the engineering profession and to the country generally that every citizen should know of it.

At the outset it may be said that the report suffers from the handicap that afflicts nearly all such Congressional documents in that the conclusion of both the majority and minority sections are too highly flavored with politics to serve as a reliable guide in the formation of an opinion on the real merits of the question investigated. In the matter of the cost of the cantonments the majority report brands the entire proceedings, as was done also in the investigation of the Air Service program, as, "a riot of waste and extravagance," whereas the minority in both of these instances, as in many others, refers to the criticized operations as a record of brilliant achievement. One side is strongly anti-administration and the other is as decidedly pro.

Such complete divergence of opinion hurts confidence in the practical usefulness of Congressional investigations, for the unbiased reader has only the two extreme statements as guides for his conclusions. As he is left to choose between recommendations, either for a prison sentence or for a Distinguished Service Medal for the government agents involved, the distracted seeker after exact truth may as well omit reading the report altogether—and it appears that this is what most of them do! This decision is all the more reasonable when it is remembered that neither side publishes any of the evidence except that which appears to support its own findings. Non-partisanship in a partisan political body is of course difficult to attain, and there are some pessimists who will insist that the reader of a Congressional Committee Report gets no better than he deserves, that is to say, he gets only what he goes after, which is evidence to sustain his own preconceived opinions, and that he discards everything contrary thereto. He accepts as gospel truth one or the other of the antipodal versions presented, and that is the end of the matter so far as that particular individual is concerned. This theory certainly has some support in the fact that nothing ever happens after such a report is published. So much for the most pessimistic view of this matter. But there are in existence unbiased men who want unbiased information. Let them seek it in what follows, and good luck to them.

The majority report charges that in the construction of the 32 camps and cantonments erected for our troops, a civilian sub-committee of the Emergency Construction Committee, headed by an architect from New York City, arrogated to themselves the powers legally vested in the army officer nominally in charge of the Construction Division of the War Department, and that this group of civilians, some of whom were interested parties in the proposed construction work, were guilty of the actions set forth below:

(*a*) That they wilfully ignored the provisions of law which required that detailed estimates be furnished for the work to be done.

(*b*) That they far exceeded their powers granted under the Act creating the Council of National Defense, by doing away with the necessity for advertising for bids, and by letting contracts illegally and arbitrarily.

(*c*) That the sub-committee secured the adoption of the cost-plus percentage form of contract, an indefensible proceeding even after considering the emergency conditions, which resulted in the waste of millions of dollars of government money. To be exact, the waste charged amounts to an average of $5,000,000 on each of the 16 National Army cantonments built, or between 40 per cent and 60 per cent of the amount of the individual contracts.

(*d*) That even after adopting the cost-plus form of contract, the sub-committee failed to provide adequate safeguards for the interests of the United States. Two safeguards were incorporated in the contract: (1) Supervision of the contractor's audits and accounts by the army quartermaster, and (2) a limitation of the total fee for the contractor to the sum of $250,000 (6 per cent on $4,166,000), but these are branded as being entirely inadequate, too easily evaded, and, in the case of (2), largely inoperative because the maximum was not reached in 315 out of 500 emergency contracts.

(*e*) That an excessive scale of rentals for contractor's equipment was authorized; that the selection and rejection of contractors indicated favoritism; and that even after reputable contractors had offered to do the work in some cases for as low as "cost plus 3 and one half per cent," the scale of remuneration was fixed at "cost plus 6 per cent" and upward.

(*f*) That the cost-plus form of contract had a ruinous effect upon labor in that it encouraged the men to loaf and malinger "on the job," and that this led to delay in the completion of the cantonments instead of expediting their

Digitized by Google

construction as has so often been urged in justification of the adoption of this form of contract.

In brief, the indictment framed in the majority report charges that the War Department, through its agents, was responsible for inefficient methods, scandalous waste, outrageous delay in obtaining results, collusion between government representatives and interested contractors—in fact, about every form of culpability possible in the contracting game, short of "sticking up" the Treasury itself from behind a mask and a Colt automatic!

Turning to the minority report we find the other side of the picture is presented. Here we are advised:

(*a*) That there can be no doubt from the testimony that the unanimous indorsement of the cost-plus contract and its subsequent approval by the Secretary of War, was in harmony with the judgment of the leading builders, architects and civil engineers of the country.

(*b*) That the cost-plus system was not only justifiable, but inevitable and unavoidable, since no reputable contractor could be expected to run the risk of financial ruin, even for the sake of patriotic service, by bidding on construction work involving not only buildings but also the installation of light, water and sewerage systems—all of this without a careful preliminary examination which lack of time did not permit, and also with the certain knowledge that the operation of the draft law would upset labor conditions to such an extent that no accurate estimate could possibly be made as to his pay-roll.

(*c*) That the framers of the cost-plus contract recognized the opportunities that would exist for waste of materials and for loafing by laborers, and employed every safeguard to protect the Government's interests in these respects. They proceeded on the theory that it was far better to waste lumber and nails than to waste American lives in France.

(*d*) That there is no testimony in the record that any contractor participated in the recommendations as to the assignments of contracts.

(*e*) That there was of course a certain amount of loafing going on, among the laborers employed on the different projects, but there is not a shred of evidence that proves, or tends to prove, that the contractors encouraged loafing. The testimony is quite to the contrary.

(*f*) That there was petty grafting on these great building projects is undoubtedly true, but the charge that the contractors for the 16 cantonments deliberately sought to increase the cost of the work in order to swell their fees is not supported by the record. On all of the 16 original projects the cost of the work was more than twice $4,166,000, the limit upon which the contractor could earn his percentage, and since all parties in the beginning recognized that the cost would far exceed the maximum figure of $4,166,000, there was no incentive for the contractor to increase the cost since his maximum fee was assured at the outset. [It might perhaps be added that there was also, apparently, no incentive for him to *decrease* it, except pure patriotism.—ED.]

It is for the reader to decide who has it—the yeas or the nays. As reflection is given to the matter it is believed that it will become clearer that neither report hits the nail squarely on the head. The truth appears to be that our cantonments were built by "profiteers"; that is, by the American people generally. This applies both to the contractor and to the laborer, for while it is not established that any actual large scale graft was put through by the contractors, there was certainly no concerted systematic effort made by them to prevent loafing and "shooting craps" on government time. The spirit was not right; the motto, "Service, not Profit," may have animated many of the head men of the contracting firms, but they did not see to it that this word went down the line to their foremen, time-keepers and laborers.

Perhaps the demoralizing effect of the cost-plus system upon the laborer was too pronounced to be controlled effectively, but the contractors might at least have tried to exercise control—and there is little evidence to show that they did this. For the subordinates themselves—the laborers and their foremen—there is even less to be said of credit. They were frankly out "to get while the getting was good," without any thought for the welfare of their country at war. For every case cited of a superintendent's urging his men to "take it easy and drag out the job," there are also a dozen instances testified of the laborers' passing around the word that the thing to do was "to keep an eye out for the boss and pretend to be busy when he is around." The workers in many cases came to the camps expecting to do a fair day's work for a fair daily wage, but found that this was not required. The spirit was not right; the thousands employed made strict supervision impracticable, and the men did not hesitate to take advantage of the situation. This condition was undoubtedly encouraged by the form of contract, and the result was that too great a percentage of the workers soon learned to loaf, to malinger, to lay off on week days and to demand the higher-paid work on Sundays.

Of course patriotism should have prevented this, but the fact remains that it did not, hence the conclusion that the cantonments were built by "profiteers"—which classification may be not unjustly extended to include the loafing laborer, the tricky time-keeper as well as the too complaisant contractor.

However, when we come down to the general conclusions to be drawn, can we say that the construction of those cantonments stands in a class by itself? Is not the majority report, insofar as it is correct, in fact an indictment of the American people? Are we not in our country to-day witnessing "hold-ups" that aggregate monthly in unjust profits far more than the $80,000,000 alleged to have been wasted on all 16 of these projects during a period of over one year? It is a regrettable thing to be compelled to say, but it does seem that profiteering is a business not limited to a small and greedy class. "Everybody's doin' it now" that can—certainly those who are not are in the great minority. Only the other day the writer heard a friend damning the profiteers, and in the next breath bewailing the fact that he had been "stuck" by renting out a house of his just before the war for $50.00 a month on a lease that stood in the way of his getting the $150.00 per month that the house would now bring.

In the *Congressional Record* for May 18th it is shown in a speech by Senator Walsh of Massachusetts that in the four great classes of products which affect the life of the average American citizen, fuel, food, clothing, and steel, in hundreds of cases corporation annual profits for the past three years have ranged from 100 per cent to 300 per cent, and that in thousands of instances these annual profits have exceeded 50 per cent—and this largely on well-watered stock holdings! According to Mr. Basil M. Manly, at one time with the War Labor Board, "In the last three years the American people have paid in net profits every dollar's worth of stock of the coal companies and all corporations in the essential lines of industry and trade," which, as further explained by Mr. Manly means that, "If the national Government at the beginning of the war had taken over the essential lines of industry, and the American people had

Digitized by Google

been required to pay the prices which private manufacturers and merchants have charged them, there would have been sufficient profit to pay for every dollar's worth of capital stock, and leave the nation to-day in possession and control of practically all its manufacturing plants."

It is safe to say that the recipients of these swollen dividends do not consider themselves profiteers at all, but only as persons gifted with remarkably far-sighted judgment in placing their investments. It may be that this vexed question is so closely intermingled with the fundamental impulses of human nature—not to mention the operation of that grand old law of supply and demand—that it would be literally impossible to separate the sheep from the goats. Just at present there is no doubt as to the identity of the "lambs," but if the sheep represent those of us who are morally incapable of stooping to benefit by the opportunity of obtaining high prices for our products, it is feared that the vast majority of us Americans are covered with hair instead of wool.

Before recommending that active profiteers be hanged without benefit of clergy, it might be well for the remainder of us—would-be profiteers—to search our souls on this question. In that case it is likely that we who are in no position to profit by high prices will rest content with saying that if such opportunity should present itself, we beg leave, as did the boy when faced with the problem of whether or not he would return a lost twenty-dollar bill to the owner, to await the event before announcing the course of action we should follow.

It has often been said that the great mistakes the administration made was in failing to draft laborers as it did soldiers, paying them as the soldiers were paid and granting like allowances to their families. The only reasonable explanation for this failure that has so far come to the writer's notice is that our government realized that the war must be won, and could not afford to bring about internal dissension in the face of this imperative need. As we look back on those days we believe that it *could* have been done without undue friction, but at that time we did not have the whole-hearted response to the draft law to act as an incentive to the necessary legislation. We were not so sure of our ground as we now are.

Our country is a great one, but as the *Brooklyn Eagle* has it, "A civilization that has advanced from head-hunting to rent-gouging and profiteering has still *some* distance to travel."

[*Note.*—Colonel Finch's review of the "findings" of the committee of Congress with reference to the efficiency of army construction gives the impression that the report makes upon an unprejudiced observer, and will be of great interest to all our readers.

As the jury has so positively failed to agree, we refrain from delivering a verdict in the case. Morcover, the guilt or innocence of the individuals in responsible charge of army construction in the United States is not the chief issue raised by this investigation. The matter goes farther and deeper than that. Colonel Finch asks if the majority finding is not an indictment of the American people. It is.

Where there is so much smoke there must, of course, be some fire. This report, following the similar one concerning aircraft production, and preceding a "washing of dirty linen" in the Navy Department, is further convincing and painful evidence of how our utter unpreparedness for war pervaded every phase of our activities. Such investigations are the characteristic aftermath of such lack of adequate preparation. It is hoped that the significance of all this may not be lost upon the American people. Probably a vain hope. The very bitterness of this report proves that we are not a united people even in defense.

We were unprepared as to the training of our men and the effective utilization of our material resources. But at the bottom of all this is the basic fact that we were unprepared spiritually. The nation was not *morally organized* for defense—as this report too plainly shows. Of little use for a President to proclaim that to our cause we pledge our lives, our fortunes and our sacred honor, unless that noble sentiment resounds in the heart of every citizen of the Republic.

As a nation we are certainly hysterically and temporarily susceptible to patriotic influences, as we are to all other less holy emotions. But patriotism, like other beautiful flowers, does not thrive and endure in the wild. It must be assiduously cultivated to attain its highest perfection and beauty. What we need in this country is less emotional, and more practical patriotism. The American people have really had too little training in practical patriotism, so it is perhaps not remarkable that they exhibit certain deficiencies when put to the test. This was revealed in the construction of the cantonments, but that was only one of many revelations.

The only sure basis of an effective national defense is the *moral organization* of the people, the sedulous cultivation of the spirit of patriotism in the heart of every citizen. This strikes at the root of the malady, of which profiteering at the cantonments is merely one of the symptoms. As General Wood has said: "Manhood suffrage implies manhood obligation of service to the country." By suffrage he means the privileges of citizenship in America, and in manhood he includes womanhood.

What do we need to prevent a recurrence of such unfortunate conditions in the future? We need moral organization, a higher appreciation on the part of all our people of their obligations to their country. We need citizens who would cut off their right hands sooner than turn the agony of their country and of mankind to their own sordid profits.

These are high sounding ideals, but can they be practically, effectively and promptly realized? They *can*. Universal training in good citizenship and practical patriotism is the evident means of accomplishing these much to be desired results, and they can be secured in no other way.

And this is the moral of our fable.—ED]

The "cost-plus" system once more

The committees of Congress investigating war expenditures have done one good thing. They have brought before the engineering and contracting professions the inherent difficulties of the cost-plus contract as applied to public work. There has been much propaganda lately favoring this system, largely based on some real advantages it has. This report shows only too clearly that the possibilities of public scandal, the ease with which proper performances can be given improper appearance, far outweigh such real advantages. In normal times, competition, based on financial outlay and assumed risk, must remain the foundation of public contracts.—*Eng. News-Rec.*

Why house-building must increase.—Mr. Wharton Clay, Commissioner, Associated Metal Lath Manufacturers, furnishes the following as to the stability of the building industry. In 1918 only 20,000 new homes were built instead of 20 times that many, as required; 70,000 were completed in 1919, with the increase of population still outstripping the building program. In 1890 there were 110.5 families and to-day there are 121 families for each 100 homes. Estimating 27,900,000 families in 1925, the housing shortage will continue unless building is increased. If but the average are constructed for the next 5 years, 409,500 homes must be built and the congestion will reach 129.6 families for 100 homes.—*Eng. & Cont.*

Adherence of cement to gypsum.—For some months past, the Bureau of Standards has been conducting researches to discover a means for causing gypsum to adhere to concrete, and also a means for causing cement plaster to adhere to gypsum. These researches have been practically completed and the Director reports that the findings may be summarized as follows:

1. There seems to be no detrimental reaction between the two materials; the tensile strength of the mixture of gypsum and cement is very nearly equal to their combined tensile strengths, dependent upon the proportions of the two ingredients used;
2. The suction of the surface to which the plaster is applied is an extremely important factor; for example, if gypsum plaster is applied to a dry concrete surface, the suction of the concrete will take so much water out of the gypsum that it will prevent its proper hardening;
3. The expansion of neat cement, when wet, is of an entirely different order from the expansion of neat gypsum, and a bond between the two materials can be permanently maintained only when enough sand is added to both materials to reduce the expansion for both. The above mentioned research work has been supported by the Gypsum Industries Association, and a report covering it has recently been made to them.

Freight Traffic and Federal Expenditures on the Great Lakes

By

Edward H. Schulz

Lieutenant Colonel, Corps of Engineers; M. Am. Soc. C. E.

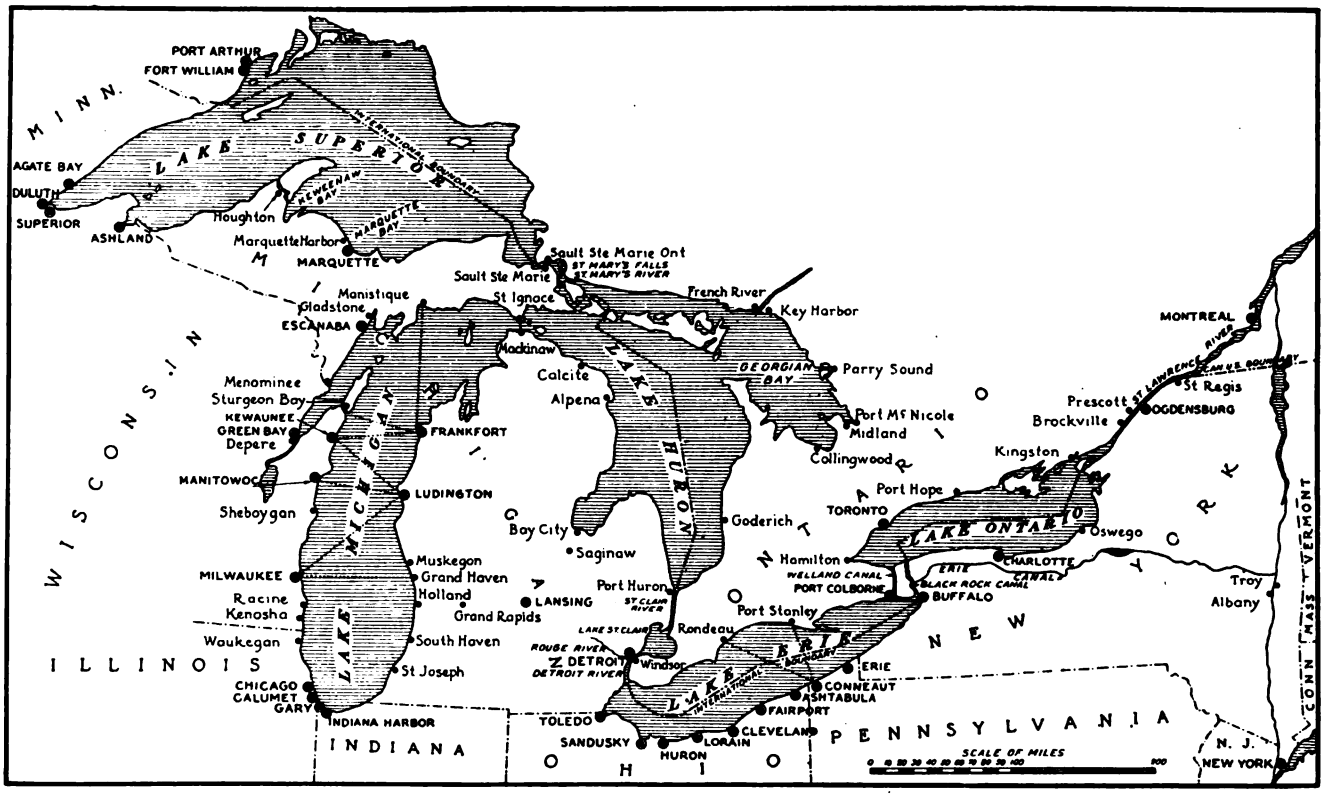
THE table following gives in simple form a general comparison of the tonnage and value of commerce and the relative cost of improvement works of the United States harbors on the Great Lakes. The data have been obtained from the annual reports of the Chief of Engineers. The districts considered are those of Duluth, Milwaukee (including the Grand Rapids sub-district), Chicago, Detroit, Cleveland and Buffalo. The information given is generally for the calendar year 1917, for all districts except Milwaukee which is, in some cases, for 1918. To avoid the introduction of a mass of figures and tables, the comparison is made generally by district, or involves only the more important harbors. A sketch map of the Great Lakes and a table or resume of traffic are printed herein.

Among the Great Lakes harbors under improvement or maintenance by the United States, there are 41 that had in 1917 (1918 for Milwaukee), a total tonnage of over 250,000 tons. Of these there are in the Duluth district, 6; in the Milwaukee district, 8 (not including Gladstone and Escanaba, private harbors); in the Grand Rapids sub-district, 3; in the Chicago district, 3 (not including Gary, a private harbor); in Detroit, 4 (of which three are principally all through-freight, and not including two others, Calcite and Alpena, private harbors); Cleveland, 8; and Buffalo, 7.

Of the Great Lakes harbors of over a million tons total commerce in 1917, Duluth district has 6, viz: Duluth, Superior, Agate Bay, Ashland, Keewenaw Waterway, Marquette Bay and Marquette; Milwaukee, including Grand Rapids sub-district, has 5, viz: Green Bay, Manitowoc, Milwaukee, Ludington and Frankfort, also Escanaba (private); Chicago has 3, viz: Chicago, Calumet and Indiana Harbor, also Gary (private); Detroit has 3, viz: St. Marys Falls, Detroit River, Rogue River, also two private harbors, Alpena and Calcite; Cleveland has 8, viz: Toledo, Sandusky, Huron, Lorain, Cleveland, Fairport, Ashtabula and Conneaut; and Buffalo has 4, viz: Erie, Buffalo, Charlotte and Ogdensburg. The total commerce of these harbors by district and its value for 1917 is as follows: Duluth district, 78,388,025 tons, at a value of $628,563,780; Milwaukee, 16,114,122 tons, at a value of $92,837,224; Chicago, 14,393,599 tons, at $445,117,147; Detroit, 97,695,569 tons, at $1,284,090,190; Cleveland, 75,817,185 tons at $449,912,528; and Buffalo, 27,539,313 tons, at $725,383,170. Of these harbors, in the Duluth district, the principal receipts are hard and soft coal and stone and the principal shipments are iron ore, grain, flour, lumber, and copper. In the Milwaukee district there is no one outstanding item of shipment, but the principal shipments are grain, manufactured goods, lumber, chemicals and leather. The receipts are principally hard and soft coal, lumber and grain. In Chicago the principal receipts are iron ore and coal, and the principal shipment is oil. Detroit's principal traffic is coal, ore, grain, flour, lumber, stone, and copper. In Cleveland the receipts are almost entirely iron ore, sand and stone, and the shipments are practically all of soft coal. The Buffalo district has a predominant receipt of iron ore with a considerable quantity of grain, stone and lumber, while the shipments are mostly of hard and soft coal.

On the Great Lakes there are twelve harbors or traffic ways, having an annual commerce of over five million tons. Of these there are three in the Duluth district; one in the Milwaukee district; one in the Chicago district; four in the Cleveland district; two in the Detroit district; and one in the Buffalo district. They are as follows:

Harbors	*Order of tonnage*	*Harbors*	*Order of value*
Detroit River	95,243,110	Detroit River	$1,269,690,776
St. Marys Falls	89,813,896	St. Marys Falls	1,196,922,183
Duluth-Superior	52,611,824	Buffalo	564,134,005
Buffalo	18,925,179	Duluth-Superior	471,309,736
Ashtabula	15,992,388	Milwaukee	362,564,868
Cleveland	14,282,687	Calumet	225,122,383
Toledo	13,710,238	Cleveland	128,239,054
Conneaut	12,956,398	Ashtabula	87,876,962
Agate Bay	10,773,241	Toledo	80,318,986
Calumet	10,269,304	Conneaut	62,501,557
Ashland	9,580,085	Agate Bay	43,020,032
Milwaukee	7,066,550	Ashland	36,137,511



The commerce at Detroit River and St. Marys Falls is practically all through-freight.

The Milwaukee district, including the Grand Rapids sub-district, had a total commerce for the calendar year 1918 of over 18,000,000 tons, valued at over $875,000,000. Of this total, Milwaukee Harbor furnished something over 7,000,000 tons at a valuation of over $362,000,000. In the combined district there is a large translake car-ferry business, amounting to about 45 per cent of the total in tons, and to about 84 per cent in value.

In 1917, the total shipments and receipts in all the districts on the Great Lakes amounted to approximately 310,000,000 tons, and was valued at over four and a quarter billions of dollars. This represents a movement of 155,000,000 tons of freight, or allowing 50 tons to the 50-foot car, an annual movement of 3,100,000 cars of freight. Taking 31 cars to a train, this would amount to 100,000 trains, having an aggregate length of nearly 30,000 miles. The amount of 310,000,000 tons is more than three times the total annual tonnage of Chicago, rail and water combined. The Detroit district had a greater tonnage for that year than any other, having a commerce of approximately 98 million tons valued at over a billion and a quarter dollars. The value of the traffic for 1917 ranges from $44.45 per ton, in the Grand Rapids sub-district, to $5.93 per ton in the Cleveland district.

The accompanying table shows a comparison of the freight tonnage and the cost of harbors on the Great Lakes with percentage of receipts and shipments, value per ton and costs per ton. This tabulation is made by district. The Detroit district is divided into two groups and the Grand Rapids sub-district is shown separately. The cost

Digitized by Google

per ton (F) is the average annual cost of Government works per ton of traffic based on the total expenditures for the five years, 1914 to 1918, and the total tonnage for the five years, 1913 to 1917. By reference to the table it is seen that this cost varies from $.0043 per ton for the Duluth district, to $.057 per ton for the Grand Rapids sub-district. The cost per ton (G), based on the investment expense of harbor improvements, is derived from the total tonnage for 1917, and 4 per cent interest on the total expenditures to 1918. This cost varies from $.0066 per ton for the Duluth district to $.0951 per ton for the Grand Rapids sub-district. It will be seen by reference to the table that the average expenditures by district, per ton, under the two methods, (F) and (G), bear a close relationship to each other.

The general conclusion is that the cost of Federal improvement works of the Great Lakes harbors has been well justified by the commerce. This is true not only of the present traffic, but also of the great traffic in lumber, grain, ore and coal of former years, when many of these improvements were begun to foster the very tonnage now grown to such enormous proportions.

Retirement of Engineer Officers

Colonel F. V. Abbot

WITH the retirement May 11, 1920, of Col. F. V. Abbot, there is stricken from the active list of the Corps of Engineers, a name which has been distinguished in its annals for nearly three-quarters of a century. The name of Abbot epitomizes the traditions and ideals of the Corps.

Frederic Vaughn Abbot was born in Cambridge, Mass., on March 4, 1858, the son of Gen. Henry L. Abbot, a brilliant and distinguished officer of the Corps, still living at the age of 89 years. He graduated from West Point in 1879 at the head of his class. Among his classmates were Thos. L. Casey, T. A. Bingham, and C. McD. Townsend, all engineers of note. Young Abbot and Casey were the sons of classmates who had graduated Nos. 1 and 2 in their class, and a spirited competition developed between them. Like their fathers, they graduated 1 and 2, but the sons reversed the previously established order.

Colonel Abbot's entire service was in the Corps of Engineers, in which he rose to the rank of Brigadier General during the World War. His first important undertaking, after leaving the Engineer School at Willets Point, was the establishment of the boundary line between Virginia and Maryland. In 1885 he was placed in charge of the harbor development at Charleston, S. C. This consisted of the formation of a deep channel through the harbor bar by means of converging jetties. Colonel Abbot remained on this work for over 12 years, and guided it to a successful completion. His next duty was on the Upper Mississippi at St. Paul, where in connection with the building of a lock he made valuable contributions to the art of concrete construction. Amongst many boards of engineers on which he served may be mentioned one which studied the project for the regulation of the Missouri River and added greatly to our knowledge of river regulation.

In later years Colonel Abbot was in charge of the important engineer districts of New York and Boston, including river, harbor and fortification work. He was for many years assistant to the Chief of Engineers in Washington. During the war he was charged with supervision of the organization of the vast force of 300,000 engineer soldiers, who contributed so powerfully to the victory over Germany. In recognition of the importance of this task he was elevated to the rank of Brigadier General.

In his retirement the Army loses an efficient, industrious and loyal worker, and the younger officers of the Corps of Engineers, in particular, will miss his ever kindly and sympathetic helpfulness and genial companionship.

Colonel W. C. Langfitt

Colonel W. C. Langfitt, Corps of Engineers, whose portrait appears as the frontispiece of this issue, former Major General and Chief Engineer of the A. E. F., was retired from active service on May 31, 1920, on his own request after more than 40 years' service. The Corps has lost one of its biggest men, a man of wide experience and ripe judgment, yet still possessed of the vigor, enthusiasm and resourcefulness of youth.

William Campbell Langfitt was born in Wellsburg, Va. (now W. Va.), August 10, 1860. He graduated from West Point in 1883, No. 2 in his class. All his service has been with the Corps of Engineers, in which he rose through all grades to that of Colonel in 1913. During the late war Colonel Langfitt was Chief Engineer of the American Expeditionary Forces with the rank of Major General.

The most striking feature of Colonel Langfitt's distinguished career was the astonishingly wide range of his activities. He was engaged in a wide variety of engineering duties at Galveston, Cincinnati, Portland (Ore.), Washington, D. C., Savannah, and New York. While in Washington he made the investigations and formulated the great project for water power development at the Great Falls of the Potomac River. He has been a member of many important boards, including the Board of Engineers for Rivers and Harbors.

General Langfitt is, however, first of all a soldier, and his thorough military training and aptitude in military affairs, eminently fitted him for the high position which crowned his military career—Chief Engineer of the greatest army that ever took the field.

He served with the engineer battalion at Willets Point, and graduated from the Engineer School at that place; was Engineer Officer of the Department of Columbia; commanded Co. B, Engineers (old battalion), and was instructor at the Engineer School. During the Spanish War he commanded a battalion of volunteer engineers. He was later instructor and commandant of the Engineer School, the post and Engineer Depot at Washington Barracks, where, as chairman of the Board on Engineer Equipment, he was primarily responsible for the successful development of the engineer organization and equipment so thoroughly tested and proven during the Great War. As Chief Engineer of the Army of Cuban Pacification he carried out the famous "reconnaissance survey" of Cuba, mapping the whole island in less than 8 months. In 1916-17 he was Department Engineer of the Southern Department, at San Antonio, Tex., and in charge of railway operations in connection with the mobilization of the American Forces on the Mexican border. He was relieved from this duty to organize one of the railway engineer regiments demanded by the British Government as America's first contribution to the war. He organized the 13th Engineers (Ry.), and conducted them to France.

Arriving in France thus early in the war, General Langfitt at once entered actively into the engineering preparation for the operations of the Great American Army that was even then streaming across the Atlantic. His first assignment was as Chief of Staff of the Line of Communications (later the S. O. S.). While serving as Commander of all American troops with the British Army and as Director of Light Railways in the A. E. F. he took advantage of the opportunity thus afforded to familiarize himself with British methods of supply and transport. On March 12, 1918, he was appointed to the new office of "Director of Utilities," in control of all transportation, roads, railroads, construction and forestry. This was virtually the position of Chief Engineer, and on July 11 he was so named, and all engineering activities of the A. E. F. were combined under his direct control. The enormous and seemingly impossible engineering projects so successfully carried out by the A. E. F., under General Langfitt's direction, are a sufficient commentary upon the nature of his services to his country in the Great War.

Digitized by Google

Colonel F. V. Abbot

Colonel M. J. McDonough

In recognition of these services, he was loaded with honors and decorations by three governments; the Distinguished Service Medal, Commander of the Legion of Honor and Companion of the Order of the Bath.

Returning to the United States at the close of the war, General Langfitt was assigned to duty as District Engineer of the 2nd N. Y. District, and Division Engineer of the Northeastern Division—his last assignment on active duty. He retires from the service to enter business life

Colonel Langfitt's high professional attainments, the force and directness of his character, combined with a genial and tactful disposition, earned for him a host of friends in all branches of the army and in civil life, all of whom will regret the loss of his services to the government.

Colonel M. J. McDonough

In the retirement from active service (for physical disability) on May 11, 1920, of Lt. Col. Michael J. McDonough, the Corps of Engineers and the Army lose one of the most brilliant and popular of the younger officers.

Colonel McDonough was well and very favorably known throughout the Army as a soldier intensely active in all matters affecting the better training and greater efficiency of our military forces, as one of the "shining lights" of the Service Schools at Leavenworth, and an author of recognized authority on tactical subjects.

He was born in Massachusetts, January 27, 1877, graduated from West Point in 1899, and was assigned to the Coast Artillery. In 1902 he transferred to the Corps of Engineers, in which he reached the grade of Lt. Col. in 1920. He served in Cuba, and in the Philippines as Director of the Military Survey of Luzon, as instructor at West Point, and on river and harbor work at Albany and Memphis. He was selected as senior engineer instructor for the experimental Citizens Training Camps at Plattsburgh, the forerunner of the Officers Training Camp for the A. E. F. He was a graduate of the Army Engineer School, and honor graduate of the Service Schools at Leavenworth.

At the outbreak of the war in 1917, Colonel McDonough organized and trained the 114th Engineers, 39th Division, at Camp Beauregard, La. This arduous duty brought on a physical breakdown which prevented his accompanying the division overseas, and ultimately resulted in his retirement from active service.

Use of heavy tractors for hauling elevating graders and wagon trains from steam shovel

The artillery type tractors designed by the War Department for military use were employed last year by the U. S. Reclamation Service in the construction of the Salmon Lake dam and Conconully dam enlargement of the Okanogan Project, Washington.

The tractors are the caterpillar type, known as "10-Ton Artillery Tractor, Model 1917." The weight of the machine, with full equipment, is 21,500 pounds.

One tractor was used for 3 months for pulling a standard elevating grader, operating in a borrow pit of fine sand and silt. This grader was loading 1½ cubic yard dump wagons hauled by 3-up teams to embankment. The other tractors were used for 4 months hauling wagon trains from the steam-shovel borrow pit to the embankment. As the length of the haul was short (1,000 feet), and turning space limited, it was considered essential to have tractor train equipment that could turn in narrow spaces. The tractors can turn completely around within their own length; the wagons used as trailers were of the common cut-under dump-wagon type having a capacity, level full, of 3 cubic yards.

Under usual conditions, the tractors easily handled three of these wagons, but under adverse conditions of wet ground, and on grades they could handle only two.

When clearing the dam site the tractors were found to be excellent stump and brush pullers. A ¾-inch steel cable was used for this work, experience showing that a ⅝-inch steel cable would not hold the machines.

On account of the lack of traction in the loose dry silt and fine sand in the elevating grader pit the use of a wheel-type tractor for pulling that machine would have been impossible, while the artillery tractor did excellent service.

The hauling by teams cost 20.1 cents per cubic yard, while the hauling by the tractors cost 19.5 cents per cubic yard. The conditions of the two hauls did not vary greatly; considering the entire period, the teams had the poorer roads

Digitized by Google

and slightly more of adverse grades, but the advantage of 200 feet shorter haul.

Based on the experience of the past season under the conditions existing on this work, it is believed that these tractors, when used for transporting earth, will show greater economy, as compared to hauling with teams, when the length of haul is greater than the average haul of 700 feet and on poor roads and steep grades where teams must be given frequent rest periods. As the length of haul gets shorter and the roads and grades improve the teams will prove cheaper, because they can be kept moving more steadily than the larger tractor units and they can make quicker turns at the end of the trip.

The above has taken no account of the question of maintaining an organization. The operation of the tractor requires the service of an operator and about half time of a repair man, both men of considerable reliability. The tractor, when working, replaced six 3-horse teams requiring the services of six teamsters who were hard to secure and much harder to keep on the job.—*Eng. and Cont.*

Should Coast Defenses be Designed like Battleships?

By

C. O. Sherrill

Colonel, Engineers

IN a recent number of the *Journal of United States Artillery,* Capt. J. K. Christmas, Coast Artillery, in an article entitled "Some principles of Naval Design applied to Coast Defense," presents certain arguments intended to show that, since the natural enemy of the fort is the dreadnaught, the former should be designed on the same principle as the latter. He says, "The principles of armament applied in battleship design suggest their application in a modified form to forts of the Coast Artillery."

It is believed that this hypothesis is fundamentally unsound and reactionary. It is contrary to the lessons of the late war and all the experiences of history.

The chief element of invulnerability of defenses, as plainly shown in the late war, is dispersion of the elements constituting the defense, so far as this is practicable without unfavorably affecting control and co-ordination of the defense. The fire of very large calibre guns, for reasons of economy and the limitations thus imposed, is practicable only against defenses concentrated in relatively small areas. Accordingly, to enjoy immunity from such fire the elements of the defense should be distributed both laterally and in depth, while still able to concentrate their own fire, which modern methods of communication render possible.

The isolated fort, bristling with guns of all calibre, the "concrete battleship" concentrated in a small space, is the most favorable possible target for big guns, whether those of an army or a fleet of battleships. It is also the most unfavorable arrangement for the delivery of fire, since guns of different range and calibre should not be concentrated in one place. In designing seacoast defenses in this way we deliberately impose upon them the limitations which the battleship cannot evade, suffering the additional disadvantage of lack of mobility, which the battleship fleet does evade.

For coast defenses to adopt Captain Christmas' suggestions would be too much like a fighter "keeping one hand behind his back" in order to give his opponent a chance to win.

The question of available space and limitations of weight are controlling and limiting considerations in the design of armament for battleships. These considerations are of minor importance in the development of coast defense fortifications. Surely no one would advocate that coast-defense guns should be equipped with the turrets used in the Navy, simply to follow naval design, for if the Navy had unlimited space available it certainly would not hamper itself by the use of the cramped space allowed in naval turrets.

The "big-gun" principle enunciated by Captain Christmas has been long in effect in the design of seacoast defenses, and the major calibre armament is, at the present time, the controlling consideration in all fortification designs. It suggests, moreover, that the armament in coast defenses be limited to 14-inch or 16-inch guns and one type of small or intermediate guns; this is being generally followed today. All new projects under consideration for the coast defenses contemplate only 16-inch guns and howitzers and nothing on fixed mounts of smaller calibre than 6-inch rifles. In fact, the present tendency is to depend on wheel and tractor artillery for all intermediate and minor calibre armament. One could safely go even further than does the author in advocating that no major calibre armament of less than 16-inch be provided for the coast defenses; nor is it agreed that the 14-inch guns mounted on railroad carriages have been practically demonstrated to be an effective type of coast-defense weapon, as stated by him.

Captain Christmas states that mortars in the coast defenses, in view of the fact that they cannot be mounted on board ship, must be considered as a special case. If his idea of following the naval design is carried out, it would naturally follow that mortars and howitzers should be eliminated from our coast defenses. The considerations making necessary the use of howitzers and mortars are based on their tactical efficiency having reference to the relative vulnerability of the side and deck of the ship, and not to any relation that naval guns have to these weapons.

The article makes the statement that major calibre guns of new battleships such as the *New Mexico* can be fired up to 30°, and, further, "if this can be accomplished on board ship, it can be more readily done with the coast guns." In reality, the present mounts under construction by the Ordnance Department of the Army will provide for 65° elevation with an effective range of 45,000 yards.

The author, in carrying out his somewhat forced comparison between naval and coast-defense design, advocates fire control command and spotting centralized in one station. This appears to be in direct violation of the present tendency of fortification design, which is more and more relying on dispersion, concealment and duplication of essential units to provide against hits rather than by concentration and excessive concrete protection. It is undoubtedly true that there is great advantage in having a simple range-finding system which will enable the location of vessels to be promptly indicated to all armament firing on any particular target, but to do this by physical concentration in one station of all the agencies necessary seems to be of doubtful utility. There is nothing in the system of coast defenses that requires a more careful study, how-

Digitized by Google

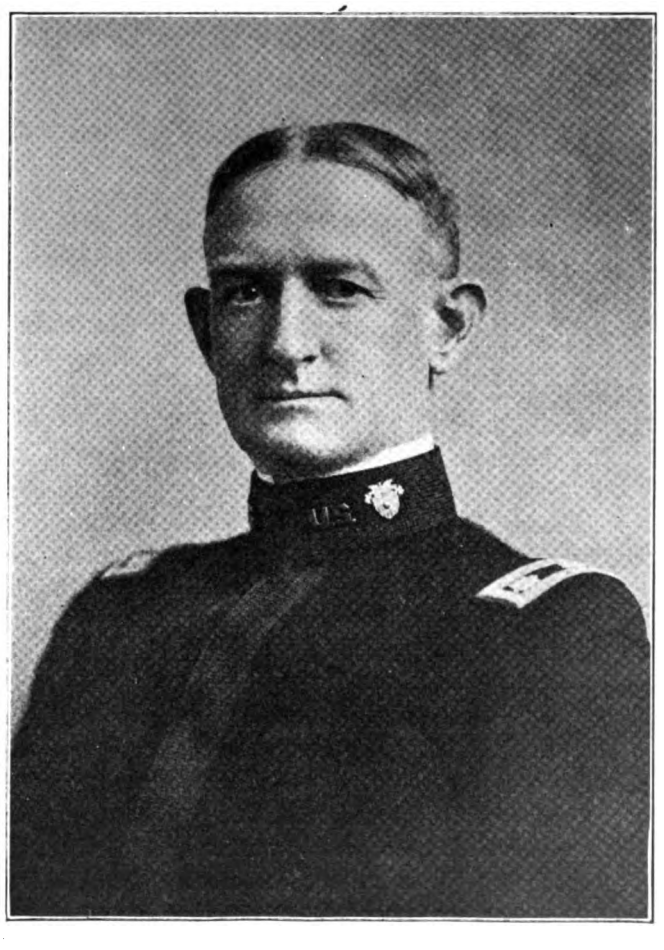
ever, than does this entire matter of range-finding, in view of the great distance at which combat between the coast defenses and battleships may take place. The most promising development along this line at present has been found to be in the system of sub-aqueous range-finding which is now under consideration by the Office of the Chief of Coast Artillery. The great advantage promised by this system is that not only will it be possible to determine ranges as far out as 25,000 to 30,000 yards, but these determinations will be entirely independent of fog, hazy atmosphere, rain and storm conditions, which have such a controlling influence on other methods of spotting and range-finding, whether from shore stations or aircraft.

As mentioned above, practically all of the conclusions of this article are erroneous, due to the fundamental error in the assumption that coast defense design must develop along the lines of naval design. It should not be forgotten that forts which, in the past, were designed with limited areas so as to contain all the elements of defense, as exemplified by the Vauban bastioned system, have in recent years developed more and more along the lines of dispersion, with a view to making each element of the defense less vulnerable to attacks made on other parts, and it appears that the development of coast-defense design in the future will be based on the construction of simple gun blocks with limited auxiliaries for fire control, practically no shelter for personnel and dispersion of all accessories, including ammunition, in small units, so that no two units will be destroyed by a single shell. All works and accessories should then be carefully camouflaged in time of war.

It is believed that such a system will have an even greater advantage over the battleship than has heretofore been the case, besides being simpler and much less costly to construct and maintain.

Death of Colonel E. R. Stuart

The MILITARY ENGINEER performs the saddest duty of its career in announcing to its readers the untimely death, on March 6, 1920, of Lt. Col. E. R. Stuart, Professor of Drawing, at the U. S. Military Academy.



Edwin Roy Stuart was born in Arnettsville, W. Va., Aug. 19, 1874. He graduated from West Point in 1896, No. 1 in his class, and attained the grade of Major in the Corps of Engineers in 1909. In 1911 he was appointed Professor at West Point, with the rank of Lt. Col., which position he held at his death, at the early age of 45.

Colonel Stuart has served on River and Harbor Work in Charleston, S. C. (3 tours), as instructor at West Point, and the Service Schools at Fort Leavenworth, and a number of tours of duty with engineer troops. His special interest was military topography. He was chiefly instrumental in the development of the topographical methods in vogue in the U. S. Army prior to the war, and in organizing and placing on a working basis the largest precise military survey ever undertaken by the U. S., that of the Island of Luzon, in the Philippines.

"Reddy" Stuart was widely and favorably known in the army. There was none more generally respected for his abilities and beloved for his personality by those who knew him. As an officer he represented all the best traditions and ideals of the Corps of Engineers; as a man "none knew him but to love him, nor named him but to praise."

His death was due to a grave tropical disease from which he had suffered ever since his return from the Philippines in 1910. During the war he went to France, but was compelled by ill-health to return to America.

A gentleman of the highest and best type by nature and breeding, a man of sterling worth, a staunch friend, a delightful companion, a mighty intellect, a strong, chivalrous and sunny character—in short, a power for good in the world, is gone out of our lives, and many hearts are left to ache.

The Tri-Lens Camera in Aerial Photography and Photographic Mapping

By

J. W. Bagley

Major, Engineers.

[*Note.*—This interesting article shows many of the difficulties attendant upon the adaptation of aerial photography to map work, which although a practical thing is treated lightly in many quarters. The so-called Bagley tri-lens camera was developed primarily with a view to covering a maximum area of ground at a single exposure, thus lessening the cost of our photographic work as well as the expensive and tedious restitution process.

Major Bagley is chiefly responsible for the development of the tri-lens camera. The transforming camera was largely developed by Mr. F. H. Moffit of the Geological Survey, with the assistance of Mr. J. B. Mertie of the Geological Survey.

The fundamental principles of multiple lens cameras, and transforming cameras were probably first enunciated by Capt. Theodore Scheimpflug, an Austrian Army Engineer, who studied the problem in connection with captive balloons.—Ed.]

THE use of aerial photographs in the construction of topographic maps is engaging the attention of a great many people in this country, and it is still so incompletely understood that it seems timely to try to give the topographic engineer's point of view of the subject. In attempting to do this it is my wish to emphasize a firm belief in the tremendous value that aerial photography, rightly understood and properly employed, is bound to have in topographic mapping. There have, however, been a great many extravagant claims set forth for aerial photographs as maps, in the form of mosaics, which indicate that the writers had not stopped to inform themselves sufficiently. To those who have fallen into the erroneous belief that in the aerial photograph we have an accurate and complete substitute for the topographic map, it is sufficient to say merely that there is no known way in which the displacements caused by hills and valleys can be eliminated from the photograph itself, and it seems unlikely that this can ever be done.

The accuracy demanded in maps which are to be used to measure distances can not be attained in mosaics, except of flat or nearly flat terrain. In making this statement it is not intended to argue that mosaics of flat country are the only photographic mosaics of value. A mosaic of quite rough country made from aerial photographs, though its pieces match unevenly, may be useful for many purposes; it might conceivably be even more valuable for some purposes than a good topographic map. Let us first, however, get clearly in mind the unavoidable limitation of mosaics as compared with topographic maps.

There has been an attempt to escape this limitation in mosaics by the argument that if the photographs are taken from a very high elevation the displacements will be reduced sufficiently to allow them to be neglected. This is true up to a certain limit, and if we could only have the photographs taken from whatever heights it suited us we could choose the elevation of the flight to accord with the amount of relief we are to deal with. But unfortunately we are quite definitely limited as to the heights of flights by the capacity of the aeroplanes used, by the cost of climbing to those high levels and by increased difficulties of work at extreme altitudes. To state the case more concretely, suppose a photographic mosaic is to be made of a terrain 15 miles square, approximately the area of a standard topographic map, which has a relief of 500 feet. The displacement caused by a relief of 500 feet will be 230 feet at the limits of the photograph, whatever the height at which the flight is made. (Fig. 1, page 362. It is assumed that the angular field of the camera is 50°.) Suppose the flight is to be made at an elevation of 10,000 feet. Each photograph will then embrace an area about 9,000 feet across. If the photographs overlap 50 per cent it will not be necessary to use the entire photograph, but only half, or about 13° each side of the center in the direction of the flight. But the part of each photograph employed will then span only 4,500 feet instead of 9,000 feet. So really, instead of one we shall be using two photographs, and on each there is a displacement equal to half that given at the outer limits of the full size photographs. However the distance from A to B (Fig. 2, page 362) is spanned, the sum of the displacements is about the same. Suppose though instead of making the flight at 10,000 feet it is decided to fly at 20,000 feet above the datum plane, or average elevation of the ground. Each photograph will then span 18,000 feet instead of only 9,000 feet, and in using them to

Digitized by Google

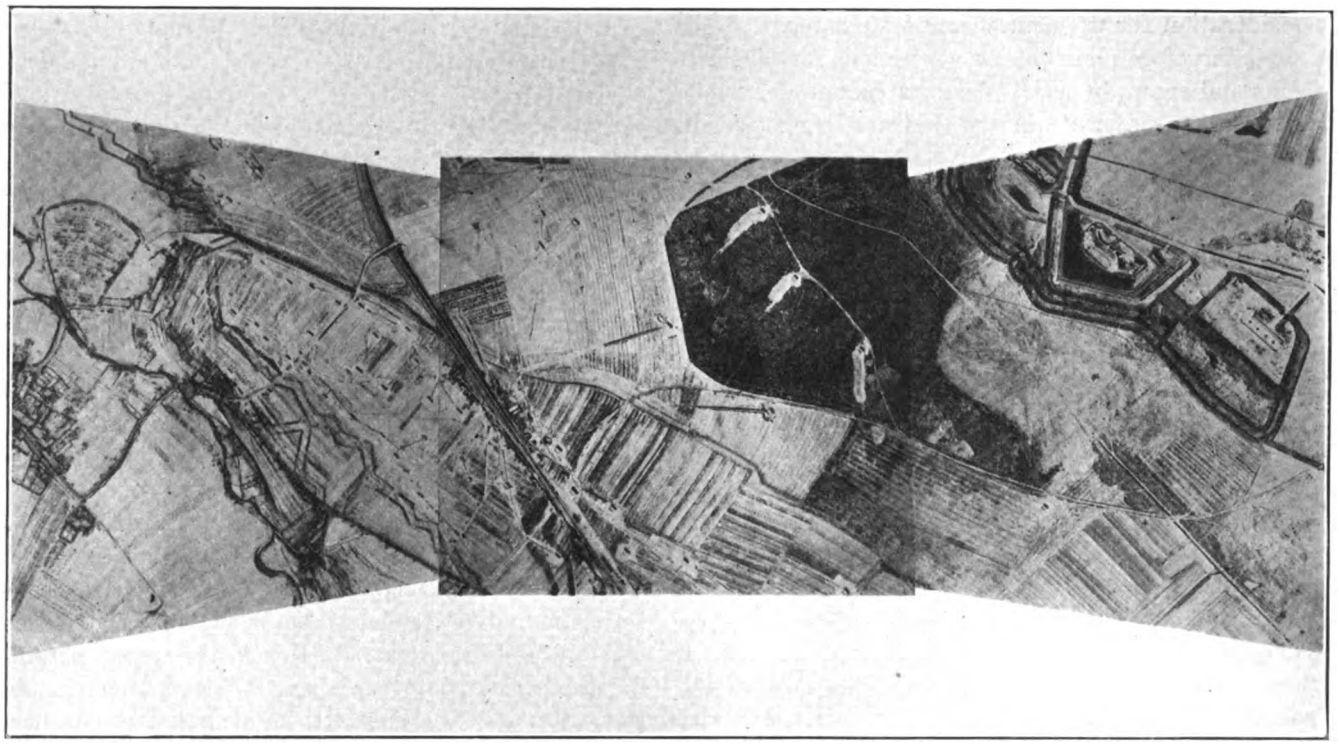
obtain the distance A-B, the error of displacement has been reduced to one-half that of the elevation of 10,000 feet. In order to do this, however, we have had to employ a more powerful and more expensive aeroplane, have had to use more fuel and fly a much longer time, and still the error in the distance A-B may be as great as 700 feet. And this is only one of several possible errors. If we add to this the errors arising from inclination of the camera, unequal changes in dimensions of photographic papers by development, the difficulties of joining the photographs together and the several other errors of lesser magnitude, it will be seen that mosaics are barred from consideration for use as accurate scale maps.

It is therefore plain that as corrections for displacements and errors in aerial photographs must be made, it is not very material whether they are large or small, provided they *can* be made, and the photographs which permit us to make them the more readily, economically and with sufficient accuracy, are the ones that will be of the most value.

The tri-lens camera was designed and constructed for the purpose of making maps as rapidly as possible. It was intended primarily to supply photographs which should be suitable for making aeronautical maps. At the time construction of the camera was commenced there seemed to be an urgent need for aeronautical maps which could not be prepared in full from existing maps, because the majority of the latter did not show woodlands, cultivated fields and other features needed to prepare maps to conform to those which our aviators would have to use in France. There was great need to have such maps as soon as they could be produced. In deciding to make a tri-lens camera to meet the above-mentioned need there were other possible uses which it was believed could be made of this instrument, if used in conjunction with a suitable transformer. There are still thousands of square miles of our coastal plains, of slight relief, which are covered only by general maps of scant detail. There are large areas of swamp lands which will have to be mapped before we can satisfactorily undertake to drain and develop them. There are many miles of our outlying coast lines about which we need accurate information, and there are vast areas of our frontiers, such as the valleys and plains of Alaska, of small relief, which probably would remain for a century almost as little known as at present, unless a more rapid and economical method of mapping them than those in general use can be devised. These were some of the reasons why it seemed that the tri-lens camera was needed. Moreover, to the topographer, experienced in the work of making maps from the ground, the question was: To what extent can aerial photographs be used in this work, what improvement will they bring about and how much will their use reduce the cost of making topographic maps? These were the important matters on which we should be informed.

In general there are three elemental steps in making topographic maps; namely,

(1) Establishing the initial control (geodetic positions and elevations);
(2) Locating the positions of all features to be shown on the map;
(3) Finding elevations to draw the contours.



The prospects were good that aerial photographs could be used to supply the second of these three requirements and that they would materially aid in improving the work of the third step, by making possible a better representation of the relief. No aid could be expected from them in the work of the first step, but on the contrary, it seemed probable that a greater amount of control would be necessary before the photographs could be made to take the place of the ground work in the second step. It was believed, however, that the aid given in the construction of contours would balance the increase necessary in control. The net result to be expected was that of supplying the locations of the great number of features to be shown on the maps, and in this would come the decided advantage of obtaining all, or a very high percentage, of the topographical features, whatever their character might be. In the matter of cost, which after all must necessarily be the deciding factor, there did not seem to be the possibility of the great reduction a first consideration might suggest. It was plain, therefore, that advantage must be taken of every means which would lead to a reduction in the cost of obtaining the aerial photographs and of using them in the preparation of the map. It seemed that a considerable reduction in cost could be obtained only by increasing the scope of the aerial cameras employed. The corollaries of an increased camera scope are:

(1) Reduction in cost of obtaining the photographs;
(2) Greater facility in using the photographs for mapping;
(3) Reduction in amount of initial ground control necessary as compared with the amount necessary for photographs of less scope.

The photographs of the tri-lens camera could not be advantageously employed in mapping unless a suitable transformer could be devised to project the side (inclined) photographs into the plane of the central one to give an assembled photograph, made up of the three parts, which would be equivalent to a photograph obtained with a wide-angle single-lens camera. Mr. F. H. Moffit of the U. S. Geological Survey made a careful study of photographic projections and satisfied himself of the possibility and accuracy of making transformations from negatives through considerable angles. Having proved the mathematical principles of this possibility of optics, he set about designing

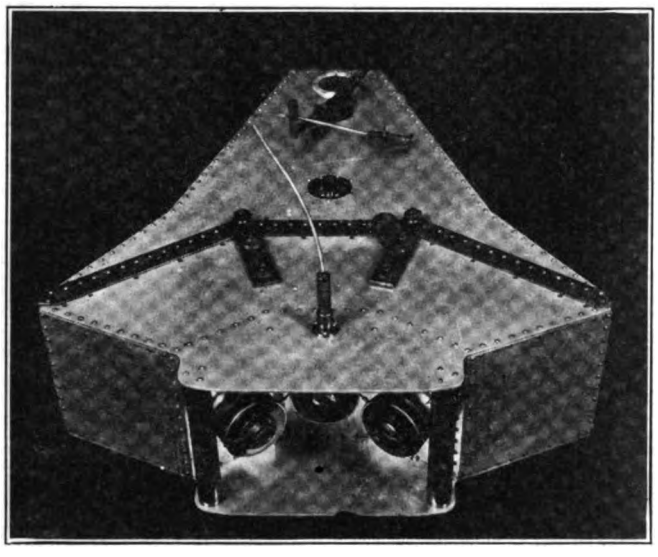
Digitized by Google

and superintending the construction of a transformer to supplement the tri-lens camera. He produced an instrument of great precision which makes it possible to project the inclined photographs of the tri-lens camera into the plane of the center photograph, and when the necessary control is available, to transform inclined photographs to the horizontal plane. Such horizontalized photographs can be readily used to eliminate from the positions of points on maps (not the photographs themselves) displacements caused by relief. The degree of accuracy possible with the transformer is limited only by the character of the lenses employed, those in the aerial camera and that in the transformer.

Transformed tri-lens photograph—Hindenburg line and outer forts of Metz

Note.—A portion of the oblique views has been cut off to limit the width of the illustration

The photographs obtained with the tri-lens camera have been found suitable for use in making maps of country of low relief (200 feet or less) on scales as large as 1:20,000, especially for those of the 1:62,500 scale (employed by the Geological Survey) and for revising maps whatever the amount of relief. Several thousand square miles of country in several states have already been photographed with tri-lens cameras. The rate at which this work was done indicates that by following a systematic procedure each camera will yield from 50 to 100 square miles of country covered per hour of photography. Each exposure will embrace from 3 to 9 square miles, depending on the elevation of the flight. Costs of mapping with the tri-lens camera have not been sufficiently well determined for the purpose of making estimates for future work, but it appears that in making standard 1:62,500 scale maps the reduction in costs below those by ground methods can not be great unless individual photographs are made to embrace large areas, the aerial photographic work done as systematically and economically as possible, and comparatively large areas (1,000 square miles or more) are undertaken as units.



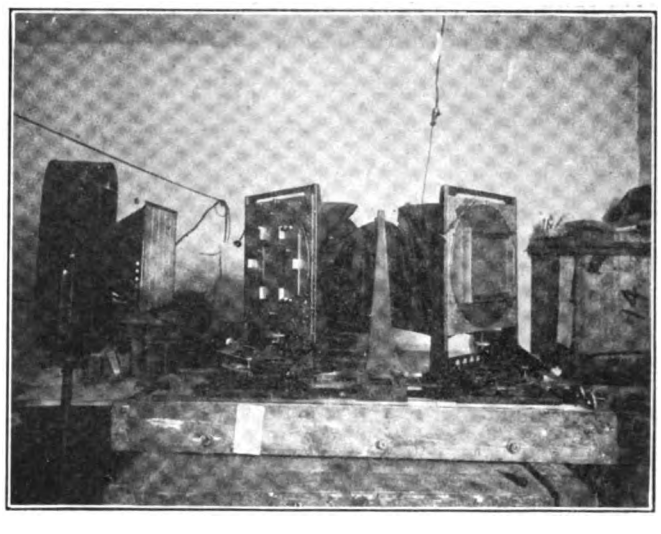
By contrast there is a greater chance to reduce costs of mapping on larger scales, because the cost of these made by ground methods is very much greater than the cost of smaller scale maps. A topographic map of a given area at the scale 1:20,000 costs several times more than a topographic map at a scale 1:62,500. Work at the larger scale requires not only more control and greater accuracy in the location of details, but many more such details must be located and a larger sheet has to be drafted, reproduced and printed. On account of this condition it is to be expected that single lens aerial camera photographs will not only have place in mapping at large scales to bring about reduction in costs, but they will supply the greater amount of details required in maps of this class more satisfactorily than will photographs of the tri-lens cameras.

Before aerial photographs can be largely useful in making topographic maps they must in themselves supply the means of readily establishing secondary control nets over comparatively large meshes of primary control nets—meshes 10 to 20 miles across, such

Digitized by Google

as are customarily laid out for standard topographic maps. A measure of this requirement in accuracy is the width of lines drawn on the map. An ordinary line is about one-tenth of a millimeter wide. Its width will represent 1 meter on a 1 : 10,000 scale map and 6 meters on a 1 : 62,500 scale map.

In order to be clear it is well to treat these two cases separately. Because of the possibility of obtaining in the near future means to hold the inclination of the camera to within 1 degree of the vertical, the assumption in both cases will be of photographs inclined from the vertical no more than 1 degree. Furthermore, it is essential in both cases that we avoid the use of photographic papers which change dimensions unequally with considerable difference in differing directions in the process of development, and that we avoid derangements of the perspective properties of the original negatives liable to arise from long exposure. (It is believed that many focal plane shutters are not suitable for aerial photographic mapping.)



Bagley tri-lens camera

Let us examine first the requirements of aerial photographs to be used for 1 : 10,000 scale maps. We will consider them as having been taken with single lens cameras, and that each one embraces an area 1½ miles wide. Radial lines drawn from the center to the limits of the photographs will represent a map distance of about ¾ of a mile. We can allow an error of 1 in 1200 (about 4 minutes of arc) in the direction of these radial lines and keep within the 1 meter line width mentioned above. It can be shown (the demonstration is too lengthy to be given here) that if the inclination of the photographs is no greater than 1 degree and the relief between successive photographs is not more than 250 feet, the map errors can be kept within the 1 in 1200 limit, provided for control purposes we make use only of points falling within a few millimeters of the center or lying well out towards the borders of the photographs. For the purpose of control it is necessary to avoid the use of points affected by relief which lie in the zone 2°-15° from the centers of photographs, for they are liable to give angular errors to radial lines too large to allow.

In the second case, namely, the requirements of aerial photographs to be used in making 1 : 62,500 scale maps, tri-lens camera photographs embracing a width of 5 miles will be considered. Here we can allow an error of 1 in 600 and keep within the 6-meter line width. As in the case given above, it can be shown that if the inclination of the photograph is no greater than 1 degree and the relief between successive photographs is not more than 500 feet the map errors can be kept within the 1 in 600 limit, provided, as in the case above, for control purposes, use of points lying in the zone 2°-15° and affected by relief, be avoided.

Mention should be made of the greater limitation on the use of tri-lens cameras as compared to single lens cameras because of atmospheric haze. This has been found troublesome for the tri-lens camera during certain seasons, particularly in seaboard regions, and it has made it necessary to take the photographs at somewhat lower levels than would have been the case with better atmospheric conditions. In the plains regions, as in parts of Texas, much less difficulty has been experienced from this cause. When it is understood that the scope of the tri-lens cameras is about three times that of single lens cameras, it will be seen that the advantage, in spite of flights at lower levels, remains with the tri-lens camera.

Moffit photo transformer

Another phase of the problem of using aerial photographs for mapping demands consideration. We are apt to be always limited to the uses indicated above unless a more accurate determination of the amount of inclination of the photographs can be

Digitized by Google

made. To do this greatly complicates the task, for it does not seem probable that aerial photographs can be brought accurately to horizontal positions except by working from an accurate and elaborate net of control points on the ground. The practical solution of de-

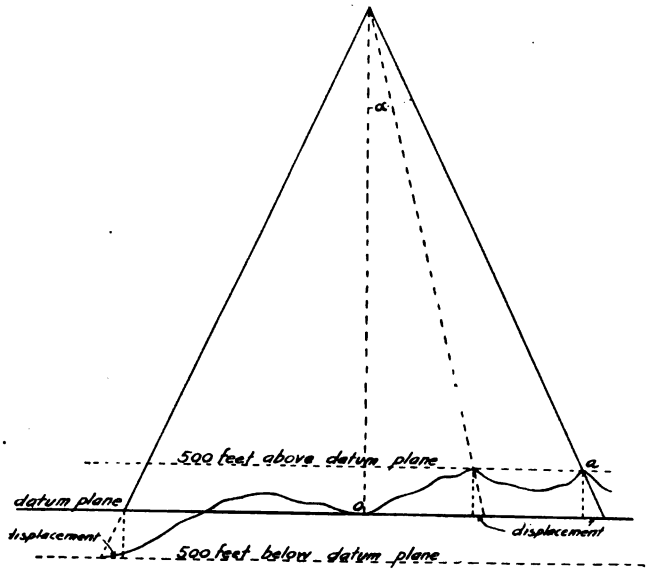


Fig. 1

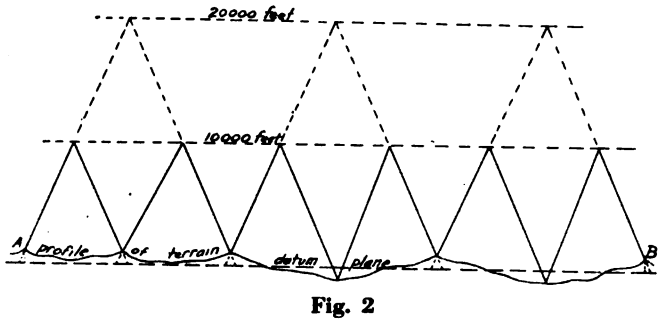

Fig. 2

termining the amount of inclination of aerial photographs with the necessary refinement, promises to give the tremendous advantage of using them to determine elevations as well as positions, and hence to make it possible to accurately draw contours on maps. Every effort should be made to work this possibility out to a practical conclusion. It is believed that the tri-lens camera may possess the essentials required for this undertaking.

Discussion

J. H. Wheat; U. S. Geological Survey

Major, Engineer Reserve Corps

Major Bagley has emphasized many important points relative to the co-ordination of air photos and topographic mapping in his extremely interesting article on the "Tri-lens Camera in Aerial Photography and Photographic Mapping."

The real value of air photos in mapping has been somewhat lessened in the opinion of many engineers, I am sure, through articles by writers, who, knowing little of the technique of the subject, have made the most extraordinary claims for the use of these photographs.

The matter of the limitations of the aerial photograph in topographic mapping is very important to consider, and Major Bagley has well brought out this phase of the subject.

Aerial photography appears to have aroused many writers to flights of fancy. A few months ago a certain mining journal published a bit of interesting news about air photos and maps. It may be stated briefly that the writer of this article claimed that in an area 10 miles square, of practically inaccessible country for men and domestic animals, five men equipped with every device known to science might explore and make a rough map of it in two years at an approximate cost of $60,000, and this for preliminary work only (?), but the airplane in one day would cover it thoroughly in a prospective flight and in three weeks' time the entire 100 square miles would be completed in mosaic maps and detailed engineers' maps (?) at a cost of $3,000. Granted the mosaic photograph; but what are the data for the engineers' map? Further on, he states "It is merely necessary for an airplane to fly swiftly over an area, and, with a camera attachment, make a record so perfect that it could not be duplicated by land survey"; and then from the photographs taken the mosaic is made and from the mosaic the completed engineers' map. Very simple, isn't it?

Perhaps this was written by one of those to whom Major Bagley refers: "That they have not stopped to inform themselves sufficiently." Let us hope so.

In reference to the tri-lens camera, I have experienced considerable difficulty in interpreting features photographed. The lack of definition after transformation is objectionable; also the oblique view of objects in relief remains the same after the inclined photograph has been reduced to the plane; the elevation of buildings and not the ground plan is shown, and the width of city streets between building lines is screened by the tall structures.

The particular field of work for this camera, therefore, appears to be marsh areas of our coast lines and open country with little relief.

The tri-lens camera has a distinct advantage over one which takes a single vertical photograph in-so-far as width of area is concerned, but the technical requirements for transforming the photographs is a factor to be considered. A map draftsman can be taught in a short time to restitute the vertical photograph graphically. It is tedious in many cases, but the only tools required are pencil and ruler. Each print requires four control points for this method, and here again the limitations of the use of air photos for mapping are shown by the amount of control required for adjustment to map form, but this does not destroy their undoubted value for use in giving all necessary detail on mapping projects.

It is hoped that more information on aerial photographs for mapping may soon be given us, especially on results of tests of various cameras and equipment worked out recently at Dayton, Ohio. Practical work was done by photographic flights carried over this part of the country for comparison with the U. S. Geological maps, and the report of the undertaking will undoubtedly prove to be of great interest to engineers.

W. E. Parker

Chief, Division of Hydrography and Topography, U. S. Coast and Geodetic Survey (formerly Captain, Engineers)

Due, undoubtedly, to the remarkable results that have been accomplished during the war, through aerial photography many persons, including some engineers, seem to have the idea that, by means of such photographs, topographic maps, suitable for all purposes, can be constructed with little if any ground control; that, in fact, a royal road

Digitized by Google

to rapid mapping at small cost has been discovered. Even among those who frequently use maps and should have better knowledge of their fundamental requirements there appears to be a belief that a mosaic of carefully matched photographs is not appreciably inaccurate as to scale.

Such articles as Major Bagley's will, I believe, do much toward correcting erroneous ideas of the present possibilities of aerial photo-topography. His clear statements of what we can and what we can not do now with such photographs, together with his conservative estimate of what we may expect from aerial photographs in the near future, deserve wide publicity.

One phase of the subject has, I believe, received less consideration than it merits. I refer to what seems to me the great possibilities offered by aerial photography for correcting and bringing up-to-date old maps and charts. The forces of nature and the activities of man are continually causing changes on the face of the earth and particularly along the banks of streams and the shores of tidal waters. To keep maps and charts corrected for such changes, it is necessary to make careful examinations and revision surveys, from time to time, unless some more expeditious method is available. From such information as we now have it appears that we can resort to aerial photography to get a record of such changes and either dispense entirely with ground surveys or at most limit the ground work to providing control for the photographs. As such changes are usually local and of small extent, unless covering a considerable period of years, it seems probable that there will be enough unaltered, recognizable features to fully control the photographs, but, if not, they probably would be of great assistance in quickly laying out the most economical control and would supply much, if not all data necessary to fill in the topography after the control had been established.

Mechanical Equipment as a Method of Curtailing the Increased Labor Costs of Handling Freight*

By

G. F. Nicholson

Chief Engineer, Port of Seattle

IN the September issue of *Freight Handling and Terminal Engineering,* Mr. James A. Shepard, Vice-President and Chief Engineer, of the Shepard Electric Crane and Hoist Company, in his article on "Modern Marine Terminals" made the following assertion, "With our present extreme costs for every kind of labor, and with no prospect for the future, except a more acute stage of the difficulty, but one resource remains: We must requisition at once every mechanical expedient which will enable us to apply our high priced labor more scientifically and thus produce for each dollar expended as much or more than was produced under pre-war conditions."

A terminal may have splendid, modern up-to-date buildings, properly located, but unless it offers all the mechanical appliances and facilities of the up-to-date port, it has failed then in the most essential point in terminal construction.

A survey of the leading ports in the United States would show very little progress in the matter of providing mechanical handling equipment for marine terminals.

It is true that some of the Great Lake ports are well equipped with mechanical equipment on their docks for the handling of such commodities as coal and ore, but the latter are bulk commodities handled in cargo lots and do not present the difficulties that we have with miscellaneous freight.

The most essential requirements of modern handling appliances are as follows:—

1. The location of the terminal warehouses used for long term storage to be as close as possible to the transit shed. Only two or three railroad tracks, serving these facilities, should separate the shed and warehouse instead of placing the latter across a wide, busy street, as has been done in so many of our ports.

2. The construction of transit sheds of timber instead of structural steel and concrete. It is the writer's opinion that there is a tendency at the present time to slight the advantages of timber construction for wharves and sheds and to overestimate those of reinforced concrete. Most probably, new mechanical devices will be introduced in the future that will require a radical change in shed construction. Timber sheds can be altered or even rebuilt at a reasonable expense, while the cost of wrecking and rebuilding the permanent sheds would be almost prohibitive.

There has been a great deal said about the vast amount of mechanical handling equipment of ports in the European countries.

Mr. Carleton Greene, in discussing cargo handling machinery, in his book on "Wharves and Piers" gives several good reasons why the European Ports have supplied numerous cranes in connection with their terminal facilities.

1. When ships arrive at home ports in Europe it has been the custom to discharge the crews and draw the fires, while at our ports crews are retained and the boilers, winches, etc., are available to work cargo.
2. The tidal variation in some of the European ports is so great that the ships' tackle cannot be used to advantage when the tide is low.
3. The cranes are supplied by the municipality which not only owns the dock but has large appropriations for such purposes while the steamship company would not in many instances install them at their own expense.
4. In nearly all European ports they use the deep-hulled barges which have no cargo gear at all, and most of the steamships are more or less deficient in the equipment of booms and winches, so that revolving cranes have a greater range of usefulness in Europe than any other form of cargo handling machinery.

It is very interesting to note that many vessels which handle cargo in European ports use the ship's gear, although the wharf is supplied with numerous cranes. Before the war the Hamburg-American Line, which had almost unlimited capital, rebuilt its piers at Hoboken, New

*Digest of a paper read before the Pacific Coast Port Authorities Annual Convention, San Diego, Cal., Dec., 1919.

Digitized by Google

York harbor, and equipped them with the New York pattern of cargo masts, when piers of the same company in Germany were equipped with over one hundred revolving cranes.

The general practice along the Atlantic Coast and in some of the pier installations on the Pacific Coast is to provide what is known as cargo masts along the sides of the pier, which are nothing more than a structural steel or wooden frame high above the roof of the shed, to which may be attached pulleys or blocks over each door opening practically at any point alongside of the pier. This is an exceedingly simple and effective method of handling freight. It is very positive in its action, and there is no swinging of booms to be carefully gauged, and although it does not serve so large an area as the revolving type of crane, its load does not have to follow as long a path. A few years ago Mr. B. F. Cresson, Jr., now Chief Engineer of the New York and New Jersey Port and Harbor Development Commission, and Mr. Charles W. Staniford, at that time Chief Engineer of the Department of Docks and Ferries, New York City, made a thorough investigation of mechanical equipment in the New York harbor and submitted a report regarding this matter to Mr. Calvin Tompkins, who was then Commissioner of Docks. Messrs. Cresson and Staniford, after an exhaustive study, stated in their conclusions that the great movable derricks or cranes installed along the docks and quays in Europe were not adapted to economical handling of American package freight under the present system of pier construction in New York harbor, and recommended a continued use of the cargo masts.

The most efficient method of handling different classes of freight at terminals are those that will relieve congestion, receive and deliver freight in the shortest time, pile it in the most compact and efficient manner, and reduce the damage claims and high cost of handling. A machine is yet to be built that will accomplish all of these things. There has been a great deal of criticism of the two-wheel hand truck, but as a matter of fact, the two-wheel truck with plenty of muscle between the handles is a mighty good all around tool. It is a crow bar, battering ram and truck all in one. It is used to good advantage for getting into small corners and in connection with piling equipment, on short hauls, especially, when there is a great deal of sorting to do. On the longer hauls the electric tractor, industrial load carry truck and trailers, which work together, go a long ways toward solving the problem of freight handling.

The stationary electric freight elevator is indispensable in the warehouse and two-story transit shed.

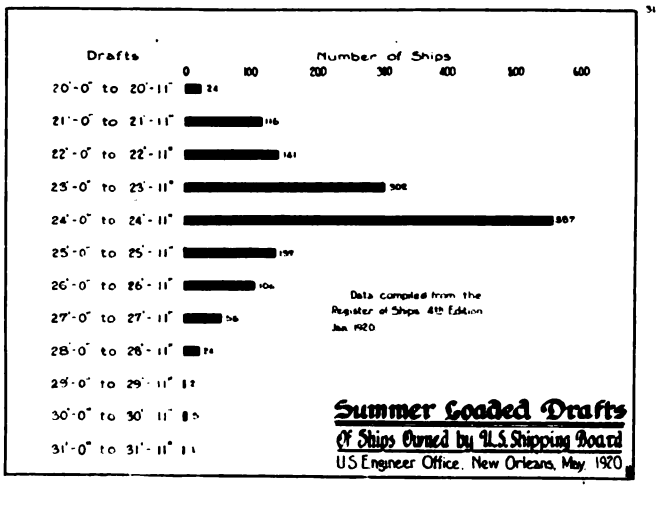
Light portable electric stacking elevators and inclined power conveyors are very necessary in connection with the two and four-wheel trucks in the piling of freight inside the shed and warehouse. Also ship conveyors for the loading and unloading of ships are most essential. For the accommodation of the second floor of the two-story transit sheds, the outside portable platform, similar to those that have been installed by the Port of Seattle, are very important. With this equipment, it is possible to land the freight from the ship's hold with the ship's tackle to the second floor level on these platforms with as much ease as it could be unloaded on the first floor wharf.

The installation of loading out chutes, running from the second floor level to the cars on depressed tracks or outside platform surface tracks, and also to the ship's hold on the water side, is important. With these inclined gravity chutes it is possible to load out goods from the second floor into cars very cheaply, and in actual practice it has been demonstrated that some sacked freight, for shipment by rail, can be loaded into cars more economically by use of gravity chutes from the second floor than it could have been trucked into cars from the first floor.

Whip hoisting machinery similar to that used at the Bush Terminals in New York is very efficient, and new warehouse designs should contemplate the use of whip hoists, and even warehouses that have been built can be equipped with these hoists very cheaply. This equipment consists of an "A" frame located on the roof of warehouse placed directly above a line of high doors in the side wall of warehouse, to which is attached a block for the accommodation of the hoisting cable.

It can safely be stated that the locomotive crane is a most necessary piece of equipment in connection with the open wharf.

A piece of heavy handling equipment is most essential on one or more of the terminals in a harbor for the handling of extremely heavy lifts. This type of crane should be the heavy handling stationary revolving type of crane.



Modern coal handling equipment for the Pacific Coast harbors is very essential in order to give good service to the steamship companies.

The Port of Seattle Commission has, up to date, installed on their terminal facilities, mechanical equipment valued at approximately $950,000.

Summing up the requirements for the handling of freight in the different port cities along the western coast, the following mechanical handling equipment divided into two classes, heavy and light, should be considered, as they are all suitable for the freight that is handled to and from water carriers, wharves and railroad cars in the Pacific Coast ports.

I. Heavy Equipment.
1. Locomotive cranes.
2. Stationary heavy capacity revolving cranes.
3. Floating heavy capacity revolving cranes.
4. Portable gantry bridge cranes.
5. Electric magnets.

II. Light Equipment.
1. Portable electric stacking elevators.
2. Electric tractors and trailers.
3. Inclined power conveyors.
4. Ship conveyor elevators.
5. Stationary electric elevators.
6. Whip-hoist machinery for warehouse.
7. Portable gravity roll conveyors.
8. Inclined gravity chutes.
9. Portable second-floor platforms.
10. Coal conveyors for coaling ships.

CURRENT NEWS

NOTE.—This department will include news items of professional or personal interest concerning individuals and organizations in the Army, National Guard, Reserve Corps, Reserve Officers' Training Corps, the Service Schools, the U. S. Engineer Department, other departments or bureaus of the Government, and other related activities, both civil and military.

In the PROFESSIONAL NOTES section will appear news items, short articles and digests on matters relating to current developments in engineering and allied sciences and the art of war—of special interest to the military engineer.

Contributions to these columns, whether from original sources or from other periodicals, are solicited from all our readers. Such contributions should be submitted in time to reach our office not later than the 15th of the month preceding each issue of THE MILITARY ENGINEER.

U. S. Engineer Department

FIRST NEW YORK DISTRICT

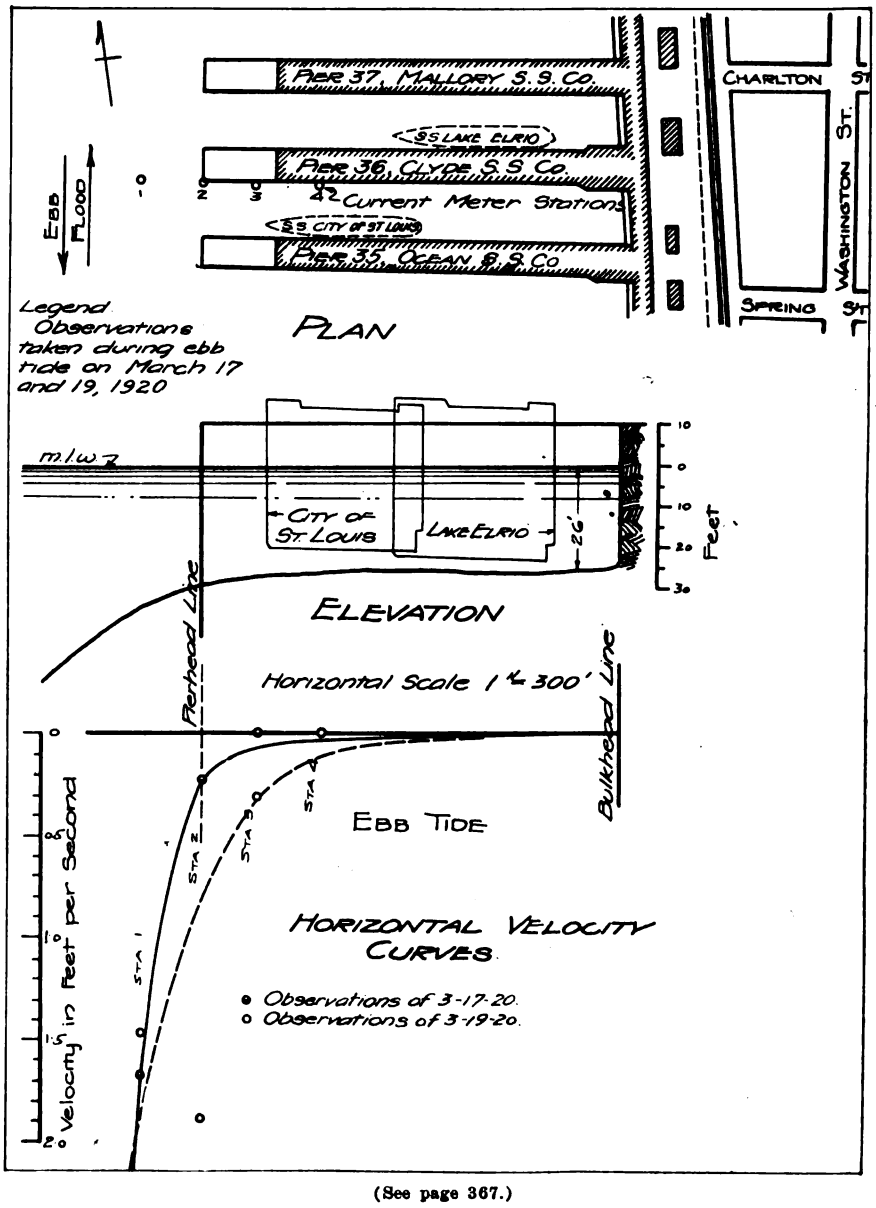
Col. EDW. BURR

Observations on tidal flow through open-pile piers.—Current meter observations have been made by this district to determine the effect of the substructure of open-pile piers and of the hulls of ocean liners lying in their berths on the velocity of tidal flow within the pierhead lines, with results shown on the accompanying diagrams. Observations were taken during both flood and ebb tide, at the surface and at intervals of depth of 10 feet. The readings were very irregular, and the velocities shown at each station are the mean of all observed. To accomplish this, the mean ordinate of the velocity-time curve for each depth at each stage was computed. The mean tide level for the period of observations at each station was then found, and the mean velocities, as determined above, were plotted at their proper depths, and a mean vertical velocity curve for the stage obtained. The mean velocity was then determined by taking the mean velocity at .2 and .8 of the depth from the mean vertical velocity curve.

At stations distant several hundred feet from the pierhead line, no revolutions of the meter were obtained, but the rating curves for these meters show that a velocity of at least 0.2 foot per second is required to overcome the friction of the meter and cause it to register.

The depth of water between piers 54 and 56, and piers 56 and 57 is 40 feet throughout; between piers 35 and 36, 24 feet; and between piers 36 and 37, 26 feet.

The principal dimensions of the vessels noted in the diagrams are as follows (in feet):



Steamship	Length	Breadth	Loaded draft
Mauretania ___	762	88	36
Ascania ______	466	56	27
Rochambeau __	559	64	27
Lake Elrio ____	392	48	24
City of St. Louis	372	50	21

Piers 54, 56 and 57 are commonly known as the Chelsea Piers. Conditions at these piers are somewhat abnormal since the tidal flow is blocked on either side by solid structures. The strongest tidal currents, moreover, occur on the opposite side of the river.

At Piers 35, 36, and 37, there are no abnormal obstructions between the bulkhead and the pierhead lines for a considerable distance upstream and downstream, and a relatively strong tide current runs just off their outer end.

The observations show that the substructure of open-pile piers and the hulls of vessels lying alongside them have a very marked effect on the tidal flow. Through a continuous series of piers, built and spaced as in New York Harbor, there is practically no tidal flow except at the outer fifth of the length of the pier. The observations are not sufficiently extensive to afford comprehensive data on the effect of different kinds of piers and of the obstruction caused by the vessels, but a comparison of the diagrams will show that the substructure alone has a large retarding effect.

The observations were taken by Mr. W. B. Whitney, Jr., Chief of Party, under the direction of Mr. W. L. Kuehnle, Assistant Engineer. The information contained in this article is abstracted from a report made by Junior Engineer Floyd C. Bedell to the District Engineer.

(See page 367.)

PHILADELPHIA DISTRICT

Lt. Col. W. B. LADUE

Contract was let on April 29, to the American Dredging Company for dredging to 35 feet in the main channel of the Delaware River through the lower part of Philadelphia Harbor. The work will begin opposite the foot of Jackson St. and extend upstream as far as available funds will permit. About $400,000 is available for payments. This sum should be sufficient to extend the work to about the foot of Washington Avenue. Work will be started immedately.

The bucket-ladder dredge *Corozal*, purchased from the Panama Canal, is being overhauled. Dump scows and other plant necessary to the operation of this dredge will be assembled during the coming season, and it is expected that the *Corozal* will be placed in operation on maintenance work during 1921. During 1920 it is proposed to rent her to private parties for work under certain contracts in the Delaware River.

Maintenance dredging with the seagoing hopper dredges *Delaware* and *Manhattan* was resumed on the river below Philadelphia during April.

Captain PAUL A. HODGSON, Corps of Engineers, has been relieved from duty as Assistant in this District, and sailed on May 5 from San Francisco for the Philippine Islands for duty with the 3d Engineers.

Mr. H. G. MCCORMICK, Assistant Engineer in charge of battery construction at Fort Saulsbury, Delaware, left the district on May 24 for the Louisville Engineer District. He will have local charge of the construction of a lock and dam on the Ohio below Louisville.

BALTIMORE DISTRICT.

Col. J. P. JERVEY.

Work on dredging the 35-foot channel into Curtis Bay, which was stopped by ice in December, was resumed by the contractor, The Sanford & Brooks Company, March 23d.

Work on the new 35-foot depth channel into Spring Garden, Baltimore Harbor, was started by The Arundel Corporation, March 19th.

Contract for redredging to project depth of 8 feet in Broad Creek River, at Laurel, Del., was awarded to the Sussex Paving Company. Work started in April, 1920.

The Maryland legislature passed a bill authorizing the City of Baltimore to float a loan of $50,000,000 for improvement of the port.

Considerable difficulty is being experienced in getting mechanics and laborers for work on fortification projects.

WILMINGTON (N. C.) DISTRICT.

Maj. J. R. D. MATHESON.

The seagoing hopper dredge *Absecon*, which was rented from the Wilmington, Del., district, left on April 17 for Galveston, after working for several months on Cape Fear Bar with the dredge *Cape Fear*.

A survey of Cape Fear Bar has been authorized with a view to a possible change in the position of the channel and the construction of a jetty to maintain same. The tidal currents at the mouth of the Cape Fear River cause a continual westwardly shifting of sand, which produces a corresponding shifting of the channel. The channel across the bar is now near the western limit, and is in the form of a reverse curve. A new natural channel appears to be forming near the eastern side of the bar, and in prolongation of the channel in the river. This new channel it is proposed to improve. The jetty would assist in maintaining the new channel by preventing the further encroachment of sand from the east.

Bids will be opened on June 28 for the sale of the clamshell dredge *Hercules* and the steam launch *Mercur*, which have become surplus in this district.

JACKSONVILLE DISTRICT.

Lt. Col. W. J. BARDEN.

Under contract with the R. G. Ross Co., extending the north jetty of the St. Johns River about 1,200 feet shoreward, and grading about 2,500 cubic yards of material at the site of the extension, was completed during the past month.

The contract with P. Sanford Ross Co., Inc., for dredging and rock removal at Drummond Creek, part of the improvement of the St. Johns River, Jacksonville to the Ocean, was completed during the past month. This work consisted in completing the channel to a depth of 30 feet and width of 300 feet.

Under contract with the R. G. Ross Co., extending the north jetty of the St. Johns River about 1,200 feet shoreward, and grading about 2,500 cubic yards of material at the site of the extension, was completed during the past month.

Work was started in May on the contract with the Seaboard Dredging Co. for dredging, rock removal, and disposition of material in Sarasota Bay. The work is to partly complete a 7-foot channel, 100 feet wide in waterway connecting Tampa Bay with the town of Sarasota, on Sarasota Bay.

Work under contract with the United Dredging Co. for dredging in Hillsboro Bay was started in May. This will consist of dredging in Tampa and Hillsboro Bay project, channel to be secured having a bottom width of 200 feet and a depth at m. l. w. of 27 feet.

MOBILE DISTRICT.

Maj. R. S. THOMAS.

Removal of water hyacinths.—An allotment of $2,350.00 was made for removing water hyacinth from the tributary streams of Mobile River, near Mobile. The material for this work has been ordered, and operations will begin at once. In the future such work will probably have to be done every year as this plant cannot be exterminated by any known practical means. The present and most efficient method of spraying with a solution of arsenic and soda only kills the heavy top growth, and prevents the hyacinth from obstructing navigation. Its appearance in this locality was first observed about the year 1903, but it has not spread as rapidly as is usually the case, due probably to the fact that these tidal streams are slightly salt during the dry season.

U. S. dredge Wahalak.—The U. S. 20-inch hydraulic pipe-line dredge *Wahalak* while working in Mobile Bay Ship Channel during February removed 882,549 cu. yds. of material, consisting of about 70 per cent mud, 20 per cent sand, and 10 per cent shells. The actual pumping time was 467 hours, and the average amount of material per pumping hour, 1889.8 cu. yds. This was the first full month's operation of the *Wahalak* after installing fuel oil-burning equipment, which has added appreciably to her efficiency and output. Based on yardage removed per pumping hour, the above is the best monthly record made during the past 5½ years by the *Wahalak*, or any other dredge of similar size working at this locality. During August, 1914, the dredge removed 915,763 cu. yds. of material from Mobile Bay Ship Channel, consisting of 90 per cent mud and 10 per cent sand. The material removed per pumping hour was 1,737.7 cu. yds., or 152.1 less than during February, which contained three less working days. During March, 1920, the performance was 807,261 cu. yds. in 475 working hours, or 1,700 cu. yds. per hour.

NEW ORLEANS DISTRICT.

Maj. E. J. DENT.

Intracoastal Waterway.—Specifications have been prepared for widening and deepening the Intracoastal Waterway from the Calcasieu River to Sabine River. The existing section of this canal is about 6 feet deep at mean low gulf and 40 feet wide on the bottom; these dimensions to be increased to 9 and 90 feet, respectively, over such length as available funds ($230,000) will permit.

The Lake Arthur Dredging Company, the contractors for the dredging between Mermentau and Calcasieu Rivers, started one dredge on the eastern end May 17, 1920.

The route of the Intracoastal Waterway between Bayou Terrebonne and Bayou Black has been approved by the department. The Police Jury of Terrebonne Parish are now raising funds for the purchase of the necessary right-of-way. The U. S. dredge *Grossetete* is continuing work on the portion in Bayou Black.

Floating plant.—This district has recently installed oil-burning systems on its two sea-going hopper dredges *New Orleans* and *Benyaurd*, and both plants thoroughly overhauled at the New Orleans Naval Station. The Staples & Pfeifer mechanical system was installed on the *Benyaurd* and the Dahl mechanical system on the *New Orleans*.

The dredges are now laid up, pending request from other districts for their services, as it is planned to stop all dredging on the bars at Southwest Pass until the jetty extensions are completed.

The U. S. tug *Donovan* is being overhauled and a steam steering gear, electric-light plant and oil-burning system (Lockett atomizer) installed. The work was being done at a private yard, but is now being held up by the metal workers' strike.

The tug *Cumberland* has been rented by the Norfolk District to tow the dredge *H. S. Taber* and equipment to that district. Her departure is also being delayed by the metal workers' strike. The tug *Deland*, recently purchased by the Philadelphia office from the Shipping Board, was rented by the Norfolk office and turned over to this office for use during the absence of the *Cumberland*.

This district has recently installed the Higgins atomizer system on the snagboat *Denison*, and at Plaquemine Lock. The dredge *Lake Charles* has the Dahl mechanical system, the U. S. dredge *Delatour* the Higgins system, and the U. S. steamer *Hyacinth* the Papillon atomizer system. It is intended to install oil-burning systems on the *Cumberland* and *Delamar* when annual repairs are made.

Mr. J. L. HORTENSTINE, Assistant Engineer, in charge of the work at the Passes of the Mississippi River, and in the employ of this office for the past 16 years, resigned and has gone into private work. He will be replaced by Mr. Frank D. Cefalu, Asst. Engr., who has been in local charge of the Burrwood substation, Southwest Pass, Mississippi River. Mr. Cefalu will be relieved by Mr. Robert G. Lynn, Junior Engineer, who has been in the main office. Mr. R. P. Rordam, Junior Engineer at Burrwood substation, and in the service of this office for the past 9 years, has resigned to go into private practice.

GALVESTON DISTRICT.

Maj. L. M. ADAMS.

Contract was authorized on April 23, 1920, with Hazell, Connerat and Quist Co. for the repair of three highway swing bridges over the Brazos River—Matagorda Bay Section

Digitized by Google

of the Intracoastal Canal. The work is to cost $11,400, and is to be completed by July 30, 1920.

The 20-inch sea-going hopper dredge *Galveston* returned to Galveston Harbor on May 15, after being employed for 6 weeks removing a shoal between the jetties at Sabine, Texas.

The 20-inch pipe-line dredge *Col. A. M. Miller* is now engaged in dredging the harbor at Beaumont, Tex., enlarging the channel by the removal of a portion of Harbor Island.

Col. SPENCER COSBY and Maj. C. L. HALL have been relieved from duty in this district, and Maj. L. M. Adams assigned as Dist. Engr.

Mr. CHAS. CROTTY, formerly Capt. of Engrs., Supt. of Floating Plant, has resigned to accept a more remunerative position with the Harbor Commisson of Houston, Tex.

Mr. E. T. KIRK, Junior Mechanical and Electrical Engineer, resigned from the service to take up other work.

Mr. F. C. WARNER, assistant engineer of the Wilmington, Delaware District, has been transferred for duty in this district.

Mr. L. P. MORRISON, recently discharged as Captain of Engineers, has been re-employed as junior engineer in this district.

FLORENCE (ALA.) DISTRICT.
Lt. Col. LYTLE BROWN

Progress on the Wilson Dam.—The construction of the Wilson Dam at Muscle Shoals on the Tennessee River has been discribed in previous issues. Preparations for pouring concrete on a large scale are now practically complete. The river is in flood and has reached the highest stage attained during the last two years, flooding out all the coffers. No serious damage is anticipated, and when the flood has subsided the placing of concrete in the dam proper will be started

The dredging fleet for the sand and gravel supply is now here. This consists of the 15-in. suction dredge *Indiana* from the Cincinnati District, the 15-in. suction dredge *Pettus* from the Montgomery District, two towboats, fifteen barges and two launches. The *Pettus* made the trip from Florida by way of the Mississippi, Ohio and Tennessee Rivers, without mishap.

The first two of seven large traveling derricks with 90-foot booms are partly erected. Two mixing plants, containing two 4-yard mixers and two 2-yard mixers, are ready for operation.

The problem of procuring supplies and material is a difficult one, in view of prevailing market and traffic conditions. The cement requirements demand an average shipment of eight cars of cement a day for the next year or two. It is planned to ship this largely in government owned cars, since no adequate guarantee can be secured from the railroads to handle it with their own equipment.

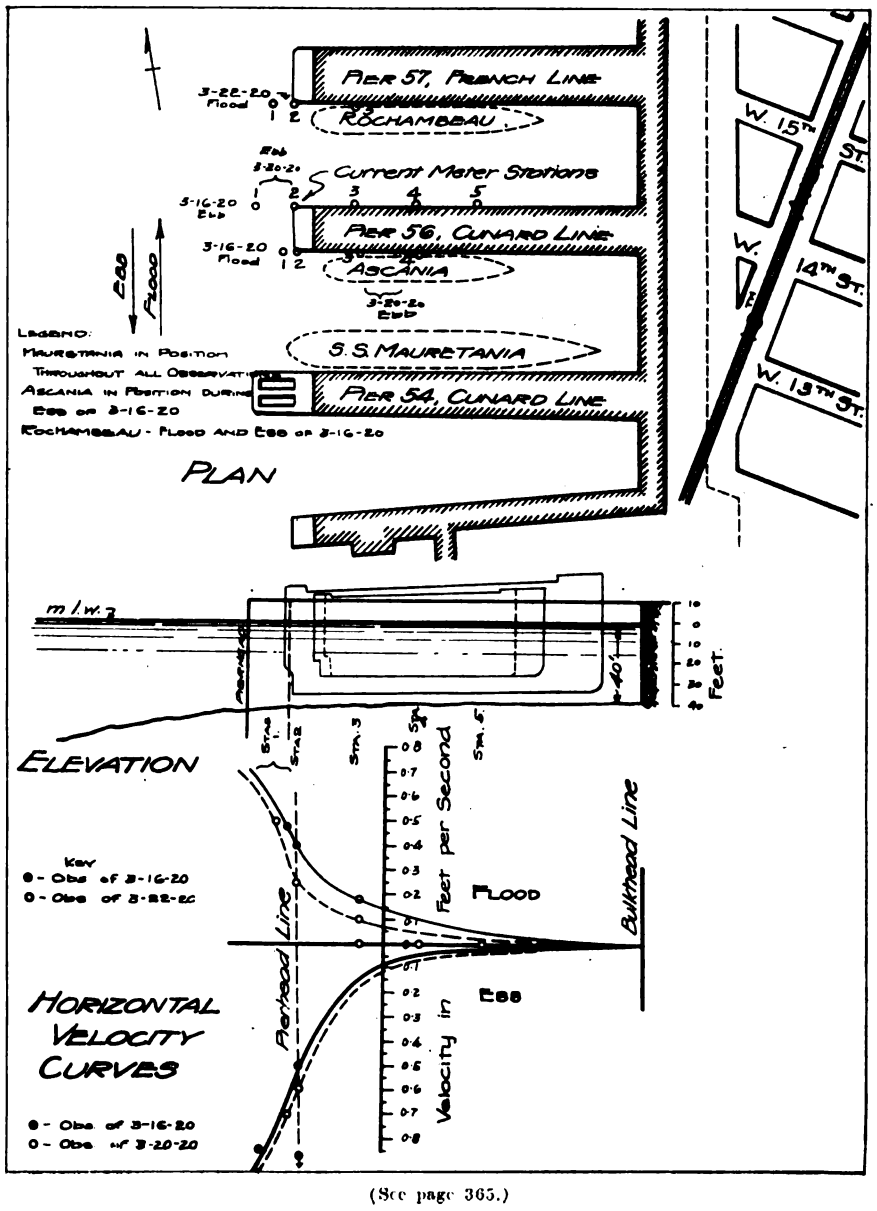
The labor force employed has averaged between three and four thousand men. This force is recruited without serious difficulty from the surrounding cities. A large construction camp has been erected, and conditions as regards messing, housing, and sanitation are excellent.

Widows Bar lock to be built.—The construction of Widows Bar lock on the Tennessee River 6 miles below Bridgeport, Ala., will be begun at once. Sufficient funds are now available only for the construction of the lock. This part of the work includes a cofferdam containing 100,000 feet board measure of timber; earth excavation amounting to 17,600 cubic yards; 2,300 cubic yards of rock excavation; 9,500 cubic yards of fill; and 16,600 cubic yards of concrete. The clear dimensions of the lock will be 60 by 300 feet. The dam will be 1,300 feet long with a lift of 10.2 feet, probably of the timber-crib type.

This lock and dam will provide 6-foot slackwater navigation up to Hales Bar lock, 33 miles below Chattanooga, Tenn. It is the first of a series of five locks and dams proposed to give 6-foot navigation between Hales Bar and the head of the pool of the Muscle Shoals power dam No. 3. All of these five dams have low lifts and no power development is contemplated in connection with them.

PITTSBURGH DISTRICT.
Lt. Col. H. B. FERGUSON.

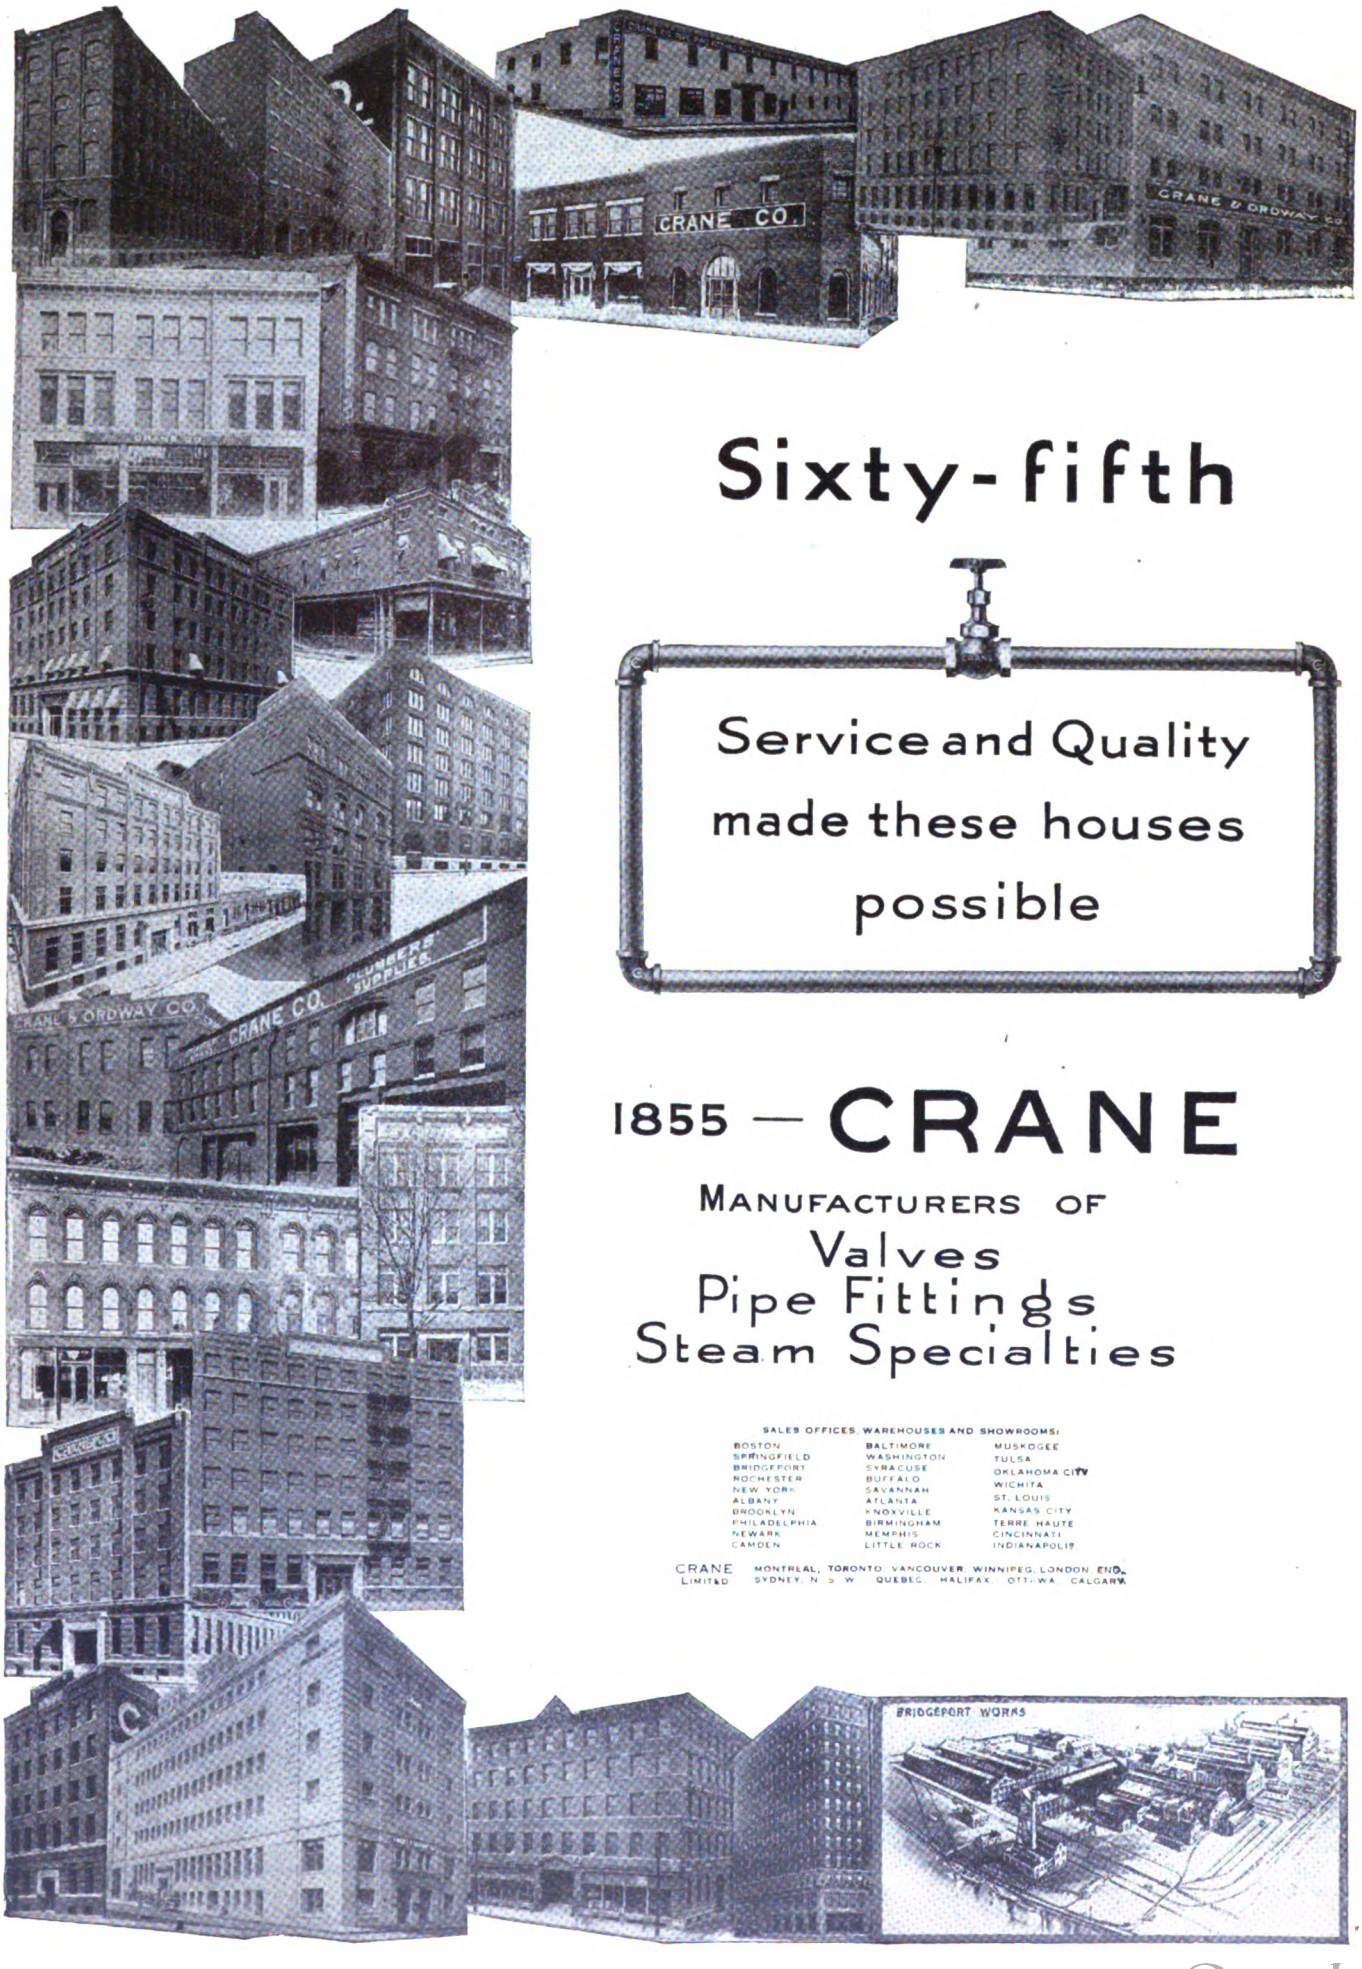
Work of assembling plant, building sidings, camp, shop, etc., for the construction of Lock and Dam No. 4, Allegheny River has been started. This work is being done by hired labor.



Captain W. M. CHUBB, Corps of Engineers, in charge of the operation and construction on the Monongahela River, has resigned to accept a position as engineer with the Winchester Arms Company, New Haven, Conn. A. B. McGrew, Assistant Engineer, has been placed in charge of operation, and E. H. Beechley, Junior Engineer, in charge of construction.

WHEELING DISTRICT.
Lt. Col. C. W. OTWELL.

Steel sheet pile cofers for Ohio River dams.—The first attempt to utilize interlocking steel sheet piles in the construction of an Ohio River dam was made at Dam No. 19 in 1909, and was abandoned, due to restricted working area caused by timber bracing within the inclosure, 39 feet 2 inches by 270 feet, which prevented satisfactory progress. The masonry was 30 feet 10½ inches and the shecting 36 feet long, with top about 16 feet above low water. It was realized early in the attempt that the type of cofferdam then in use was not as economical as that known on the Ohio River as the box type.



Another contractor attempted to use a steel cofferdam at Dam No. 16, Ohio River, during the season of 1914. The inclosures were 47 by 70 feet, and only two successive sections of the work were constructed, when future attempts were abandoned, owing to restricted area in which to work and excessive pumping. The masonry was 35 feet wide, and the length of shecting 35 feet, with the top about 13.5 feet above low water.

A third attempt with steel sheet piling cofferis now successful at Dam No. 23. Enclosures are 42 by 160 feet, built of 30-foot 14-inch Lackawanna steel piling, driven to rock, held in position on the inside of the inclosure by 12 by 12 inch and 14 by 14 inch suitably disposed timber bracing, and on the outside by banking to within 5 or 6 ft. of the top. The top of the shecting is about 16 ft. above

low water, and the masonry is founded on and keyed into a hard gray sandstone. Work is carried on inside the cofferdam until a 12-foot stage is reached, giving a head of 26 feet. The masonry is 35 feet in width, thus leaving ample room for construction forms and conducting water to the battery of three 10-inch centrifugal pumps. A sand-bag ditch 2 feet high and 18 inches wide takes care of all leakage which is usually handled by one 10-inch pump. Three sections of 160 feet each have been completed. The lower course of timber bracing, which is set 2 to 4 ft. above rock, is concreted in place, but all other timbers are removed. The timber bracing is such as to leave clear openings or pockets approximately 13 feet square. The design of foundation calls for a channeled cut 3 by 6 ft. in the rock, which serves as a key to resist sliding. This cut is formed by drilling vertical holes in line close together and broaching the intervening rock between adjacent holes. This method was adopted as the bottom row of timber prevented the use of channeling machine. The work is und r contract with The Dravo Construct on Co. of P ttsburgh, Pa., in immediate charge of J. S. Miller, Supt. The main detail for the conduct of the work were carefully designed in the home office of the contractor, and during construction are rigidly adhered to.

It is too early in the life of this contra t to make any reference to the question of economy of the steel coffer as compared to the usual box-coffer type generally preferred by Ohio River contractors. However, for a working season frequently interrupted by river stages higher than 16 feet the advantages of the steel coffer are unquestionable as judged by the experience at Dam No. 23, compared with others in the district.

The advantages of the steel cofferdam briefly stated are: Enclosure quickly unwatered after each rise; little or no cleaning up to do; no plant to remove and return before and after each rise; less excevation required; less plant, and therefore smaller labor force required; also less of an obstruction to navigation when built in sections successively from one side. The disadvantages, as compared to box cofferdams, are: Slower progress for favorable working season; probable excessive cost of pumping when computed on the basis of entire work, and activities inside the cofferdam always more or less restricted by timber bracing. Both types of coffer are subjected to damage during and after construction, also each should be properly designed and carefully constructed. Therefore, advantages and disadvantages with respect to these features are balanced. However, it is considered pertinent to mention that, owing to shorter period required for building a section of the steel type there is less risk of damage before completion than for an equal length of box cofferdam, an important consideration in river work. G. W. Bebout, Asst. Engr.

LOUISVILLE DISTRICT.
Lt. Col. G. M. HOFFMAN.

The construction of Lock and Dam No. 45, Ohio River, by hired labor will shortly begin, no bids having been received after advertising four times.

The brick powerhouse at Lock and Dam No. 48, Ohio River, will soon be started by hired labor, all bids received having been rejected.

It is expected to finish and put in operation by the end of the season, the new lock at Louisville (No. 41, Ohio River), and also Lock and Dam No. 43, 3 miles below West Point, Ky. Locks and Dams Nos. 44 and 45 will be begun, by hired labor. Lock and Dam No. 48, below Evansville, Ind., is being constructed by contract, but will probably not be finished this season.

Lieut. Col. G. M. HOFFMAN, district engineer, will be relieved prior to August 15, in order to attend the next course at the War College.

Assistant Engineer H. G. MCCORMICK, recently transferred from the Wilmington (Del.) Dist. will take charge of the construction of Lock and Dam No. 45, Ohio River.

DULUTH DISTRICT.
Lt. Col. F. A. POPE.

Duluth-Superior Harbor.—Statistical report of marine commerce for the navigation season of 1919, issued by the district engineer shows receipts and shipments of 42,895,681 short tons, a decrease of 10,850,677 tons under 1918, and an increase of 10,366,380 tons over 1909.

Receipts of coal at head of lakes to May 31, 1920, amounted to 476,806 tons, a decrease of 1,416,506 below the corresponding period of 1919.

The navigation season covered a period of 240 days. Record load during the season 15,355 short tons of iron ore. Steamer arrived in harbor July 5th at 6:15 p. m., and departed at 12:35 a. m. July 6th. In port just 6 hours and 20 minutes.

The Duluth Canal was closed with ice from January 5th to March 19th. Such a condition has obtained heretofore for only short periods of a few days at a time, the current as a rule having kept the canal open. The great field of ice in Lake Superior doubtless had its effect on the current this year. Coast-wise navigation in Lake Superior opened April 16, 1920, and inter-lake navigation April 21.

Work on government harbor improvements began April 28th with dredge *Gaillard* to remove shoals at East Gate Basin. This work was practically completed June 15. This dredge goes to Keweenaw Waterway, Michigan, to widen the lower harbor of refuge.

The Duluth-Superior Dredging Co. began work on the Superior Harbor Basin the latter part of April. During the month of May, a total of 161,857 cubic yards of sand and soft material were removed. This company now has two large dipper dredges and one hydraulic pump on this work in order to hasten its completion on account of labor conditions. The 2,083,000 yards in this contract should be removed by the middle of July and the contract completed. No further contract work will be let this season.

The Annual Report of the Duluth City Harbor Master lays great stress upon the necessity for a breakwater in Lake Superior to protect the Duluth Harbor entrance.

Contract dredging in Superior Harbor Basin and dredging with government plant at East Gate Basin was resumed about the middle of April.

Keewenaw Waterway (Mich.).—Bids invited recently for stone work shows a great lack of contractors on this class of work and it may be the general industrial condition which precludes their bidding at the present time. The U. S. plant is therefore doing its utmost to keep the works in fair condition.

The Legal Department of the United States is about to begin condemnation proceedings to secure the land necessary for the cut through Princess Point to straighten the channel at that place which is very much desired by vessel interests.

Rainy Lake, Minn.—It is understood the Lighthouse Department expects to place a number of large arc lights at certain points throughout the lake to eliminate dangers which beset operators of small boats in the narrows separating the numerous lake islands.

GENERAL NEWS OF THE DISTRICT.

A very successful dinner and reunion of the Engineer Officers from the Lake Superior District who participated in the World War, was held at the Kitchi Gammi Club, Duluth, Saturday evening, June 12th. At this meeting a local branch of the Society of Military Engineers was formed. The idea of forming such an association was enthusiastically received by all present and by many others who were unable to attend.

The receipts of coal in the early part of June show considerable increase which would indicate the arrival of cars at the mines which was given as the principal reason for the shortage in shipments. The Oliver Mining Company has been shipping coal all rail from the mines in Illinois through to the iron mines on the Minnesota ranges, something which has never happened heretofore. This was made necessary in order to keep their iron mines in operation, even though with great expense.

The 1920 budget for industrial building in this district is about $12,000,000.

Nine millions will be expended by the Minnesota Steel Co. in the enlargement of its plant.

On the 3rd, 4th, and 5th of June, the International Joint Commission held meetings at Duluth; on the 7th at Superior, Wis., and on the 8th at Ashland, Wis., in connection with the deep-sea route from the head of the lakes, and through the St. Laurence River. Interested perosns testified as to the resources of Minnesota, Wisconsin, and the Northwest generally. The District Engineer at Duluth tendered the Commission the courtesies of his office and showed them about the harbor before their departure.

Carrying charges on iron ore to lower lake ports have been fixed for the season of 1920 at $1.00 per gross ton.

From present indications iron ore shipments from the Lake Superior District will make a record during the 1920 season.

The U. S. Supreme Court handed down a decision March 8, 1920, on the boundary line between the states of Minnesota and Wisconsin along the upper and lower St. Louis Bays and St. Louis River. The Court supported the contention of the State of Minnesota that the boundary was the center line between the shores of the two bays and also the river. As a result of this decision nearly $50,000 in taxes collected by Wisconsin authorities on West Duluth dock property will have to be returned. Interested attorneys claim that the Court's decision apparently reverses the decision in the U. S. Circuit Court of Appeals at St. Louis in 1910, which affirmed that the boundary line was the center of the channel of the St. Louis River and not a line midway between the shores. It was this decision of 1910 that led the Wisconsin authorities to tax the West Duluth docks and finally caused the state boundary controversy.

The Duluth papers have contained articles lately which give evidence that big developments affecting this District are pending in the steel industry as a result of the picking up of large blocks of property suitable for industrial plants by outside parties just opposite the Minnesota Steel Company's plant. These purchases aggregate a thousand acres on the Wisconsin side of the St. Louis River. The report states that a vast amalgamation of the leading independent steel manufacturing interests of the country with a capitalization second only to the U. S. Steel Corporation is among the possibilities. The proposed merger

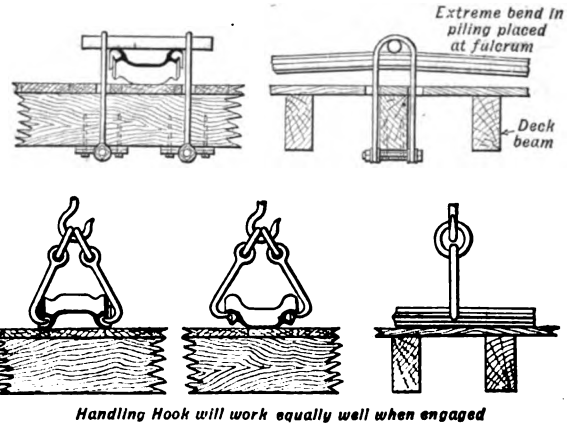
An Economical Method of Straightening Old Sections of

Lackawanna Steel Sheet Piling

DOUBLE-LOCK LACKAWANNA INTERLOCK



A balanced section with similar interlocks on each edge, permitting accurate and economical straightening for reuse.

Due to its uniform section a bar of used and bent Lackawanna Steel Sheet Piling can be straightened without fear of any twisting effect.

A simple method of straightening that was very successfully applied to bent steel sheet piling from the cofferdam for raising the U. S. S. Maine at Havana Harbor in 1911, and one which experience has proven preferable, is illustrated. A level floor, such as the deck of a scow, or the ties of a railroad track, is selected, and at a point about under the center of movement of a derrick boom, two links are securely fastened. Through these a pipe is inserted to act as a fulcrum against which the sheet piling section is set with point of extreme bend under the fulcrum, against which the sheet piling section is set. The weight of a few men will in extreme cases bend the section so that it will go under. The piling section is then raised by taking hold of one end and the upward lift and pull continued until the piling section is bent slightly past straight to allow for springing back. A badly bent piling section can be straightened in a very short time by repeating this operation, each time putting the point of extreme bend under the fulcrum.

Decidedly short kinks, especially near the end of the sheet piling section, are more economically removed by heating or cutting off.

Handling Hook will work equally well when engaged with thumbs and fingers of pile section.

We Also Offer for Better Construction

Elcannes

Concrete Reinforcing Bars

The Elcannes Bar combines maximum bonding surface, minimum weight, and uniform strength. The bonding surface is 15 per cent greater than that of a plain square bar of equal nominal size. The cross-sectional area is practically the same at all points and the regular surface facilitates fabrication and handling.

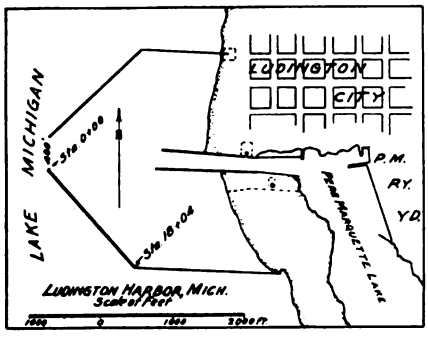
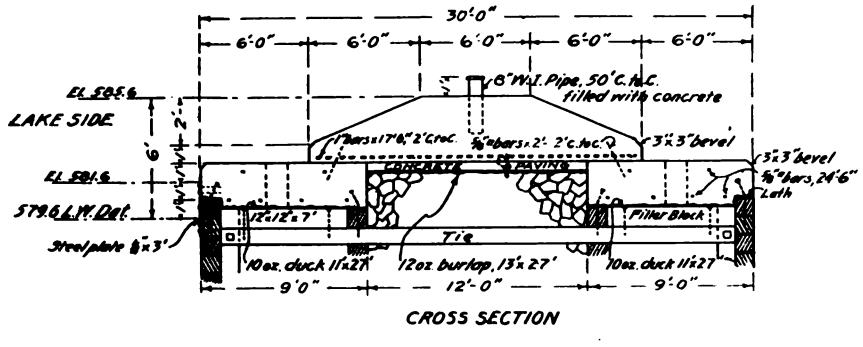
would take in companies holding iron ore properties on the Minnesota ranges with manufacturing plants in the East, in order that they might be in a position to compete with the Steel Corporation for western trade in finished steel products in the event of the "Pittsburgh plus" freight basis being discontinued as a result of the recent inquiry of the Federal Trade Commission.

On Feb. 25, 1920, the Duluth City Commission was notified by the Railroad Administration that storage charges would be made on all freight east and west bound stored in ports in railroad-owned warehouses and on railroad docks on Lakes Superior and Michigan. The charges are detailed under freight rate authority of the Interstate Commerce Commission No. 22967, Feb. 20, 1920. This is the successful culmination of a determined effort initiated in 1912 to remove discrimination against Duluth dealers. Whether this condition will continue with the railroads under private ownership remains to be seen.

The widow of the late Chester A. Congdon, who donated to the City of Duluth a right-of-way for a drive along the Lake Superior shore to the Lake County line, has now presented to the City and County authorities an offer to pay up to $125,000 for half the cost of the improvement, provided the whole shore drive is improved and paved. The matter is under advisement for acceptance.



MILWAUKEE, WIS. DISTRICT.



Lt. Col. EDWARD H. SCHULZ.

This district includes the former Grand Rapids District. Mr. J. A. B. Tompkins, who was District Engineer during the war is Principal Assistant Engineer for the entire district. Mr. L. W. Goddard is Assistant Engineer in local charge of the Grand Rapids sub-district.

Bids were opened on April 29, for repairing and placing concrete superstructure on 1,000 linear feet of south breakwater, Ludington, Mich. (See cross section below).

The low bid for concrete foundation blocks was $26 per cubic yard, and for top blocks, $22 per cubic yard.

CROSS SECTION

The lowest bids were greatly in excess of the estimated cost, and this work will probably be done by hired labor.

Caisson construction at Milwaukee, for Indiana and Chicago harbors.—Bids were for cement, 2.51 per barrel, net; for stone and sand, $3.60 per ton; for steel reinforcing, $4.297 per hundredweight for ¾-inch bars, $4.347 per hundredweight for ⅝-inch bars, and $44.397 per hundredweight for ½-inch bars.

The above were all for delivery at breakwater. The bids for cement and steel were accepted. The stone and sand will be purchased and delivered by United States vessel at an estimated cost of $2.50 per ton.

Removing wrecks.—The past winter has been severe in causing wrecks of lake vessels. On March 8, the *Pere Marquette No. 3*, a passenger and freight vessel plying between Milwaukee and Ludington sank off Ludington about ¼ mile due west of the breakwater entrance. The owners have marked the wreck and will shortly decide upon its removal or abandonment to the United States.

FIRST SAN FRANCISCO DISTRICT.

Col. E. E. WINSLOW.

Jetties at the entrance to Humboldt Bay, Cal.—The project provides for two parallel jetties 5,100 feet long. Work closed down in 1917 on account of the war has been resumed. When working on the jetties from 1911-17 the stone was obtained from the local quarries by a combined rail-and-water haul, but since the work has been shut down the long trestle necessary for connecting the railroad with water deep enough to float a car ferry, has been practically destroyed by the teredo. The cost of reconstructing this trestle at present prices would be prohibitive, and as the construction of 4 miles of railroad is all that is necessary to give an all-rail haul from local quarries to the north jetty, provision has been made for building this connecting railroad. The preliminary surveys have been completed; the most suitable route has been selected, and arrangements have been made with property owners for lease of a right-of-way across the several properties for a period of five years. Under the present arrangement the government constructs the connecting link of railroad; the Northwestern Pacific Railroad furnishes the necessary railroad equipment and hauls the stone from a junction point on its road to the north jetty; the contractor quarries the rock, loads it on the cars of the railroad company and delivers the cars over the quarry railroad to the junction point of the Northwestern Pacific.

The project is about 80 per cent completed. The south jetty has been completed to full length, and the north jetty to within about 500 feet of its ultimate outer end. The effect of the rebuldng of these jetties on the channel has been quite pronounced. The depth of 16 feet existing prior to commencement of work has increased to about 27 feet, according to the latest soundings. As was experienced when these jetties wre originally built, some thirty years ago, there has been a very pronounced scour of the north spit. The first rock work to be done, therefore, will be the rebuilding of the inshore end of the old north jetty, originally designed to prevent this scour, which, if not checked, might eventually cut a channel through north of the jetty and thereby defeat the whole purpose of the project.

Crescent City Harbor, Cal.—This project provides for a breakwater 3,000 feet long to protect the harbor from heavy ocean swells and storms. Work has begun, and it is expected that the contractor will make rapid progress on this important project. This harbor is 70 miles north of Humboldt and 250 miles south of the mouth of Columbia River. It is the only harbor on a long stretch of coast line, is the natural outlet for a very extensive area of timber land, and is expected to open up a very important lumber supply.

SEATTLE DISTRICT.

Lt. Col. J. A. WOODRUFF.

Lake Washington ship canal.—A design is being prepared for a movable dam to be erected on the lock wall at the upper entrance of the large lock, to stop the flow of water through the canal and locks, in case a lock gate is wrecked by accident, causing a velocity in the locks so great that the mitering gates can not be closed until the current has been checked.

In general, the dam will consist of a swing-bridge with unequal arms, with center pivot-bearing and rack-and-pinion mechanism for turning. The long arm carries a horizontal truss, 6 wicket girders, 24 wickets and their operating machinery, while the short arm supports the machinery for swinging the bridge, and a concrete counterweight

The bridge can be swung until the long end rests on the opposite wall and the horizontal truss comes in contact with a concrete bumper on the top of each wall. From the horizontal truss, when the bridge is in position across the lock, wicket girders which are hinged to the upstream chord of the truss will be dropped until their lower ends rest against a concrete sill which has been constructed between the walls of the lock at the floor level. The wickets, which are supported by flanged wheels on roller bearings, are lowered into place over a track on the upper flange of the girders; these wickets are placed in horizontal rows, all the wickets in each row being lowered simultaneously, thus diminishing gradually the head as well as the area of the waterway.

The estimated cost of the structure is $300,000. It is expected that the plans and specifications will be completed in about three months, when a contract will be entered into for the fabrication and erection of the entire work except the substructure, which will be constructed by hired labor and government plant.

Salinity tests.—The locks and dams described elsewhere in this issue form a barrier separating the salt water of Puget Sound from the fresh water of Salmon Bay, Lake Union and Lake Washington. Prior to the construction of the locks, Salmon Bay was an estuary of Puget Sound, and large quantities of salt water remained in the bay when the lock gates were closed and Salmon Bay filled with fresh water. The elevation of the surface of Lake Union is 7 feet above extreme

EMERSON

STEAM PUMPS

Emerson Foot Valve and Quick-Cleaning Strainer

Adapted to All Pumps or Intakes

Emerson Standard
Made in Eight Sizes

The EMERSON is a steam vacuum pump designed and built to handle air, sand, mud and grit in percentages with the water impossible by any other kind or make of pump.

It is invaluable for all work in cofferdams, caissons, and for keeping excavations dry—continuously.

EMERSON PUMPS are in daily use by U. S. Engineers in River and Harbor Work, Reclamation, and on the Panama Canal, where 64 EMERSONS have been in service

The Latest Type EMERSON is built of steel pipe instead of cast iron, is increased in capacity 10 per cent, with a decrease of 35 per cent in weight, less parts and steam consumption.

high tide, and it was originally controlled at this elevation by a wooden dam with sliding gates, at its westerly end. High tide flowed up to the lower side of this dam through a cut between the head of Salmon Bay and Lake Union. This small wooden dam was destroyed in 1903 and again in 1914, allowing large quantities of salt water to enter Lake Union. There was no connection between Lake Union and Lake Washington through which the waters of Lake Union could enter Lake Washington until the completion of the canal.

The present channel between Lake Washington and Lake Union is 26 feet deep. Lake Union has a depth of 40 to 50 feet, and the controlling depth in the channel between Lake Union and Salmon Bay is 32 feet.

Directly above the large lock is a large sump 2,000 feet long with an average width of 200 feet and a depth 6 feet lower than the upper sill of the lock. This sump is connected with the spillway dam by a concrete pipe, the area of which is 30 square feet, its entrance is 4 feet lower than the upper sill of the lock, and its outlet at the spillway is about mean high tide level.

The object of this pipe is to carry back to the lower pool the salt water which finds its way in through the locks to the pool above. How well this object is being accomplished is shown by the following table:

Parts of chlorine per 1,000,000 *parts of water.*

Snagging in Lake Washington.—Upon the completion of the Lake Washington Canal and the lowering of Lake Washington to the elevation of Lake Union, about 12 feet, it was found that submerged trees existed at three areas in the lake. Most of these trees were standing vertically or nearly so. One tree, 97 feet high, was located a half mile from shore in 100 feet of water. Another was 2,000 feet from shore in 90 feet of water with only 4 feet of water over the top.

Over 400 such trees were removed or cut off by blasting by the snagboat *Swinomish* after having been located by a wire-drag party of the United States Coast and Geodetic Survey.

After a tree had been located a fastening was made to it by dragging the bight of a large cable held suspended at the proper depth. After the tree was thus placed in the bight of the cable one end of the cable was passed through an eye in the other end and the loop run down to the tree. If it was found impossible to thus lift the tree, a charge of dynamite was lowered to the required depth and the top section cut off and removed. The largest tree removed was 120 feet long and 5½ feet in diameter at the butt, with a 20-foot spread of roots.

The indications are that these trees had been under water for a very long time. All the branches have disappeared, and the trunks are water-logged, and when dried out the wood is very light and porous.

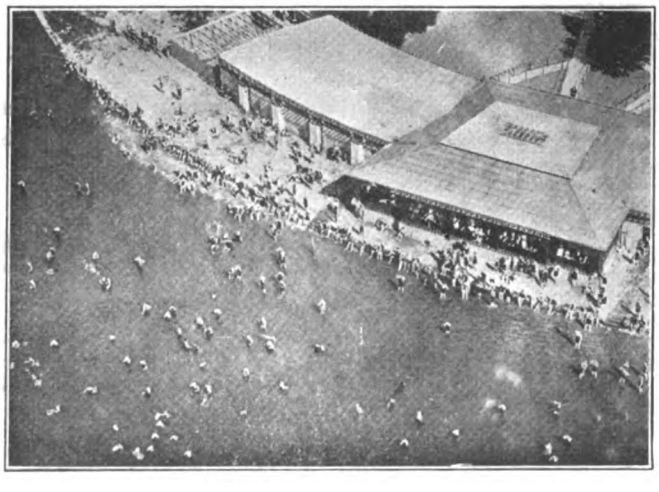
FIRST AND SECOND MISSISSIPPI RIVER DISTRICTS, MEMPHIS, TENN.

Maj. J. N. HODGES.

Construction of two additional dikes on the east side of Robinson Crusoe Island was commenced February 16, but was interrupted by high water in March.

Robinson Crusoe Island is on the west side of the Mississippi River, a few miles upstream from Memphis, and was formed by the Mississippi River cutting through Old Hen Island during the high water of 1912-13.

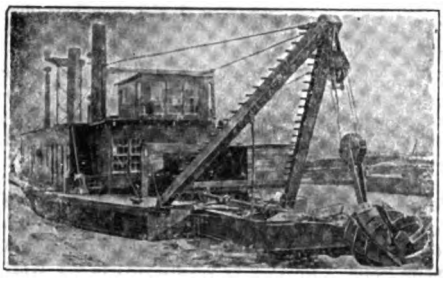
The dikes are similar to the type extensively used in the St. Louis District, and consist of three piles, from 4 to 6 feet, c. to c. of clusters, depending upon the depth of water. To prevent the cluster of piles being scoured out by the current, they were driven through foot-mats of willow fascines.



The purpose of the dikes is to deflect the current from the east side of Robinson Crusoe Island and cause it to impinge on the west side of the large sand-bar which has formed in the Memphis harbor, in the hope that the current thus deflected will eventually carry the bar away.

PUBLIC BUILDINGS AND GROUNDS, DISTRICT OF COLUMBIA.

Maj. C. S. RIDLEY.



Washington, D. C.—The Office of Public Buildings and Grounds is now operating a bathing establishment in Washington on the tidal basin in Potomac Park. The bath house and beach were originally constructed in 1918 and are now being enlarged and improved. Originally there were 845 lockers for men and 268 for women. With these basic accommodations it provided bathing facilities for a maximum of 10,000 patrons per day. An extension which is practically complete provides 700 additional lockers for men. The beach, which is of artificial construction, is 450 feet long at the life line. The width at the center is 120 feet. It required 25,000 cubic yards of fill. Water is sterilized by a chlorination plant installed at the inlet gates to the basin near the site of the beach. The building is of hollow tile construction, stuccoed, with slag roof. The initial arrangement featured a central pavilion of arrival permitting spectators to pass directly to a view of the beach and dividing men and women into right and left lines passing counters where valuables could be checked and suits rented. The pavilion also included refreshment booth, offices of administration and toilets, in four sections, serving men and women bathers and spectators, on either side of the pavilion. Following the curve of the beach, extend low wings with the top third of the sides open to the air, rows of lockers placed at right angles to a central aisle filled every available foot of space with supplementary dressing booths on the women's side. From the outset the establishment was taxed beyond capacity with long lines of waiting patrons. Various expedients were devised to meet the situation. For the men, a fenced inclosure was provided with a covered check space where their clothes could be placed on coat hangers—an arrangement preferred by many to the use of a limited locker space. For the women a large room was provided with sealed "tote-boxes" for checking their garments. A third system which served a very large number of patrons in a limited space, consisted merely of a coat-check for those who donned and doffed their clothes at home and came in motors to the beach. With additional appropriation permitting extension of the men's wing the first revision of the scheme was to shift the point of arrival of the bathers from the central pavilion to the center of the wing thereby greatly relieving the congestion and mixing of groups. After bathing, the exit line returns them to the central pavilion, as spectators, where parties may reunite and refreshments be obtained. Other changes, the desirability of which had been indicated by experience, were increases of space between lockers, substitution of concrete and steel for wooden floors and lockers, and various detailed modifications tending to save seconds of time and speed up the movement of the line. With the next available funds, the women's wing will be extended with alterations to meet special needs and consideration will be given to more ample provision for spectators.

The establishment was designed by Horace W. Peaslee, architect, and the construction work was supervised by F. F. Gillen, engineer in this office.

LESCHEN
WIRE ROPE

BACK of every Leschen Wire Rope is a large modern factory directed by experienced wire rope engineers and operated by skilled workmen. Every Leschen rope is proven to be up to the Leschen standard by rigid tests.

For heavy and exacting work we recommend HERCULES (Red Strand) Wire Rope, for the unusual strength, toughness and durability of this rope make it safe and economical on even the most severe conditions.

PANAMA CANAL DISTRICT.

Col. C. S. RICHE.

The District Engineer, Panama Canal, acts both as District and Department Engineer, though two separate offices are maintained. All district work is handled by the Fortification Division, Panama Canal, which is under the control of the District Engineer.

All department work is handled directly by the Department Engineer, by contract or by work order on the Fortification Division, Panama Canal.

Clearings and trails.—Under this appropriation, work is carried on in accordance with the wishes of the Department Commander. Clearings and trails are constructed and maintained so as to carry out the local defense projects.

During October, 1919, at the request of the District Engineer, two aeroplanes made a reconnaissance in the vicinity of Chame Point in order to locate a pass through the foothills of the continental divide. The flight took one hour and thirty-three minutes, and the pass was successfully located. It is interesting to note that this aero reconnaissance accomplished in an hour and a half what had baffled a survey party for three weeks, and it is extremely doubtful if the pass could ever have been located except by aero reconnaissance.

During January, 1920, another aerial reconnaissance was made of the Chagres watershed, and a great deal of useful information was collected.

In the early part of March, a reconnaissance party was sent from this office to investigate the route from Nombre de Dios to Gamboa. Party made the trip in four days and obtained considerable valuable information.

Department engineer work.—Construction of four ponton sheds and one garage at the Engineer Depot, Corozal, C. Z., was started in February, 1920; and completed in May, 1920.

Two survey parties are in the field working on the Progressive Military Map in accordance with the approved project for this department. The dry season here lasts from December to April, inclusive, and it is impossible to do much field work at other times.

Full use is being made of the aeroplane squadron located here. By means of aerial photography, existing maps are being revised and brought up-to-date.

Engineer Troops

SECOND ENGINEERS, CAMP TRAVIS, TEXAS.

Col. E. GRAVES.

The steady arrival of recruits has produced a marked improvement of morale in the Second Engineers. The strength of the Regiment was more than doubled during March. The new men are of excellent material and average 19 years of age. So far none of them are illiterates. At present the drill of these recruits covers four weeks. Infantry drill, Instruction in Physical Training, Small Arms Firing, Practical Military Engineering, etc., are alternated throughout the day, thereby making the course more interesting. The schedule, although very elastic, makes it necessary that each recruit cover each of these important elementary subjects before being returned to his company for duty. The willingness of these new men to do everything required of them and their questions regarding the different phases of the instruction make both the instructors and recruits work harmoniously toward the efficient completion of the course.

SECOND BATTALION, THIRD ENGINEERS, COROZAL, CANAL ZONE.

Capt. D. L. NEUMAN, *Commanding.*

At present there are but three officers on duty with this Battalion, and as a rather heavy program of engineer work is being carried out no garrison school is being held, and no drills except for recruits.

A two weeks' garrison course in topographical surveying for the enlisted men in the battalion has been completed, the students have now been placed on detached service with the Military Survey of Panama and will complete their training in the field.

Detachments from the battalion are engaged in road work on the Pedro Miguel—Empire road; topographical surveying on the Military Survey of Panama; road location survey for the new Gamboa—Alhajuela road; and the refitting and operation of launches to be used on the Military Survey.

Capt. A. L. Ganahl is attending the Engineer School at Camp Humphreys, Va. Capt. D. L. Neuman is commanding the battalion, and in charge of the Military Survey of Panama, and the Pedro Miguel—Empire road. Capt. A. C. Lieber, Jr., is Supply Officer at the Engineering Operating Base and Acting Department Chemical Warfare Officer in Maj. D. D. Pullen's absence. Capt. L. B. Gallagher has received orders to report to the Engineer Examining Board in New York for examination for promotion to captain. Capt. F. Miller is on detached service with the Military Survey of Panama. 1st Lt. J. B. Newman, Jr., went to the States for examination for promotion.

FOURTH ENGINEERS, CAMP DES MOINES, IOWA.

Maj. S. L. SCOTT, *Commanding.*

Regimental insignia, 4th Engineers.—In order to arouse the interest of, and provide suggestions for Engineer regiments which have not adopted a regimental device (see Circulars 444 and 527, W. D., 1919.) We publish herewith the regimental device, 4th Engineers, which will be submitted to the War Department for approval. This device was designated and drawn by the personnel of the 4th Engineers.

Interpretation of the regimental device, 4th Engineers.—The *Spear-head,* representing the Northwest, where the Regiment was organized and recruited, is divided into three segments by means of the Regimental motto, *"Volens et Potens"* (meaning willing and able), and the *Rods bound with thongs* (symbolizing unity and loyalty within the organization).

The *Laurel wreath* in the upper left-hand segment is the official designation of the War with Germany, in which this Regiment took part.

The *Castle* with the numeral 4 above it, represents the 4th Engineers, and the fact that it is enclosed in the *Laurel wreath* indicates that the Regiment was organized for the purpose of taking part in the World War.

The *Blue Ribbon* in the upper right-hand segment, represents the *Vesle River* of France, The *Arrows* represent the armed forces which cross the river to engage the enemy. The *Mailed fist* grasping the *Arrows* represents the 4th Engineers who constructed the bridge which made the crossing possible. In accomplishing this feat there were 210 casualties in the Regiment.

The Esnes-Malancourt Road, represented by the *White ribbon* in the lower segment, was constructed September 26, 1918, by the 4th Engineers and used by two divisions. Sixty casualties resulted from this extremely difficult task of crossing No-man's land. The *Four Bronze stars* represent the following operations for which the Regiment has been officially credited, Aisne-Marne, St. Mihiel, and Meuse-Argonne offensive and Vesle River and Toulon defensive sectors.

The *Blue, white* and *red* in the lower segment represents the colors of Franc, on which soil we fought.

The *Ivy leaves* on the haft is the 4th Division insignia worn by the 4th Engineers duirng the World War.

FIFTH ENGINEERS, CAMP A. A. HUMPHREYS, VIRGINIA.

Col. RICHARD PARK, *Commanding.*

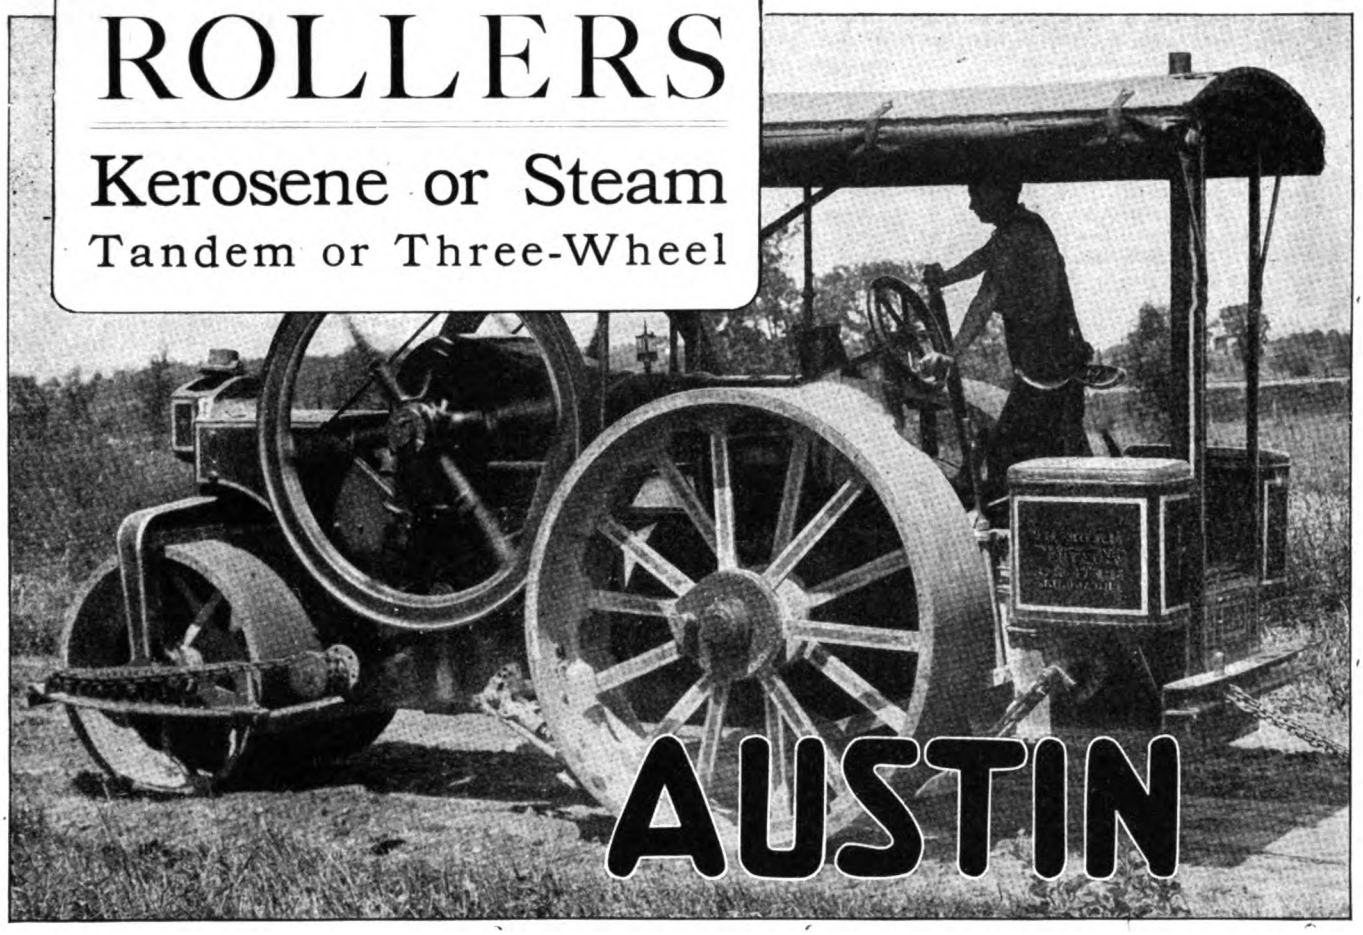
During the past two months the regiment has been getting recruits daily, and a large number of the men for drill have been taking up the recruit course of instruction. A forty-day schedule for recruits has been prepared for all men reporting.

Vocational School courses closed on May 31st, and selected men were put in Trade School classes, which they attend during the morning hours for the summer months. Engineer drills are being carried on in road work, demolition, field fortification, bridge building and surveying. The shortage of officers to properly direct these drills has been overcome by the assignment of five lieutenants, and there have been six more attached for duty.

The influx of recruits has enabled the Vocational Schools to enlarge their activities greatly, and this work is being constantly improved in scope and efficiency.

The Fifth Engineers celebrated its third birthday on the 21st of May, and the program for the day was varied and interesting. Escort to the Color was held at 9 o'clock, followed immediately by a review by General Connor. From the parade grounds the regiment was marched to the Liberty Theater, where band selections were rendered and addresses delivered by General Connor, Colonel Park and Captain Robb.

A number of boxing tournaments were held, and the honors were about evenly divided between the three companies—A, B and C.



On Flag day, exercises were held in the afternoon in the open air amphitheater, at

Digitized by Google

which the Fifth Engineer Band played. On June 16 graduation exercises were held for the Engineer School at the same time and place, and every one on the post was invited. Addresses were given by the Secretary of War and the Commanding General.

A horse show was held on May 12, 1920, at which the Secretary of War was the guest of honor. Many jumping events, a polo race, mounted wrestling, an obstacle race and a race between four-mule chariots were held.

The regiment lost Capt. H. L. Robb and 1st Lieuts. W. J. Regan and John R. Hardin by transfer to the Massachusetts Institute of Technology, but gained Capt. William C. Atwater, Capt. Frank N. Smith, 1st Lts. Frederick B. Butler, Leverett G. Yoder, Wilson G. Seville and Archie T. Colwell, who finished their work at the Engineer School on June 16.

Two excellent bathing beaches have been prepared in Gunston Cove for officers and families and for enlisted men. Rafts, diving towers and spring-boards were constructed, and during the recent hot weather these have proved to be very attractive. Life-guards are maintained at both points, and one company is allowed the beach each afternoon.

The baseball team of the Fifth Engineers has been playing consistently and has won six games in a row. It now stands second in the Camp League with a good chance to win the Camp Championship.

Lt. O. G. HOAAS has gone to Wichita to direct the recruiting activities of the Fifth Engineers in our allocated States and has been doing excellent work in building up the Fifth. The regiment has nearly 700 men.

Maj. H. V. PITTMAN has had complete charge of sixteen counties in West Virginia and has sent in a large number of recruits. He has been recommended for transfer to the Milwaukee District for his good work.

D Company will be formed the end of the month, and Capt. John E. Harris will probably be in command. All new men reporting to the Fifth will be assigned to D Company, and the other three companies will be able to go ahead with their drills without the necessity of drilling new recruits.

The Fifth staged a series of engineer stunts for the benefit of the movie weeklies; the films will be circulated over the country in the pictorial news films for the purpose of stimulating interest in the recruiting drive. A two-line crater was blown with a charge of 800 pounds of ammonal at a depth of 25 feet. The calculation of the charge proved quite accurate. A section of French high wire was destroyed by a Bangalore torpedo. During these stunts the movie men and the large audience occupied elephant shelters in the immediate vicinity. A section of light railway was then blown up with triton, after which a wrecking train rushed to the scene and repaired the damage so that a supply train could pass over. A four-bay bridge was then built with tripod legs, a detachment sent across it with wagons, and it was blown up after them. After dark the searchlights were turned on, and demonstrations were given of signaling with bombs, flares and rockets. Considering the fact that the bulk of the men engaged in the work were recruits of not more than one month's service and that they had had very little time for practice, the performance was quite satisfactory.

SIXTH ENGINEERS, CAMP PIKE, ARK.

Col. C. L. STURDEVANT, *Commanding.*

Since our last issue the regiment has received several trophies in reward for its excellence in athletics during the past fall and winter. It won the championship cup for regimental football teams and second place in the basket-ball league and the relay race.

A base-ball game between the officers of the Sixth Engineers and the 9th M. G. Battalion resulted in a 6-2 victory for the Engineers.

The Engineer polo team took the field for the first round robin on March 19, winning three and tying one of its four periods. The team has been making rapid strides, and good ponies have been developed. Major Worsham is now trying out for the Division polo team against players of much longer experience.

An excellent horse show was staged at Miller Field May 15, 1920. Many fine animals were entered and the exhibition was highly gratifying. The organization, under Colonel Sturdevant, built the riding ring and remodeled the interior arrangements of the field, constructing space for over 1,000 box seats in record time. Receipts from the horse show as reported by Major Hutchings, treasurer, were somewhat in excess of $1,000.

Two interesting cards of races have been held on the new Division Race Track. Colonel Elliott, 30th Infantry, entered his thoroughbreds Lady "A" and Amalgamator. Their races were thoroughly enjoyed.

Colonel Sturdevant has been ordered to Camp Perry to try out for the Cavalry Rifle Team, leaving Major Worsham in command.

The Regiment has just returned from preliminary range practice. Excellent results were achieved by our recruits, and it is expected that almost 95 per cent of our men will qualify the coming season, which for us will open June 19.

The Regiment captured second place in the Division Track Meet recently held. We won more points on track events than any other organization, but lost out on equipment races and the greased pig contest. The Division Track Team has been picked and ordered to the Department Meet. Out of 28 men on the team, we have 11. In addition, two of our officers, Captain Pohl and Lieutenant Hough, have qualified and will join the team upon its arrival at Charleston.

The base-ball team is going strong in the "Argonne" League, but, due to numerous discharges, its personnel is constantly shifting, and we have small chance of being the champions.

An officers' colony is now being established in the regimental area. Small houses are being moved for the purpose. We expect to have quite a settlement here. A large Y. M. C. A. building will be fitted out as an officers' club.

Captain Wieland has been placed in charge of road work, and with assistance of several of our Master Engineers is doing much toward alleviating the bad situation which has previously existed here.

Graduation exercises from Camp Pike College were held on May 8, 1920. The attendance in the regiment and in the camp had been very gratifying. Eighty men of this regiment were graduated at the close of the school term.

Majors Worsham and Hutchings have been ordered to report for duty at Boston Tech. The majors left for their new station on June 9, leaving Capt. Hiram B. Ely in command of the Regiment.

9TH ENGINEERS (MOUNTED), CAMP TRAVIS, TEX.

Maj. R. F. FOWLER.

Although the 9th did not go overseas, it made an enviable reputation during the emergency as an efficient organization, ready for anything. The only real excitement during this period occurred when Villa made his raid on Juarez and the 9th performed its share in protecting El Paso.

The demobilization of the emergency men left us pretty low in numbers, as it did all other organizations. During the last three months we have surely though rather slowly increased from six engineer officers and one hundred and fifty enlisted men to seven engineer officers and two hundred and ten enlisted men, present and absent. Capt. G. A. Counts reported to this organization for duty on March 26th.

The period from January 1st to March 31st was spent in reorganizing, trying out non commissioned officer possibilities, cavalry drill, recruit instruction, conditioning animals, etc.; practically no engineer drill was given, except the usual special duty work, all efforts being made with the limited time and personnel to put the battalion in the proper disciplinary shape.

About three weeks notice was given for the change of station of the regiment from El Paso to San Antonio. Immediately upon such notice work was commenced on the collecting and turning in of property. The distance of Camp Courchesne from Fort Bliss and the shortage of transportation and men, made this feature of the preparation the most difficult to finish in the time available. All escort wagons were used daily and such trucks as could be obtained, but it was necessary to use even the last day to complete the shipping. Headquarters, El Paso District, gave us all the help they possibly could. All organizational property not a part of Equipment "A" or not designated to be taken was shipped by rail; also all excess mules from the train and some horses which were excess or unable to make the trip overland.

Considerable difficulty was experienced in turning in all the property of the train. Besides the equipment for three light ponton divisions, the engineer tools and equipment for a division, cavalry, had to be taken to Fort Bliss after checking and inspecting them. This equipment included the tractors and steel boats and such equipment as had been drawn to go with them.

Orders were issued to take on the march equipment "A," plus extra blankets, surplus kits, and such articles as would add to the comfort of the men or would be of value on the march, and for which there was room. It was planned at first to take one light ponton division, but when orders were received to take no ponton equipment extra mules and scort wagons became available from the train. This allowed us to take more equipment such as heavy forges, extra horseshoes, wagon wheels, kitchen equipment, etc., and still have the wagons fairly light. The inexperience of all concerned in a march of such length in that section of the country, and the lack of knowledge of what might be needed, made it necessary to play on the safe side.

On account fo the depleted strength of the battalion and the fact that a large percentage of the personnel were recruits, it was decided to leave some of the equipment. The headquarters map and tool wagons, and the B Co. tool wagon were shipped by rail. Each company also shipped one-half of its engineer pack equipment, which left extra pack animals for each company. This still left more complete sets of engineer tools and equipment than would be required for us by the number of men present.

Thirteen escort wagons were taken, as follows: Train 4, Hdqrs. 2, A Co. 2, B Co. 3, C Co. 2. Two days' rations and one day's reserve grain were carried. All horse-drawn rolling kitchens were shipped. Company messes were combined into one mess and the motor-drawn rolling kitchen of the train was taken. All ration and baggage, and water carts were shipped. G. I. cans carried in the truck or wagons were used as a substitute. Two light 2-mule wagons which were on hand

construction, renovation of existing installations, barracks, buildings, procurement of articles and materials for construction and equipment and the furtherance of the Public Utilities.

Before the march there were in the organization only one experienced horseshoer and two experienced packers, the latter being 1st sergeants. Immediately upon notification of the change of station, the company pack trains were organized completely and training commenced. All animals were shod by our own personnel, except those shod by six men from the Remount Depot at Fort Bliss working for one day. Steps were taken immediately for the return of all men from recruiting, military police duty, and schools, but these men were slow in returning and few were available to assist in the preparation for the march. Enough draft and riding animals were kept to give the organization about 25 per cent led animals on the march.

The march each day was conducted as follows: the field and general orders issued by headquarters gave the details of the march. All motor transportation left camp just ahead of the column and proceeded as fast as the roads permitted to the new camp. The 3-ton truck carried from 1 to 5 days' rations, less beef, bread, and ice, kitchen equipment, including two No. 1 field ranges and the mess sergeant, cooks and kitchen police, besides trailing the rolling kitchen. Beef, bread, and ice were received daily by rail, and other rations every five days. The rolling kitchen was turned in at Marfa, as it was found to be of no advantage under this arrangement and somewhat of a disadvantage, as it was difficult to trail on bad roads. The 1½-ton truck carried forges, blacksmith tools, horseshoes, coal, canvas watering troughs, and one horseshoer from each company. The touring car carried one officer. Upon arrival at camp the kitchen was set up, water and rations drawn, and lunch prepared. The forges were set up and the horseshoers then had the time before the arrival of the column to rest; this plan gave the horseshoers more time to work and resulted in better work on account of their being fresh. The advance party consisted of the officer who went ahead in the touring car and the motorcycle drivers. This party selected the camp site, set up the watering troughs when necessary, drew and distributed the forage and dug latrines. The pack trains preceded the column by from one-half to one hour in order to enable them to make their own gait. The wagon train started as soon as it was ready, ahead of the column, but was usually passed within the first hour and a half of march.

The trucks left the column at Sanderson and were away for seven days. A small amount of property was shipped to Comstock by rail, although this was not necessary; the rest was distributed between the trucks and wagons, sending with the trucks that property which was not needed during the seven days. This of course did not allow the sending ahead of the cooks and horseshoers, who were either mounted or rode on the wagons. The two light wagons, each carrying one cook, started each morning as early as possible and preceded the column, in order to prepare lunch at the new camp. During this period also the pack trains carried the watering troughs when necessary.

The watering troughs proved to be indispensable and should be had by every organization; they are not issued. The combined mess proved to be the proper thing as it necessitates less equipment, fewer kitchen police, and makes less trouble in drawing and distributing rations; where companies are at full strength or are liable to be separated, separate messes should be run. It is believed that under conditions which do not justify the sending ahead of a kitchen truck that the motor-drawn rolling kitchen would be of value. Our short experience with the two types showed the animal-drawn to be better than the motor-drawn for cooking, but of course the animal-drawn would not ordinarily be available for the noonday meal. The light wagons are very valuable, as they are ordinarily able to keep up with the column; they are not authorized but every company should have one. The cavalry have them and there is no reason why the mounted engineers should not have them.

Water carts are of value and should be taken in the future, but not those of the present type. It is well to fit the water tank and connection on a four-wheeled wagon, improvised if necessary, with a wagon tongue. The present cart causes sore backs and soon tires out the wheel mule, even if the lead mule is brought back beside the wheel mule. The 12th Cavalry has rigged up such a water wagon, which appears to be very practical. The same should be said of the ration and baggage cart, although the cart should be replaced by an escort wagon. The present type of limber and caisson tool wagon are too heavy for use under adverse conditions, and too liable to be broken. Experiments should be conducted on a lighter limber and caisson wagon to be compared with the escort wagon.

The conduct of the personnel of the organization on the march was all that any one could ask. The spirit was excellent and great credit is due to both officers and enlisted men for that spirit and the thoroughness of the performance of their duties.

The march was made between April 15 and May 22, the distance being about 700 miles.

During the march the 9th Engineers was very cordially entertained by the 5th Cavalry at Marfa, the 12th Cavalry at Del Rio and the 13th Cavalry at Fort Clark. Each of those organizations gave a dinner and dance, and in addition rendered every assistance possible in the matter of supplies and equipment. The organization has taken station at Camp Travis and has been attached to the 2nd Division for training and administration. The camp area is alongside the 2nd Engineers, and through the kindness of Colonel Graves the 9th joined the 2nd in the Exchange and in the Officers Mess.

The battalion is just getting settled in its new home. Quarters for married officers are not available, but those officers whose wives have arrived found no difficulty in obtaining suitable quarters in San Antonio.
