Uniformity of mixing and maximum of speed—consistent with quality of the mix are features that appeal to practical men. These mixers are built for efficiency and service. The number of working parts is reduced to a minimum and each part is extra strong.

Keystone ALL-STEEL Mixers

POWER-LOADER—LOW CHARGING

The simplicity, efficiency, strength, portability and durability of these machines commend them to engineers. In the construction and operation of the mixing drum are embodied principles that engineers are quick to appreciate. Details of the mixers will be sent upon request.

daily demands upon G-4 of the First Army for additional transport, a casual inspection of either of the two main roads in the corps areas generally disclosed a large number of empty or partly loaded trucks going in both directions. This condition improved somewhat as the shortage of trucks forced the various staffs to more rigid economy in their use.

The several reasons given by Major Young for the "bending" of the system of fixed assignment thoroughly cover the situation, but some amplification may be of interest. To the factor of "Shortage of Vehicles" should be added the failure to obtain spare parts and repairs; which, despite the heroic efforts of the Motor Transport officers of the 1st Army and of the smaller units with the pitifully few means at their disposal, brought the condition of the motor transport of the army to a point that would have made a winter campaign a rather desperate venture from a supply standpoint. It is fortunate we did not have one.

The maintenance of such motor transport as the army possessed was primarily handicapped by the large number of different makes of vehicles represented; by the actual shortage of essential spare parts in France, caused probably by inability to secure these parts from the manufacturer, also by the faulty system with which they were forwarded abroad, and by the faulty existing practice of operating the greater part of the transport by personnel from arms of the service other than the Motor Transport Corps and over which the Corps had no technical control. The functions of operation and maintenance are so inter-related that to place the responsibility for the proper use of vehicles upon practically every arm of the service but the Motor Transport Corps, and then to expect the Corps to be prepared to supply parts and to make repairs made necessary by abusive treatment over which the Corps could exercise only the most remote control, is a fundamental error in organization.

The shortage in motor vehicles in the 1st Army fell heaviest upon the units of corps and army troops, particularly engineers and artillery. The divisions were reasonably well equipped, to each complete division being assigned seven hundred (700) "truck-tons" of cargo and ammunition vehicles, or 89 per cent of the authorized allowance. Priority in assignment was always to the divisions, while the corps and army troops came in for the small amount of transportation that was left, generally operating with about 40 per cent of the authorized vehicles. Part of the army services met this situation early by organizing pools, as did also the several corps.

In addition, three provisional water-tank trains were formed by the army and operated under the control of the Army Engineer, while, during the Meuse-Argonne operation, a gasoline-tank train was organized to distribute gas and oil to the various divisions and other units.

Finally, in late October, 1918, the general shortage and the increasing length of haul as the army went forward, created a situation that caused the army commander to issue instructions to G-4 to form a general pool of cargo transportation in the army, by withdrawing operating units from the divisions. G-4 recommended that this pool be formed by withdrawing the various division supply trains, each to be equipped with three hundred truck-tons. This would leave four hundred tons with each division, of which one-half would be for general supply and technical purposes while the other half would be for ammunition. The army pool would then consist of fifteen divisional supply trains and one composite train from the three corps (two companies each), or a total of sixteen hundred trucks with a carrying capacity of forty-eight hundred tons or thirty thousand men.

Digitized by Google

It was further recommended that the pool be formed and operated in conformity with plans, at this time being prepared at G. H. Q. to accomplish the same purpose. This recommendation was approved, and after consultation between G-4, G. H. Q. and G-4, 1st Army, Col. L. D. Gasser, G. S. of the former section, drafted a proposed order for the formation of the army pool, and the operation of the same, this order to take effect November 15. This pool was to have been operated along the lines of the French C. R. A., but on account of the Armistice was never organized.

From beginning to end of the battle operations of the 1st Army the only motor transportation available for troop movement was that furnished by the French. Prior to the concentration for the St. Mihiel offensive, arrangements were made through the 4th Bureau Etat Major of the French Group of Armies of the N. E. whereby the American 1st Army would have at its disposal sufficient trucks of the French *Service Automobile* to move a complete division, or about 20,000 seats, and in addition about 2,000 tons of cargo trucks for the movement of munitions and supplies. This transportation was to be operated by the *Service Automobile* through the Commission Regulatrice Automobile (C. R. A.) stationed at Toul and Ligny en Barrois, and which controlled not only the operation of these trucks, but also all traffic on the roads of the army area.

The control of traffic for this operation was largely handled by the C. R. A. functioning under G-1 of the army, while the operation of the troop and cargo truck convoys was handled through G-4 of the army.

The writer believes that a system by which two different staff sections are responsible, one for traffic control and the other for the movement of supplies and men, is as fundamantally wrong as would be the case of a railroad division superintendent sending out a series of trains when and from where he pleased, for a dispatcher not under his direction to control.

The operations of the C. R. A. are by far superior to any other means of controlling dense traffic, used by the A. E. F. With the approval of G-1 of the army the C. R. A. laid out the main road system for the supply of the army. Certain roads were assigned to animal transportation, while the main axial roads (Routes Gardees) were reserved for motor transport only. The "Routes Gardees" were under the absolute control of the C. R. A., who, by means of movable cantons of special road police, connected together by a special telephone system, insured proper dispatching of all convoys.

The "Routes Gardees" could be crossed by animal-drawn transportation or marching troops when such crossing did not interfere with any movement of controlled truck convoys.

In addition to the special police the C. R. A. maintained a sign-making department, in which sufficient road signs were made for the proper marking of all roads in the army. This was an extremely important phase of road control, especially where dense movement was made at night and without lights. The best signs were made so that they could be illuminated enough to be seen at a short distance, though not enough to be seen by enemy avions.

"Loop" roads, sometimes called by the French "Gare d'automobile," were laid out as part of the road system in circling divisional billeting areas in rear of the Army Zone, as well as at forward debussing points. This was necessary as it is not practicable to turn around a convoy of a thousand trucks on a single road.

The best example of troop loading seen by the writer was somewhat as follows: Trucks to move a division were parked in a complete circle around a divisional area

pointed, of course, in the direction toward which they were to go and divided into convoys of sufficient size to carry the various units of the division, and parked as closely as possible to the billeting area of the unit they were to carry. The rear truck of each convoy was slightly in advance of the point at which the head of the column of troops was directed to reach the road. All the truck drivers were gathered by the convoy commander at the rear of the trucks, and as the troops came up they were cut off into groups of 20 men, the first group being turned over to the driver of the leading truck, the second group to the driver of the second truck, etc., and were conducted by the drivers directly to the trucks and embussed. This system of embussing worked quickly either by day or night and is worthy of record in that it is one of the many well worked-out details which made possible a large troop movement by truck during the two operations.

By means of the French trucks at the disposal of the 1st Army, 108,490 men were moved an average distance of 91 kilometers for the St. Mihiel concentration, while for the Meuse-Argonne offensive 428,635 men were moved an average distance of 77 kilometers, this latter being one of the largest troop movements by truck carried out in France. Both of these movements were executed entirely by night, without lights and with only two serious accidents.

With the French cargo trucks at its disposal G-4 1st Army moved a total of 12,988 tons of ammunition and supplies during the St. Mihiel offensive and 42,233 tons, of which 81 per cent were munitions, during the Meuse-Argonne operation. A much larger tonnage could have been moved during this latter operation but for the badly jammed roads and the poor layout of many of the forward ammunition dumps, at which trucks were generally forced to turn around on soft ground, resulting in much miring and consequent delay.

The writer believes with Major Young that only the necessary technical vehicles and a minimum number of cargo trucks should be assigned directly to tactical units. All other trucks should be pooled under the direction of the High Commander and either operated under the direction of Army Headquarters to carry out requests for transportation made by corps and divisions, or temporarily assigned by Army Headquarters to these units if conditions warranted their use in this way. He further believes that the principles of traffic control should be made known to the army through incorporation in Field Service Regulations.

Latticed wooden derrick booms, 135 feet long, were built for the English Navy for war service. The required service was to lift a three-ton load up to a platform 100 feet high, the boom being connected to a 50-foot mast. Saving of weight was the reason for choosing wooden construction; it is claimed that the wooden boom weighs only one-third as much as an equivalent steel boom and yet had a higher factor of safety. With end fittings and equipped with a 21-inch hoist sheave it weighs only 6,000 pounds.—*Eng. News-Record.*

Echoes of the St. Lawrence Waterway Project

Discussion by NORMAN M. McLEOD.

In reference to the article on Great Lakes-St. Lawrence Route to the Sea by Maj. J. C. H. Lee, I wish to make the following comment:

(1) With a speed of 6 feet per second, a canal 200 feet wide at the bottom, 31 feet at the top, with a 25-foot depth of water, would provide 200,000 gross horsepower instead of 2,000,000, as stated. This would require a slope of about 6 inches per mile, which, in 182 miles, would mean a gross fall of 91 feet, which reduces the power head from 225 feet to 135 feet gross. From St. Regis to Ogdensburg, the drop in 54 miles would be 27 feet, leaving 63-foot head out of 90-foot fall. From Lake St. Francis to Lake St. Louis a drop of 7 feet in 16 miles leaves 73 feet for power head.

(2) The river water is estimated at 200,000 cubic feet per second average. If the channel is 500 feet wide and 40 feet deep, this would require a velocity of 10 feet per second and about 6-inch slope per mile.

This means that to obtain the full horsepower out of the river water a series of dams must be built. In that case the water will flow more rapidly in the narrow portions. A channel 500 feet wide would give 200,000 cubic feet per second at 10-foot velocity, which at 5 horsepower per cubic foot gives 1,000,000 horsepower in the first section, with an efficiency of 50 per cent, the consumer would get 500,000 horsepower, giving a gross income of $10,000,000 per year, in which project not more than $50,000,000 could be profitably invested.

NORMAN M. McLEOD.

[Abstract from *Electrical World.*]

Before a recent meeting of the Boston Society of Civil Engineers, in discussing a paper on New England waterpower resources by H. K. Barrows, a consulting engineer of Boston, Harry I. Harriman, president of the New England Power Company of that city, commented upon the possibilities of the St. Lawrence River hydro-electric project and outlined additional phases of the proposed development. The speaker said that in the St. Lawrence 240,000 cubic feet of water drops 221 feet per second. Four or five dams would be built with effective operating heads of 35 feet to 60 feet. On the St. Lawrence the maximum flow varies less than 25 per cent from the mean, owing to the 9,000 square-mile drainage area of Lake Ontario. The storage of this lake is so vast that it can be utilized to produce energy to equalize the low season of many New England and New York waterpowers and to supply the peak load of the winter months. If New England were to get behind the project, it would be entitled to about 6,500,000,000 kw.-hr. from the river plants, or say to 6,000,000,000 kw.-hr. at local substations.

In 1919 the railroads of New England used about 6,000,000 tons of coal on their 5,000 miles of track. Eighty per cent of this was consumed on less than 1,500 miles of track. The speaker said that $25,000 per mile should cover the track structures and substations, making about $40,000,000 to electrify the 1,500 miles, which burn most of the coal in that section. Electric locomotives will add another $40,000,000, but in so far as these are used to replace obsolete steam locomotives, their cost should not be charged to capital. Further, electrification probably will not proceed more rapidly than the steam equipment wears out. Accordingly, Mr. Harriman said, it seems fair to assume that the electrification of the main lines of the New England railroads will not cost more than $50,000,000.

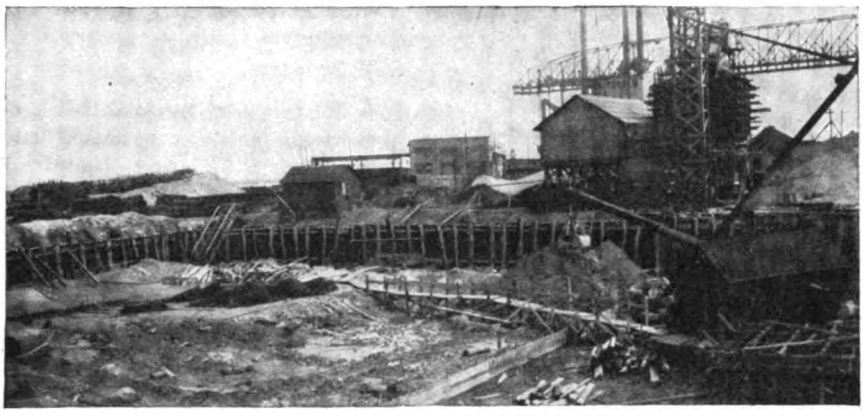
The coal now burned by the New England main lines per year could be replaced by about 1,800,000,000 kw.-hr. from the St. Lawrence, costing about $18,000,000 and yielding a saving of from $20,000,000 to $30,000,000 for fuel outlay. The cost of electrification will be covered in a very few years of full operation. After that the New England roads will obtain their power on as favorable a basis as roads passing through the coal regions.

The electric utilities of New England generate about 2,000,000,000 kw.-hr. a year, of which more than 75 per cent is produced in steam plants. The present combined use of the railroads and utilities of the section is less than 3,500,000,000 kw.-hr., leaving 2,500,000,000 if the St. Lawrence supplies all of the energy.

There are about 18,500,000 cotton spindles in New England, and, allowing 22 spindles per horsepower, it is estimated that on the basis of a 48-hour week these mills use something less than 1,400,000,000 kw.-hr. yearly. At least 25 per cent of these spindles are driven mechanically by water, and therefore 1,000,000,000 kw.-hr. would replace all of the coal-produced energy in these cotton mills.

In New England there are about 2,100,000 woolen spindles, with 4,200 cards. These spindles require about 200,000 horsepower. Much heat is needed in process work. Not over half the power required by the woolen mills can be supplied by the central station, hence about 175,000,000 kw.-hr. would be required by the woolen mills. The paper mills would use about 200,000,000 kw.-hr. from the St. Lawrence. The boot and shoe factories, wire and rubber-goods plants, and brass establishments might utilize 100,000,000 kw.-hr. It is doubtful if the present industries of New England would use over 2,000,000,000 kw.-hr., and there would be a surplus of 500,000,000 if the railroads used 2,000,000,000 and the utilities 1,500,000,000. Enough is known, said the speaker, to assure that power can be delivered to the New England states in wholesale blocks from the St. Lawrence for less than 1 cent per kilowatt-hour.

R. O. T. C.



The small-bore rifle team of the R. O. T. C. Alabama Polytechnic Institute, Auburn, Ala., met and defeated the R. O. T. C. team of the Oregon Agricultural College of Corvalis, Oreg., in a telegraphic gallery match on January 29. The course consisted of the usual course as outlined in the S. A. F. M. Ten men composed the team of each institution. The final score was: A. P. I., 946; Oregon, 927. During the 1921 season, the Alabama Polytechnic Institute has matches scheduled with Texas A. and M., University of Illinois, and Cornell.

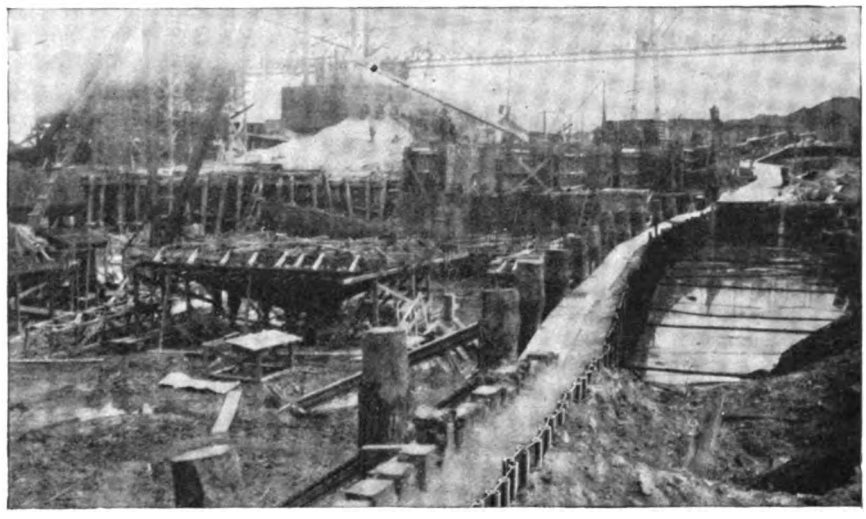
Here is an excellent Lackawanna Steel Sheet Piling Construction for Sewage Disposal Plants

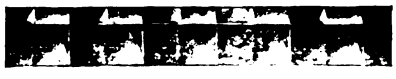
The cofferdam shown was constructed by the American Construction Company in connection with sewage disposal facilities installed for the Masters & Mullen Company, Cleveland, Ohio. It is 250 feet wide by 280 feet long, the walls being composed of a single line of Lackawanna 8½-inch Straight-Web Sheet Piling in cantilever and reinforced for stiffness by timber piles and wales.



This large cofferdam is located on filled land on the lake front and the level of the lake is only two to three feet below the top of the steel sheet piling line. *In spite of these very unfavorable conditions the entire cofferdam is kept dry by a 3-inch pump working part time.*

For watertightness, it would be hard to improve upon such performance, but it will also be noted that the general arrangement is very economical in both first cost and maintenance.

If you have any shallow cofferdam work, let Lackawanna Engineers submit some interesting designs, with cost comparisons.



Large shallow cofferdams, especially in wet soil or standing in water, should always have walls of Lackawanna Steel Sheet Piling, because this steel sheeting keeps the water out, is very easy to install, and can be used temporarily or permanently as the conditions may demand. In the former instance, the salvage value of the Lackawanna Steel Sheet Piling should be close to 100 per cent, and in the latter there is practically no time limit for the full efficiency.

We Also Offer for Better Construction

Elcannes

Concrete Reinforcing Bars

The Elcannes Bar combines maximum bonding surface, minimum weight, and uniform strength. The bonding surface is 15 per cent greater than that of a plain square bar of equal nominal size. The cross-sectional area is practically the same at all points and the regular surface facilitates fabrication and handling.

When An Officer Leads His Men

By

C. A. Bach

Lieutenant Colonel, General Staff, U. S. Army

[*Note.*—The following article is from an address delivered by Colonel Bach to the students at the Officers' Training Camp, Fort Sheridan, Ill. It sets forth the fundamental principles of military leadership in a particularly clear and convincing manner, and cannot fail to be helpful to any who may ever be called upon to exercise such leadership.—ED.]

IN a short time each of you men will control the lives of a certain number of other men. You will have in your charge loyal but untrained citizens, who look to you for instructions and guidance.

Your word will be their law. Your most casual remark will be remembered. Your mannerisms will be aped. Your clothing, your carriage, your vocabulary, your manner of command will be imitated.

When you join your organization you will find there a willing body of men who ask from you nothing more than the qualities that will command their respect, their loyalty and their obedience.

They are perfectly ready and eager to follow you as long as you can convince them you have these qualities. When the time comes that they are satisfied you do not possess them, you might as well kiss yourself goodbye. Your usefulness in that organization is at an end.

From the standpoint of society, the world may be divided into leaders and followers. The professions have their leaders, the financial world has its leaders. We have religious leaders and political leaders, and society leaders. In all it is difficult, if not impossible, to separate from the element of pure leadership that selfish element of personal gain or advantage to the individual, without which such leadership would lose its value.

Not All Officers Are Leaders

It is in the military service only, where men freely sacrifice their lives for a faith, where men are willing to suffer and die for the right or the prevention of a great wrong, that we can hope to realize leadership in its most exalted and distinguished sense. Therefore, when I say leadership, I mean military leadership.

In a few days the great mass of you men will receive commissions as officers. These commissions will not make you leaders; they will merely make you officers. They will place you in a position where you can become leaders if you possess the proper attributes. But you must make good—not so much with the men over you as with the men under you.

Men must and will follow into battle officers who are not leaders, but the driving power behind these men is not enthusiasm, but discipline. They go with doubt and trembling and with an awful fear tugging at their heart strings that prompts the unspoken question: "What will he do next?"

Such men obey the letter of their orders, but no more. Of devotion to their commander, of exalted enthusiasm which scorns personal risk, of their self-sacrifice to insure his personal safety, they know nothing. Their legs carry them forward because their brain and their training tell them they must go. Their spirit does not go with them.

Great results are not achieved by cold, passive, unresponsive soldiers. They don't go very far, and they stop as soon as they can. Leadership not only demands, but receives the willing, unhesitating, unfaltering obedience and loyalty of other men; and a devotion that will cause them, when the time comes, to follow their uncrowned king to hell and back again if necessary.

You will ask yourselves: "Of just what, then, does leadership consist? What must I do to become a leader? What are the attributes of leadership, and how can I cultivate them?"

What Leadership Is

Leadership is a composite of a number of qualities. Among the most important I would list self-confidence, moral ascendency, self-sacrifice, paternalism, fairness, initiative, decision, dignity, courage.

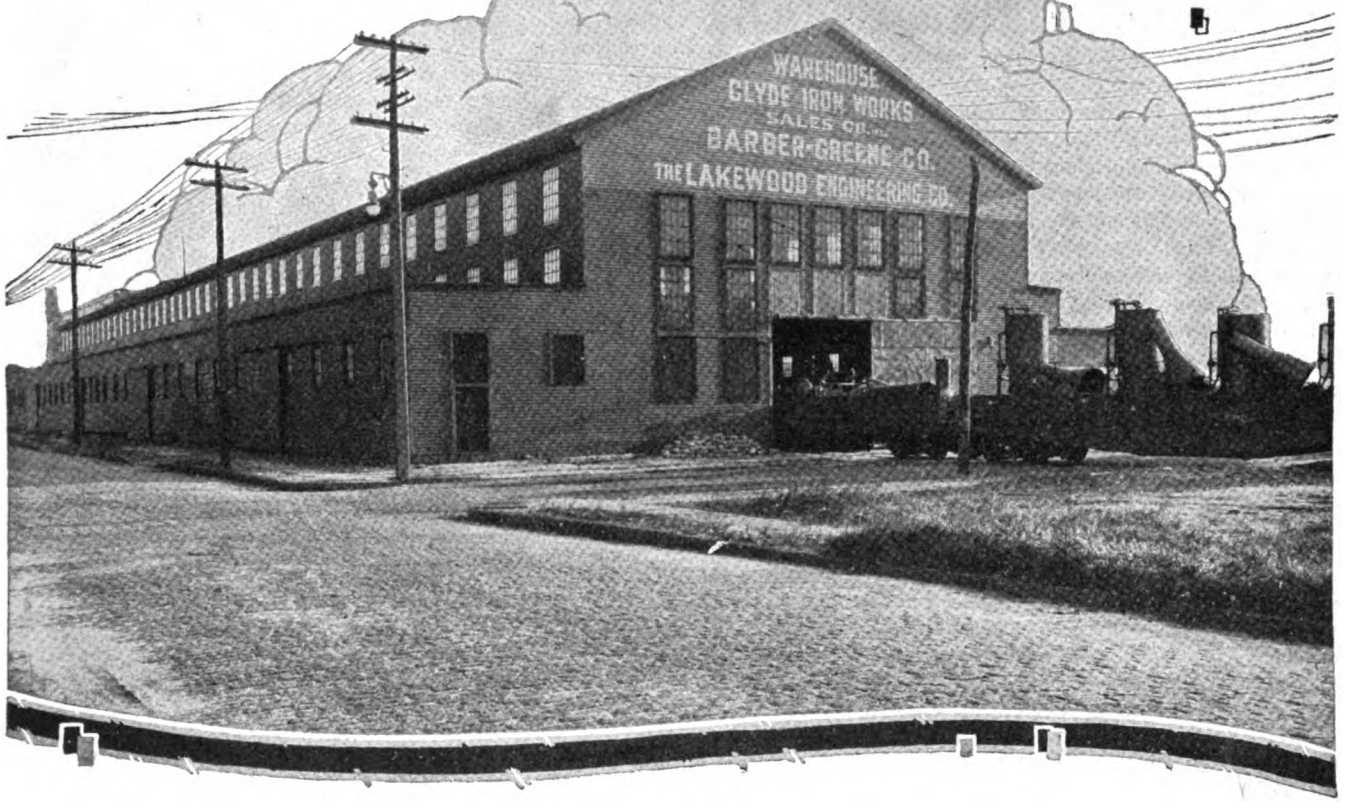
Let me discuss these with you in detail.

Self-confidence results, first, from exact knowledge; second, the ability to impart that knowledge; and, third, the feeling of superiority over others that naturally follows. All these give the officer poise.

To lead, you must know—you may bluff all your men some of the time, but you can't do it all the time. Men will not have confidence in an officer unless he knows his business, and he must know it from the ground up.

The officer should know more about paper work than his first sergeant and company clerk put together; he should know more about messing than his mess sergeant; more about diseases of the horse than his troop farrier. He should be at least as good a shot as any man in his company.

If the officer does not know, and demonstrates the fact that he does not know, it is entirely human for the soldier to say to himself, "To hell with him. He doesn't know as much about this as I do," and calmly disregard the instructions received.



There is no substitute for accurate knowledge. Become so well informed that men will hunt you up to ask questions; that your brother officers will say to one another, "Ask Smith, he knows."

And not only should each officer know thoroughly the duties of his own grade, but he should study those of the two grades next above him. A twofold benefit attaches to this. He prepares himself for duties which may fall to his lot at any time during a battle; he further gains a broader viewpoint which enables him to appreciate the necessity for the issuance of orders and join more intelligently in their execution.

Not only must the officer know, but he must be able to put what he knows into grammatical, interesting, forceful English. He must learn to stand on his feet and speak without embarrassment.

Bringing Clyde Distribution to the Door of Eastern Customers

FOR the past quarter century, Clyde Grade equipment has reached a continuously higher quality standard. During the same period the sales organization has developed correspondingly. Users of Clyde Hoists and Derricks in the Eastern United States have increased to such number that the New York warehouse has been established to facilitate deliveries.

The above photograph shows an arrival of Clyde Hoists in car load lots. A complete line of Hoists, Derricks and spare parts is carried at this location, which is one block from the East River on East 136th Street at Locust Avenue and on the N. Y., N. H. & H. tracks.

I am told that in British training camps student officers are required to deliver 10-minute talks on any subject they may choose. That is excellent practice. For to speak clearly one must think clearly, and clear, logical thinking expresses itself in definite, positive orders.

While self-confidence is the result of knowing more than your men, moral ascendency over them is based upon your belief that you are the better man. To gain and maintain this ascendency you must have self-control, physical vitality and endurance and moral force.

You must have yourself so well in hand that, even though in battle you be scared stiff, you will never show fear. For if you by so much as a hurried movement or a trembling of the hands, or a change of expression, or a hasty order hastily revoked, indicate your mental condition, it will be reflected in your men in a far greater degree.

In garrison or camp many instances will arise to try your temper and wreck the sweetness of your disposition. If at such times you "fly off the handle," you have no business to be in charge of men. For men in anger say and do things that they almost invariably regret afterward.

An officer should never apologize to his men; also an officer should never be guilty of an act for which his sense of justice tells him he should apologize.

Another element in gaining moral ascendency lies in the possession of enough physical vitality and endurance to withstand the hardships to which you and your men are subjected, and a dauntless spirit that enables you to not only accept them cheerfully, but to minimize their magnitude.

Make light of your troubles, belittle your trials, and you will help vitally to build up within your organization an esprit whose value in time of stress cannot be measured

Moral force is the third element in gaining moral ascendency. To exert moral force you must live clean, you must have sufficient brain power to see the right and the will to do right. Be an example to your men. An officer can be a power for good or a power for evil. Don't preach to them—that will be worse than useless. Live the kind of life you would have them lead, and you will be surprised to see the number that will imitate you.

A loud-mouthed, profane captain who is careless of his personal appearance will have a loud-mouthed, profane, dirty company. Remember what I tell you. Your company will be the reflection of yourself. If you have a rotten company, it will be because you are a rotten captain.

Self-sacrifice is essential to leadership. You will give, give all the time. You will give of yourself physically, for the longest hours, the hardest work and the greatest responsibility is the lot of the captain. He is the first man up in the morning and the last man in at night. He works while others sleep.

You will give of yourself mentally, in sympathy and appreciation for the troubles of men in your charge. This one's mother has died, and that one has lost all his savings in a bank failure. They may desire help, but more than anything else they desire sympathy.

Don't make the mistake of turning such men down with the statement that you have troubles of your own, for every time that you do you knock a stone out of the foundation of your house.

Soldiers As Children

Your men are your foundation, and your house of leadership will tumble about your ears unless it rests securely upon them.

Finally, you will give of your own slender financial resources. You will frequently spend your own money to conserve the health and well-being of your men or to assist them when in trouble. Generally you get your money back. Very frequently you must charge it to profit and loss.

When I say that paternalism is essential to leadership, I use the term in its better sense. I do not now refer to that form of paternalism which robs men of initiative, self-reliance and self-respect. I refer to the paternalism that manifests itself in a watchful care for the comfort and welfare of those in your charge.

Soldiers are much like children. You must see that they have shelter, food and clothing, the best that your utmost efforts can provide. You must be far more solicitous of their comfort than of your own. You must see that they have food to eat before you think of your own; that they have each as good a bed as can be provided before you consider where you will sleep. You must look after their health. You must conserve their strength by not demanding needless exertion or useless labor.

And by doing all these things you are breathing life into what would be otherwise a mere machine. You are creating a soul in the organization that will make the mass respond to you as though it were one man. And that is esprit.

And when your organization has this esprit you will wake up some morning and discover that the tables have been turned; that instead of your constantly looking out for them they have, without even a hint from you, taken up the task of looking out for you. You will find that a detail is always there to see that your tent, if you have one, is promptly pitched; that the most and the cleanest bedding is brought to your tent; that from some mysterious source two eggs have been added to your supper when no one else has any; that an extra man is helping your men give your horse a supergrooming; that your wishes are anticipated; that every man is "Johnny on the spot." And then you have arrived.

Fairness is another element without which leadership can neither be built up nor maintained. There must be, first, that fairness which treats all men justly: I do not say alike, for you cannot treat all men alike, for that would be assuming that all men are cut from the same piece; that there is no such thing as individuality or a personal equation.

You cannot treat all men alike; a punishment that would be dismissed by one man with a shrug of the shoulders is mental anguish for another. A company commander who for a given offense has a standard punishment that applies to all is either too indolent or too stupid to study the personality of his men. In his case justice is certainly blind.

Study your men as carefully as a surgeon studies a difficult case. And when you are sure of your diagnosis apply the remedy. And remember that you apply the remedy to effect a cure, not merely to see the victim squirm. It may be necessary to cut deep, but when you are satisfied as to your diagnosis don't be diverted from your purpose by any false sympathy for the patient.

Hand in hand with fairness in awarding punishment walks fairness in giving credit. Everybody hates a human hog.

When one of your men has accomplished an especially creditable piece of work, see that he gets the proper reward. Turn heaven and earth upside down to get it for him. Don t try to take it away from him and hog it for yourself. You may do this and get away with it, but you have lost the respect and loyalty of your men. Sooner or later your brother officers will hear of it and shun you like a leper. In war there is glory enough for all. Give the man under you his due. The man who always takes and never gives is not a leader. He is a parasite.

Digitized by Google

There is another kind of fairness—that which will prevent an officer from abusing the privileges of his rank. When you exact respect from soldiers, be sure you treat them with equal respect. Build up their manhood and self-respect. Don't try to pull it down.

For an officer to be overbearing and insulting in the treatment of enlisted men is the act of a coward. He ties the man to a tree with the ropes of discipline and then strikes him in the face, knowing full well that the man cannot strike back.

Consideration, courtesy and respect from officers toward enlisted men are not incompatible with discipline. They are parts of our discipline. Without initiative and decision no man can expect to lead.

In maneuvres you will frequently see, when an emergency arises, certain men calmly give instant orders which later, on analysis, prove to be, if not exactly the right thing, very nearly the right thing to have done. You will see other men in emergency become badly rattled; their brains refuse to work, or they give a hasty order, revoke it; give another, revoke that, in short, show every indication of being in a blue funk.

Regarding the first man you may say: "That man is a genius. He hasn't had time to reason this thing out. He acts intuitively." Forget it. Genius is merely the capacity for taking infinite pains. The man who is ready is the man who has prepared himself. He has studied beforehand the possible situations that might arise, he has made tentative plans covering such situations. When he is confronted by the emergency he is ready to meet it.

In Emergencies

He must have sufficient mental alertness to appreciate the problem that confronts him and the power of quick reasoning to determine what changes are necessary in his already formulated plan. He must have also the decision to order the execution and stick to his orders.

Any reasonable order in an emergency is better than no order. It is better to do something and do the wrong thing than to hesitate, hunt around for the right thing to do, and wind up by doing nothing at all. And, having decided on a line of action, stick to it. Don't vacillate. Men have no confidence in an officer who doesn't know his own mind.

Occasionally you will be called upon to meet a situation which no reasonable human being could anticipate. If you have prepared yourself to meet other emergencies which you could anticipate, the mental training you have thereby gained will enable you to act promptly and with calmness.

You must frequently act without orders from higher authority. Time will not permit you to wait for them. Here again enters the importance of studying the work of officers above you. If you have a comprehensive grasp of the entire situation, and can form an idea of the general plan of your superiors, that and your previous emergency training will enable you to determine that the responsibility is yours and to issue the necessary orders without delay.

Don't Cheapen Yourself

The element of personal dignity is important in military leadership. Be the friend of your men, but do not become their intimate. Your men should stand in awe of you—not fear. If your men presume to become familiar, it is your fault, not theirs. Your actions have encouraged them to do so.

And, above all things, don't cheapen yourself by courting their friendship or currying their favor. They will despise you for it. If you are worthy of their loyalty and respect

and devotion, they will surely give all these without asking. If you are not, nothing that you can do will win them.

It is exceedingly difficult for an officer to be dignified while wearing a dirty, spotted uniform and a three-days' stubble of whiskers on his face. Such a man lacks self-respect, and self-respect is an essential of dignity.

There may be occasions when your work entails dirty clothes and unshaven face. Your men all look that way. At such times there is ample reason for your appearance. In fact, it would be a mistake to look too clean—they would think that you were not doing your share. But as soon as this unusual occasion has passed, set an example of personal neatness.

And then I would mention courage. Moral courage you need as well as physical courage—that kind of moral courage which enables you to adhere without faltering to a determined course of action, which your judgment has indicated as the one best suited to secure the desired results.

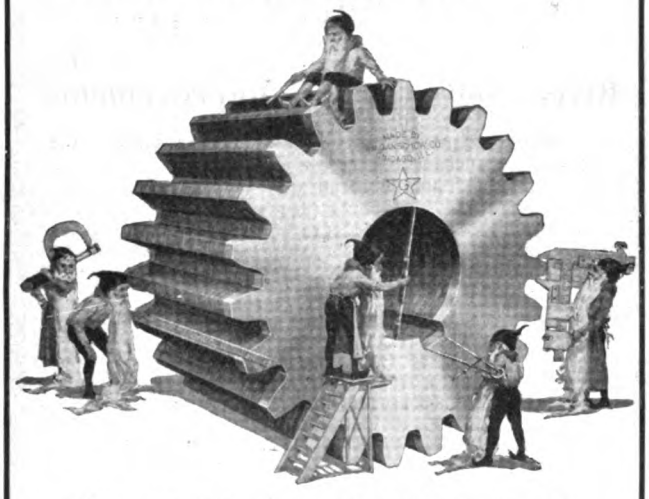
You will find many times, especially in action, that, after having issued your orders to do a certain thing, you will be beset by misgivings and doubts; you will see or think you see other and better means for accomplishing the object sought. You will be strongly tempted to change your orders. Don't do it until it is clearly manifested that your first orders were radically wrong. For, if you do, you will be again worried by doubts as to the efficacy of your second orders.

Every time you change your orders without obvious reasons you weaken your authority and impair the confidence of your men. Have the moral courage to stand by your order and see it through.

Moral courage further demands that you assume the responsibility for your own acts. If your subordinates have loyally carried out your orders, and the movement you directed is a failure, the failure is yours, not theirs. You would have been the honor had it been successful. Take the blame, if it results in disaster. Don't try to shift it to a subordinate and make him the goat. That is a cowardly act.

Furthermore, you will need moral courage to determine the fate of those under you. You will frequently be called upon for recommendations for the promotion or demotion of officers and non-commissioned officers in your immediate command.

Keep clearly in mind your personal integrity and the duty you owe your country. Do not let yourself be deflected from a strict sense of justice by feelings of personal friendship. If your own brother is your second lieutenant, and you find him unfit to hold his commission, eliminate him. If you don't, your lack of moral courage may result in the loss of valuable lives.



If, on the other hand, you are called upon for a recommendation concerning a man whom, for personal reasons, you thoroughly dislike, do not fail to do him full justice. Remember that your aim is the general good, not the satisfaction of an individual grudge.

I am taking it for granted that you have physical courage. I need not tell you how necessary that is. Courage is more than bravery. Bravery is fearlessness—the absence of fear. The merest dolt may be brave, because he lacks the mentality to appreciate his danger; he doesn't know enough to be afraid.

Courage, however, is that firmness of spirit, that moral backbone which, while fully appreciating the danger involved, nevertheless goes on with the undertaking. Bravery is physical; courage is mental and moral. You may be cold all over; your hands may tremble; your legs may quake; your knees be ready to give way—that is fear. If,

nevertheless, you go forward; if, in spite of this physical defection, you continue to lead your men against the enemy, you have courage. The physical manifestations of fear will pass away. You may never experience them but once. They are the "buck fever" of the hunter who tries to shoot his first deer. You must not give way to them.

A number of years ago, while taking a course in demolitions, the class of which I was a member was handling dynamite. The instructor said regarding its manipulation: "I must caution you gentlemen to be careful in the use of those explosives. One man has but one accident." And so I would caution you. If you give way to the fear that will doubtless beset you in your first action, if you show the white feather, if you let your men go forward while you hunt a shell crater, you will never again have the opportunity of leading these men.

Use judgment in calling on your men for displays of physical courage or bravery. Don't ask any man to go where you would not go yourself. If your common sense tells you that the place is too dangerous for you to venture into, then it is too dangerous for him. You know his life is as valuable to him as yours is to you.

Occasionally some of your men must be exposed to danger which you cannot share. A message must be taken across a fire-swept zone. You call for volunteers. If your men know you and know that you are "right," you will never lack volunteers, for they will know your heart is in your work, that you are giving your country the best you have, that you would willingly carry the message yourself if you could. Your example and enthusiasm will have inspired them.

And lastly, if you aspire to leadership, I would urge you to study men.

Get under their skins and find out what is inside. Some men are quite different from what they appear to be on the surface. Determine the workings of their minds.

Much of Gen. Robert E. Lee's success as a leader may be ascribed to his ability as a psychologist. He knew most of his opponents from West Point days, knew the workings of their minds, and he believed that they would do certain things under certain circumstances. In nearly every case he was able to anticipate their movements and block the execution.

You cannot know your opponent in this war in the same way. But you can know your own men. You can study each to determine wherein lies his strength and his weakness; which man can be relied upon to the last gasp and which cannot.

Know your men, know your business, know yourself.

Wire Mesh Roads—Loose sand, smoothed and leveled and covered with chicken wire netting, firmly pegged down, made roads which gave good service to the British Army in Egypt and Palestine. These roads were very satisfactory for foot troops and of some use for motor transport, but were rapidly rendered useless by animal drawn transport. Repairs are easily made. As ruts develop the netting is raised and the rut wiped out.

As an example of the successful practice of the art of the military engineer, namely, utilizing for his purposes whatever is available, these roads are most interesting.

Chicken wire has many military uses other than the retention of chickens, for which purpose it has been found almost useless in time of war. It is employed for roads, trench revetment, reinforcement for concrete, support for camouflage, or for siding for temporary buildings, etc.—*Reserve Engr.*

The Three Hundred

A lamentation of the ineligible

[With apologies to Ella Wheeler Wilcox, Lord Tennyson, The Three Hundred, the rest of the Army, and anybody else who may take umbrage.]

In accordance with the provisions of the Army Reorganization Act of June 4, 1920, the War Department, in General Order 74, December 16, 1920, published the initial list of some 300 officers eligible for General Staff duty.

The act further provides that, "After the completion of the initial General Staff Corps eligible list the name of no officer shall be added thereto unless upon graduation from the General Staff School he is specifically recommended as qualified for General Staff duty."

This procedure, as was of course inevitable, has moved some to laughter and others to tears. Our anonymous correspondent, whose contribution appears below, is moved to versification:

I

Half a life, half a life,
All a life working.
All in the Service Schools,
All but three hundred.
Cheers! for the staff brigade!
Cheers! for the schools they've made!
Cheers! for the life we'll lead!
All but three hundred.

II

Hurrah for the Staff Brigade,
Are any undismayed?
Not though the army knew,
Some one had blundered.
Theirs not to make reply,
Theirs but to school to hie,
There just to bone and die,
All but three hundred.

III

Schools to the right of them,
Schools to the left of them,
More schools in front of them,
Nothing but schools.
All know 'tis but a sell,
All who have worked like hell,
But 'tis fixed all too well,
'Tis of our hopes the knell,
All but three hundred.

IV

Flashed all our records bare—
Examined all with care,
Selecting this staff affair,
Back in some secret lair,
While the world wondered.
Screened in department smoke,
Till one day the service woke,
Undone at a single stroke.
All but three hundred.

V

Schools to the right of them,
Schools to the left of them,
More schools in front of them,
Nothing but schools.
Mark you the orders fell,
Hark to the tale they tell,
You that have fought so well.
Come through the jaws of death,
Back to a life of hell,
Back to your student's cell.
All but three hundred.

VI

When can their glory fade?
Oh! the fine schools they made!
While a world wondered.
Honor the schools they made,
Honor the Staff Brigade,
Lucky three hundred.

12th Engineers, Camp Grant, Illinois

"I know of no better motto than 'Essayons' for the Corps of Engineers," was the remark of the Camp Commander when he inspected the recently constructed officers' quarters upon their completion. The entire building work, which provided housing facilities for fifty families, was performed by the 12th Engineers.

From the exterior the neatly arranged bungalows present a pleasing colony effect, and the interior arrangements and conveniences leave nothing to be desired.

"Everybody and his wife" has moved in from Rockford, and in the evenings "Home Sweet Home" seems to the passerby to be Camp Grant's favorite tune.

An interesting feature of the instruction being given to the officers of the regiment is the series of lectures on "Civil Duties of Officers of the Corps of Engineers," by Col. T. H. Jackson, C. of E., commanding officer of the regiment. A number of years in charge of a flood-control district of the Ohio River and as a member of the California Debris Commission, enables the colonel to make his talks particularly valuable.

Although much regret was expressed by the members of the Sixth Division and their friends in Rockford over the loss by fire of the beautiful and commodious hostess house of the camp, the new building now practically completed in its stead by the 12th Engineers, bids fair to be a worthy successor. The arduous work of transporting the material for the new structure from distant parts of the cantonment in all kinds of weather did not daunt the officers and men of the regiment who have in a short time constructed a building that is the admiration of the camp.

The officers and ladies of the regiment gave a Valentine dinner-dance on February 8 at the Jewish Welfare Hostess House. Since the burning of the Camp Hostess House this building has been used in its place. Brig. Gen. George Bell, Jr., Camp Commander, was the guest of honor of the evening. Sixty couples were present and enjoyed dances between the courses and following the dinner.

The tastefully decorated rooms evoked much favorable comment. Hearts in Engineer colors were prettily displayed. A large one bearing the motto "Essayons" occupied a conspicuous place.

Music for the occasion was furnished by the 12th Engineers' orchestra.

The enjoyment of the evening was largely due to the painstaking efforts of Mrs. T. H. Jackson, who, in customary manner, worked for the success of the entertainment.

Capt. A. B. Shattuck, Jr., First Lieuts. William W. Wanamaker, W. P. Trower, Charles B. Jewell, Chester K. Harding, and W. A. Calla-way have left for the Engineer School, Camp Humphreys, Va.

Prior to their departure the bachelor officers of the group gave a farewell card party to the officers and ladies of the regiment. Refreshments were served and a very enjoyable evening spent.

Engineer officers recently assigned to the regiment are: Second Lieuts. G. H. Lambert, S. C. Joslyn, H. F. Hannis, T. T. Knappen, L. B. Robinson, and J. S. Seybold These officers are graduates of the latest U. S. Military Academy class, and completed a course of instruction at Camp Humphreys, Va., prior to their assignment to this command.

An Engineer Chapter of the Army Relief Society has been formed among the ladies of the regiment. The officers chosen for the coming year are: Mrs. T. H. Jackson, President; Mrs. B. B. Browne, Vice-President; Mrs. Alva H. Perkins, Secretary and Treasurer; Mrs. F. T. Bass, Relief Work.

The foreign-service detail has claimed four of the camp's most popular officers, all members of this regiment. Capt. R. H. Stock, First Lieuts. G. H. Stough, and J. P. Hyde have been transferred to the 13th Engineers, Hawaii, and First Lieut. A. B. Jones goes to the 11th Engineers in the Canal Zone.

After two months' sole possession of the southwest corner of the cantonment, orders have been issued from headquarters that we make arrangements to accommodate the 6th Field Signal Battalion in the area.

Everybody is working to have things in good condition for the signalers when they move in, and pleasure is expressed by all in anticipation of the arrival of such pleasant neighbors.

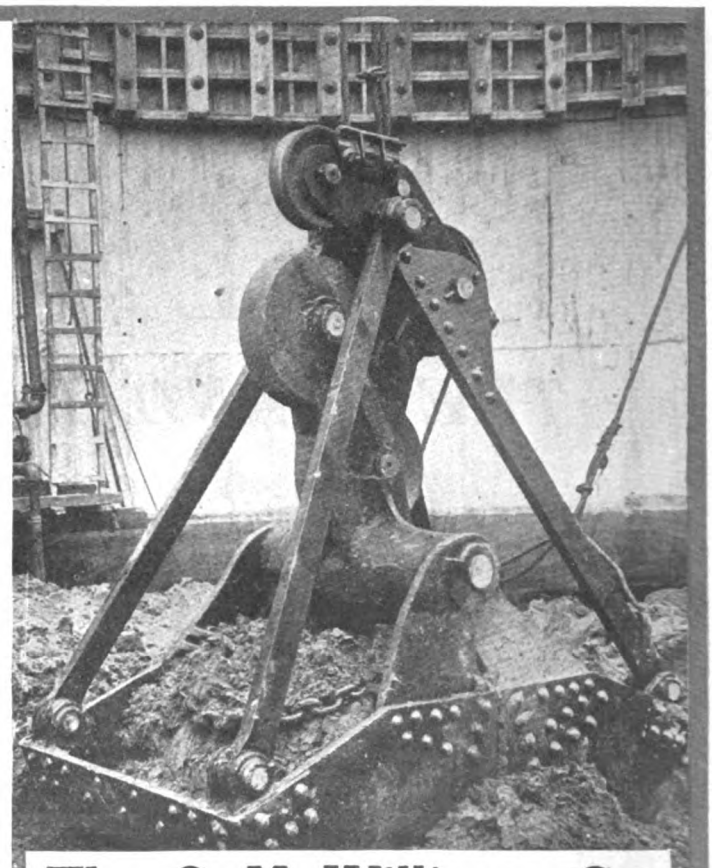
Williams Buckets

Simple, Speedy, Efficient and Easy to Operate

WILLIAMS BUCKETS are built to meet any condition. That is one reason why you will find them in use by all large steel plants and contractors in the world, by the United States and French Governments.



Note its sturdy, all-steel triangular construction—that insures rigidity and perfect alignment of all parts. Large bearings and fewest parts are other features. These with perfect lubrication reduce friction to a negligible quantity.

And remember we build them to dig—in addition to economy of operation, long life and *low cost of upkeep.*

Let us send you *full* details, including catalog.

A Rural Safeguard
~that only Good Roads could realize

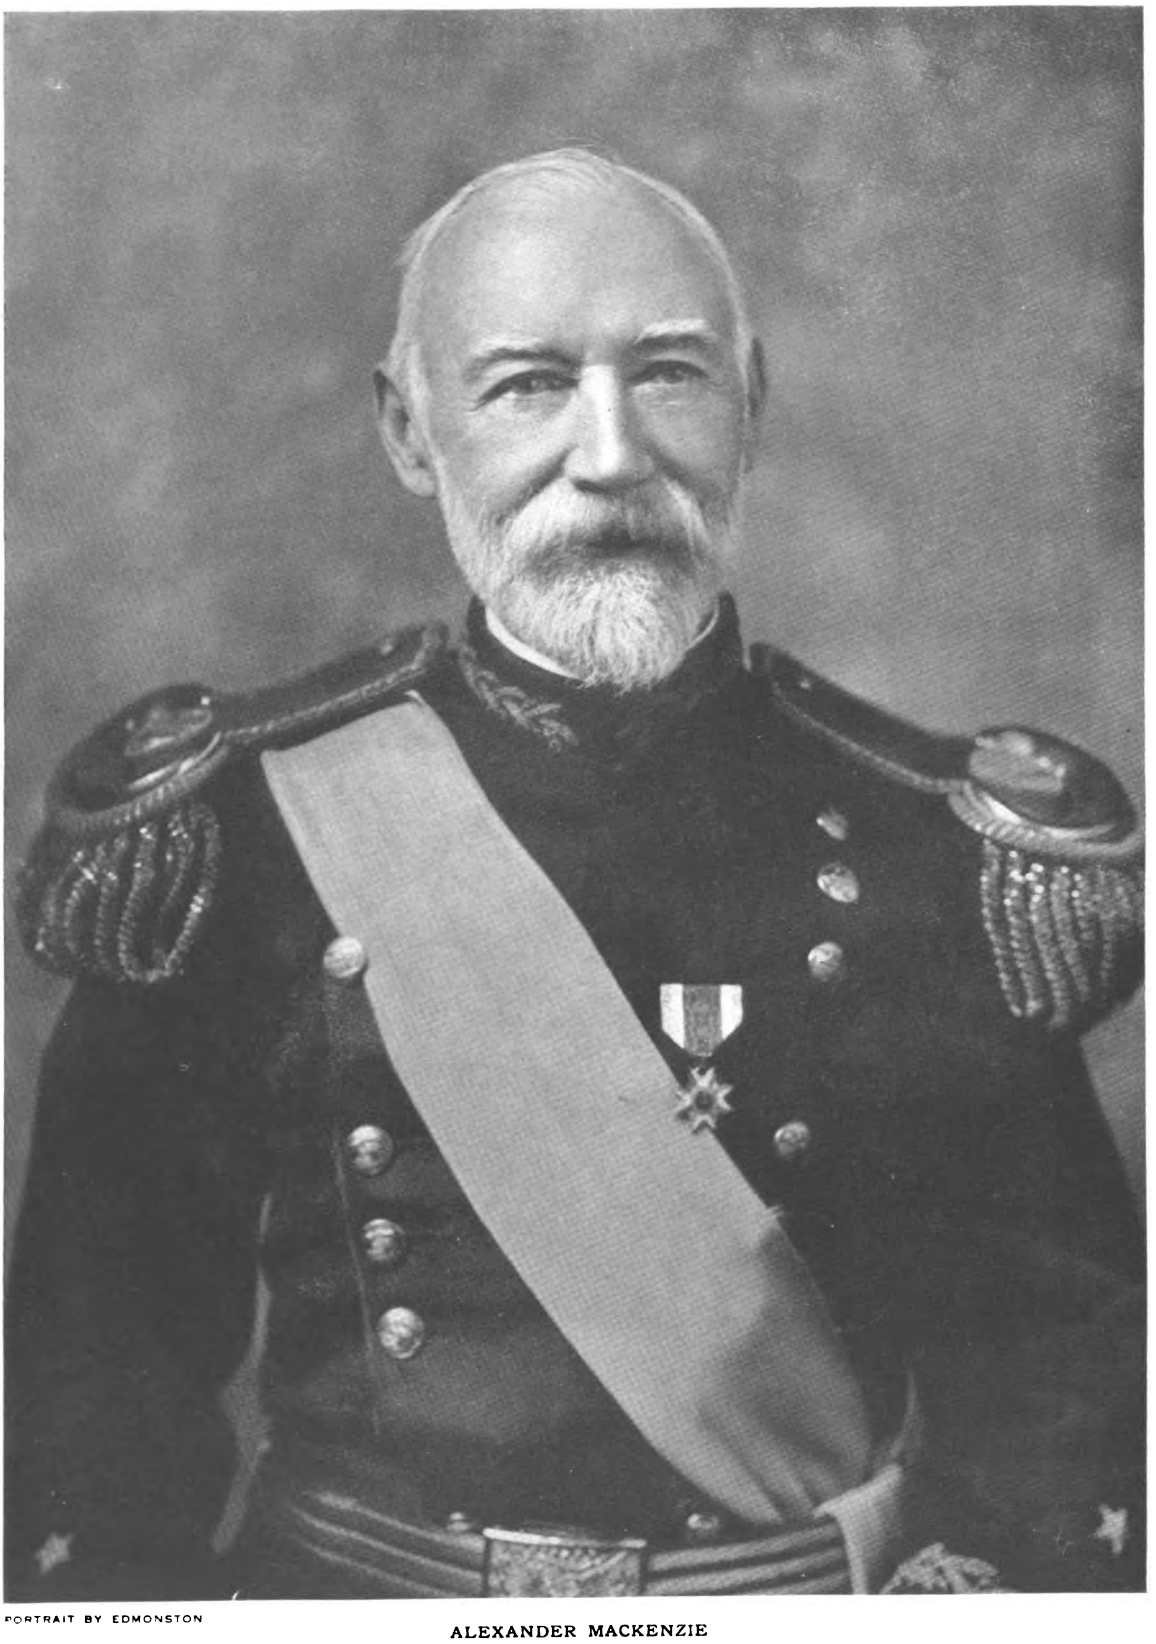
ON THE good roads of the future will come to rural communities every safeguard, every convenience, every substantial contribution to better living that restricted transportation facilities have hitherto limited to the city.

Let your vote be a recognition of these facts—let it be a recognition of the city, town, county and state officials who believe in and work for good roads. For remember that nothing can be a more fitting mark of national and community progress than complete—and permanent—highway systems.

KOEHRING Concrete Mixers standardize concrete

In the drum of the mixer are decided the durability of pavements and the strength of structures. The distinctive re-mixing action of the Koehring drum produces concrete that is uniform to the last shovelful—every fragment of stone, every grain of sand thoroughly coated with cement—*dominant strength concrete*, by official test, stronger than the concrete mixed by other mixers.

Koehring pavers and Koehring-equipped contractors are contributing enormously to the DOMINANT STRENGTH HIGHWAYS of today and tomorrow. The contractor who owns a Koehring concrete mixer is ready to assume responsibility for *Dominant Strength* concrete.



Write for Van Vleck's Book, "Standardized Concrete."

The Vicksburg Campaign

By

Peter C. Hains

Major General U. S. A. (retired)

THE annals of history do not disclose the story of a military campaign of greater interest than the campaign of Vicksburg fought by Gen. U. S. Grant in 1863, nor one that teaches better the lessons of grand tactics. Grant had already proved himself a great general on other fields, but the Vicksburg Campaign stands out in bold relief as the most daring and at the same time the most completely successful one in all the career of this remarkable man. The Appomattox Campaign that culminated in the surrender of Lee and the collapse of the Rebellion was the climax to which that of Vicksburg was the prelude.

While too much can not be said in praise of the brilliancy of Grant's maneuvers, it must be confessed that if Lee or Stonewall Jackson had been in command of the Confederate Army of the Mississippi at that time, the story would have been, in some respects at least, different.

Grant was no stickler for the rules either of strategy or logistics as laid down in the books. It is probable that he never opened a book on those subjects after he left West Point. He followed the dictates of common sense, and he had more of that commodity in his make-up than most men. If one were to define strategy, it would be difficult to describe it better than to say, it is the art of applying common sense to the directing of masses on the theater of war. As a matter of fact, the rules of strategy are based on common sense. One fundamental rule, is that it is wise to do that which your antagonist does not think you will do, and to avoid doing that which he thinks you will do. This rule of common sense was followed by Grant in the entire Vicksburg Campaign, as well as other of his campaigns, both before and after. It contributed in no small measure to his success.

The first attempt to capture Vicksburg was made in December, 1862, and this might be considered as the opening chapter of the Vicksburg Campaign. In this attempt Grant organized an army of about 22,000 men at Grand Junction and proceeded south along the line of the Mississippi Central Railroad, Haynes Bluff being the objective aimed at. At the same time another army of about 35,000 men under Sherman was collected at Memphis and proceeded south on transports with the idea of entering the Yazoo River and attacking Haynes Bluff from a westerly direction. The two armies were expected to co-operate and unite somewhere near Haynes Bluff. They were so far apart, however, that co-operation was not practicable. Grant's force proceeded down to the vicinity of La Grange, when his depot established at Holly Springs was raided by a force of cavalry and his supplies destroyed. As these were necessary to the further advance of his army he was compelled to fall back. Sherman succeeded, with the aid of Porter's fleet of gunboats, in entering the Yazoo River and made a fierce frontal attack on Haynes Bluff, but was repulsed with heavy loss. Both expeditions proved to be lamentable failures. Sherman did not hear of Grant's failure until after he had himself failed and Grant did not know of Sherman's failure until after he himself had failed. The difficulty of trying to combine tactically the movements of two separate armies operating on exterior lines is illustrated in these movements. They were both directed by Grant but they do not look like his work.

While these attempts might be considered the beginning of the Vicksburg Campaign, they are not generally so considered. The campaign is generally assumed to have begun April 30th, when Grant crossed the Mississippi River. The trouble with regarding the campaign as beginning April 30th is, that it leaves out of consideration the preliminary movements that took place between April 1st and April 30th. As some of these movements have an important bearing on the campaign, it is thought best to treat it as beginning April 1st. Moreover, it was about April 1st that Grant decided to move by the southern route. After the two failures referred to, some months were spent in trying other routes to reach the great stronghold—one by way of Yazoo Pass, which seemed to be promising, but which, after an unsuccessful trial, was given up. Another route by way of Lake Providence was carefully investigated and given up, and the same fate fell to other routes.

In the early part of 1863 the Army of the Tennessee, consisting of three corps, was organized and Grant took the field in personal command. About April 1st this army had its advance forces at or near Millikens Bend, almost in sight of the goal. The avowed objective of this Army of the Tennessee was the capture of Vicksburg and the opening of the Mississippi River to navigation.

Between January and April all known routes of approach to Vicksburg were carefully investigated and studied. All were eliminated from further consideration except the route by way of the Mississippi-Central Railroad with Memphis as the base of operations, known as the northern route, and the one by way of Richmond, Perkins Plantation or New Carthage, from the vicinity of which a crossing into the State of Mississippi was to be made.

From a purely military standpoint the northern route had many advantages and comparatively few obstacles that could not be readily overcome so far as human foresight could determine. A railroad was already in existence and while it was not in first-class condition and lacked rolling stock, these disadvantages could be readily overcome. Moreover, once the army was in rear of Haynes Bluff, the defenses of that place would be taken in reverse and must be abandoned by the enemy. The long railroad line could then be abandoned and a short one by way of Yazoo River and Haynes Bluff could be opened. This was an important consideration and was equally so even if the southern route should be adopted. In fact, either the northern or southern route looked to the opening of a short line of communication by way of the Yazoo River if a siege had to be resorted to.

Digitized by Google

The northern route avoided all the obstacles that were inherent in the southern, which were serious and not few in number. The fact that in December, 1862, Grant had been foiled in his attempt to reach Vicksburg by this same route, did not militate against it now. His former failure was due to the fact that he attempted it with too small a force and in consequence could not adequately protect his line of supply. With a much larger force he would be able to protect his long line of supplies until he opened the contemplated new one.

This northern route was advocated by his friend and military adviser, General Sherman, who commanded the 17th Army Corps. Sherman was regarded at the time as one of the ablest generals in the army and Grant shared in this high opinion of his friend and subordinate. The latter was so opposed to a southern route that he felt compelled to write a letter to his chief setting forth his objections, but at the same time stating that in case Grant decided in its favor, he would give it his most hearty support.

One of the most serious objections to the northern route was that it involved a retrograde movement of the army just at a time when our international relations with Great Britain and France were in a somewhat strained condition. Both these countries were almost ready to admit the Southern Confederacy as an entity in the Society of Nations. They had already acknowledged them as belligerents. Our crushing defeat at Fredericksburg, the doubtful victory of Murfreesboro, the slow progress made in recruiting the army, the great national debt that was piling up, and many other things of a political nature, had produced a most disturbing effect on the people of the North. To take away the Army of the Tennessee, now concentrated almost in sight of the goal it had set out to capture, without accomplishing anything, would have been looked upon as disastrous. It would have been hailed throughout the Confederacy as a Union defeat, encouraging the southern people to renewed efforts, and would have caused dismay among the Union people of the North. From a military standpoint the northern route appeared the safer and better one. From a political standpoint it was almost unthinkable.

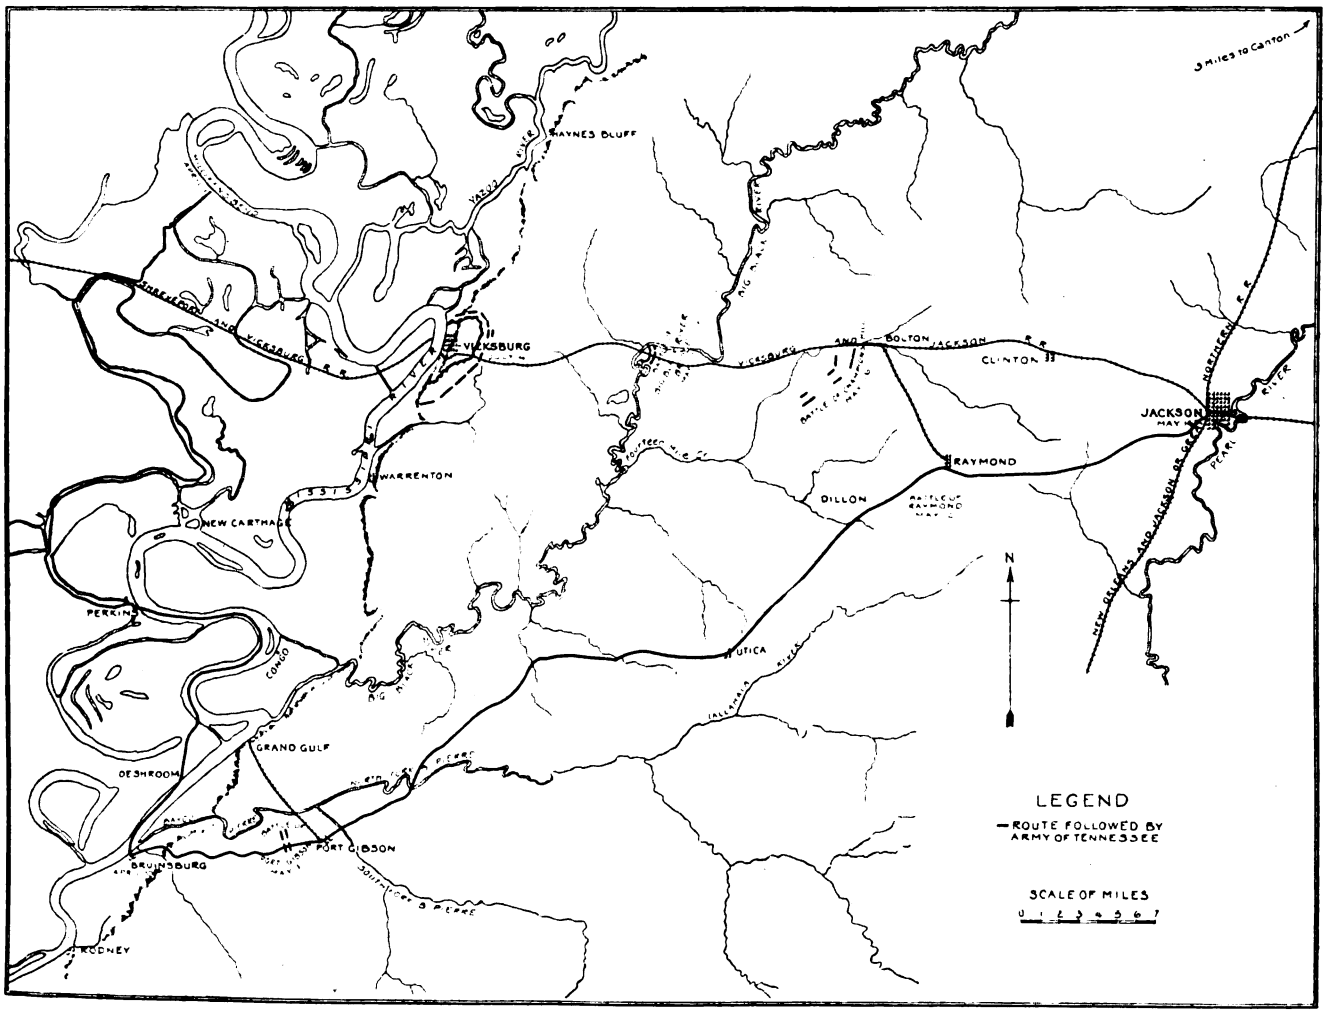
The southern route was beset with difficulties. To transfer the army from Millikens Bend to Perkins Plantation or New Carthage, was no easy task. The whole country was inundated by the high water in the Mississippi River which had come through the cuts in the levees made by the enemy. There were numerous bayous to cross which could only be crossed by bridges, which bridges had to be constructed by our own soldiers with timber growing in the swamps. The few pontons we had, belonging to a short section of a ponton bridge train, had been impressed into the service of carrying provisions to the advanced part of our army.

After all the army, if moved to some point near Perkins Plantation, would be worse off than it was at Millikens Bend, unless it was also provided with the means of transporting it across the river. That meant that transports and barges must be brought there from above Vicksburg. There were more below. Could the ordinary river steamboat run past the Vicksburg batteries without being so damaged as to be useless as a transport? There were many officers who believed it could not be done. Suppose, however, that enough transports and barges could run by the batteries and come out in a serviceable condition. Could a landing be effected in the face of an army as large as our own? Could our army after crossing be supplied with food and ammunition over the precarious line of communication behind us? These were weighty considerations. The difficulties to be overcome were great, but Grant was a great man and he decided to face them. Grant believed that some of the transports would be lost in running the batteries but he thought enough would get by to serve his purpose.

It was determined to try an experiment on the night of April 16. Three transports and about a dozen barges were selected to make the trip. The crews at once deserted and the volunteers had to be secured from the army. Of the three sent, one was destroyed, the other two got by in a damaged condition. They were quickly repaired, however, and made ready for service. General Sherman was so anxious about the result of this experiment that he spent the whole night in a small boat waiting below Vicksburg to see the result.

Ten days later, another consignment of transports had better luck. Six transports and twelve barges loaded with coal for the Navy were fitted out and ran the batteries. One transport was totally destroyed and six of the barges were lost. Of the five transports that got by in safety, some were damaged, but not seriously. They were soon repaired and we now had seven transports, and about a dozen coal barges ready for service.

This settled the question of our ability to ferry the army across the river so far as transportation was concerned. The only doubtful question now was what would the enemy do to prevent our landing on the east side of the river?



It is believed that the political conditions referred to above had something to do with Grant's determination to take the southern route. At that time he did not know the General in Chief of the Army. Halleck had no confidence in the plan of moving northward immediately after crossing the river. He had no objection to Grant's crossing the river, in fact, advised him to do so, but after doing so, to go south with about two-thirds of his army, and join Banks at Port Hudson. After reducing this place their united forces should go north and take Vicksburg. An order of Halleck forbidding the movement that Grant actually made was dated May 11th and sent by special messenger to him from Washington. It was delivered on the battlefield at Black River Bridge on the 18th, too late to be obeyed, and on the face of it an impolitic order, even if it had not been received too late. Halleck subsequently acknowledged that Grant was right and he himself was wrong.

The next thing was to find a suitable place to land on the Mississippi side of the river. Congo Landing, about 5 miles above Grand Gulf, was considered, but given up as unsuitable, as the bluffs were about five miles off, and the intervening ground low, flat, and only recently overflowed. Besides there was only one narrow road available and that unsuited to the movements of artillery.

General Grant and Admiral Porter held a conference on the question of landing, and it was decided to try to effect one on the water front of Grand Gulf itself. It was arranged that Porter, with his fleet of gunboats, would attack the batteries and silence the fire of the enemy's guns, while Grant would hold 10,000 men on transports and barges, ready to land as soon as the batteries were put out of action. It was thought that this could be done, as Porter had *81 guns*, nearly all of large caliber, to take into action, and it was known that the Confederates had only a few, and most of them of small caliber.

At 8 a. m. on the 29th of April, the gunboats went into

Map of the country between Millikens Bend, La., and Jackson, Miss., showing route followed by the Army of the Tennessee

Taken from Atlas accompanying official records, Part VIII. Original map prepared under the direction of Lieutenant-Colonel J. H. Wilson, A. I. G., and First Lieutenant Engineers. Surveys by First Lieutenant P. C. Hains, U. S. Engineers

action, and kept up a steady bombardment for five hours, moving up and down in front of the batteries, while Grant held his men ready to land. At the end of this time, no visible impression having been made on the batteries, the gunboats, having lost heavily in men, and having been damaged, some seriously, withdrew out of range. After another conference between Porter and Grant, it was determined that it was not wise to resume the fight, though Admiral Porter expressed a willingness to do so. Herein Grant displayed that keen judgment for which he was so noted, for if an attempt had been made to land our troops on that shore front, we would surely have been repulsed.

In this fight the Navy lost 11 killed and 56 wounded—a total of 67. The Confederate loss was only 3 killed and 15 wounded, a total of 18. The damage to the gunboats was serious, that to the batteries was practically nothing. The navy had 81 guns in action, mostly large ones of 9 or 11-inch caliber. The Confederates had only 13 guns, mostly of small caliber, a 30-pounder parrot being the largest.

It was decided in an interview between Grant and Porter, after the engagement, that a landing must be found lower down the river.

We now had a sufficient number of transports and barges to ferry the army over the river with some rapidity. But we had no time to waste, for we could not expect our enemy was going to make no further resistance to our landing.

It was Grant's intention at first to go to Rodney, but during the night of the 29th he learned from reliable sources that the landing at Bruinsburg was a good one with a good road leading to Port Gibson, ten miles inland. He decided then to land at Bruinsburg, and at daylight on the 30th the ferrying began from *De Schrooms Landing, where the 13th Corps spent the night.

To cross a river of moderate size in the face of an alert and enterprising foe, of about equal strength, is as a rule, no easy proposition. The difficulties are not lessened if the river is very deep, very wide, and with a 5-mile current. Ordinarily your adversary would be watching you from his side and would be prepared to give you an enemy's welcome when you arrived. Of course we expected a royal welcome of this kind, but when we landed there was not a Confederate picket or patrol in sight. No one but a poor old negro, who was anxious to lead us to a corral where he said there were a number of horses. As very few of us had horses, this was welcome news and we proceeded to benefit by that information.

The 13th Army Corps was about 22,000 strong and after having had 3 days' rations distributed to it, was rapidly pushed out on the road toward Port Gibson. When we

(NOTE: This is spelled Deshroom on the map.—ED.)

Digitized by Google

landed we had no idea of the piece of good luck that had fallen into our hands. The land was literally flowing with milk and honey. There was bacon and beef in abundance, corn meal and all the eatables that a hungry soldier, who had been floundering for six months in mud and swamps, could want. Not the least welcome of all things was good dry ground on which to sleep with no mosquitoes to keep us awake. The mosquitoes were so bad near Perkins Plantation that it is said two men were actually killed by them. The Army of the Tennessee actually had issued to it only five days' rations between April 30 and May 19. It lived practically on the country.

But where was the enemy? We had fought him only the day before at Grand Gulf only ten miles from Bruinsburg. Evidently the Confederate commander had been completely hoodwinked into the idea that Grant's main attack was to be on his right flank at Haynes Bluff, so he reinforced that flank and left the other to take care of itself. But why Bowen, who commanded the left wing, should have gone from Grand Gulf to Port Gibson to oppose our advance into the state, is incomprehensible from a military standpoint. He should have met us at Bruinsburg with all the force that could by any possibility have been spared from other places.

General Hovey's division, going out on the road leading to Port Gibson, came in contact with the Confederate pickets about four miles west of Port Gibson. The men on both sides rested on their arms until daylight. By the morning of May 1st, Grant had on the field or close up, five divisions, four of the 13th Corps and one of the 17th Corps. In all they amounted to about 27,000 men. Bowen had only 7,500; he himself says about 5,000. The result of the fight was, as might be expected, an overwhelming victory for the Union troops. That night Bowen fell back across Bayou Pierre and destroyed the bridge behind him. This delayed our pursuit, for as we had no ponton bridge train, the bridge had to be rebuilt of such material as could be hastily gathered together.

This first encounter was unfortunate for the Confederates as it dampened their courage and raised the spirits of our men. The battle also decided the fate of Grand Gulf which, after spiking the guns, was immediately abandoned by the enemy.

After taking possession of Grand Gulf, Grant had two lines of operations open to him, *first* the one he actually followed moving northeastward to Jackson, and *second,* the one due north, crossing the Big Black River at one or more of the ferries, from each of which fairly good roads led to Warrenton and the rear of Vicksburg. Warrenton once in our possession would have afforded a good line of operations. This line would have put our army on the weakest flank of the defenses of Vicksburg and we would have had the close co-operation of the Navy, but we would still have been under the necessity of keeping open the precarious line of supply from Millikens Bend to New Carthage or Perkins Plantation. The base that Grant was after was that at or near Haynes Bluff, which could be reached by his transports via Yazoo River.

Besides, it was important to capture Jackson and destroy its usefulness to the Confederates, and it was important to keep in view the probability of an attack from that direction after we had established our line of circumvallation around Vicksburg.

From May 1st to May 12th the time was utilized in converting Grand Gulf into a temporary base, and in getting together the fragments of our army which had become somewhat scattered. At the same time the biggest part of the army moved northeastward leisurely along the left bank of the Big Black to Fourteen Mile Creek. Grant had now gotten his troops well in hand. During this period Pemberton's army was apparently waiting for something to turn up, and it soon did. He was more fortunate than Micawber.

On May 12th McPherson, with two divisions of his corps en route to Jackson, encountered two Confederate brigades at Raymond, and after a spirited engagement lasting about two hours, drove them away toward Jackson. This was another unnecessary fight, in which we had a preponderance of three to one.

On May 14th Grant attacked Jackson, the capitol of the State of Mississippi, which was an important railroad center for the Confederates. His attack was made by two divisions of Sherman's Corps, and two divisions of McPherson's, in all about 22,000 men. The Confederate general, Joseph E. Johnston, who had just arrived and assumed command of all the forces in the vicinity, including Pemberton's command, had about 11,000 men. Jackson was supposed to be strongly fortified, but was not. The Confederates made no serious attempt to hold it and after a brief engagement hurriedly retreated northward toward Canton. The retreat was so precipitate that General Grant and his staff, who had gone to the right of our line to investigate conditions, found an unguarded road leading into the town, which they followed and were the first troops there.

McClernand had one division at Bolton, with two others in supporting distance. Grant had thrust the largest part of his army in between the two Confederate armies and the order of Johnston, that Pemberton join him via Clinton, could not be carried out. Pemberton made no attempt to carry it out. Instead, he notified Johnston that he would at once move his army southward and attack Grant's rear at or near Dillons Plantation. He started to carry out this design, but being delayed by heavy rains had only proceeded a few miles when he was overtaken by a second order from Johnston directing him to abandon Vicksburg and unite his army to that of Johnston then retreating towards Canton. Pemberton now started to comply with this last order, which was in reality a repetition of the first, when he came in contact with Hovey's Division of McClernand's Corps, which had been at Bolton and was now on the march westward toward Vicksburg. This meeting, wholly unexpected by Pemberton, brought on the battle of Champions Hill, in which the Confederates were disastrously defeated. Again it was a case of fine tactical maneuvering in which Grant brought on the field a preponderating force of not less than two to one. The Confederate loss was fully 8,000 men, including Loring's Division, which was cut off from the main body and went to Jackson. The rest of Pemberton's army fled in great disorder towards Vicksburg. Pemberton seems never to have given any serious consideration to the possible necessity of evacuating Vicksburg. Consequently when the necessity was forced on his consideration, he had made no preparation looking to that emergency and finally when he was ordered to do so, he could not obey the order.

The pursuit was taken up early on the morning of the 18th and a detachment of about 1,600 men was overtaken at Black River bridge where the detachment had been left to guard the crossing until Loring's division arrived. But Loring's division having been cut off, did not arrive. There were two bridges across the Big Black protected by a strong bridgehead, but the latter was carried by assault chiefly by Lawler's brigade of Carr's division. The

Digitized by Google

bridges across the Big Black having been prematurely burned, the entire garrison was trapped by their own act and compelled to surrender. In this engagement our forces outnumbered the enemy at least five to one.

A bridge was hastily constructed out of the unburnt timbers of the old railroad trestle and from cotton gin buildings, before the morning of the 19th, and the 13th Army Corps immediately began to cross rapidly in pursuit of the flying enemy.

As the Confederates were supposed to be very demoralized as well as disorganized, an attempt was made on the 19th to carry the defenses of Vicksburg by assault before the enemy had time to recover their morale. It failed. After the enemy got behind their line of works they seemed to recover their spirits and made a good defense.

The 20th and 21st were spent in pushing our lines up close to their works and in getting our artillery in position.

On the morning of the 22nd after a severe bombardment of the enemy lasting two hours, from all the guns in position, about 200, aided by all the guns and mortars of Porter's fleet in the river, a fierce assault was made along the whole line, but this was also repulsed. The men who could not apparently fight in the open now fought like demons behind their fortifications. Some of our regiments succeeded in planting their colors on the parapets, but they could advance no further. That night after dark our troops were withdrawn to more secure positions and siege operations were ordered to begin at once. But we had no tools and had to wait for them to be sent from the North. The siege lasted just 42 days, only two over the number laid down in the books as allowable. On July 4th the Confederates stacked their arms just outside their works and we took possession of them. We found they had better rifles than we had, that they still had a small supply of ammunition, but they had nothing to eat. Soldiers cannot fight without somehing to eat, so they surrendered.

Pemberton was a fine looking soldier in steel gray uniform as he sat down at the table to sign the document of capitulation, but one looking at him at the time could not help pitying him. He was a broken man. He had staked everything on a policy of defense, which he doubtless realized too late was a mistake. He had now lost Vicksburg and his army as well.

Grant's Clearcut Project

When General Grant crossed the Mississippi River he had a well-defined project of operations in mind. He hoped and expected (1) to move his army northward, (2) to capture Jackson, the capital of the state, (3) to open for his own army a short line of supply via the Yazoo river, (4) to bring Pemberton, if possible, to battle in the open field, and (5) then to drive him into Vicksburg and lay siege to that place if he could not carry it by assault. If, however, this program could not be carried out, he was prepared to go south with a part or all of his army to aid Banks in the capture of Port Hudson and after capturing that place for their united armies to come up the river and capture Vicksburg.

The capture of Jackson was important because three railways, one from the north, one from the east and one from the south centered there. These roads were the main lines over which the supplies and reinforcements of the Confederate army were received. Besides, it was the left flank of the line of defense that it was supposed Pemberton would take up. To break through that line was essential to the opening of a short line of supplies for our own army. We might get along temporarily by means of the precarious line from Millikens Bend to Grand Gulf, but this was liable to be broken. The Yazoo line was safe and sure as soon as we could get possession of Haynes Bluff. Hence the haste with which Grant dispatched Sherman's Corps to that place on May 18th.

The magnitude of Grant's victory was amazing, even to ourselves. He totally destroyed an army almost as large as his own, captured 260 guns of all calibers, besides about 60,000 muskets, caused the surrender of Port Hudson with all its armament and about 6,000 more men, opened the Mississippi River to the navigation of the great northwest, broke the Confederacy into two pieces, destroyed almost absolutely all communication of the Confederacy with foreign nations, cut in two the lines of supply the Confederacy had established to Mexico, and carried dismay to the hearts of the southern people, many of whom saw in the fall of Vicksburg the downfall of the southern Confederacy. All these results were accomplished with a loss on the part of the Union forces of about 10,000 men.

To what was success due?

To what can the magnificent success of the campaign be attributed? Certainly not to overwhelming numbers in Grant's Army. The field army of the Tennessee was not greatly different from that of the Confederate Army of the Mississippi. There is an old saying that "figures do not lie," but it is well known that figures given by writers, of the numbers in contending armies, seldom agree. We can estimate, however, the number in the Confederate Army of the Mississippi, say on May 1st, which is a fair date of comparison, by working backward.

Total number of men and officers surrendered at Vicksburg on July 4th	31,600
Their loss during the siege is conservatively estimated at about	1,000
Prisoners taken at Black River Bridge, May 18th	1,600
Loring's Division (estimated) cut off in the battle of Champions Hill	5,000
Lost in the battle at Champions Hill	3,000
Lost in the battle at Jackson, May 14th	700
Lost in the battle at Raymond, May 12th	500
Lost in the battle at Port Gibson, May 1st	700
Total	44,100

(This number includes only the troops in the second or Vicksburg military district. It does not include those in the 1st, 3rd, 4th or 5th military districts. The troops in these excluded districts would have added something at least to Pemberton's total.)

The Army of the Tennessee

Number for duty as per muster rolls in the 13th Army Corps (4 divisions)	22,000
Total estimate in the 15th and 17th Corps, each consisting of 3 divisions	33,000
Total	55,000

It is to be stated, however, that there were no sick men in the Army of the Tennessee. The sick were all left behind when we crossed the river, but on the other hand the Confederate Army was on the defensive, and being on the defensive it had many advantages which the Army of the Tennessee did not have. All the intelligent people of the South were its friends and practically all were our enemies. Their means of getting information as to the numbers and organization of the opposing force were far above ours. Many of their people believed they were fighting a holy war against an invader who was stealing their property. The rank and file were practically on an equality in other respects, so that taking into consideration the conditions existing on both sides, it is fair to assume that

Digitized by Google

the two armies were not materially different in strength.

To what then can we reasonably attribute the magnitude of the victory? First and foremost it was due to the fact not known to everybody at that time that the army of the Tennessee was commanded by one of the greatest generals in history, and had two of the best corps commanders that the Civil War produced. In all his maneuvers, both tactical and strategical, after May 1, Grant made no blunders and but few mistakes, whereas his adversary made few mistakes but many blunders. The Confederate commander may not have been in all cases responsible for the blunders, but blunders were made and they contributed in no small degree to our success.

Grant, in his "Memoirs," states that Providence dictated the Vicksburg campaign of the Army of the Tennessee. Grant was not a conspicuously religious man, nor was he an irreligious one. He possessed many Christian virtues that professing Christians did not, but for him to attribute to Providence what seems clearly to most of us as due to his own merits as a general looks as though he was overmodest in stating the case. The Army of the Tennessee, it is true, did the fighting, but he directed it. The army was the tool used. The mechanic who handled the tool was Grant. Does any one believe that if the campaign had been a failure Grant would have sought to put the blame on Providence? Not a bit of it. He would, with his inherent magnanimity have taken the whole responsibility on his own shoulders. Shall he not then have the credit for success?

To sum up in a few words, the success of the campaign was due, first, to Grant's ability as a general, second, to the valor of his army, and third, to the blunders of his adversary.

One conspicuous blunder made by our adversaries was in failing to make any provision whatever for an attack from the south. The problem for the Confederate Army was to prevent the crossing of the Mississippi River by the Union forces in such numbers as would threaten the capture of Vicksburg or the destruction of the Confederate Army protecting it.

It is obvious that if the crossing of the river could be prevented the object of the Confederate Army of the Mississippi would be achieved. The first thing, therefore, was to prevent, if possible, the crossing of the river. There was no place between Vicksburg and Grand Gulf where the river could be safely crossed, and roads found by which the army could proceed inland and attack Vicksburg. Consequently, the crossing would be made, if at all, at or below Grand Gulf. If made below Grand Gulf the army would in all probability proceed north by some of the numerous roads that existed in that section. The problem then was to prevent the crossing, and, failing that, to meet Grant's army in the field before it could be concentrated for attack. Pemberton made no effort to prevent our crossing the river, nor did he make any effort to attack us. He merely waited, apparently, to see what Grant would do.

The waiting policy is well known to military men to be dangerous, and is only justified when *it is known* that one's forces are greatly inferior in numbers or morale to those of one's antagonists. The Confederate force was not greatly inferior to ours in numbers or morale. Field fortifications constructed at important points should not then be omitted if there is a possibility that they might be needed. The importance of this is seen in the repulse of Grant's army on May 19 and 22. Field fortifications cost little and sometimes prove to be invaluable.

It must be assumed that Pemberton did not believe that Grant would land at Bruinsburg. If he had so thought he should have made some disposition to meet him. If Grant had not landed at Bruinsburg, he would have landed at some other point farther south, as Rodney. There were good roads leading from both places into the interior.

As to the possibility of attack via the Yazoo River, it was unreasonable to expect that to be repeated so soon after Sherman's disastrous failure. It was hardly probable that Grant would try that route again until the floods in the Mississippi River, which were an important factor in causing Sherman's failure, had subsided.

As to the probability of an attack from the north via the Mississippi Central Railroad, Pemberton must have known that if Grant moved his army back to Memphis it would be regarded as an acknowledgment of failure, that it would, in any case, take considerable time to do it, and that it could not be done without his knowing it. An attack by way of the Yazoo or Memphis being improbable, there was only one other route, and that led from the south. There was a probability that Grant might go south and join Banks in reducing Port Hudson. After taking which, the two armies, united, would come north to invest Vicksburg. This project would take time, but was a safe one for Grant, and it is almost certain that Grant would have taken advantage of it had his project of turning north from Grand Gulf failed.

The idea that Vicksburg was designed to protect a field army, and the field army was to protect Vicksburg, are incompatible. These duties were not dependent upon each other. If there was a field army, its place was in the field, not around Vicksburg. The army of the Mississippi was a field army, or, at least, it was used as such, and yet it was a garrison army as well. As a field army it was too small. As a garrison army it was too large.

Vicksburg, itself, was of no special value to the Confederacy except insofar as the guns mounted on the river front closed the river to navigation. How, then, were these guns to be protected? The answer to that question depends on the answer to the further question, By what would their destruction be threatened? Certainly not by a cavalry raid nor by the navy alone operating from the river. The menace could only come from a field army, and the menacing army must be met by an opposing field army. The batteries could not be protected by chaining the army to the guns, but by giving it mobility.

History abounds in records of armies that have taken refuge in fortresses where there was a large civil population. Such civil population is a great hindrance to the defense. It is an aggravated hindrance when supplies from the outside are in danger of being cut off. In that case the fortress generally falls a victim of starvation, if not to the superior force of the enemy.

It is not claimed that an army may not take *temporary* refuge in a fortress liable to investment, but the commanding general who takes his army into such a place must have the most positive assurance that it will not be left there to take care of itself. Vicksburg when once invested was completely cut off from all supplies and from all communications with the outside world. Its only hope thereafter was in a relieving army. Failing that, its doom was sealed.

It is easy to criticize, but not always easy to suggest a course that would forestall criticism. In this case, however, certain things were obvious at the time. For instance, a strongly entrenched camp should have been established from which a mobile army could operate on the front, flank or rear of an invading army from the south.

The next thing in order was the creation of a field army out of whatever forces were in the Department of the Mississippi or could be brought there. For this purpose every place of minor importance should have been alto-

Digitized by Google

gether abandoned. If not abandoned, they should have been temporarily occupied by detachments only, made from the field army. The idea should have been inculcated and fostered that the defense of Vicksburg was dependent on a field army and not on a garrison stationed behind the forts around the town.

The field army concentrated in an entrenched camp midway between Vicksburg and Jackson would have protected Vicksburg on one flank and Jackson on the other. Haynes Bluff could be quickly reinforced from there, if necessary. The entrenched camp should have been formed by strong *enclosed* redoubts connected in whole or in part by light infantry parapets. Redoubts open in rear are liable to be taken in reverse when a part of the weaker infantry parapet is broken through, as was the case at Jackson. The lines of circumvallation at Vicksburg were about twelve miles long. They could have been reduced under these circumstances to three or four. No army could seriously threaten Vicksburg from the rear if a field army was camped at Bolton or thereabouts.

The railroad connecting Vicksburg and Jackson would have afforded the means of rapid movement of forces and made the line between the two cities a strong one for defense; beside the railroad there were several good wagon roads to supplement the railroad in the rapid concentration of troops on either flank.

Jackson was not only an important railroad center, but it had several factories where war material was manufactured for the Confederate Army. Besides, all reinforcements for the Confederate Army must naturally come by way of one of the railroads that centered at Jackson. Consequently Jackson should have been adequately fortified. The elaborate works at Black River Bridge would have been unnecessary.

Beside the above, Raymond being at an important intersection of roads, should have had a strong enclosed redoubt to be occupied when danger seemed imminent. Willow Springs should also have been fortified. Bruinsburg and Rodney should both have had advanced field works. The bluffs at both places afforded excellent sites for defensive works.

If ever a defensive campaign was fought where a force of cavalry would have had telling effect, it was the Vicksburg Campaign. When Grant crossed the Mississippi River, he did not have a single squadron of cavalry with him. Indeed, he had none to speak of at any time during the campaign. The official returns show that Pemberton had in his Department of the Mississippi on April 1, the following cavalry organizations:

Gallelyn's Mississippi Cavalry, Second Tennessee Cavalry, Martin's Cavalry Company, Johnson's Cavalry Company, Van Dyke's Cavalry, Smith's Partisan Rangers, Adams' Cavalry, First Arkansas Cavalry, First Missouri Cavalry (dismounted), Third Missouri Cavalry (dismounted), First Tennessee Cavalry, Ninth Tennessee Cavalry, Ninth Louisiana Cavalry, Bolen's Cavalry Company, Gant's Cavalry, Teny's Cavalry Company, Garland's Cavalry, First Mississippi Rangers, Miller's Cavalry.

From the above formidable list of organizations, even though some may have been mere skeletons, it would seem that a respectable cavalry force could have been organized. An insignificant force of cavalry patrolling the shore from Vicksburg to Rodney could have kept Pemberton advised of the position of Grant's force, the number of transports, the position of Porter's fleet, and other items of information of value to a commanding general. A good brigade of cavalry under a competent officer could have delayed Grant at the landing until the whole of Bowen's Division could have been deployed along the bluff.

Another blunder was made when Pemberton, on May 14, undertook to cut off Grant's communications with his base at Grand Gulf, when he ought to have known that the only one he then had was a movable one of about two hundred (200) wagons loaded principally with ammunition. Grant's Army was actually living on the country.

But the train was absolutely vital to Grant's army unti a new base could be established at Haynes Bluff.

From the Confederate standpoint the battle of Port Gibson was a blunder. If fought at all, it should have been fought at Bruinsburg, while Grant's army was being landed from the transports. Moreover, the Confederates should have had at least 20,000 men to oppose Grant at the landing, and if that number was not available it would have been better not to have fought any battle at all.

When we consider how good a fight the enemy put up at Port Gibson on May 1st and at Grand Gulf on April 29th, it is probable that a good temporary defense might have been made at Bruinsburg, even with 7,500 men. The bluffs there, being about three miles back from the river, were beyond the range of the guns of Porter's fleet.

When the map is studied, one is naturally inclined to ask what did Bowen go to Port Gibson for? The place was of no particular value to the Confederates nor to us. Under some conditions it might have been useful as a position from which Grant's line of operations from Grand Gulf, if he had kept it, could be menaced, but Grant never intended to hold Grand Gulf as a base. The paltry 7,500 men sent to Port Gibson were not capable of accomplishing anything of value.

It was a serious blunder when on April 29th, Pemberton mistook the demonstration against his right flank, made by Sherman, for a real attack and the real one on his left flank made by Grant for a feint. There was no sufficient reason for this blunder. Of course, Pemberton did not know how many men Sherman had with him in his demonstration at Haynes Bluff, nor how many men Grant had on the other flank, but it is one of the tricks of the trade to fool your adversary if possible and the adversary if he is wide awake must see to it that he is not easily fooled.

It is not claimed that Pemberton might have found out exactly how many men were in each column. But he ought to have been able to determine approximately the number Sherman had. Sherman went up the Yazoo River on transports. This river was a narrow crooked stream, heavily timbered on each side. The most incompetent secret service department ought to have been able to count the number of transports and estimate approximately the number of men on each. If Pemberton did not have any such department one should have been organized. In default of an organization, some of his soldiers could have done it with little risk.

On May 1st Sherman, having accomplished his work of frightening Pemberton into the idea that he was going to attack in force, withdrew from the Yazoo and joined Grant at Grand Gulf a few days later without fighting at all and without the loss of a single man.

The conditions at Haynes Bluff on April 29th were precisely what they were on January 1st, four months prior. At the latter time Sherman attacked that place with 35,000 men and was defeated. Was it reasonable to suppose he was about to repeat that attack with a smaller force?

Did Grant make any blunders? In the light of all the information now available, and which was not available at

Digitized by Google

the time, it must be conceded that Grant made no blunders. Some mistakes of judgment he made, but they were few. It is believed his worst mistake was made when on May 22d he ordered an assault along the entire line in an effort to carry the enemy's works by storm. However, he had good reasons for it at the time. It was a case of assault or siege. If an assault succeeded a siege would be avoided. If it did not, a siege would follow as a matter of course.

The Army of the Tennessee was not prepared for a siege. It had no entrenching tools whatever and they could not be had in much less than ten days or two weeks from the North. There were no engineer troops in his army. Hot weather was coming on and with it would come much sickness. We were liable to be attacked in the rear by an army that it was known was being formed under Johnston for Pemberton's relief, and it was possible the relieving army might be larger than Grant could cope with in addition to that of Pemberton. Moreover, the men themselves were averse to settling down to the hard labors of a siege until after a trial had been made to take the place by storm. The men felt after the successful assaults on the works at Jackson and Black River Bridge that they were well nigh invincible. These reasons, it is believed, were sufficient to justify the order.

While we believe Grant was justified in ordering the assault, it is believed he made a tactical error in ordering it made simultaneously along the whole line. It is a military maxim that one man behind good field works is equal to three or more in the open. As the number in Grant's army at that time and place did not exceed Pemberton's by more than about 30 per cent at the most, it is easy to see that he was taking risks—that theoretically the advantage would be with the enemy. Moreover, we had been repulsed in a similar but less intense assault on the 19th when Pemberton's army was supposed to be demoralized from its recent defeats in the field.

It is believed that it would have been a better tactical arrangement to have massed, say four divisions, on some one point and have made it the assaulting column. Between the right of McClernand's Corps and the left of McPherson's, there was a far weaker place than most of the other parts of the line. A large deep ravine existed in rear of this part of the line and gave advantages for massing such a force during the night. These four divisions could have been taken, say two from McClernand's Corps and one each from McPherson's and Sherman's. Of course, an attack would have been kept up along the whole line at the same time, but not with the fierceness with which it was made under the orders received. It is not claimed that this form of attack would have succeeded, because the Confederate works were generally strong, but it is certain that the chances of success would have been better.

The Siege

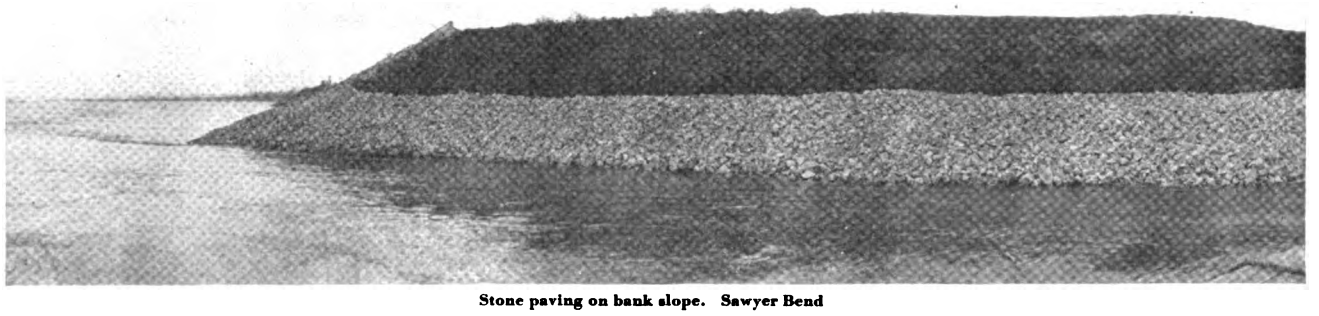
The siege of Vicksburg officially began on May 23rd, the day after the unsuccessful assault. In reality it did not begin until about June 1st, as up to that time there were not tools to work with. The ground for the most part on the hills around Vicksburg was dry and hard, having almost the tenacity of indurated clay. Picks were essential as well as shovels, and it is believed there were not 100 picks in the whole army.

The deep dry bayous that intersected the neighborhood of Vicksburg afforded excellent means of approach to the near vicinity of the fortifications but in many places they formed almost impassable obstacles. They afforded us sufficient cover, however, to lay out the first parallel at an average distance of about 600 yards.

The Confederate works consisted of a series of redoubts, irregular in shape and generally open in the rear, connected by light trenches for infantry. The redoubts had a strong profile with dry ditches about 6 to 7 feet deep and from 6 to 10 feet wide. The infantry parapets had no ditches and were constructed by throwing the dirt from the trenches up in front of them. It is curious to note that the works, even for the more important redoubts, seldom provided flanking defenses for the ditches, so that when our men got into the ditch of a redoubt they were generally comparatively safe, except from lighted shells which could be rolled over the parapets from the inside. Lighted shells were used as hand grenades but there were no hand grenades at first in either army. We got some from the navy later on, but in the early stages of the siege no hand grenades were used.

The redoubts were generally built on spurs that projected out from the main line and these redoubts invariably attracted the storming parties. The redoubts were the most prominent parts of the work and the most severe fire came from them. To avoid being taken in flank the men naturally swerved toward the point from which the fiercest fire came. In that way the attacks of each division were made on the strongest points—just where the Confederates wanted them made.

By reason of the lack of engineer troops and the almost total lack of tools, progress was very slow. The fact is, the siege was carried to a successful issue by main strength and awkwardness. The men in the ranks for the most part were intelligent farmer boys who learned quickly how to handle entrenching tools, as they already knew how to handle a rifle, but it took time for them to learn. If the siege had began about the 1st of July instead of the 22nd of May, a much better showing would have been made as to speed.



In the early days of the siege there were only two officers of Engineers serving in their professional capacity as engineers, Captain Fred Irvine and the writer. Two others were in the Army of the Tennessee, Major General McPherson, commanding the 17th Army Corps, and Lieutenant Colonel James H. Wilson, who was Grant's Inspector General. Captains Comstock, McAllister and J. M. Wilson arrived after the siege was half over.

The unscientific way in which some of the siege work was carried on is illustrated in the establishment of the second parallel in front of the 13th Corps. Lawler's Brigade, composed chiefly of Iowa troops, occupied a part of the line just where a wide deep ravine existed in front of them. The crest of the near side of this ravine was occupied by our people and that of the farther side by the Confederates. The two sets of pickets being close enough to engage in conversation (they were not more than 50 feet apart) soon became sociable and made an agreement not to fire on each other without giving warning. The Confederate picket line was exactly on the ground that we wanted for a part of the second parallel. The writer notified General Lawler that he wished to occupy that ground and requested him to advance his pickets when the two lines took their places for the night.

On the evening of June the 20th, the two picket guards deployed and started forward from their works at a double-quick on the sounding of retreat, each trying to get as far forward as possible. In this double advance the two picket lines met and then passed each other before they could be

Regulation of Middle Mississippi River

By

DeWitt C. Jones* and **Jas. W. Skelly†**

Major, Corps of Engineers — Formerly Major, 12th Engineers

[*Note.* An air of romance has clung to our great river, since the days of the aborigines, through the times when it silently witnessed the exploits of the daring explorers, La Salle and De Soto, the pioneer period immortalized in song and story by Mark Twain, Tom Sawyer and Jim Bludsoe, who are real characters in the minds of many American boys.

The Mississippi, with its great tributaries, is the largest navigable river system in the world. Millions of people live in its broad valley, and every one of them is interested in its problems. Not a few have their own solutions of these problems, as indicated by the many suggestions received by the Mississippi River Commission as to how to control "the Father of waters."

The methods employed in the regulation of the Mississippi River, in the interests of navigation and flood abatement, are based upon experience extending over many years. Major Jones has described them in most entertaining fashion in the article which follows.—ED.]

General Description and History

Geography. The "Middle Mississippi" comprises that section of the Mississippi River included between the mouths of the Mississippi and the Ohio Rivers. Considered just above the mouth of the Ohio, near Cairo, Ill., the Middle Mississippi drains an area of 707,000 square miles. It forms a central link of the great system of navigable waterways which may eventually connect the Great Lakes with the Gulf of Mexico.

Physical Characteristics. The Middle Mississippi flows through alluvial "bottoms" composed of sand and silt with occasional deposits of gravel and limited in width by lines of rocky bluffs from 3 to 7 miles apart. Above Commerce, Mo., these bluffs impose strict limits upon the lateral movements of the stream. At Commerce, however, they diverge almost at right angles to the direction of the stream and below this point exercise no restraining influence.

The river bottoms, in their natural state, are largely subject to overflow in times of flood, and are covered with heavy growths, principally of willows in the newer deposits and of mixed timber in the older. The lands are extremely fertile and have in large part been protected by levees and put into cultivation.

The bottoms contain a number of lakes and dry lakes formed by cut-offs of the stream, or the closing of chutes or minor river channels, or, in some cases, by the river having completely forsaken one bed for another. The channel of the stream was divided and obstructed by many islands, "towheads" and shifting sandbars. "Towhead" is the colloquial name given to a more or less permanent small island.

The distance from the mouth of the Missouri to the mouth of the Ohio, measured along the present river channel, is 200 miles. Measured along the line midway between the limiting bluffs, this distance is 160 miles.

Low water at the mouth of the Missouri is 395 feet above mean gulf level, and at the mouth of the Ohio 275 feet. The slope of the valley is therefore .75 foot per mile, while the mean slope of the river is about .6 foot per mile.

The banks of the stream are stationary only at points where they are artificially fixed. In general, the concave sides of the bends are marked by caving banks, while the convex sides are being built up by accretion. The river channel is constantly changing position. The river as a whole moves from side to side and the bends and straight reaches move downstream. The stream at long intervals completely abandons some section of its bed, and adopts a new channel opposite this section.

In addition to the movement of the stream bed as a whole, there is a continual shifting of the navigable channel within the bed itself. This movement is due to the changing slope of the banks and bottom of the stream, and to fluctuations in water stage, all of which influence the currents which maintain the channel.

A longitudinal section of the river shows a succession of pools and bars. The bars move downstream at varying rates with respect to the shore. Their crests rise as the water stage increases and are cut through by the current as the water falls. In general, the crest of a bar will rise about two-fifths as much as the increase in the water stage. A gradual fall of the river allows time for the crest of the bar to be washed off into the pool below, but a rapid fall leaves these crests near the surface, formerly in the unimproved river, reducing the navigable depth over some of the bars to 3¼ or 4 feet. A continued low water stage allows time for the current to deepen the channel across the bars.

In general, the pools are formed in the narrow portions of the river and in the concave bends where the current exercises a concentrated scouring action. The bars occur in the broad stretches of the river, and at points where the current is deflected diagonally across the stream from one concave bank to another.

Upon the Middle Mississippi there are about sixty of these bars, any one of which may become obstructive at

*District Engineer, St. Louis Engineer District. †Assistant Engineer, St. Louis Engineer District.

Digitized by Google

low water stages. Many of these potential obstructions lie dormant and give no concern during a long succession of years, while a few are chronic trouble makers. At present it may be said that from eight to sixteen of these bars may be expected to rise to within 8 feet of the water surface at some period during each low-water season and to require engineering treatment in order that an 8-foot channel may be maintained. The combined length of these shallow stretches is insignificant, probably not exceeding three miles even at the lowest stages. The *average* low water depth of the main channel of the Middle Mississippi is about 18 feet. The low water discharge is about 40,000 cubic feet per second. Even at the lowest stages there is ample *water* for all purposes of navigation. The problem is to control the *sand* so as to prevent its piling up on the crests of the bars. The finer material normally carried in suspension is an important factor where shore deposits are concerned, but is relatively unimportant in its effect upon the sand bars.

Engineering problems presented

The principal engineering problems presented by the Middle Mississippi are:

(*a*) *Flood control.* The oscillation between the average annual high and low water stages is 25 feet. The extreme recorded differences are 44 feet at St. Louis and 56 feet at Cairo. The control of floods and the protection of land from overflow is in charge of The Mississippi River Commission, acting under The Chief of Engineers and The Secretary of War.

(*b*) *Protection of land against erosion—Reclamation—Irrigation.* The Middle Mississippi presents possibilities for such works, but the Federal Government has never undertaken them. Works designed primarily for flood control or channel improvement have, in many cases, the secondary result of protecting land from erosion by the current. Although riparian interests are constantly striving to secure governmental action in saving private property from destruction by the river, such work has never been recognized as of such national importance as to warrant independent Federal action.

(*c*) *Water-power development.* Possibilities exist for power development on the Middle Mississippi, but definite projects have not as yet advanced beyond preliminary investigations.

(*d*) *Terminal facilities.* Terminal and unloading facilities have been constructed and maintained by municipalities and private interests. The Federal Government, in connection with channel improvement, has protected these facilities and provided a proper channel to give access to them.

The usual river landing or "levee" consists of a paved ramp, or incline, extending along a section of the river from high to low water limits. Recent municipal and private installations at St. Louis include pile docks extending to deep water and carrying freight handling machinery and a concrete dock with vertical wall to deep water and carrying modern machinery and freight houses. Within the past year the Federal Government has undertaken to construct certain terminal facilities at St. Louis.

(*e*) *Channel improvement and maintenance.* Channel improvement and maintenance is the duty of the District Engineer of the St. Louis Engineer District of the Engineer Department at Large, acting under the Division Engineer Western Division, The Chief of Engineers, and The Secretary of War.

Generally speaking, the work consists in stabilizing the river bed and the main river currents as far as possible, so as to prevent the formation of obstructive bars and to decrease the difficulty to navigators of knowing and following the channel, the prompt removal of bars when formed, and the removal of snags, wrecks, and other obstructions to navigation. Maintenance of river lights and other aids to navigation is a function of the Lighthouse service. The Engineer Department supplements this work by marking with buoys all dredged channels and difficult crossings. A crossing, as the term is here used, means a stretch in which vessels pass from a navigable channel on one side of the river to that on the other; usually this will be a reach between two bends in opposite directions.

District organization

In order to accomplish the improvement of the Middle Mississippi River, the St. Louis Engineer District is organized into an office force, a field force, and an engineer depot.

Office organization—

The District office comprises:

(*a*) *An engineering section* which develops plans, for channel improvement in accordance with approved projects, recommends the adoption of sub-projects and the distribution of available funds, designs the necessary engineering works, organizes the field forces and supervises the actual construction of the engineering work.

(*b*) *A clerical and accounts section* which handles all money accounts, disbursements, civil service and general records, property accounts and miscellaneous business.

(*c*) *A drafting and map section* which directs the necessary surveys, prepares maps, supervises gage readings and keeps the necessary records.

Field organization—

The field forces vary in strength and composition, each party being organized and equipped to perform its own definite duty as described in detail hereafter.

Engineer depot—

The depot is maintained at St. Louis, Mo., and consists of the various shops necessary to maintain the river fleet, machinery and equipment, a subsistence section to handle rations for the working forces, a property section to handle property and the purchases of fuel and supplies, and a force of watchmen and shipkeepers to protect the fleet.

Improvement projects

Original condition of channel—

In its natural condition, the channel of the Middle Mississippi was obstructed by many snags. The stream was divided at many places, even at low water stages, into several separate channels or chutes, and the sand bars reduced the navigable low water channel depths in places to as low as 3½ or 4 feet. The constantly shifting channel required skillful piloting for navigation and the great fluctuation of water stage made construction of loading and transfer facilities difficult. Despite these adverse channel conditions, the rapid development of the Mississippi Valley, the absence of railroads, the development of the steamboat, and the imperative demand for transportation facilities produced a great and thriving river traffic. As early as 1836, the Federal Government provided small amounts of money for the improvement of St. Louis harbor. At this time, the annual river traffic at St. Louis approached 500,000 tons. With the rapid growth of commerce upon the river, the Federal Government, in a small way, under-

Digitized by Google

took to make navigation less dangerous by the removal of snags and wrecks from the channel. It was not, however, until 1872 that a Board of Engineers presented a definite project for the improvement of any part of the Middle Mississippi. Curiously enough, this year marks approximately the peak of the curve showing annual river traffic at St. Louis. At this time the annual average of freight handled by water at St. Louis approached 2,000,000 tons Since 1872, the river channel has been steadily improved, but river traffic, due to causes other than channel conditions (chiefly railroad development), has steadily declined until at our entrance into the World War it amounted at St. Louis to less than 150,000 tons annually. During the past three years Government activity in water transportation has greatly stimulated the river traffic.

The project of 1872—

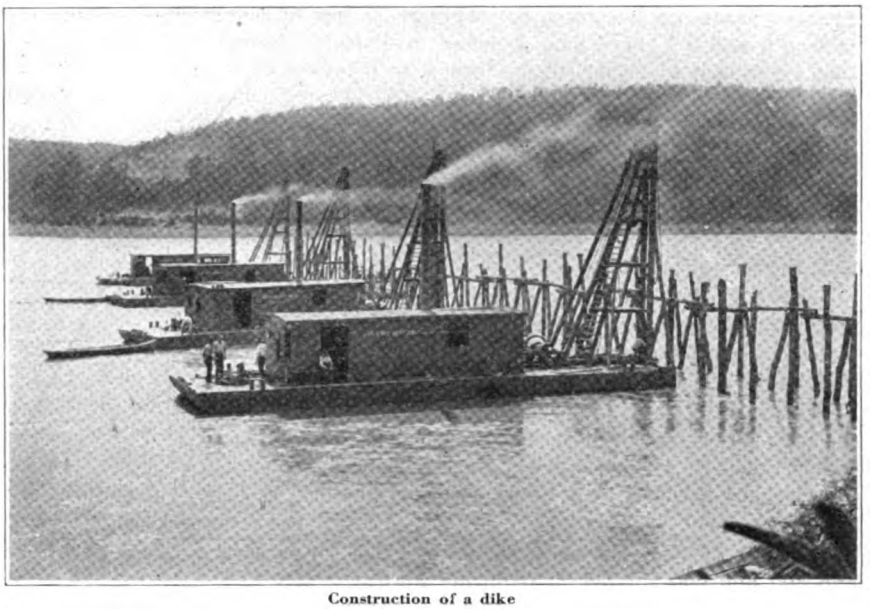
This project was concerned with the improvement of the river in the immediate vicinity of St. Louis and included recommendation for a survey of the river as far south as Cairo.

The theory of the original and all later projects is that the stream bed must be fixed by means of bank revetments, walls or dikes, that the channel width must be reduced where excessive, and that the low water flow must be forced into the main channel by the closing of the chutes and secondary channels. The purpose is to maintain a gently winding course rather than to shorten or straighten the channel. It is folly for man to violently oppose nature on the Great River.

The true object to be attained is the regulation of the movement of the *shifting river sands.* The current is the great regulating power, the engineering devices being but the harness used to apply the power of the current. Experience and experiment have changed the details of engineering construction, but the current remained the sole moving power until 1896 when it was supplemented by the hydraulic dredge.

About $1,500,000 was expended under the original project. Dikes, training walls and revetments were constructed in the vicinity of St. Louis, and the survey was completed to Cairo.

Existing project, 1881—



The existing project, as originally submitted in 1881, was to make the improvement continuous, working downstream from St. Louis. The banks were to be stabilized by revetments; the widths, where excessive, to be reduced to 2,500 feet by dikes; the side channels were to be closed by dikes or dams. By these means, it was intended to maintain a low water channel depth of at least 8 feet.

This project was interrupted and practically abrogated by acts of Congress in later years, but was restored by the Rivers and Harbors Act of 1910, which also provided for maintenance by dredging which had been employed upon the Middle Mississippi since 1896. The revised project contemplated a minimum low water channel width of 200 feet and a low water depth of 8 feet from St. Louis to the mouth of the Ohio and of 6 feet from St. Louis to the mouth of the Missouri. The project was to be completed in a period of 12 years at an estimated cost of $21,000,000 in addition to the $13,000,000 already expended. After completion of the project maintenance costs would, according to estimates, be $400,000 per year.

Work upon the revised project, amounting to about $1,000,000 annually, was pushed forward until 1914 when appropriations were cut to about $300,000 per year—a sum sufficient for maintenance and dredging only. Since 1914, no new work has been done except where necessary as a step in maintenance of existing works. At present, the project is about one-third completed. The present day cost of completion is estimated at $25,000,000 to $30,000,000.

Location and works of improvement

Each section requiring improvement must be studied carefully in connection with the proposed works above and below the section, and conclusions must be reached as to the character and exact location of the regulating works required in the section to insure that the general scheme of improvement will be maintained. In general, experience has shown that mattress and stone bank revetments have proved successful in the concave bends, and that permeable dikes or hurdles have been successful on convex banks where it is desired to hold or build up the shore, and in chutes and side channels to be closed. Revetments on convex banks are superfluous and hurdles or dikes placed in concave bends are ineffective. The general plan of fixing or contracting a channel is to fix the concave side of the bend by revetting the bank, and if contraction be required, to accomplish it by construction of hurdles on the convex shore approximately at right angles to the current. Detailed descriptions of the construction of the engineering works used on the Middle Mississippi are given below:

Construction of a dike

Materials of construction

The principal materials used in construction of hurdles and bank revetments are piles, brush or lumber for mattress construction, stone and spalls for revetments and ballasting, wire and nails. These are generally found within the district, and are procured either by hired labor or by purchase.

Piles are delivered by contractors to designated localities

Digitized by Google

as required, or are loaded on Government barges and towed by Government steamers. Two general classes of piles are used. Piles of the first class are cypress or white oak, not less than 10 inches in diameter at the small end, exclusive of bark, nor more than 20 inches in diameter at the large end. Lengths range from 36 feet to 65 feet. Piles of the second class are cottonwood, cypress, oak, hickory, elm, pecan or sycamore, not less than 8 inches in diameter at the small end, exclusive of bark, nor more than 18 inches in diameter at the large end. Lengths range from 30 feet to 65 feet.

Willow brush or cull lumber, depending on the available supply of willows and the cost of lumber, is used in construction of subaqueous mattress for hurdles and bank revetment. The supply of willows depends on the rate of use as well as the extent of bar formation which is promoted by hurdle construction. The increased cost of lumber has of late years considerably decreased its use. Desirable willows are live fresh cut saplings 30 feet or more in length and not more than 4 inches in diameter, except that 5 per cent of larger brush, from 4 to 6 inches in diameter, may be used.

Mattress lumber must be of sound live timber, cut not more than three months before being sawed, free from large knots, shakes, brittleness and other defects rendering it unfit for use. The boards are 1 inch in thickness, not less than 12 feet in length and 4 inches in width, nor more than 6 inches in width.

Stone and spalls must be of such kind and quality of rock as will not deteriorate under action of the elements, and stone must be in pieces weighing not more than 100 pounds nor less than 20 pounds.

Wire is soft steel, annealed, usually about 0.08-inch in diameter. It is made into lashings of four wires or twisted into strands of sixteen wires. Approximately 3 pounds of wire are used to each linear foot of standard width mattress.

Nails are of steel wire in sizes 10d and 20d for lumber, and 20d and 60d for brush, requiring approximately one-half pound per linear foot of mattress. Square steel boat spikes, ¼ inch by 6 inches, are used for clamping wire strands in mattress construction and in clumping piles.

Permeable dikes or hurdles

A hurdle, as the term is here used, is a silt-arresting device, consisting essentially of a row or parallel rows of piles, driven usually in clumps, forming a permeable dike through which the silt-laden current can pass, but with greatly diminished velocity, resulting in deposits of silt above and below the hurdle, which are soon overgrown with willows. Hurdle lines have generally been built normal to the direction of river flow or slightly inclined upstream therefrom.

A hurdle construction plant includes a number of pile-drivers, usually four to eight, each with its crew, small flatboats, at least two to each pile-driver, a derrick-boat for transferring piles from barges to flatboats, one or more steam tenders or small steamboats, a complete mattress construction outfit, including bank paving force, one or more quarterboats for quartering and subsisting men, field office, blacksmith shop, store boat, etc., the total force varying from less than one hundred to two hundred or more men, depending upon the amount of work to be done.

A broad flexible mattress is first sunk on the hurdle line to prevent loss of the piles by scour and through this mattress the piles are driven. In order to provide an apron to catch the overfall due to the head, about two-thirds of the mattress width is placed below the piling line. At the shore end, the bank is protected against scouring or caving by a revetment about 300 feet in length, of which two-thirds is placed below the hurdle. Mattress and revetment for hurdles are very similar to those described under bank revetment.

For many years hurdles have been constructed of clumps of piles, generally three, though sometimes four piles to a clump. The clumps are grouped in rows of one, two or three to a hurdle. The piles are driven so that when their upper ends are drawn together by means of a wire rope they form a sort of pyramidal structure, the horizontal distance of the piles from each other at the surface of the river bed being 8 to 10 feet, depending mainly on the depth of the water. About one pile to the linear foot of hurdle is required.

The tops of the piles are generally at an elevation of 20 feet above extreme low water, except that in the upstream row, the top of one pile in each clump is at an elevation of about 25 feet above that stage in order to intercept drift at high stages and prevent it from crossing the line of hurdle and dragging the top of the latter with it.

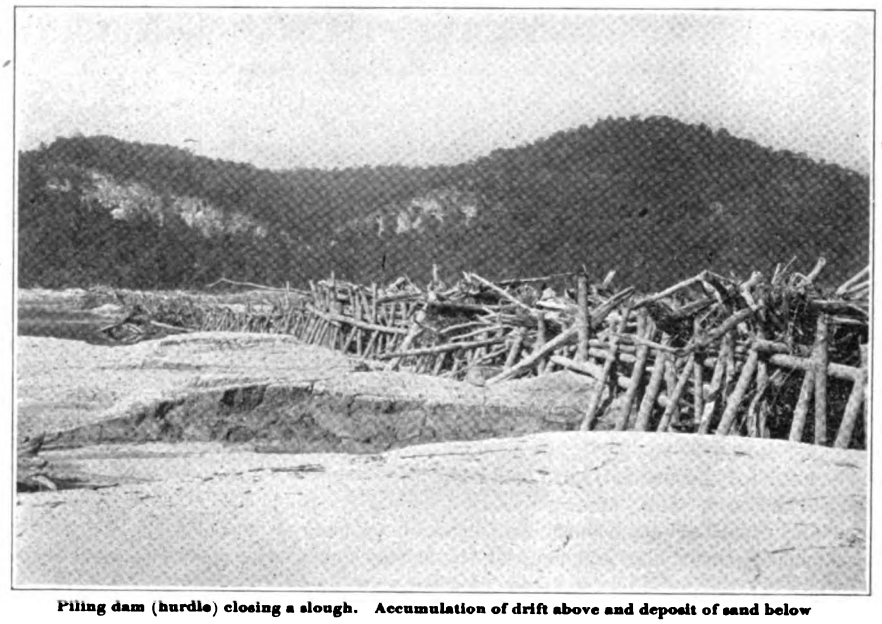
Since 1913, outer ends of hurdles have been sloped down to an elevation lower than the remainder of the hurdle. This is done to conform to the bank slope of the ideal cross-section, to diminish the resistance to the current, and to lessen the cost. These outer heights have varied from the 17-foot to the 14-foot stage, depending on the stage of the river at the time of construction.

Previous to the World War the usual cost of hurdles did not exceed $25.00 per linear foot. Repairs varied from $10.00 to $20.00 per linear foot, according to circumstances. With the general rise in wages and in costs of materials of all kinds, construction and repair costs have practically doubled.

A hurdle, as at present constructed, is subject to attack by scouring action at its outer end, breaching during high stages and the action of ice. The scouring action is set up by the increase in current and depth, and the eddy which tends to form below the hurdle, due to the side contraction of the channel, and becomes less violent with the enlargement of the narrower but deeper channel. Scouring and loss of piling, etc., are prevented by building a section of mattress and hurdles at the outer end at right angles to the general line of hurdle (parallel with the bank) forming a T-head, and by liberal use of stone ballast.

Breaching may occur at any point, particularly at the shore end, where it may be avoided by careful attention to the bank paving. Accumulations of drift may cause breaches through scour induced underneath or around the shore end. Drift may be sunk by overlaying it with a light mattress of brush, lumber or of woven wire, and ballasting with stone. When sunk it solidifies and strengthens the hurdle.

When in large fields and passing at rather high stages, ice is destructive to hurdles in deep water. It is preferable to construct hurdles during the spring season, when the fill from succeeding rises will generally reduce the depth so that ice of the following winter will be harmless. Loss at the outer end is minimized by extending the hurdle to fairly deep water and by constructing substantial buttresses of stone.



The earliest form of channel construction devices were stone dikes, which were built at a number of localities from 1872 to 1879. They were constructed on foundations of brush held in place by piles, the brush being placed in

Digitized by Google

layers alternately parallel to and across the current and with the greater part of the width downstream from the crest of the structure to protect the bottom against scour by overfall. Stone was dumped on this foundation and allowed to take its natural slope until the crest had reached the required height, usually 10 to 15 feet above extreme low water. These structures gave increased channel depths locally, but, being difficult to maintain on account of the overfall, they were abandoned in favor of permeable dikes, which build up new dikes and thereby, in a measure, protect themselves.

Permeable dikes, or hurdles, as first used in 1879, were spaced about 300 feet apart, and consisted of a brush mattress foundation with a single row of piles driven 5 feet apart. The length of the hurdles and their distances apart were determined by local conditions, such as currents, velocities, and depths. These permeable dikes gave results much more satisfactory than the solid dikes and secured thick deposits of sediment, but being frail and low in height, did not build up new banks high enough for revetments.

Hurdles were gradually made stronger, first by driving the piles in two rows and bracing the upper row against the lower by means of diagonals and later by grouping the piles in clumps of three or four, driving two or three rows of clumps, depending on the depth of water. The diagonal braces were omitted, but horizontal stringers (piles) were placed between the rows, binding and bracing all clumps together and equalizing the strains thereon. This distance between dike lines has been increased from 300 feet to 1,000 feet, using approximately the same number of piles in one hurdle as were formerly used in three. The penetration of piles, which at first was sometimes as little as 5 feet, has been increased to 20 feet by the use of the water jet and improved pile-driving machinery. At first, for greater ease in pile driving, the foundation mattress was placed around the piles after they were driven, but it was found that scouring of the river bottom, induced by the piling, often proceeded so rapidly as to endanger the structure and prevent placing the mattress. The method was changed and, at the present time, the foundation mattress is always placed first and the piles are sharpened and driven through it, butts down.

Piling dam (hurdle) closing a slough. Accumulation of drift above and deposit of sand below

Portable jetties

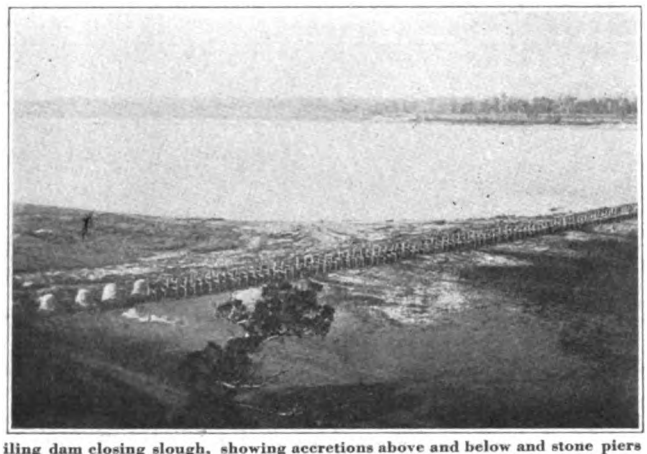
Experiments were formerly made with cheap devices, designed to concentrate the water at shoal places and by increasing its velocity to induce sufficient scour to give a channel depth sufficient for the pressing needs of navigation. These devices were to be removed as soon as they had effected their object or the river had risen.

The system may be briefly described as follows: Having determined upon a direction that should be given to the jetty in order to produce the best results and admit of the easiest possible construction, piles are driven along this line at intervals varying from 10 to 20 feet, depending upon the depth of water and the strength of current. In extreme cases, instead of single piles, clumps of two or three may be driven. Along these piles, at a proper distance above the water surface, other piles are made fast longitudinally by wire or rope. These stringers are to support the upper ends of corrugated sheet-metal panels, the lower ends of which are to rest upon the bottom of the river. Each panel is 10 feet in width, measured in the direction of the jetty, and from 10 to 20 feet long, depending upon the depth of the water in which it is to be used. It is made of No. 14 U. S. standard corrugated sheet metal, riveted to three 5-inch I-beams, 12.5 pounds per foot. Suitable links or clevises are provided for handling the panels. To prevent scour taking place along the lower edge of the panels, and thus permitting them to swing through between the piles, a mattress 8 to 10 feet wide is made by placing small fascines side by side. This is tied to the lower edge of the panels and sunk with stone.

At the end of the low-water season the jetties are removed. The panels are taken up, cleaned, painted and stored. The piles are also removed, to be used in future work.

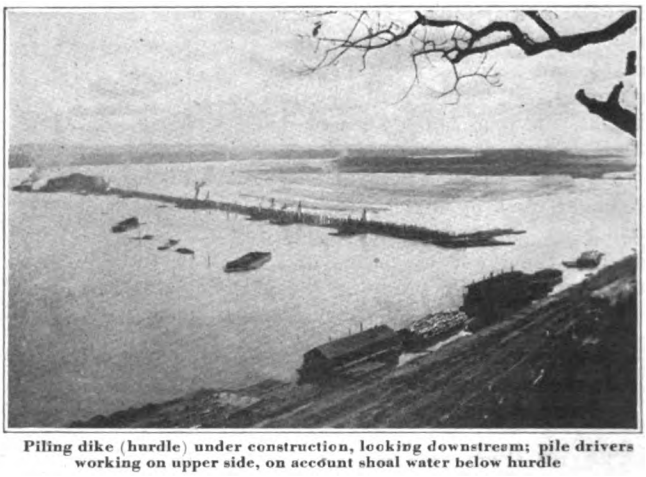
The total cost was $3.00 to $4.00 per linear foot.

The results of this device, though positive, were meager. Since a gain in depth exceeding 1 to 2 feet was rarely attained, this form of improvement was abandoned in 1899, coincident with the development of dredging, which gives better and quicker results.



Bank revetment

The protection of caving banks in this reach of the Mississippi was commenced at Sawyers Bend, in the northern harbor of St. Louis, Mo. The project for this work contemplated a continuous foot-wall or dike of brush and stone placed at and below low water for the support of a continuous revetment of stone extending from low water to the top of the bank on a slope of 2 horizontal to 1 vertical. Construction under this project was begun in 1872 and continued to 1875, with minor repairs in 1877 and 1878, since which last date no work has been done in this locality.



The above-water section of the work was proposed of the form then and now in common use. The subaqueous protection was one of the earliest attempts to prevent deep-water erosion upon the Mississippi River in its alluvial sec-

Digitized by Google

tions. At the foot of the sloping bank a longitudinal trench was excavated by a dredge to a depth of 8 feet below lowest water. A loose mass of brush was placed in the trench with its top extending outward into the stream in order to protect the base from scour. Upon the brush was piled stone to a height of 6 feet above lowest water, giving the structure a height of 14 feet. 4,745 linear feet of this wall or dike was built, and for 1,118 feet of its lower end a continuous revetment of stone was carried from the top of the dike to the top of the bank. For the temporary protection of a part of the bank at the close of the working season a number of stone cross dikes 6 feet high and 50 feet long were built upon the sloping bank at intervals of 120 feet. The cross dikes served the purpose so well and proved so much more economical than the continuous revetment that they

iling dam closing slough, showing accretions above and below and stone piers (shore end) over rock ledge

Piling dike (hurdle) under construction, looking downstream; pile drivers working on upper side, on account shoal water below hurdle

were used for the protection of the remaining 3,627 feet of the above-water bank. This protection served its purpose well and is still in good condition, although untouched for twenty-two years. The efficiency of the subaqueous section of the work is probably due to the relatively stable character of the bank and small depth of water, which was only about 18 feet in 1872, and is from 20 to 25 feet at low water at the present time. With a depth of 40 feet, such as is commonly found in front of caving banks between St. Louis and Cairo, it seems hardly probable that such a form of construction would have withstood undermining. Its cost, $21.50 per linear foot, was also high.

From 1875 to 1881 subaqueous protection was sought by rafts of brush that were built upon the water surface on a grillage of poles spaced about 6 feet in each direction, and upon which were placed two layers of brush held in place by cross poles and securely bound together. The total width of the protection afforded thereby varied from 40 to 70 feet, dependent upon the length of the brush, the tops of which extended outward into the stream. The rafts were built in sections, which attained, in 1881, a length of 700 feet and were designated mattresses or mats. In relatively shoal water this protection was effective, but in deep, swift water, with active bottom erosion, they failed to hold the bank. Their failure was, no doubt, due to insufficient width, with undercutting on the stream edge, such as would occur with any form of construction that did not reach the foot of the eroding slope.

In 1881 the form of subaqueous protection was adopted that has since remained in use, with changes only as to details. For a time, lumber was substituted for brush in this construction. Briefly stated, this protection consists of a woven or wattled mattress of willow or cottonwood brush, preferably the former, on account of its greater flexibility. Having but one thickness of brush, woven upon poles, this mattress is thin and flexible. Sufficient strength during construction and sinking is secured by ample fastenings of nails, spikes, wire and cables. In form and handling it does not differ materially from the lumber mattress hereafter described in detail.

The standard width for these mattresses is 125 feet, and they ordinarily are made continuous for each locality, any break in continuity being due to external or unforeseen causes. Lengths of from 5,000 to 10,000 feet have been built, launched and sunk in ordinary work. When firmly settled and held upon the bottom with sufficient stone ballast, they have furnished permanent protection to underwater slopes reaching to the normal and full depth of 40 feet. The few known failures have been due to undercutting of the outer edges of mattresses laid in shoal water which was subsequently greatly deepened by changes of regimen. The protected banks include all classes of material from tough clay to alluvium and nearly clear sand.

Location, limits and references. The location of each bank protection is determined in advance and plainly marked in 100-foot sections with substantial stakes.

The District Engineer determines the widths of mattresses and paving at each locality, and the lengths and lap of mattresses if built in sections. In swift current or very deep water, mattresses sometimes may be made and sunk in 500 to 1,000-foot sections, but ordinarily mattress is made downstream in one continuous section, and of such width as will cover a bank zone at least one hundred and twenty-five (125) feet wide below standard low water.

The inner or shore edge of the mattress is placed as near standard low water as practicable and consistent with expeditious work. If placed at a higher stage, the required width of mattress may be more than 125 feet.

Paving is continuous on a slope of 2½ horizontal and 1 vertical, from the inner edge of the mattress to the top of the river bank, or to such lower level as may be determined upon.

Time when work may be carried on. As a rule, mattress work is done only when the river is below the mean stage (12.6 feet St. Louis gauge), which, on an average, obtains from July to March. Usually the river falls gradually from about the mean stage, in the early part of August, to extreme low water caused by ice, in December. It is during this period, about 125 fair working days, that bank protection can be carried on to the best advantage.

After the mattress is placed, bank paving may be car-

Digitized by Google

ried on at any time when the bank to be paved is not submerged.

Preparation of site. All logs, snags, stumps, trees and other obstructions, that will prevent the mattress from lying evenly and in contact with the river bed, are removed. The mattress is then constructed of lumber as described below, or of brush.

Brush mattress is very similar to lumber, except that laps or splices are made about 50 per cent longer when brush is used.

Lumber mattress. Construction is begun by laying across the foot of launching ways, mounted on flat boats or weaving barge, three thicknesses of boards, breaking joints not less than three feet, and thoroughly nailed and wired together to form the bottom half of a header, or clamp, at the upstream end of the mattress.

On the bottom half of the header and at right angles thereto, selected boards, called weavers, are laid in double thickness and spaced about 4 feet apart, depending upon the pliability of the boards to be woven; the ends of these weavers are securely wired and spiked to the bottom half of the header. As a rule, each weaver is made continuous throughout the length of the mattress by lap splicing not less than 3 feet, and is nailed along the lap and lashed with wire at each end thereof.

U. S. Dredge "Fort Chartres" (No. 6) laid up in winter harbor

The lumber in the main body of the mattress is woven parallel to the header, under and over the ends of the system of weavers, and is then shoved down along the weavers in courses spaced not more than 4 inches apart. Weaving progresses simultaneously from the inner and outer edges of the mattress toward the middle. Wherever a board fails to reach a weaver, the next board in that course laps back to the last weaver caught. In weaving, one gang of laborers is employed on each side of the mattress, with one or more additional gangs in the middle, depending on the width of the mattress.

In each successive course, the boards are passed under and over those weavers that the preceding course passed over and under, respectively, and the board ends are shifted to break joints from one to three weavers to avoid continuous lines of splices.

All ends of boards are left above the weavers, except at inmost and outmost weavers, where every fourth or fifth end is woven underneath, all woven boards are securely nailed to each weaver passed over.

Top planks, or longitudinal binders, are laid on top of the woven boards directly over the weavers, breaking joints with them and with adjacent top planks, are lap-spliced not less than 3 feet, and are securely spiked and wired to the weaver at intervals of about 5 feet.

The top half of the header, similar to the bottom half, is placed on the ends of the top planks directly over the bottom half and breaking joints with it. The whole is thoroughly spiked and wired together to form a strong clamp for the ends of the top planks and weavers across the upstream end of the mattress. To give suitable connection for head lines to anchorages, a second clamp, similar to the header, is generally constructed 5 to 10 feet therefrom, and a similar but lighter clamp completes the downstream end of each section of mattress.

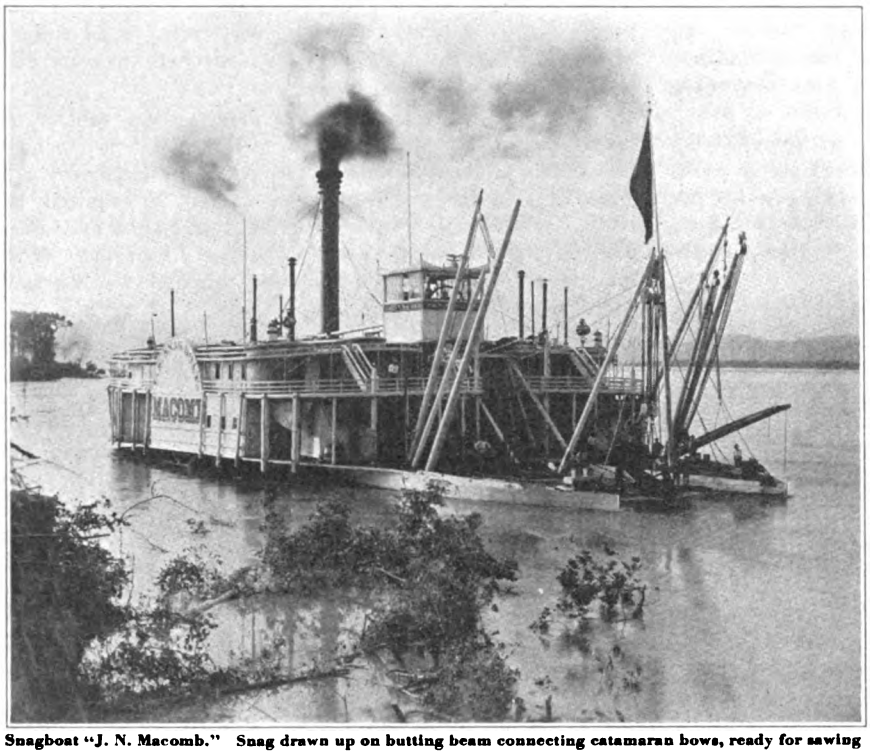
To act as cross binders, double or triple thicknesses of boards, as needed, spaced about 25 feet apart or at every launch of mattress from the ways, are laid across the top planks for the entire width of the mattress, are lap-spliced at least 3 feet, and are spiked and wired to weavers and top planks.

When mattress is to be sunk along steep, submerged banks or in swift current, cribs of sufficient depth to hold the sinking stone in place are formed, along either or both edges or over the entire mattress, as may be required, by increasing the thickness or ordinary top planks and cross binders, and, in special cases, by adding intermediate cross binders, all of the required thickness, thoroughly spiked and wired in position.

From ten to twenty wire strands are fastened to the header and weavers, and usually are made continuous throughout the mattress, each strand is twined around its weaver and top plank, is drawn taut with blocks and tackle, or capstan, and clamped at each turn with ¼-inch by 6-inch spikes. The number of strands used varies with velocity of current and depth of water. Usually one strand is placed on each of the first four to six outer weavers, and the spacing then increases toward the inner edges of the mattress. In gentle current, strands are omitted on the two to six inner weavers. After the mattress is launched off the ways, all wire lashings are tightened and all weavers, top planks, cross binders and woven lumber that may have been broken in launching are repaired.

Sinking of mattress. The mattress is held in position ready for sinking with the necessary complement of head lines and body lines made fast ashore and under equal strains, and a barge load of stone is moored at the water upstream corner of the mattress.

The upstream end of the mattress is supported by 10 to 15 slip lines from a mooring barge, or flat boats, and is ballasted for a length of about 10 feet with as much stone as the slip lines and stiffness of mattress will allow. Slip lines from flat boats are also used when needed to support the mattress along its outer edge and middle portion. The ballasting is then gradually extended downstream and carried over a length of 150 to 300 feet with just enough stone to take the buoyancy from the mattress. The first 150 feet is sunk deep enough to permit swinging the now partly unloaded stone barge across it, stone is rapidly thrown from each side of the barge as it is swung across, and, by slackening the slip lines, the head of the mattress is steadily lowered to the river bottom.



After the head of the mattress is sunk, sinking the remainder proceeds more slowly, and usually without prior ballasting. The stone barge is dropped broadside over the mattress and about as much mattress is sunk each day as is made.

When mattress is built and sunk in sections, an entire section is ballasted before sinking.

Digitized by Google

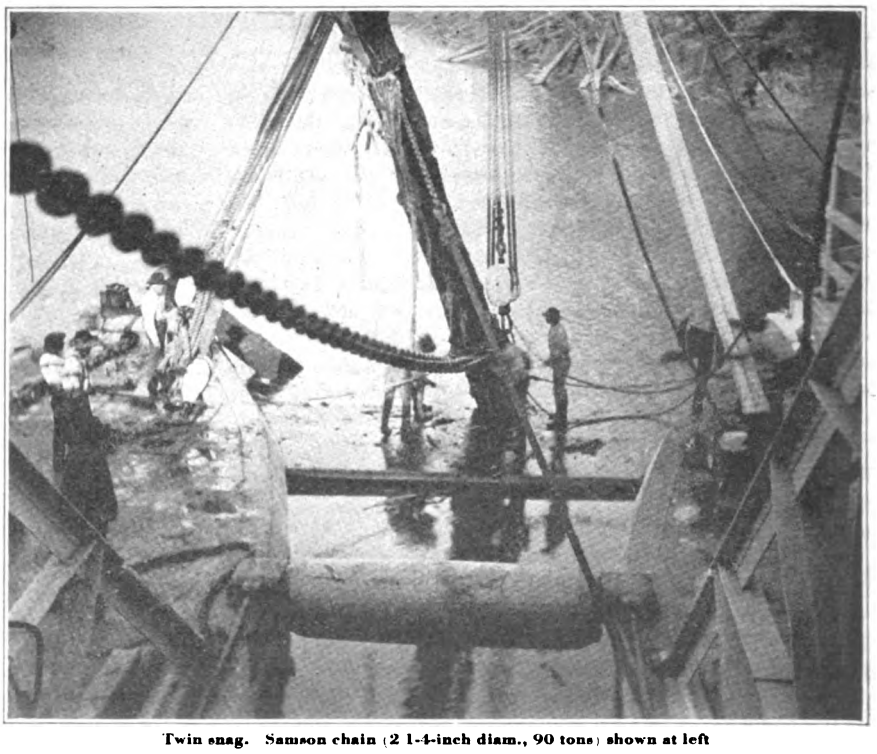
All stone placed on mattress must be evenly distributed and not dropped or thrown with sufficient force to break or injure the mattress.

The mattress, when completed, requires on each 10,000 square feet not less than 50 cubic yards of stone evenly distributed. An additional 50 to 100 cubic yards more than necessary for sinking is required on the upstream of 10,000 square feet of each section of mattress.

Snagboat "J. N. Macomb." Snag drawn up on butting beam connecting catamaran bows, ready for sawing

More stone is used if needed to shape the mattress to the river bed and secure close contact therewith.

Irregular bank and broken mattress. In bays or other indentations in the shore line, to which it is not practicable to fit the main section of mattress, a "pocket" mattress is placed, generally after sinking the main section, to make substantial connection between the inner edge of main mattress and the shore. Should mattress be broken in sinking, the break is covered with a second overlying mattress.



Grading. The bank above the inner edge of the mattress is graded on a regular slope 2½ horizontal to 1 vertical to such height as may be required. All logs, trees, snags, stumps and other obstructions are removed and the slope, when finished, presents a neat, even surface.

If grading is done with a water jet after the mattress has been sunk, a thick coat of spalls may be required along the inner edge of the mattress to prevent gullies being washed thereunder. No filling, unless of spalls or water-tamped earth, is permitted in making the required bank slope.

Paving. Paving is riprap stone compactly and evenly laid in a single layer 12 to 14 inches thick and extended from the inner edge of the mattress up to the graded bank slope to the required height, each stone being placed by hand, in contact and breaking joints with the preceding course and without jutting markedly above the general top surface. One cubic yard of stone covers about twenty-five (25) square feet of bank slope. Spalls are used, as needed, along the inner edge of the mattress to fill holes, furnish a footing for and filling between paving stone and form a good connection between mattress and paving. The total quantity of spalls used does not exceed 25 per cent of the total quantity of riprap stone.

Working force. The force required for mattress construction is about 86 men, in addition to the boarding crew of about 10 men, and is composed of the following classes of labor: 1 overseer, 3 foremen, 1 shipkeeper, 6 boatmen and linesmen, 75 laborers divided as follows: 9 wire cutters, twisters and cable makers; 18 unloading and passing lumber; 18 weaving; 18 nailing, repairing, tightening cables, etc.; 12 sinking.

The cost of subaqueous mattress of standard width, and of standard bank paving, was, prior to the war, about $5.00 per linear foot each. At present the cost is fully 100 per cent greater.

The Officers' Reserve Corps and the Organized Reserves

Their Place in Our Policy of Defense

By

William G. Haan

Major General, U. S. Army

Director of the War Plans Division, General Staff, U. S. A.

[*Note.*—Measured by the march of events, rather than by the flight of time, the engineering profession has long been interested in the Reserve Corps. The echoes of the first shock of arms in 1914 had scarcely ceased to sound before some of the leaders visualized in some degree the role of engineering science in modern warfare. Within six months after the first battle of the Marne a small group of farseeing men met in New York to discuss means and methods whereby the engineers in civil life might prepare for service in the war which they so truly anticipated was bound to come.

This little group of pioneers decided that, given proper legislation, the engineers could and would organize a Reserve Corps to be called into active military service when the hour should strike. Committees were formed to lay the matter before the War Department and the issue resulted not merely in an Engineer Section of the Reserve Corps, but sections for all arms of the service as well. The plans of the committee were embodied in the National Defense Act of June 5, 1916. Under this Act we entered the World War, and the part played therein by the officers of the Engineer Reserves is now a matter of history.

Actual experience in war developed a few weaknesses in the organic act, and after exhaustive studies Congress amended the statute by the so-called Army Reorganization Act of June 4, 1920. This was eighteen months after the signing of the Armistice, and another ten months have passed during which committees of the General Staff, comprising in their membership officers of the Reserve Corps itself, have been engaged in formulating plans and regulations for the reorganization, administration, training and mobilization of this major component of the Army of the United States.

Following the passage of the Act of June 4, 1920, appointments in the Reserve Corps were wholly suspended until October 4, 1920, and pending the publication of definite information as to the rights, duties and privileges of Reserve Officers, there has been a marked decrease in the strength of the Reserve Corps as a whole. This has been a matter of grave concern, not only to the War Department, whose duty it is to provide for the defense of the country, but also to those in civil life who have at heart the best interests of the nation and who believe in the obligations of a democratic citizen-soldiery. We, therefore, take particular pleasure in publishing the following article prepared by Maj. Gen. Haan, who has taken a very prominent part in formulating the plans and regulations which will undoubtedly govern the Organized Reserves for some considerable time to come.—ED.]

UNDER the military policy provided for by Congress in the National Defense Act as amended by the Act of June 4, 1920, the Organized Reserves are the principal war component of the Army of the United States, and are raised, supported, and employed by the United States under the powers granted to Congress by the Constitution. The Organized Reserves are, therefore, a purely Federal force with a well-defined mission, and in a war of any magnitude will constitute the major component of the Army of the United States. The War Department is now engaged in the development of this component in accordance with the approved policies and plans for the organization of the peace establishment so as to permit of an immediate mobilization in the event of an emergency declared by Congress, as required by Section 3, National Defense Act, as amended.

Under the approved plans above referred to, the reorganization of the Regular Army component of the Army of the United States has been effected within the limitations prescribed by Congress, and a program has been prepared and accepted by the States which provides for the development of the National Guard component up to its prescribed strength by June 30, 1924. These two components will provide within themselves the essential elements of three field armies, and may be employed separately or together in minor or major emergencies. In the event of mobilization, all deficiencies in the Regular Army and National Guard components will be made good by units organized from the reserves for this special purpose. In addition to the above, there will be organized in the Organized Reserves, three field armies complete in every respect, and the Communications Zone and Zone of the Interior troops required in a mobilization involving the maximum effort.

The initiation of the organization of units in the Organized Reserves has been held in abeyance pending the preparation of necessary regulations and allotment tables, and in order to give the National Guard a reasonable period for reorganization. The War Department is now prepared to proceed with the organization of units of the Organized Reserves and, with this object in view, the following important actions have been or are about to be taken:

First, the promulgation of Special Regulations No. 46, General Policies and Regulations for the Organized Reserves, approved February 16, 1921. These regulations are general in nature and are designed to set forth in a comprehensive manner the basic plan for the organization of units in the Organized Reserves. The regulations consist of three parts. Part I is a statement of general policies, including the mission and affecting the organization, administration, training, and mobilization of the Organized Reserves. Part II consists of provisional regulations affecting matters relating to the composition of units, the officers and enlisted personnel and their assignment to units, the administration, the training and the mobilization of the Organized Reserves. Part III consists of extracts from existing law and notes on organization methods. The latter are arranged in narrative form and cover the various steps from the organization of a divisional area to the organization of a company.

Second, regulations for the Officers' Reserve Corps, which are now in the process of publication. These regulations are of special interest to all reserve officers, as they cover all matters relating to the appointment, assignment, promotion, transfer, and discharge of reserve officers. Under these regulations all reserve officers are arranged into classes for assignment after appointment as follows:

(*a*) For duty with the Regular Army.

(*b*) For duty with the National Guard.

(*c*) For duty with the Organized Reserves.

(*d*) For special duties and activities exclusively controlled by the War Department or its branches.

Under these regulations the qualifications of reserve of-

Digitized by Google

ficers are now being determined and lists are being prepared for the information of corps area and other commanders. It is proposed to give every reserve officer a definite war assignment and to train him for such assignment. For example, Major Brown, Ordnance Reserve Corps, of Boston, is assigned to duty as Assistant Commandant, Watertown Arsenal. Upon mobilization, or when called to duty for the annual training period, Major Brown goes to Watertown Arsenal and performs duties in accordance with his war assignment. On the other hand, Captain Dowd, Infantry Reserve Corps, of York, Pennsylvania, is assigned to command Company C, 316th Infantry. He is called to active duty for training and is mobilized with his company.

Third, regulations for the Enlisted Reserve Corps have been prepared and are in process of publication. These regulations cover all matters affecting the enlistment, assignment, promotion, transfer, discharge, etc., of the reserve enlisted personnel.

It is of interest to note here that all regulations affecting the reserve component are formulated and proposed by committees of the War Department General Staff, of which at least one-half of the members are reserve officers.

Fourth, allotment tables showing the units of the Organized Reserves to be organized in each corps area have been published for the information and guidance of all concerned. Based upon these tables, studies are being made in each corps area and the localization of units is being considered by local boards, the majority of which are reserve officers.

As stated above, Appendix II, Part III, Special Regulations No. 46, is designed to visualize the various steps in organization of a division and subordinate units thereof. It should be understood that this is purely a hypothetical study and is intended to illustrate in a general manner the methods to be employed in the organization of units. In view of the fact that advance copies only of these regulations have been distributed and that it will be some time before all reserve officers can be furnished with copies, some pertinent extracts which are typical are given here:

Establishing Divisional Areas. Among the organizations of the Organized Reserves allotted to the Third Corps area by the War Department, are three Infantry divisions. Designations of World War divisions placed at the disposal of the Commanding General of the Third Corps area are the 79th and 80th. In establishing divisional areas the first consideration is the distribution of the military population throughout the area. In this corps area it is divided as follows:

Pennsylvania	1,573,496
Virginia	245,675
Maryland	192,995
District of Columbia	53,425

Distribution as follows:

(*a*) 1 division to the eastern half of Pennsylvania.

(*b*) 1 division to the western half of Pennsylvania, and

(*c*) 1 division to Maryland, Virginia and the District of Columbia, would be sufficiently equitable on this basis, as the distribution of corps and army troops throughout the entire area would readily balance the inequalities. These areas are the most symmetrical that could be arranged. The two States and the District of Columbia forming the area (*c*) are contiguous. It would be impossible to divide the corps area in such a manner that either of the World War divisions, the 79th or the 80th, could be exactly reconstituted. After consideration of the foregoing, the corps area commander establishes the divisional areas as stated. Headquarters of these divisions are to be established at Philadelphia, Pittsburgh and Richmond, respectively.

Designation of Divisions. The 79th Division was composed of men from Maryland and Eastern Pennsylvania, and the 80th Division of men from Virginia, West Virginia, and part of Western Pennsylvania. Eastern Pennsylvania furnished a large majority of the men of the 79th Division. The corps area commander, therefore, decides that the division in the eastern half of Pennsylvania will be designated the 79th Division. The State of Virginia furnished a large portion of the men in the 80th Division and this division was organized and trained at Camp Lee, Virginia. The division in the area comprising Virginia, Maryland and the District of Columbia is, therefore, designated the 80th Division. The other division in the corps area is assigned a new number.

Localization and Designation of Subordinate Units. The 79th divisional area being wholly contained within a single State, the location and designation of the subordinate units thereof are functions of the board provided for in Section 3a of the National Defense Act, as amended by the act of June 4, 1920. Specific instructions for the formation and functioning of these boards have been issued by the War Department. The corps area commander submits to the Board for the State of Pennsylvania the question of localizing and designating the units of the 79th Division, advising them of the names and numbers available for their use. This board localizes and designates the units of the 79th Division, locating the 316th Infantry in southeastern Pennsylvania.

Organization of a Division. The War Department has made available to the corps area commander certain officers and enlisted men of the Regular Army for assignment to organizations of the Organized Reserves in his area. From their number the corps area commander designates Colonel Adams to organize the 79th Division and places at his disposal for this purpose eleven other officers of the Regular Army and twelve enlisted men. Colonel Adams is also furnished with a list of the reserve officers available for assignment to this division residing in the divisional area, with such information regarding their qualifications as is necessary, in order to enable him to recommend their assignment intelligently. Colonel Adams is ordered to take station at Philadelphia, and having arrived there he establishes divisional headquarters. In proceeding with the organization of the 316th Infantry in southeastern Pennsylvania he assigns Captain Ball and one enlisted man of the Regular Army to this regiment, and directs them to proceed with the organization. Colonel Adams and his staff, from examination of the records of the available officers, determine that Colonel Crew of the Infantry Reserve Corps, residing at Lancaster, Pennsylvania, is the most available officer to command the 316th Infantry, and Colonel Adams recommends that the corps area commander assign him to command that regiment. This assignment having been made, Captain Ball and his enlisted assistant report to Colonel Crew. He explains thoroughly the plan of organization. As Colonel Crew resides in Lancaster, this city is designated as regimental headquarters of the 316th Infantry. Colonel Crew and Captain Ball carefully consider the officers available within their area and recommend assignments based on records and Colonel Crew's personal acquaintance with these officers. These assignments are made by the corps area commander. While the organization of the 316th Infantry is thus initiated, similar action is being taken with the other regiments of the division and with the special units. Certain qualified reserve officers are also assigned to the Division Staff. While the officer personnel is not complete, the distribution throughout the divisional area is such that practically all units have had assigned to them at least one officer. The first stage in organizing the division has, therefore, been accomplished.

Organization of the Regiment. Authority is now given to recruit all units to an enlisted strength, which, for the purposes of this study, will be assumed to be one-third their number of non-commissioned officers and specialists, and organization commanders are directed to recruit this strength and to complete their commissioned personnel as soon as possible.

Colonel Crew and Captain Ball after numerous conferences, which included other officers assigned to the 316th Infantry, have developed a working plan for the further organization of this regiment. Residing in the City of York, Pennsylvania, are Captain Dowd, First Lieutenant Elwell and Second Lieutenant Ford, all holding commissions in the Officers' Reserve Corps, Infantry Section. These officers have been assigned to Company C, 316th Infantry, which was localized at York. Captain Ball proceeds to York for a conference with the officers assigned to Company C. He explains in detail the plan of organization. Captain Dowd and his lieutenants invite into this conference Mr. Gray and Mr. Hall, both of whom served as Infantry lieutenants in the Army during the World War. They are urged to apply for commissions in the Officers' Reserve Corps, which they do. In forwarding their applications, Captain Dowd requests that they be assigned to Company C. Captain Dowd and his officers then call a meeting of ex-service men. Captain Ball is introduced, and plans for the organization of the Organized Reserves and the requirements of membership in the Enlisted Reserve Corps are presented. Those present are told of their local officers who have been assigned to this company. A number of these present served under Captain Dowd in the Army and are desirous of perpetuating their old company. With the impetus to recruiting given by this meeting, Captain

Digitized by Google

Dowd and his officers are able to enlist the fifteen men which their present order authorizes. The number enlisted includes men who served in the following grades:

1 first sergeant,
1 mess sergeant,
8 sergeants and
5 corporals.

These men are given their warrants in due course, and Lieutenants Gray and Hall receive their commissions and are assigned to this company. The first stage in the organization of Company C has been accomplished.

Captain Ball works along the same lines in the other cities which have been given companies in the 316th Infantry. He holds frequent conferences with Colonel Crew. During the progress of the organization, Colonel Crew designates the officers for his regimental staff, who are properly assigned thereto. Captain Ball is assigned as Adjutant of the Regiment. Battalion commanders and their staffs are assigned.

Organization of Auxiliary Arms. Colonel Adams is confronted with a somewhat different problem in the special arms, as for instance the Artillery, yet he succeeds in placing the divisional artillery in fairly compact and regular districts. In doing this he finds that he requires complete co-ordination with the State committee under section 3a, National Defense Act, as amended by the Act of June 4, 1920, to the end that the Artillery contingent of both division and higher units is equitably distributed over the whole area. He frequently finds places for technical units, such as Medical and Signal Services, in connection with hospitals and colleges located within the divisional area.

Training a Company on Inactive Status. Captain Dowd finds that all of his officers and men will agree to devote one evening a month to instruction. He arranges with Captain Ball to conduct conferences a designated evening each month, and secures the use of an available meeting place for this purpose. Throughout the winter and spring these assemblies are continued, while Captain Dowd and his officers are given additional instruction whenever Captain Ball's time will permit.

Lieutenant Elwell applies for admission and is sent to Camp Benning for a special course of one month at the Infantry School.

Several afternoons during the spring the members of the company go out for tactical problems, which are conducted by Captain Dowd.

The interest of the officers and men increases and all look forward to their annual field training.

A reading of the foregoing will indicate that throughout these regulations runs the policy of giving reserve officers assignments as near their homes as possible, usually in their home town. This should stimulate local interest and make it possible to interest the community to the extent frequently of assisting in securing suitable meeting places and possibly other assistance of a material nature—not to speak of the intangible support that will be given to local organizations by the fact that they constitute in a sense a representation of the community.

The extent and nature of the training that is proposed for individuals and organizations of the Organized Reserves is dependent upon the funds appropriated by Congress for this purpose. It is recognized that while the annual training period of 15 days affords the principal means for the training of the Organized Reserves, it must be supplemented by voluntary training to the greatest practicable extent. In the exercise by the War Department of the authority granted by law to require 15 days of active duty in each year, due consideration will be given to the occupation or other civil duties and responsibilities of the reserve officers and enlisted men. When practicable, divisions will be called for training as units and all organizations and all members of the divisions will be called at the same time. When so called, the chain of command and the duties and responsibilities of all commanders of reserve units insofar as the administration, training and supply are concerned, will be the same as prescribed for the Regular Army. As a general rule, it will not be practicable to train all of the divisions and corps and army troops in any corps area in any one year. Officers and enlisted men of units not called for training with their organizations will be given such individual and special training as funds available will permit.

In this connection it should be noted that reserve officers and enlisted men may attend the General and Special Service Schools where special courses are arranged for their instruction and training. The number of officers and enlisted men who may be designated to attend these schools depends again upon availability of funds and upon accommodations at the schools. The War Department has made strong representations to Congress as to the necessity for funds for these purposes. Unless adequate funds are appropriated and made available, the best intentions and efforts of the War Department and of the reserve personnel will be able to accomplish but little in the practical development of the Organized Reserves. The funds that will probably be available during the fiscal year beginning July 1, 1921, will not permit of the training of units and it is proposed that the maximum number of officers be assembled in each corps area for instruction and training in basic policies and organizational methods. These assemblies should be most useful in establishing a basic doctrine and in insuring uniformity of methods to the end that the initial steps in the organization of units in the Organized Reserves will result in the successful development of this component of the Army of the United States.

Deaths of Prominent Engineer Officers

Maj. Gen. Alexander Mackenzie

IT was with keen regret that his wide circle of friends learned of the death on February 21, 1921, of Maj. Gen. Alexander Mackenzie, who was the Chief of Engineers, United States Army, from January 23, 1904, to May 25, 1908. Alexander Mackenzie was born in Wisconsin on May 25, 1844, and was appointed to the United States Military Academy from Illinois, entering on September 1, 1860, and graduating on June 13, 1864, sufficiently before the close of the Civil War to permit him to render gallant and meritorious service, especially in the Department of Arkansas, for which he was brevetted captain. Commissioned first lieutenant in the Corps of Engineers on graduation, he was successively promoted to captain on March 7, 1867; major, April 5, 1882; lieutenant colonel, February 3, 1895, and colonel, May 3, 1901. As noted above, he became Chief of Engineers, with the rank of brigadier general, on January 23, 1904, and, in accordance with the provision of law especially applicable to certain officers who had Civil War service, he was promoted to be major general on retirement on May 25, 1908.

During his forty-four years of active service his experience was naturally a broad one. He first served on the lower Mississippi River, and thereafter, for a brief period, on the Great Lakes; following this, from 1866 to 1874, he commanded a company of engineer troops at Willets Point, N. Y. From June, 1874, to the time of his retirement his entire service was either in connection with works of river

Digitized by Google

and harbor improvement or in the office of the Chief of Engineers at Washington. While, for about six years, between 1874 and 1880, he was connected in turn with the improvement of the Ohio River, and with the construction of harbor works and lighthouses on the Great Lakes, it is the period between 1880 and 1895 that is the most notable in his career as an engineer engaged in actual construction.

Between 1880 and 1895 General Mackenzie was in charge of the improvement of the Mississippi River between St. Paul and the mouth of the Missouri, and during these fifteen years the work, which at the time he assumed charge of it was in an elementary and formative stage, developed into what, in all probability, is the most successful example of river regulation known to engineers. River regulation is probably as difficult a problem as engineers have to cope with. The variable factors are numerous and are sometimes hard to identify, their influence is frequently obscure and dependent upon circumstances and conditions that may originate at points far distant from that which is under treatment; no two seasons are at all alike, and, all told, the problem of attempting to convert a seemingly lawless, alluvial stream into one that shall have a smooth, regular channel flowing in gentle curves with adequate depth is one whose solution has usually defied the efforts and patience of engineers of all climes and countries. General Mackenzie's mind was, however, peculiarly adapted to the handling of a problem of this kind, and under his careful and patient direction there came into being standardized plans and methods for treating this stream which have left it today, although the project is even now not entirely completed, with a channel of enormously greater capacity for navigation than it had in 1880, when operations under General Mackenzie were begun. Within the limits of an article of this sort, it would be superfluous to attempt to describe in detail what were the methods pursued, but it is fitting to say that when he came to the upper Mississippi River it virtually had no really useful channel at low-water stages. Such a channel as existed permitted navigation with a draft of not to exceed 1½ feet as far as LaCrosse, while above that point, during low-water periods, nothing was possible in the way of navigating the river upon a practical scale, although, of course, logs and rafts could be floated. To-day the river is navigable to the Falls of Saint Anthony for boats which, at extreme low water, can always safely draw as much as 4 feet, while at ordinary low water considerably deeper channels may be counted on.

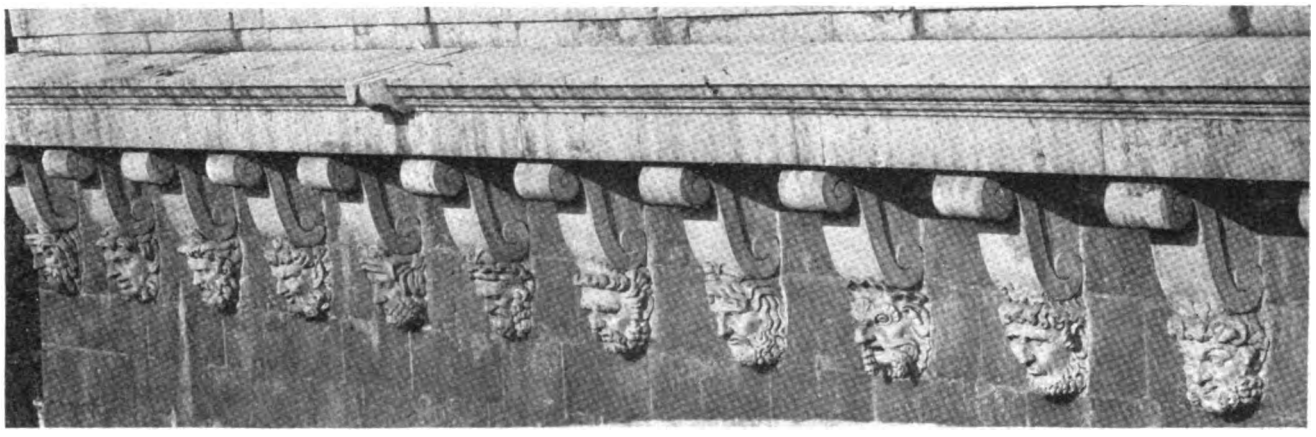
It was while he was on duty on the upper Mississippi River that General Mackenzie became best known among engineers and to the people of the Central Valleys, where his kindly, congenial manner, his patient consideration for others, and his shrewd practical judgment won him the confidence, respect and affection of all who knew him.

In June, 1895, General Mackenzie was called to Washington to become the principal assistant in the office of the Chief of Engineers, where he remained in charge of all matters relating to river and harbor improvements until on January 23, 1904, he was promoted to be Chief of Engineers. During his service in Washington he was brought into intimate contact with Congress, with members of the Cabinet, and with Presidents, all of whom learned to admire him and to respect his judgment and integrity. On his retirement on May 25, 1908, he took up his residence in Washington and remained there without active occupation until he was recalled to active duty on May 11, 1917. At that time, at the age of 73, he was still physically quite active and, although no longer very strong, he responded cheerfully to the call of the emergency. With singular appropriateness, his duty took him back to the upper Mississippi River, where he had spent the happiest and most fruitful years of his service, and where he was hailed with joy by the large number of old friends who still survived. He continued on active service for two years, until 1919, but during this time he found the strain of the work greater than he had anticipated, and here, no doubt, germinated the seeds of the organic disease that led to his sudden death. He was, however, singularly devoted to the discharge of his duty and determined to do everything that one man could do to help in carrying the burden of the Nation, so that, in spite of several warnings that other men would have taken more seriously, he persisted in remaining on duty when it was evident that his health was hardly adequate to the task. On his return to Washington his many friends were with regret forced to admit that he had noticeably failed during his absence, but his sudden death was a shock and great grief to all.

It is difficult to summarize in a few words the character of any man, but it seems fitting to say that General Mackenzie was distinguished among men by unaffected simplicity and kindliness of manner, by approachability, and by unassuming but hard-headed common sense that enabled him early in his career to be a successful executive and later in life to be, first, a shrewd and far-sighted assistant, and later a Chief of Engineers whose career was marked by the success with which he handled the difficult problems of administration constantly besetting the head of a busy governmental bureau. With his passing the world has lost a most lovable character and the engineers of the country a wise and generous friend and adviser.

Colonel McDonough

Lieut. Col. M. J. McDonough, Corps of Engineers, died at the Fitzsimmons General Hospital, Denver, Colo., on February 13, 1921. His death was due to tuberculosis, brought on by the strain incident to the World War.



Our issue of July-August, 1920 (Vol. XII, No. 64) contained a brief account of Colonel McDonough's life and services, with his portrait. He was retired from active duty for physical disability May 11, 1920, and in spite of every care his health continued to decline.

Colonel McDonough was in all respects splendidly representative of the highest development of the American army officer. In him were combined an intellect of the highest order and greatest versatility, a positive, forceful and rigidly upright character, and a wonderful ability for winning friends, whom he numbered by thousands and in every walk of life. His expert knowledge of everything connected with his profession, his great talent for achieving practical results, and the unvarying cheerfulness and helpfulness which nothing could discourage or abate, won for him the respect and affection of his equals in rank and the loyalty and devotion of his subordinates.

That so positive and energetic a personality should have been without an enemy in the world, is a remarkable fact and a tribute to a remarkable character. His life and services were a source of inspiration and guidance to all who were so fortunate as to enjoy the friendship and helpfulness which he so generously dispensed. Here was truly a man amongst men.

Colonel McDonough leaves a widow, a son, Robert, and a daughter, Alice. Mrs. McDonough was Miss Alice Kinzie, daughter of Gen. D. H. Kinzie, a prominent officer of the Regular Army and a veteran of the Civil War.

Carvings on the Pont Neuf

The Bridges of Paris

By

Carl L. Rimmele

Formerly First Lieutenant, Engineers

[*Note.* As Victor Hugo says, the early history of his beloved Paris is written in stone. In their architecture we may read the history of nations. In her monuments and bridges Paris has recorded the great events of her history and expressed her ideals, her hopes, her dreams.

We are grateful to the author for this very complete and beautifully illustrated history and description of the bridges of Paris. It is interesting from an historical, an artistic and an engineering point of view. In no other place in the world can be found such a complete historical and technical exhibit of the development of municipal bridge construction. For no other great city affords so favorable an opportunity. Paris is built upon the convolutions of the Seine. And as it is a narrow and insignificant stream, according to our American ideas, and as the traffic of the city is very great, there is every inducement to construct bridges, which can be built at a comparatively low cost.

The author traces the design, the development of types, the details of construction, and the cost of the Bridges of Paris over a relatively long period. Most of the early bridges are still in existence, and may be compared with the more recent types.

The multiple arch municipal bridge is common enough in our own country, but the multiple span suspension bridge, so common in France, is unknown in the United States, it being, of course, an uneconomical type. Curiously enough, it is also absent in Paris, but for a different reason. It appears that at least two such structures were erected, but they were evidently regarded as not sufficiently artistic in appearance for beautiful Paris, and have been replaced by the arch type.

Another notable fact is the absence of reinforced concrete arch types. Although the French were the originators of concrete, they employ it very sparingly. The most recent of the bridges described by the author, the Pont Alexandre, is of the single span segmented steel arch type. It was completed in 1900.

The development of types, the relative costs, and the curious expedients employed in construction, will be of interest to all lovers of bridges. American engineers will probably wonder at the apparently very careless foundations so frequently employed. And it is to be remarked that these inadequate foundations on several occasions made necessary very expensive reconstruction.

The most striking thing in connection with the bridges of Paris is the proof they afford that a bridge may be at once useful and beautiful.—Ed.]

THERE is no record of when the first bridges were built in what is now the City of Paris. However, it is known that during the Roman occupation under Julius Cæsar, as well as under the Emperor Julian in the 4th century, there were only two bridges over the Seine. One was called the Grand Pont (Great Bridge), on the site of the present Pont au Change, and the other was known as the Petit Pont (Little Bridge), located on the site of the present bridge of that name.

It was not until many years later, under Charles V, that the third bridge was built. It was called the Pont Notre Dame, as is the present bridge on its site. This bridge was replaced during the reign of Louis XII, the new bridge remaining in use until 1853.

The fourth bridge was constructed under Louis XIII, on the site of the present Pont Michel and was known by that name.

Until the end of the 16th century, then, the Ile de la Cite, or what was then the city of Paris, had only four bridges, making two complete crossings over the two channels of the Seine, the Petit Pont and Pont Notre Dame making one, and the Grand Pont and Pont St. Michel the other.

In 1578 Henry III ordered the construction of the Pont Neuf, or New Bridge, which is still in use to-day.

At the present time there are 32 bridges over the River Seine within the city limits of Paris, making 24 complete crossings; one crossing requiring 3 bridges, six requiring 2 bridges, while 17 are single bridges. Twenty of these bridges are masonry arches and 12 are metallic arches.

The descriptions which follow are arranged in the chronological order in which the bridges were constructed, except that all masonry structures are described first, the metallic bridges following.

It may be interesting to note that until the end of the 18th century all masonry bridges in Paris were built with semi-circular or almost semi-circular arches; from 1787 to 1852 all had segmented arches and after that time, beginning with the new Pont Notre Dame, all had elliptical arches.

The information given concerning the bridges of Paris was obtained through the kindness of M. Restraint, Chief Engineer of Bridges, and from "Annales des Ponts et Chaussees," 1835 to 1916.

[*Note.* For the benefit of our readers who may wish to locate the bridges described, there is reproduced herewith a plan of the City of Paris and a table showing the locality of the various bridges. We regret that a better plan was not available, but with the aid of a magnifying glass it will be found quite readable.—Ed.]

The Pont Neuf

Quite the opposite of what its name implies, the "New Bridge" is the oldest bridge in Paris and the best known. It is the patriarch of the Seine bridges.

The first stone was laid by Henry III himself in May, 1578, and the work was carried on until the piers were

Digitized by Google

well above the water. At that time, however, owing to the Civil Wars, operations were suspended and were not resumed until several years later, when Henry IV (Henry of Navarre) ascended the throne. The bridge was finally completed in 1604.

This bridge is 232.88 meters long and divided into two sections, one over the main branch of the Seine composed of seven masonry arches, the other separated from the first by the extreme western end of the Ile de la Cite, composed of five arches.

The arches are very nearly semi-circular, built of cut stone, and are slightly skewed. The spans vary from 14 meters to 17.55 meters. The depth of the arches at the keystone is 0.75 meter. They are 20.65 meters long between faces in the northern or main branch section, and 20.35 meters long in the southern section. The deck is 20.30 meters wide between parapets, accommodating an 11.30-meter roadway and two 4.5-meter sidewalks.

The piers rest on timber platforms, which, although laid directly upon the sand, were, when the bridge was constructed, about 3 meters below the river bed. These platforms consist of 0.40 by 0.40 by 7.0-meter sleepers parallel to the center line of the bridge, spaced 1 meter center to center, covered with a floor of 16 centimeters (6″) oak planks.

This bridge, completed in 1604, was in constant use until the middle of the last century without any repairs having been made. In 1848, however, the bridge was found to be badly in need of repairs; in fact, many of the arch stones had become loosened and fallen out. The work started that year included the reconstruction of seven of the arches, lowering the roadway and constructing galleries for water lines. Care was taken that the original appearance of the bridge should not be altered and sculpturing which could not be restored was replaced with accurate copies, for Paris has a tender affection for the old Pont Neuf. This entire work was carried on under traffic, half the roadway being kept open at a time, and covered a period of four years.

In 1885 one of the piers settled to such an extent that longitudinal fissues over a half meter wide appeared in the roadway. Investigation showed that the upstream half of the pier had been undermined, and that, since the construction of the bridge, the bed of the river had been lowered more than 3 meters, so that in some places it was below the pier footings. The repairs, which were started immediately, included the rebuilding of half the pier and half the adjoining arches.

The new footing was built in a caisson sunk to a depth of 4 meters below the old footing. Around the rest of the pier narrow caissons, 2 meters wide, were sunk to the same level and filled with masonry, completely surrounding that half of the pier. Over the new halves of the reconstructed arches spandrel walls were used instead of the filling as in the old part.

After this work had been completed, sheet piling was driven around the other piers, as well as around the abutment footings, and capped with masonry. Cement grout was then pumped in under the old footings to partly consolidate the sand.

The total expenditures charged to this famous bridge during its more than 300 years of service, have been less than 3,000,000 francs.

Pont Marie

Ten years after the completion of Pont Neuf a bridge was started connecting the north bank of the Seine with the Ile St. Louis. This bridge was designed and its construction begun by Cristophe Marie, whose name it bears, but was later taken over and completed by Delagrange, in 1635.

The Pont Marie is 92.27 meters long between abutments and consists of five nearly semi-circular arches of cut stone. The largest arch has a span of 17.65 meters, and the smallest, 13.76 meters. The width between faces is 23.60 meters. The keystone depth is 1.75 meters.

The foundations are masonry footings placed directly upon the gravel of the river bed.

In 1658 two arches were washed out and were replaced six years later. Except for this, there is no record of any expenditures during 300 years of use.

Pont Tournelle

In 1654 the Pont Tournelle was constructed over the southern channel, opposite the Ile St. Louis, which, with the Pont Marie, completed the crossing at that point.

The bridge, as originally built, consisted of six semi-circular arches of cut stone; the largest of these was 17.58 meters between piers and the smallest 15.57 meters. The total length of the bridge between abutments was 117.88 meters, and its width between faces was 13.80 meters. The piers are 3.95 meters thick, and rest on piles.

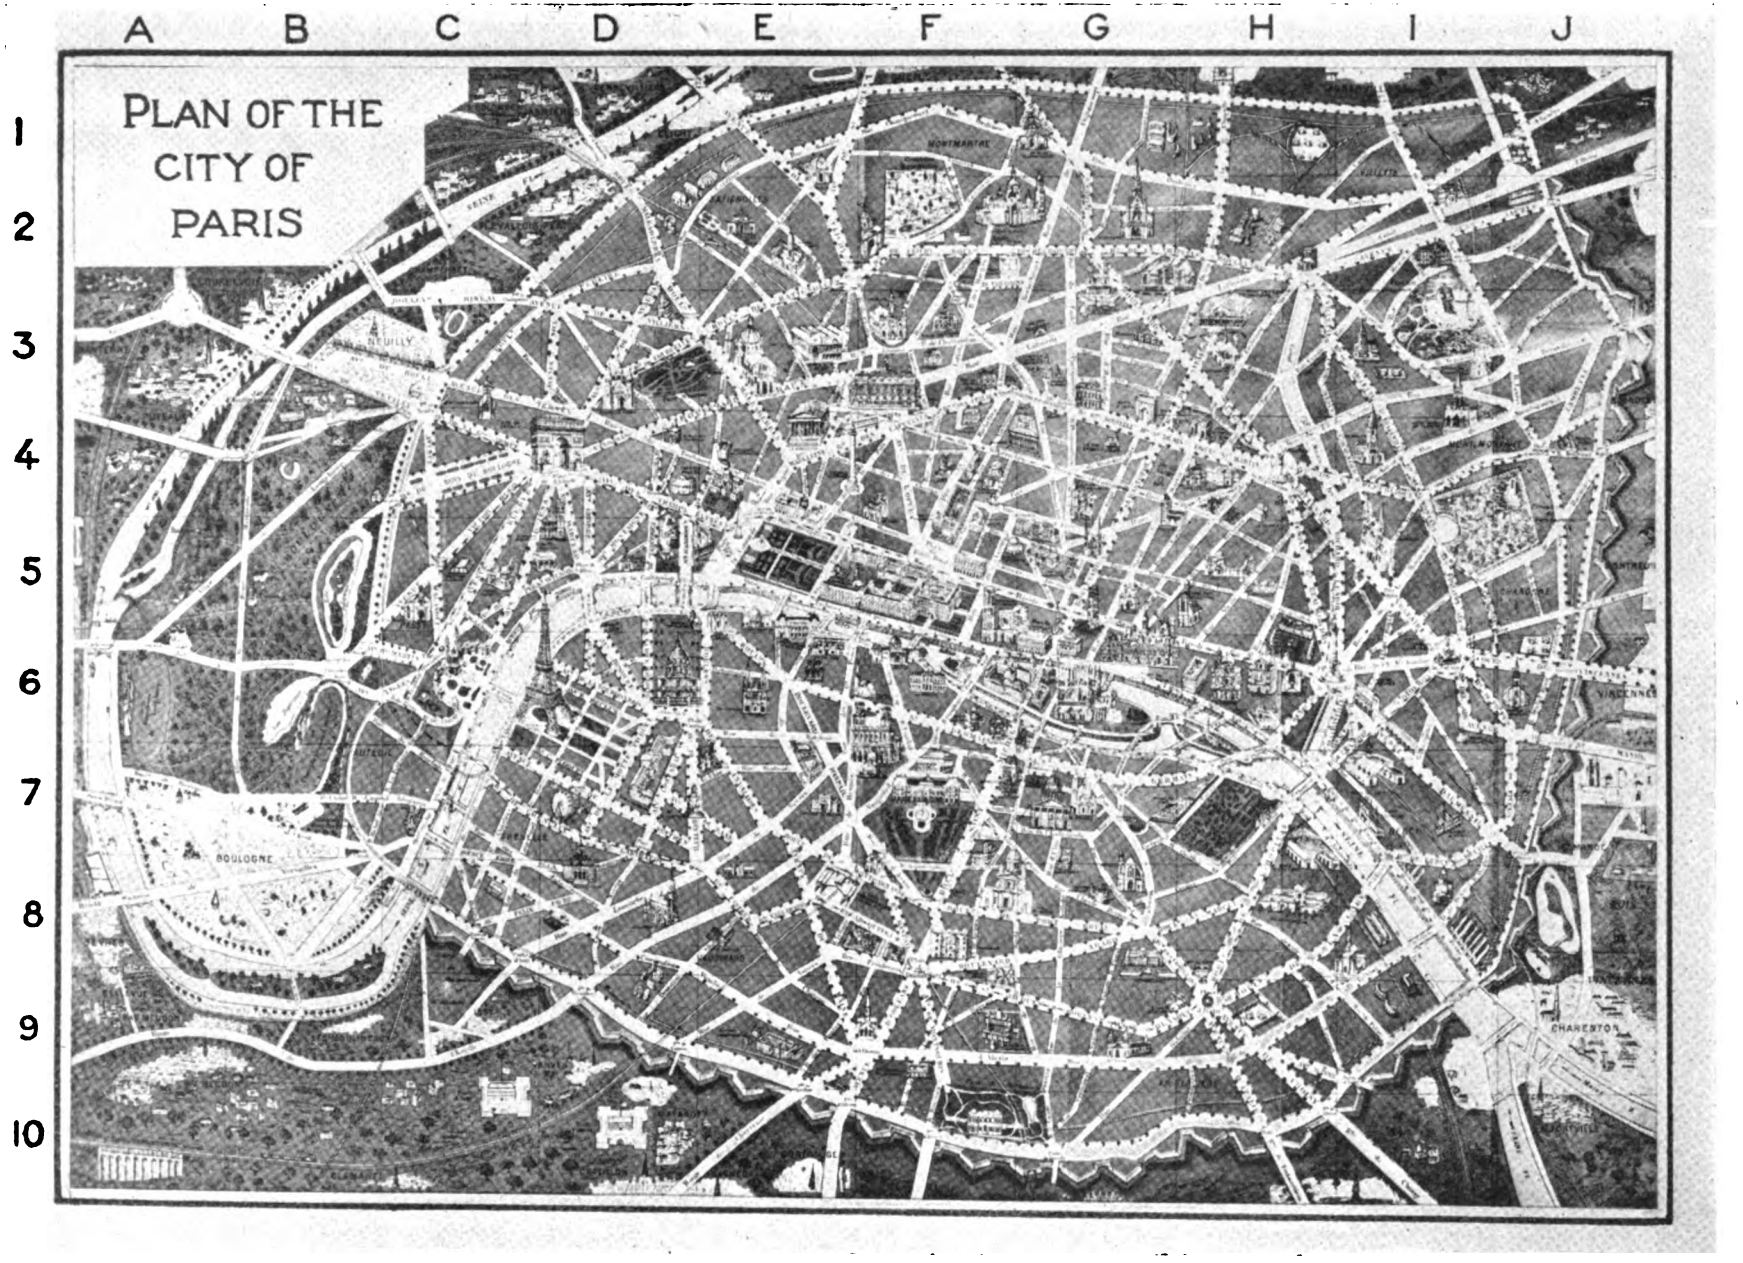
In 1845 it became necessary to widen the deck. This was accomplished by utilizing practically the entire width of the original structure for the roadway, raising the pier heads to the level of the sidewalks and carrying the sidewalks on metallic arches.

These arches are semi-circular. Each rib consists of five cast iron sections bolted together. In cross section they are channels 450 by 135 by 50 millimeters, and are the same depth throughout the entire length of the arch. The spandrel work was cast in six sections, and is bolted to the arch ribs.

Pont Royal

The Pont Royal was completed in 1689 and is composed of five semi-circular masonry arches; the center arch has a span of 23 meters, the adjacent arches 22.60 meters, and the shore spans 20.58 meters. The arches are 17.0 meters long between faces and carry a roadway of 10.4 meters and two 3-meter sidewalks.

The entire bridge is constructed of cut stone and rests on pile foundations. The depth of the arches at the keystone is 1.42 meters. The piers are 4.86 meters thick.



Pont de la Concorde

With the construction of the Pont de la Concorde, in 1787, a new type of bridge was inaugurated, the segmental arch, which type was employed exclusively until the middle of the next century.

The Pont de la Concorde was designed and constructed by M. Peronet, Chief Engineer of Bridges and Highways under Louis XVI. It is composed of five segmental circular arches of masonry resting on four 2.92-meter piers and two 15.59-meter abutments. The pier footings are stepped out to a width of 6.82 meters and rest on timber platforms on piles.

The bridge is 15.59 meters wide between faces, accommodating a roadway 8.75 meters wide and two 3-meter sidewalks. The central arch has a span of 31.18 meters with a rise of 3.97 meters; the adjacent arches span 28.25 meters and have a rise of 3.69 meters; the shore spans are 25.33 meters long with a rise of 2.98 meters. The keystone depths are, for the middle, adjacent and shore arches, 1.09, 1.01 and 0.88 meters, respectively.

Pont d'Austerlitz

The original Austerlitz bridge was begun in 1801 and completed in 1805, the year of the victory of Napoleon over the Austrians at Austerlitz, from which it received its name. It consisted of five cast-iron arches of 32.36 meters span each, and resting on masonry piers set on pile foundations. The width of the deck was 12.74 meters.

This bridge was in use until 1854, but by that time traffic had increased to such an extent that a wider bridge was necessary.

The cast-iron arches were removed, and were later replaced with masonry. The piers were lengthened by driving piles at each end, capping with concrete, and new stone masonry carried up and joined to the old. The piers were then joined by segmental masonry arches of cut stone, having a rise of about ⅛ meter. The deck of the reconstructed bridge was 18 meters wide.

This additional width, however, was not great enough to accommodate the ever-increasing traffic, so, in 1884, the bridge was again widened. This time the piers were lengthened equal amounts upstream and downstream, as before, but independent footings were poured in caissons sunk to rock and about 2 meters below the old. The stone masonry was joined to the old just below the water line. The width of the deck after the extension was 30.4 meters.

The original cost of this bridge was about 2,500,000 francs. The reconstruction in 1854 cost 950,000 francs, and the extension in 1884, 1,450,000 francs.

Pont d'Iena

The Pont d'Iena is composed of 5 masonry arches, circular arcs having a chord of 28 meters and a rise of 3.42 meters. The depth of the arches at the keystone is 1.44 meters.

The piers are 3 meters thick and the abutments 15 meters. The left bank abutment and 3 piers were constructed in caissons set on piles; the other pier and abutment rest on timber platforms.

The length of the arches between faces is 14 meters and the width of the deck between parapets 13.70 meters. The bridge has an 8.7-meter roadway and two 2.5-meter sidewalks.

Construction was started in 1806, the year of the French victory over Prussia at Iena-Auerstadt, and the bridge opened to traffic in 1814. There is no accurate information on the cost of the work.

Pont de l'Archeveche

This bridge is composed of three segmental masonry arches. The central arch has a span of 17 meters with a rise of 2.31 meters, and the others have spans of 15 meters and a rise of 1.91 meters. The depths at the keystone are 1.07 meters and 0.96 meter, respectively.

The piers are 2.30 meters thick and the abutments 9 meters. The right bank abutment is built on a timber platform directly upon the soil. The other abutment and the piers are on pile foundations.

The arches are 11 meters long between faces and carry a roadway 7 meters wide, with two 2-meter sidewalks.

Construction was begun in April, 1828, and the bridge completed the following November.

The cost was approximately 380,000 francs.

Petit Pont

There have been bridges on this site since the days of the Romans. The bridge just preceding the present structure was built in 1719 and consisted of three masonry arches. In 1852 this bridge was demolished and replaced with the single arch in use to-day.

This arch is a circular segment with a rise of about 1/10 of the chord. The upstream chord is 31.0 meters, while the downstream chord is 32.5 meters long. This difference was caused by the alignment of the quays.

The arch is constructed of cut stone set in cement mortar and has a depth at the keystone of 1.35 meters.

The old abutments were utilized, the only change being to widen them slightly.

The cost of this bridge was 385,000 francs.

Pont National

The Pont National, known until the fall of the Empire as Pont Napoleon III, was constructed by the Terminal Railways of Paris in 1852-3.

It is composed of five segmental masonry arches of 34.5 meters span and 4.6 meters rise, not including two 12-meter arches, one on each bank, over streets.

The bridge is 16.10 meters wide, divided between 7.74 meters for the railway (double track) and 7.8 meters for the highway.

The arches are constructed of course rubble and have a keystone depth of 1.20 meters. They rest on piers carried on piles. The piers are 4 meters thick and the abutments 12.5 meters.

The original cost of the bridge was 2,237,000 francs.

The work was carried on under the supervision of M. Couche, Chief Engineer.

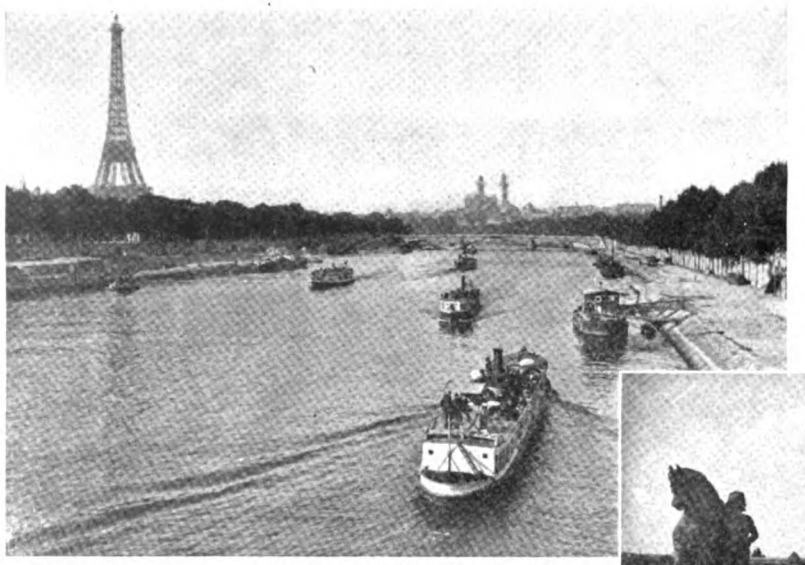
Pont Notre Dame

The present Notre Dame bridge replaced a 6-arch structure built in 1499-1507 by the Joconde Brothers, an Italian religious organization. The type of foundation used in this bridge was the same as that employed later for the Pont Neuf, as heretofore described.

They are timber platforms laid directly upon the sand, but, unlike those of Pont Neuf, they were immediately enclosed in sheet-piling walls and further protected by loose rock dumped at the upstream ends.

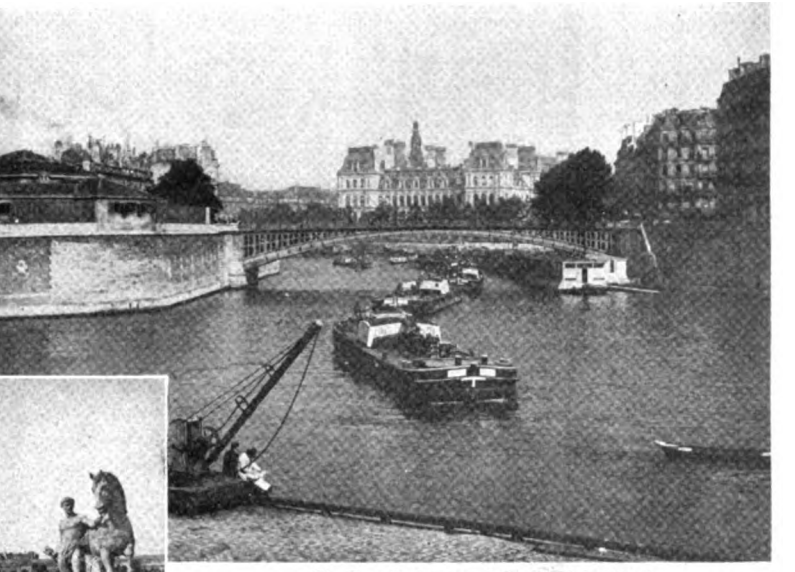
In 1852 it became necessary to lower the roadway some three or four meters to conform to the new level of the streets approaching it, so it was decided to completely wreck the old superstructure and rebuild the bridge on the old foundations. Accordingly, the superstructure was demolished to a point slightly above the water line, and the piers rebuilt with a thickness of 3.5 meters. They were connected with five elliptical arches, varying in span from 18.76 meters for the largest to 17.40 meters for the smallest The central arch has a rise of 7.5 meters and the shore spans 7.25 meters. The depth of the arches at the keystone is 0.88 meter.

The sixth arch of the old bridge had been built to span the head of a canal which was no longer in existence.



The length of the arches between faces is 21 meters, and the width of the deck 20 meters between parapets. The bridge has a 12-meter roadway and two 4-meter sidewalks.

For the greater part, stone from the old bridge was used, set in natural (Vassy) cement mortar.



The reconstruction required approximately one year and cost 713,000 francs.

These were the first elliptical arches used, beginning another new era in bridge construction. During the next ten years, six more bridges of this type were built.

Pont des Invalides

The first two bridges on this site were both suspension bridges, erected in 1824 and 1829.

The bridge of 1829 had three spans, the piers resting on pile foundations. The central span was 67.78 meters long and the shore spans each 24.68 meters.

In 1854, at the time of the Exposition, it was decided, for æsthetic reasons, to replace this bridge with a masonry arch structure, using, as far as possible, the old piers and abutments.

The new bridge is composed of four segmental arches; the shore spans are 31.87 meters, with a rise of 3.10 meters, and the central spans are 31.69 meters each, with a rise of 4.10 meters. All arches are 1.2 meters deep at the keystone and 1.8 meters at the skewbacks.

The central pier is the only one entirely new. It rests on piles capped with concrete. The old piers were lengthened and the abutments increased to 11 meters thickness.

The roadway is carried on seven arched spandrel walls.

The estimated cost of the reconstruction was 800,000 francs, but, owing to a change in the plans after the work had been started, changing the width of the proposed bridge from 14 to 16 meters, the actual cost was about 990,000 francs.

Repairs in 1876 consisted of replacing some broken skewbacks and arch stones, at a cost of 156,000 francs.

In 1878 some movement was noticed in the right-bank arch and was traced to the shifting of the first pier. It was discovered that some of the piles in the foundation were shattered and others displaced to such an extent that the caisson in which the footing was built did not rest squarely upon the heads of the remaining piles. In addition to this the ice flow during the winter of 1879-80 did so much damage that it was necessary to reconstruct practically the entire bridge. The central pier and the pier next the left bank, which had just been replaced, were the only exceptions.

The reconstruction did not change the appearance of the bridge, although the arches are slightly lower.

The cost of reconstruction from 1878 to 1881 was 1,396,000 francs.

Pont l'Alma

In 1854, when news of the victory of Alma was brought from the Crimea, it was decided to construct a bridge commemorating the battle.

Work was begun immediately and pushed as rapidly as possible, since it was desired to open the bridge to traffic the first day of the International Exposition, the year following.

This bridge is composed of three elliptical masonry arches of cut stone, set in cement mortar, the center arch having a span of 43.38 meters, with a rise of 8.6 meters, and the shore spans 38.88 meters, with a rise of 7.70 meters each. The depth at the keystone of all the arches is 1.50 meters.

The deck is 20 meters wide between parapets and accommodates a 12-meter roadway and two sidewalks.

The piers are 5 meters and the abutments 8 meters thick. The left bank abutment rests directly upon the soil and less than 1 foot below the water level; the other abutments and piers are built on pile foundations.

The figures on the pier heads represent four types of French soldiers.

Work was begun at the end of 1854, and the bridge completed about the middle of 1855.

The cost was 1,620,000 francs.

Pont St. Michel

The present St. Michel bridge was constructed in 1857, and is composed of three elliptical masonry arches, 17.20 meters span, with a rise of 6.50 meters. The arches rest on two 3-meter piers and two abutments 6 meters thick.

The arches are of cut stone taken from the old bridge on this site, set in Portland cement mortar. The depth at the keystone is 0.70 meter.

The width of the bridge between arch faces is 31 meters, and between parapets 30 meters. It carries an 18-meter roadway and two sidewalks.

The pier foundations were built in caissons.

Construction was started in May, 1857, and the bridge completed in December of the same year.

The total cost was 552,000 francs.

Pont au Change

It might be of interest to note that there have been bridges on this site since before the beginning of the Christian Era.

At the time the Boulevard Sebastopol was opened the bridge then on the site did not exactly line up with the streets. The old bridge, a 6-arch masonry structure, was demolished and the present bridge erected in 1858-60.

The present structure is composed of three elliptical arches of 31.60 meters span each, with a rise of 7.22 meters, resting on two 4-meter piers and two abutments. The width of the bridge between parapets is 30 meters, accommodating an 18-meter roadway and two 6-meter sidewalks. The keystone depth is 1.0 meter.

The piers rest on concrete footings 2.72 meters thick, poured in caissons. The abutments rest on stone masonry footings.

The arches are built of stone taken from the old bridge; the spandrels are Chateau-Landon rock. All stone is set in hydraulic lime mortar.

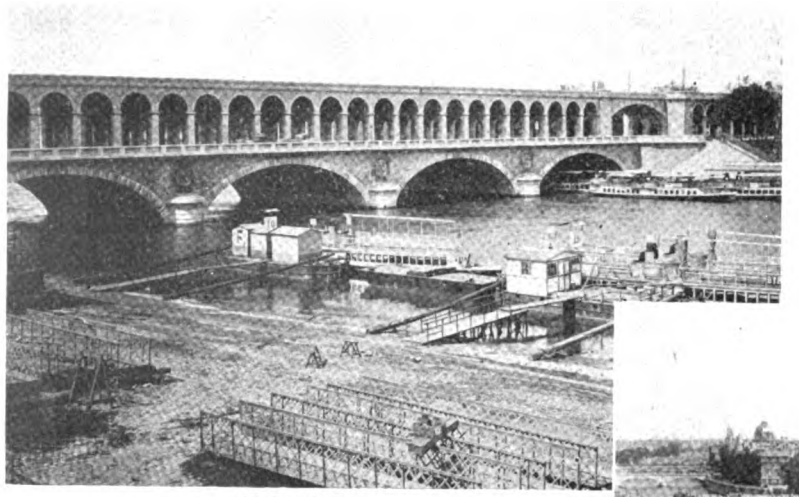
The demolition of the old structure was begun in 1858 and the new bridge opened in 1860. The work of demolishing the old bridge required more than a year.

The total cost, including the wrecking of the old structure, was 1,272,000 francs.

Pont Louis-Philippe

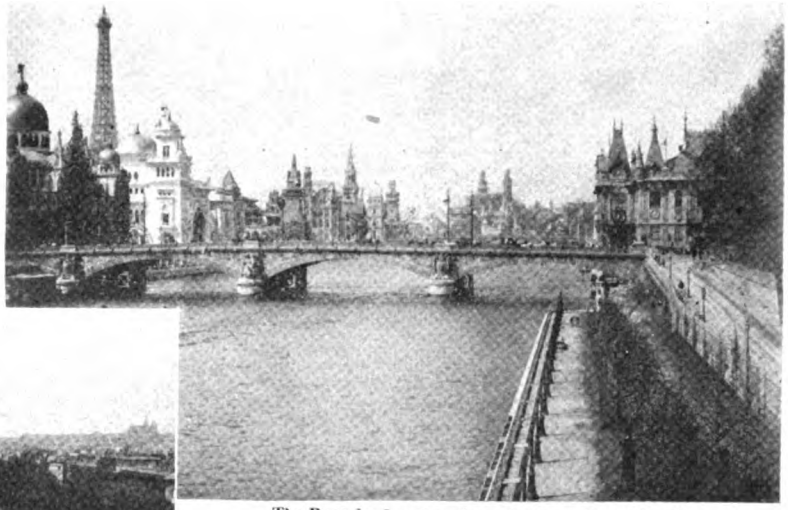
This bridge is composed of three elliptical masonry arches; the center arch has a span of 32.0 meters, with a rise of 8.25 meters, and the shore spans 30 meters, with a rise of 7.73 meters. The depth at the keystone is 1.00 meter and at the skewbacks 1.50 meters.

The piers are 4 meters wide and set on concrete footings 3.6 meters thick. The right bank abutment rests directly upon the gravel of the bank, and the other partly on the soil and partly on the piles of an old quay.



The work was begun in 1860 and completed in 1862. The total cost was 785,000 francs.

Pont de Bercy



The Pont de Bercy is composed of five elliptical arches of 29.0 meters span and 7.44 meters rise. The intrados of the central arch is 9.25 meters above low-water level; that of the two adjacent arches 8.75 meters, and the shore spans 8.25 meters. The depth of the arches at the keystone is 0.90 meter.

The abutments are 7.5 meters thick, and the one on the right bank rests on a timber platform on 30 by 30 by 8.5 meter piles. The left bank abutment rests directly upon the soil.

The piers are 4 meters thick and set on concrete footings poured in caissons sunk to a depth of 4.5 meters below normal water level.

The width of the bridge between parapets is 19.12 meters, with a 10-meter roadway and two sidewalks.

The total cost was approximately 1.000.000 francs. Construction was begun in 1863 and the bridge completed the year following.

Viaduct d'Auteuil

The highway bridge is 30 meters wide between parapets, and in the center is carried a double-track railway viaduct of masonry.

The total length of the bridge between abutments is 174.85 meters.

It is composed of five elliptical masonry arches of 30.25 meters span and 9 meters rise; four 4.72-meter piers and two abutments 7.5 meters thick at the ends, carried out to 13.0 meters under the railway viaduct. The deck is carried on seven spandrel walls.

Those portions of the arches under the roadways have a depth of 1 meter at the keystone and 1.75 meters at the skewbacks; under the viaduct, a section 11 meters wide, they are 1.6 meters deep at the keystone and 2.8 meters at the skewbacks. The reinforced belt in the center terminates in straight cut-stone joints, dividing each arch into three nearly equal sections.

The piers rest on concrete footings on chalk rock; the right bank abutment rests on piles driven into the chalk and the left bank abutment rests directly on the bank gravel and is enclosed with sheet piling.

The railway viaduct is 9 meters wide between faces and 10 meters high, measured from the roadway to the top of rail. It is composed of 31 semi-circular arches, with a 4.8-meter span on the bridge itself and two 20-meter segmental arches, one on each bank over the highways. Each large elliptical arch of the bridge carries 6 viaduct arches, the axis of every third arch coinciding with the axis of either a large arch or a pier. The depth of the arches is 45 centimeters at the keystone and 65 centimeters at the skewbacks.

The viaduct occupies 9.20 meters in the center of the bridge, on either side of which is a roadway 7.25 meters wide and a 2.3-meter sidewalk. Each viaduct pier has two 2.25 meters wide arched openings, which, while cutting down the weights of the superstructure considerably, also permit pedestrians to use the center of the bridge.

The bridge and viaduct are constructed of cut stone set in hydraulic lime mortar.

The work was begun in 1863 and finished in 1865. The total cost was approximately 2,864,000 francs.

The structure was erected under the supervision of MM. Bassompierre-Suvrin and Villers-du-Tenage.

Pont de Tolbiac

This bridge was constructed in 1879-82 and is composed of five elliptical arches whose springing lines are 1.36 meters above normal water level. The spans diminish from the center toward either bank, being 35.20, 32.15, and 29.10 meters, respectively, with rises of 8.18, 7.61, and 7.09 meters. The depth of the keystone is 1.0 meter.

The abutments are 7.50 meters thick, and that on the right bank rests on piles, the masonry footing dropping 1 meter below the cut-offs, while the left bank abutment rests directly upon the soil with the bottom of the footing about 1 meter below the water level.

The piers are 4.10 meters thick at the springing lines, and their concrete footings rest directly on the gravel.

The width of the bridge between parapets is 20 meters, with a 12-meter roadway.

The cost of construction was 1,500,000 francs.

Pont des Arts

The Pont des Arts is a foot-bridge designed by Cesart & Dillon and constructed in 1804.

It was originally composed of nine cast-iron arches, each having a span of 17 meters.

In 1852 the docks on the left were widened, necessitating the removal of one span and one pier. The second arch was replaced by a steel arch having a span of 23.7 meters.

The original cost of the bridge was 780,000 francs.

Pont du Carrousel

This bridge is composed of three circular metallic arches with spans of 47 meters and a rise of 1/10. The arches are carried on piers and abutments resting on piles capped with concrete and enclosed with wood sheet-piling.

Each arch is made up of five ribs spaced 2.8 meters c. to c. The ribs are made of wood and enclosed in cast-iron. These wooden ribs, which, in cross-section, are nearly elliptical, with a major axis of 60 centimeters and a minor axis of 32 centimeters, are composed of eleven thicknesses of 2-inch material with surfaces and joints tarred, and are securely held together by their cast-iron casing. The casing is 37 millimeters thick and cast in two sections, bolted together by flanges at the top and bottom. All joints are sealed with tar. The ends of each rib are closed with cast-iron caps. The depth of the ribs, from top to bottom of the casting, is 89 centimeters, uniform throughout their length.

The spandrels are cast-iron circles, decreasing in diameter from the piers toward the center of the arches.

The deck is carried on timber stringers, ten 8 inch by 12 inch, and covered with plank, on which the paving is laid.

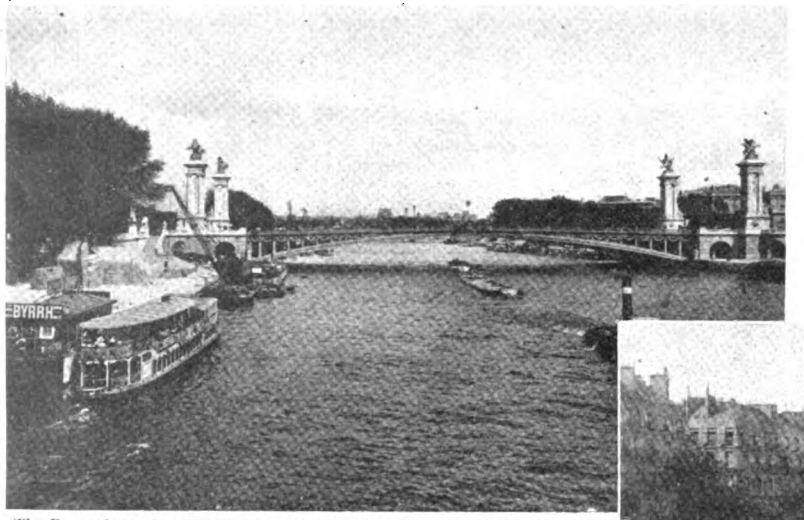
The hand-rails are cast-iron.

The bridge is 12 meters wide between hand-rails and has a 7-meter roadway and two sidewalks.

This bridge, begun in 1831, was completed in 1834.

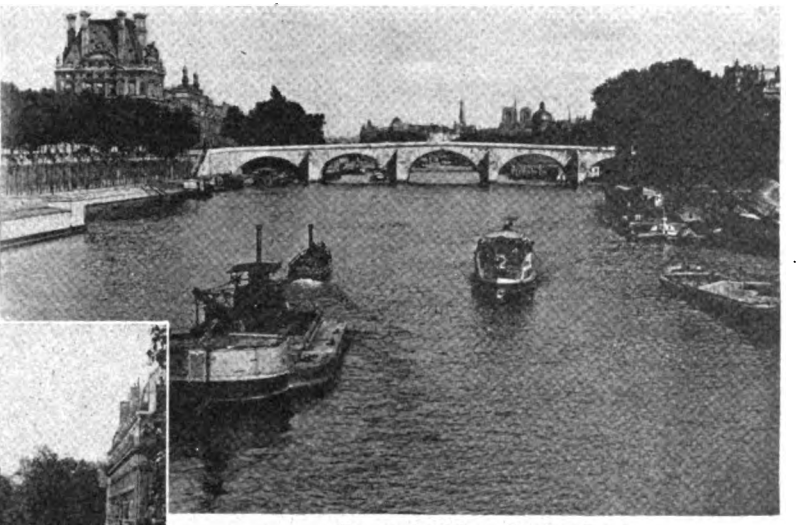
Pont d'Arcole

In 1828 a suspension foot-bridge was erected on the site of the present Pont d'Arcole and was known, first, as the Passerelle de la Greve, and later as the Passerelle d'Arcole. By 1854 traffic had increased in this section to such an extent that it was decided to replace the foot-bridge with a highway bridge.



The plans prepared by the bridge department provided for a triple-arch masonry structure, but M. Oudry, then Chief Engineer of Bridges and Highways, presented, in the name of a local company, a proposition to cross the river with a single wrought-iron arch having a span of 80 meters. This plan had so many advantages that it was immediately accepted.

The arch is a circular segmental arc with a rise of 1/13, or 6.12 meters, over a clear span of 80 meters between abutments. The crown of the arch is 9.25 meters above normal water level.



It is composed of twelve fabricated wrought-iron ribs, each 1.33 meters deep at the abutments and 0.33 meter at the crown. The ribs are spaced 1.33 meters c. to c. under the roadway, with one rib under each sidewalk. They are tied and braced with wrought-iron T's riveted every 2.5 meters along the intrados.

The ribs are fabricated in I-section; the web plate is 10 millimeters thick, the angles 100 by 90 by 10 millimeters, and

the four cover plates, top and bottom, each 530 by 10 millimeters. T-stiffeners, 200 by 100 by 12 millimeters, are riveted every 1.25 meters along their entire length.

The deck is entirely of iron and carried on wrought-iron spandrels. It is 20 meters wide between hand-rails, which are of cast-iron, and carries a 12-meter roadway and two sidewalks.

The abutments are of stone masonry on pile foundations.

The original cost was 1,143,000 francs.

This structure was designed and erected by the "Campagnie des Ponts en Fer," under the supervision of M. Oudry.

Pont de Solferino

This bridge was begun in 1858 and completed in 1859, shortly after the victory of Solferino, from which it received its name.

It is composed of three metallic circular arches of 40 meters span each, which rest on two piers 3.35 meters thick and two 9-meter abutments. The central arch has a rise of 4.0 meters and the others 3.55 meters.

The left bank abutment rests on a masonry footing directly upon the soil, the bottom of which is at the water level. The right bank abutment has a concrete footing, also directly upon the soil, but about 1.5 meters below the water line. Both piers have concrete footings.

Each arch is made up of nine cast-iron ribs having a double I-section 1.20 meters deep at the origin and 80 centimeters deep at the crown, spaced 2.5 meters c. to c. Each rib is cast in 15 sections with flanged connections, bolted together; the end sections are bolted to bearing plates set in the masonry. The ribs are tied together by 20 equally spaced cast members. The deck, of cast-iron I-beams, with brick arches between, is carried on cast-iron spandrels.

The original cost was 1,090,000 francs.

Pont au Double

The Pont au Double consists of a single circular metallic arch of 35.42 meters span and 2.94 meters rise, resting on two abutments of coursed rubble masonry set in Portland cement mortar. The bridge is 20 meters wide between hand rails, with a 12-meter roadway and two sidewalks.

The abutments are built directly upon the soil with the bottom of the footings about 2.5 meters below the normal water line. The right bank abutment is protected by sheet-piling, and the other by the retaining wall of the quay.

The arch is composed of eleven cast iron ribs, spaced 2 meters c. to c. The ribs are 80 centimeters deep at the origin and 50 centimeters at the crown, with the exception of the outside ribs, under the sidewalks, which are 60 centimeters at the crown. They are cast in 9 flanged I-beam sections and bolted together. The lateral bracing is also cast iron. They rest on steel wedges on cast iron bearing plates sunk in the masonry. The deck is carried on cast-iron I-beams 500 by 280 by 30 on cast spandrels.

Digitized by Google

Pont St. Louis

The present Pont St. Louis was constructed in 1861 and consists of a single circular metallic arch of 64 meters span and 5.85 meters rise on masonry abutments.

The arch is composed of 9 cast-iron ribs spaced 2 meters c. to c., which carry the deck of brick arches on cast-iron spandrels. The ribs have an I-beam cross-section with a web thickness varying from 52 millimeters at the abutments to 38 millimeters at the crown. Each rib is cast in eleven sections, bolted together. The depth is 1.8 meters at abutments and 1.20 at the crown. All joints are rigid.

The abutments are 10 meters thick and are built of rubble masonry in Portland cement mortar, with cut-stone facing. The left bank abutment rests on piles, and at the other directly upon the soil.

The bridge is 16 meters wide and has a 10-meter roadway.

The total cost was 656,000 francs.

Ponts Sully

These bridges span the main and lesser channels of the Seine at the extreme upstream end of the Ile St. Louis. They are 20 meters wide and carry a 12-meter roadway and two sidewalks.

The abutments and piles of the bridge over the main channel are skewed to an angle of 51° 10′, with the center line of the bridge, and those of the other bridge, to an angle of 66° 26′.

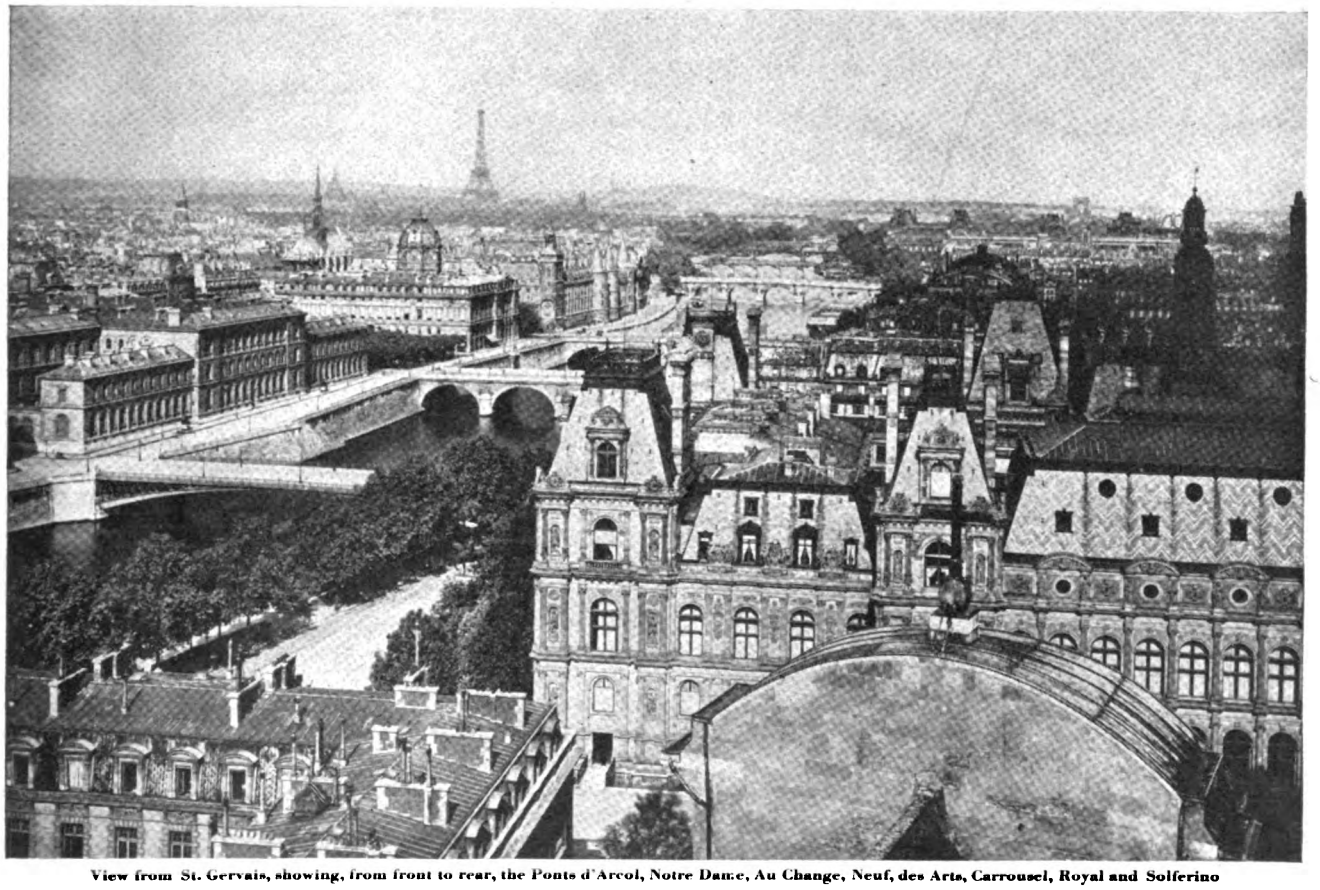
The bridge over the main channel is composed of three cast-iron circular segmental arches; the central arch has a span of 49.56 meters and a rise of 5.66 meters, and the remaining arches have spans of 46.35 meters with a rise of 4.88 meters.

The bridge over the lesser channel is composed of one circular cast-iron arch with a span of 42.28 meters and a rise of 5.45 meters, and two semi-circular masonry arches, one at each end, having a diameter of 15.35 meters.

On the main channel bridge the left bank abutment is built directly upon the sand; the piers are on concrete footings on rock, about 4 meters below the water level, and the right bank abutment rests on piles. The abutments of the smaller bridge rest directly upon the sand.

Each metallic arch is composed of eleven cast-iron ribs spaced 2.0 meters c. to c. In cross-section they are I's, with a web thickness varying from 30 to 52 centimeters. They are 60 centimeters deep at the crown and 90 centimeters at the abutments. They are cast in sections of equal length, measured along the intrados—11 in the arches of the main bridge and 9 in the other. The joints are planed and the sections bolted together. The arches are braced laterally on top of the spandrels by 8-inch cast-iron I-beams, which also carry the brick arches of the deck.

The cost of the bridge over the main channel was 516,000 francs for the masonry and 682,000 francs for the metal; the smaller bridge cost 481,000 francs for the masonry and 193,000 francs for the metallic parts.



Work was begun in 1874 and completed in 1876.

Passerelle de Debilly

This foot-bridge is separated into two parts by the Ile de Cygnes, the one part being 120 meters long between abutments and the other 89.80 meters. Both sections are composed of two structural steel-deck cantilever trusses. The piers are two steel cylinders, filled with concrete.

The central span of the larger section is 44.20 meters long and that of the smaller 32.20 meters.

The depth of the trusses is 50 centimeters at the connecting pin and 3.5 meters over the piers.

View from St. Gervais, showing, from front to rear, the Ponts d'Arcol, Notre Dame, Au Change, Neuf, des Arts, Carrousel, Royal and Solferino

Digitized by Google

The bridge was constructed in 1878 and cost 420,000 francs.

Pont de Grenelle

In 1825 a bridge of six framed arches on masonry piers was constructed, as was also the dike separating the Grenelle basin from the river proper, and which divides the bridge into two equal sections. It became necessary to rebuild the superstructure in 1875, and cast-iron arches replaced those of timber.

The old masonry work was built on pile foundations and was still in good condition. The piers were used without any change, but the abutments were increased in thickness to approximately 6.4 meters.

The new arches are composed of five cast-iron ribs each, spaced 25 meters c. to c. The ribs have I cross-sections and are 70 centimeters deep throughout their entire length. The thickness of the metal is 24 millimeters for the interior ribs and 18 millimeters for the two outside.

The lateral bracing is also cast-iron, bolted to flanges on the ribs.

The work was done during 1874 and 1875 and cost approximately 375,000 francs.

Pont Mirabeau

The Pont Mirabeau is composed of two deck cantilever trusses on two pier abutments. The central span is 93.20 meters and the two shore spans each 32.42 meters between pier faces.

The piers are built in caissons sunk to solid rock, about 10 meters below the river bed. The two end abutments rest on piles. The piers are built entirely of Cherbourg granite in Portland cement mortar, and the abutments are limestone in hydraulic lime mortar.

The bridge is 20 meters wide between hand-rails and has a 12-meter roadway.

Each cantilever is composed of seven structural steel trusses spaced 3 meters c. to c. under the roadway and 3.72 meters for the two outside trusses. The two halves of the bridge are symmetrical, resting on cast-steel rockers on the piers, and pinned together in the center. The shore ends are anchored to the abutments by means of vertical rods set in the masonry.

The channel arm of each cantilever is 49.67 meters long, measured from center line of rocker to center line of connecting pin; the other arm is 37.30 meters from center line of rocker to the end.

The top chords of the trusses are horizontal, the bottom chords take the form of parabolic curves.

The Pont Alexandre III and the Grand Palais

The depth of the trusses is 84 centimeters at the central joint, 50 centimeters at the shore ends, and 53.5 centimeters over the piers.

The deck is carried on brick arches between transversal I-beams spaced 2.0 meters c. to c.

The bridge was designed by M. Resal, and cost 728,000 francs for the masonry, 1,221,000 francs for the steel, and 141,000 francs for the bronze decorative figures.

Pont Alexandre III

The Pont Alexandre III, the most ornate and elaborate of the bridges of Paris, is a single metallic arch with three pin connections, having a clear span of 109 meters between abutments. The end pins set out from the abutment in their bearings 75 centimeters, making the span of the metallic arch itself 107.5 meters c. to c. of pins. The arch has a rise of 6.28 meters, 1/17 approximately.

The approaches on the quays are masonry arches. The

Digitized by Google

bridge is 40 meters wide between hand-rails, with a 20-meter roadway and two 10-meter sidewalks.

The arch is composed of 15 ribs equally spaced. The arch ribs are cast-steel and the spandrels structural steel. The decorative work is cast-iron.

The abutment footings are 44 by 33.5 by 3.5 meters, poured in caissons sunk to approximately 6 meters below the river bed. They are built of coursed rubble masonry to a point about 1 meter below the water level, and from that point up of cut granite. All stone is set in Portland cement mortar. In back of the bearing plates the rock is laid in courses approximately 45° to the horizontal and well toward the center of the abutment.

The arch ribs are cast in 30 voussoirs and 4 joint sections. The interior ribs have I cross-sections, and the two outside ones are decorated channels. The sections are approximately 3.5 meters long and have flanged connections bolted together. The depth of the ribs vary from 1.03 meters at the abutments, 1.52 meters at section No. 7 to 90 centimeters at the central joint. The web thickness is 5 centimeters (2″).

Work on the foundations was begun in April, 1897, and the bridge completed just three years later.

The total cost of the structure was 6,585,000 francs, of which 1,000,000 francs were for decoration.

The bridge was designed and constructed by MM. Resal & Alby.

Viaduct de Passy

The Viaduct de Passy is composed of four structural steel deck cantilever trusses. Over the main branch the central span is 54 meters and the shore spans each 29 meters; over the other branches they are 42 meters and 23 meters, respectively. The width of the deck is 24.70 meters and has an 8.7-meter central promenade, two 6-meter roadways, and two 2-meter sidewalks.

In the center of the bridge is the railway viaduct, 7.3 meters wide and 7.5 meters above the roadway. The viaduct consists of deck-plate girders supported on cast-iron columns.

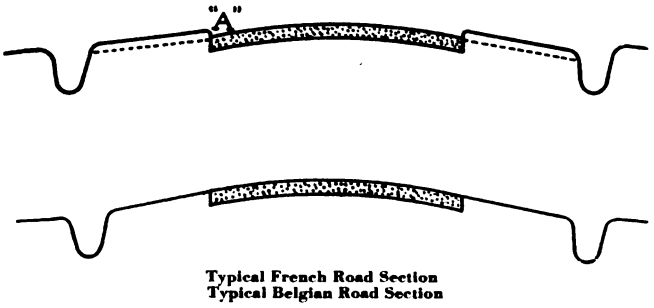
Work was started in 1903 and the viaduct completed in 1906. The total cost was 5,500,000 francs.

The Secret of Universally Good Roads in France

By

Perry K. Miller
Captain, Engineer Reserve Corps

THE difference in the method of road repair between the French and the American is a true indication of the difference in the natures of the two nationalities. It is inherent in the American to get a fair or good result in the shortest time while with the French it is to get the best possible result irrespective of time.



To compare our American roads to French roads is unfair to our engineers unless several important differences in existing circumstances are taken into consideration. One must make due allowances, especially for the following: Our severer climate with frost going from three to five feet, the enormous truck loads and the high speed of most of our traffic.

After the armistice was signed, the American army set out on the tremendous work of putting into shape the thousands of miles of French roads which had been either severely damaged or practically destroyed. Never has there been such an enormous road repair work attempted or accomplished in so short a time. Just how did the army measure up to this work? It is an absolute fact that some if not nearly all of the French Departmental Road Engineers, who correspond to our State Highway Engineers, have, after observing our methods and results, begged that the American army would only distribute road material along the sides of the road and leave all repair work to be done by the French cantonnier (caretaker of from two to five kilometers of road). Here again there must be one more condition taken into consideration. The American soldier in the ranks was not interested in the rebuilding of French roads. He was home-sick and craved for the time when he would embark for home.

Were the French and the Americans to work under conditions most favorable to themselves, the French would far excel in road repair. The secret of it is the patience of the man which keeps him constantly at his endless task.

Many engineers say that road drainage is over fifty per cent of road repair or construction. The French drainage systems are marvelous in their design, construction and upkeep. However, were we as skilled in this part of the road repair we would still have far poorer roads because the reckless haste of our impatient natures would prevent us from giving to the road surface the care which French roads receive.

The Frenchman's thrift presents itself in the design of the roadway proper. His repair practice is the last word in road maintenance. The typical French road section is shown in the figure. The typical Belgian road section has a continuous road wearing surface drainage plan and it is also shown in the figure.

Typical French Road Section
Typical Belgian Road Section

The Belgian road section makes it possible to totally eliminate the standing water troubles often experienced in the use of the other type, particularly on flat grades. The French type, with well attended lateral drains, drains the roads properly and accomplishes the important work of holding at "A" most of the worn particles of the road surface, which play so important a part in the continuous French road repair.

The cantonnier starts out for his work with a two-wheel cart in which he has a stone fork, a shovel, a pick, a rake and above all his improvised brush road broom.

Digitized by Google

The road metal is always seen very neatly piled at frequent intervals along the road side. The binder he brushes from "A." Very rarely does he require new material for binding the road metal.

It is the every-day attention that keeps the French road in the state of perfection that we always find it. After rains or showers the cantonniers are particularly active. Every meter of road is worked at intervals of from one to five days. Every piece of road metal finally is brushed into its proper place and there becomes fixed. It is not unusual to see French road workers make several steps to brush single pieces of stone into some particular spot.

It is patience, untiring patience, that is the true secret of the excellence of French roads.

What and Why is a General Staff?

By

Donald H. Connolly

Major General Staff, Engineers

[*Note.* Major Connolly, the author of this article, by reason of his present position as a member of the General Staff at Washington, D. C., and his experience as a staff officer, is exceptionally qualified to speak with authority on the subject of the General Staff.

Moreover, in the preparation of this article, Major Connolly has consulted with many members of the General Staff, and their views are also embodied herein.

We are able to say, therefore, that this article presents a consensus of opinion of experienced General Staff officers as to what a general staff should be and how it should function. It must, therefore, command interest and respectful attention.—ED.]

IN the November-December issue of THE MILITARY ENGINEER there appeared an article by Maj. J. C. H. Lee on Staff Organization. As engineers we are all vitally interested in this subject, with special reference to where and how the engineers fit into the scheme. Maj. Lee's article, read in connection with Maj. G. R. Young's article in the same issue and the comments on both of them, has helped greatly in clarifying the subject. However, there were two points made which are open to argument:

First. That the main duties of the General Staff are in connection with supply questions and the actual command of staff and staff troops.

Second. That the General Staff should be organized on the basis of actual command of certain other staff units rather than along functional lines.

Let us examine the first idea expressed above. Major Lee's conception appears to be that the division commander has four principal assistants; that the three brigadiers are his principal tactical assistants and are held responsible for tactical details; that the Chief of Staff commands the staff and all the staff troops in his own person just as the brigadier generals command their brigades, and that he is responsible for all staff details. The concept appears to be that the staff units virtually form a fourth brigade under the direct command of the Chief of Staff. The article is not clear as to the exact relation of the Chief of Staff to the tactical details connected with the division. Major Lee's contention that the three brigadier generals are the division commander's principal tactical assistants was objected to by several commentators and in his final summing-up the author admits that the Chief of Staff and G-3 are the division commander's tactical advisors. However, from the fact that the Chief of Staff holds direct command of all the staff troops, which the author himself says is fully as responsible a position as commanding a brigade, it seems fairly clear that he probably would not have any more time to devote to tactical details of the work of the division as a whole than an infantry brigadier would have, after attending to the details of his brigade. It seems quite evident that the author considers the tactical work as a secondary mission of the General Staff, as he states: "In other words, the true mission of the General Staff, not only for the division but for any military body, is the duty of fitting the military activities of supply (material and otherwise) into a soundly organized system for control by the superior commander."

In discussing this point, let us first try to answer the question, What and Why is a General Staff?

In his hearing before the Senate Committee on Military Affairs when it had under consideration the provisions to be included in the last amendment of the National Defense Act (Act of June 4, 1920), Col. John McA. Palmer* stated: "I am perfectly satisfied that one of the principal causes of the confusion of thought in regard to a General Staff is that very few people know what a General Staff is. That is true in civil life; it is true in the Army; and it is also true in the General Staff itself."

The Origin of the General Staff

Let us consider what was the origin of the General Staff system, and what is the fundamental idea in foreign armies as to its mission.

The first traces of the General Staff are found about 1655 in the Brandenburg Army which preceded the Prussian Army. Incidentally, for over one and one-half centuries there was a very close connection between the engineers and what later became the General Staff. However, it was Frederick the Great, who as the result of experience in the Seven Years' War, started the system of taking *junior* officers and training their tactical judgment with a view to using them to assist general officers along tactical lines.

Carlyle, in his history of Frederick the Great, describes how Frederick, recognizing that the question of troop leadership on the battlefield was a question of action and not one of merely theoretical knowledge, started to develop in himself a practical sense of tactical judgment. Frederick, while riding through the country, constantly put to himself practical problems as to what orders he would issue were he commanding troops on this or that particular piece of ground, assuming that the enemy did this, or that, or the other thing. Later, Frederick de-

*Colonel Palmer was selected by General Pershing for detail on his staff as his First Chief of Operations, American Expeditionary Forces, and served as such during the initial days until his health broke down. At the time of his hearing before the Senate Committee referred to here, he was Chief of the War Plans Branch of the War Plans Division, War Department General Staff.

Digitized by Google

veloped this idea still further on the theory that what had benefited him would also benefit others. At the close of the Seven Years' War he started a school for improving the tactical judgment of officers through this method of making them solve concrete problems. His plan was to select men with tactical aptitude and give them the precise training in higher troop leading and other matters in which the general officer should be expert.

Note the following in reference to his original General Staff system:

(1) That the training given an officer for General Staff duty was precisely the same as that given for high command of line troops.

(2) That after a command reached a certain size the commanding officer needed assistants in his control of the line troops, in addition to those he already had in using the staff troops.

(3) That Prussia had created a body of officers trained in this system of troop leadership and had had a General Staff with troops for over half a century before the Great General Staff at Berlin was established.

The Germans adhered to these original ideas throughout their development of the General Staff system. For instance, consider the type of problems given by Von Moltke to captains and lieutenants in the War Academy as candidates for the General Staff. In some of these problems these officers were required to state what arrangements they would make in a given tactical situation if they were in command of a given army corps or a given division. Von Moltke was not giving these junior officers this training and these tests to demonstrate their ability along these lines because he had any idea of employing men of this rank to command divisions or army corps, but because he expected to use them as assistants to generals who would train and lead these units.

Education for the General Staff or Etat-Major in France proceeds along similar general tactical lines. All candidates for the General Staff attend the Ecole-de-Guerre. Men like Foch and Petain are products of the French system.

The British have the same general idea that education for the General Staff must be along tactical lines.

The Japanese have the same idea that a General Staff officer is a specialist in troop leading and tactics. Of course they borrow their ideas direct from Germany, but they had considerable experience themselves in applying this system during the Russo-Japanese War. They went to what we would consider extreme lengths in applying the idea that the commanding general should keep his mind clear for the big decisions and turn over to his Chief of Staff the issuing of the tactical orders necessary to carry these decisions into effect.

All of these nations have had a chance since the adoption of the General Staff system to try it out in time of war, and the fact that they have retained it still organized on the same basic ideas, shows that their experience in war has given them no reason to make fundamental changes. The main point to be noted in all this is that, to quote Colonel Palmer: "A General Staff officer in that sense is primarily a trained troop leader; he is a man who is trained in tactical values; and when he comes to co-ordinate other agencies or other services it is purely in that direction that he ought to influence them. He should not do their business for them."

Under the French and German systems the tactical faculty has been determined and developed in the General Staff officer, and that is the primary reason why he is on the General Staff. He may be in the G-4 Branch (a supply branch) and deal with something other than tactics, but he is always dealing with it from the tactical point of view. The trained General Staff officer in G-4 will inform the supply services as to what they ought to supply in order to conform to the tactical plans. If you put a quartermaster or an engineer in there who is not trained along General Staff lines, he will feel, of course, that he is put there to do something, and not knowing exactly what, he may be inclined to take over complete control of the quartermaster or engineer activities. Some instances of this occurred in our own army during the World War.

The origin of the General Staff system and its development abroad may be summed up somewhat as follows:

When armies were small and the maneuvering, quartering and fighting formations were prescribed by rigid regulations, the general in command could personally work out what few details his orders necessitated, and often conducted the battle from what he personally knew about the terrain, the enemy, his own troops, and what he himself could observe as to the progress of the battle.

As details became more numerous and could no longer be governed by fixed rules, a commander in the field shifted more and more of the details of supply questions to the shoulders of subordinates in order to keep his own attention more clearly on his main job, which was to maneuver his fighting units in such a way as to accomplish the defeat of the enemy. Thus was developed the supply staff. As armies grew still larger and tactics changed and developed with the improvement in weapons, a point was finally reached where the need was felt for a distinct group of staff officers to relieve the commanding general of some of the details connected with the tactical handling of the fighting units. In most armies this group of staff officers is called the "General Staff." The General Staff group of the entire staff necessarily became charged with the duty of keeping the supply services and other specialist staff officers in touch with the needs of the tactical and strategical situation.

Colonel Palmer summed this up very concisely when he said that originally the General Staff was organized to perform staff functions that previously had not been performed at all except possibly by the commander in his own person, and was not organized merely as a new agency to perform functions already being performed by assistants to the commander.

This was the reason for the establishment of the General Staff system, and after the test of war it is still regarded as its mission in most important foreign armies.

The Creation of Our Own General Staff

Let us examine briefly the conditions under which the General Staff was established in the United States Army, how we started out, and the subsequent developments.

The basic fact is that we started from the top down instead of from the bottom up, as the Germans, French and British did.

The Germans had a General Staff with troops over fifty years before they had a Great General Staff in Berlin, just as we had our Army Quartermasters and a proper conception of what a quartermaster should be long before we had a Quartermaster General in Washington. On the other hand, we had what would correspond to the present War Department General Staff before we had what would correspond to the present General Staff with troops. In fact, at the time that the General Staff was first organized, we did not have organized bodies of troops large enough

Digitized by Google

to utilize a General Staff or, in other words, we did not have any organized bodies of troops large enough for the commander to need assistants in his own peculiar function of command. Few, if any, of the original members of the General Staff Corps had training or experience as General Staff officers, on which to base their conception of what a General Staff officer should be and do; consequently they looked to Germany where the system had been in operation since about 1760, but they did not look very closely. To some people words are of more consequence than ideas. We borrowed the words, but missed a large part of the fundamental idea back of them.

We took the term "General Staff" from the German term "Generalstab." However, the ordinary English meaning of the words "General Staff" is quite different from the German idea expressed by the word "Generalstab." Because of this faulty translation, many people, looking merely at the words and not at the idea, have assumed that a General Staff officer is an officer whose activities are of a *general* character in that they extend over all matters that concern more than one special branch of the service. In other words, that his duties are of a general nature rather than of a special nature.

The German and the French idea are both to the effect that he is a specialist of the most restricted type. Even the British, who started their General Staff a year after we did ours, avoided making our mistake. In the discussions of 1904, which preceded the organization of their General Staff, it was particularly pointed out that this warping of the original meaning should be avoided. It was suggested that a better name than General Staff would be to call it the "Military Operations Staff," in order to make its mission clearer. It was pointed out that one of the first duties of the General Staff was to establish an educational system and standards of eligibility for the General Staff with accompanying lists of officers who came up to those standards.

The literal translation of the idea expressed by the words "Generalstab" is the "General's Staff" or the "Generalship Staff" or "Military Operations Staff." As confirmatory evidence that the Germans understand it this way, consider the fact that although the Army General Staff had been developed during many years before the German Navy had progressed to the point where they required an agency for the Navy corresponding to the General Staff of the Army, the Navy did not call this new agency the "Naval General Staff." They called it the "Admiralstab" or the "Admiral's Staff." The German idea was that just as a general officer needed an Engineer Staff to advise him on engineering matters, a Medical Staff to advise him on matters concerning the health of his command, so also he needed a Generalship Staff to assist him in the performance of his own peculiar functions of leading troops in battle.

To Mr. Elihu Root (while Secretary of War), more than any other one man, belongs the credit for establishing a General Staff Corps in the United States Army. In his report for 1903, Secretary Root said: "The important military event of the year affecting the Regular Army has been the reorganization of the system of military control under the General Staff Act approved February 14, 1903 * * *. This act abolishes the separate office of Commanding General of the Army, provided for the President a military Chief of Staff who, acting under the direction of the President or the Secretary of War, representing him, should have supervision not only of all the troops of the line, but also of special staff and supply department, which have heretofore reported directly to the Secretary of War; and created for the assistance of the Chief of Staff a corps of 44 officers who were relieved from all other duties."

In the regulations issued by the Secretary of War (Mr. Root), by direction of the President, putting into effect the law establishing the General Staff, will be found the following:

"Under the Act of February 15, 1903, the command of the Army of the United States rests with the constitutional Commander-in-Chief, the President, . . . The President's command is exercised through the Secretary of War and the Chief of Staff. The Secretary of War is charged with carrying out the policies of the President in Military affairs. He directly represents the President and is bound always to act in conformity to the President's instructions. Under the law and decisions of the Supreme Court, his commands are the President's commands and his directions and orders are the President's directions and orders. The Chief of Staff reports to the Secretary of War, acts as his military advisor, receives from him the directions and orders given in behalf of the President and gives effect thereto in the manner hereinafter provided. . . .

The supervisory duty vested by statute in the Chief of Staff covers *primarily* duties pertaining to the command, discipline, training, and recruitment of the Army, military operations, distribution of troops, inspections, armament, fortification, military education and instruction and kindred matters, but includes also in an *advisory* capacity such duties connected with fiscal administration and supply as are committed to him by the Secretary of War. . . . In the performance of the duties hereinafter indicated and in representation of superior authority, the Chief of Staff calls for information, makes investigations, *issues instructions*, and exercises all other functions necessary to proper harmony and efficiency of action upon the part of those placed under his supervision."

Note that Mr. Root clearly understood what the primary duties of the General Staff should be and that such instructions as it issued to the staff and supply departments were to be those necessary to bring their work into harmony with the Army as a whole.

It is now prescribed by law that an officer shall not be detailed to our War Department General Staff unless he is competent to perform General Staff duties with troops. In our original organization of the General Staff, which did not include a General Staff with troops, we did not have available men with the basic experience or training which foreign armies considered necessary for General Staff duty with troops. Our original idea seemed to be to get men of marked ability in their various specialties and let them run things. We got together what was probably the ablest body of men in the service at that time, but it was not a General Staff. It was an aggregation of exceptionally able infantry, cavalry and artillery officers, engineers, quartermasters and other gifted specialists. Our General Staff system soon started doing on a grand scale for the military establishment just about what Major Lee recommends on a smaller scale for a division. The General Staff gradually worked itself into power and took command of things. Note again that it did this mostly along the lines that Major Lee advocates—that is to say, technical and supply service lines. It began to take actual command of the technical and supply services while slighting its own peculiar tactical and planning functions as understood in all important foreign armies. It is worthy of note that most of the criticism of the General Staff down to date has come from the various staff bureaus, and not from the line.*

*This does not prove that the General Staff did not in fact improperly assume line functions. The line was inarticulate as it had no chiefs or spokesmen for its various branches except for the Coast Artillery, whose chief was a member of the General Staff and had no occasion to publicly criticise his co-members. Forceful, strong minded infantry or cavalry officers in the General Staff became in effect, if not in name, the chiefs of their respective branches and influenced from within the actions of the General Staff in all matters pertaining to their respective arms.—Ed.

The volume of the criticism and the caliber of many of the officers doing the criticising should make us pause and think before we dismiss the subject with a few pitying remarks about pigmy minds. There is an old proverb about fire where there is much smoke. Is it not possible that even in recent years, the General Staff has sometimes forgotten the basic reason for its existence?

In 1906, Major Morrison (now Major General) revolutionized the educational system of the Army by putting into effect at the Fort Leavenworth Schools a definite system to prepare officers for tactical command of troops and General Staff duty. Note again here that the training for the two is the same, as the primary function of the General Staff is to assist and relieve the commanding officers of burdensome details in their own peculiar function of tactical training and handling of troops.

The result of our experience in the World War has been to strengthen the belief in the correctness of the doctrine taught at Fort Leavenworth as to the mission of the General Staff, and the training necessary for a General Staff officer.

Since the war, thought on this question has become further crystalized to the extent that the training system now prescribed for qualification for appointment to the General Staff is designed to insure that a General Staff officer shall be a specialist along tactical lines. I am not to be understood as saying that, because a man is an excellent division Chief of Staff, he will necessarily develop into an excellent division commander, or that an excellent division commander must necessarily have the same detailed technical knowledge as an excellent Chief of Staff; other factors enter in. The general must know enough about strategy, logistics, and tactics to come to a sound decision on the project as a whole. Just as the commanding general will consult his Chief Engineer as to whether or not an engineering project involved in his plan is feasible and his Chief Engineer may suggest another one in case the one thought of by the commanding general is not feasible, so the Chief of Staff must be able to furnish his commanding general technical advice along generalship lines. For instance, he knows the details as to the position of each unit of the command, how much road space each one will take up, how long it should take to get the command into a given formation or position, the latest information known as to the enemy, the state of supplies and transportation, and other essential details. All this must influence any tactical decisions made by the commanding general. The mind directing the division, or army corps, or other unit is not a composite mind. It is the mind of one man—the commanding general. However, this mind should not clutter itself up with details either of information (tactical, engineering, etc.) or of execution (the orders it is necessary to give to each unit to carry out his decision). This is not to bolster up a figure-head but to leave a big-caliber man's head clear for the big aspects of the problem. The credit for success, or the responsibility for failure, is rightfully his.

The Chief of Staff and the Fourth Brigade

Taking up the point that the division commander divides his task and personnel into four parts and allots one part to each brigade and one part to the staff troops commanded by his Chief of Staff, it is not believed that the tactical mission assigned a division permits of such an allotment and even if it did, the Chief of Staff is not the man to command the fourth brigade (composed of the staff troops).

If a tactical mission is subdivided on lines of direct responsibility and command, all subdivisions are tactical. Normally, the staff and staff troops are auxiliary means at the disposal of the division commander to assist his tactical units in achieving their missions. If he divides the mission of his division amongst the brigades, he must see that the means are also distributed so that each brigadier shall have proper assistance. He may allot engineer and signal troops to each brigade and may even take batteries from the field artillery brigade and place them directly under the orders of the infantry.

In subdividing the tactical mission of the division, the staff troops do not act as one body and receive one integral section of the mission. They are functional troops (so to speak) and are the means to assist those units that do take over sections of the tactical mission.

Even if the staff troops were to be combined in one brigade (which is believed to be wrong in principle) the Chief of Staff should not command it. His education and the uses to which he is to be put in the division are mainly tactical.

The idea that a division commander should rely on his brigadiers for tactical information and advice appears highly questionable and is entirely aside from the fact that they are not always available. Each is naturally more interested in his own brigade than in the others and ordinarily has neither the time nor the opportunity to study the problems of the division as a whole, as have the division commander and his Chief of Staff. If time allows, the division commander would probably talk over with the various brigadiers the missions to be assigned them and possibly make some changes in boundary lines of the sectors and other details. However, it is believed that ordinarily the brigadiers would not be consulted until the division commander (with the assistance of his Chief of Staff) had blocked out the plan for the division as a whole.

Most of the successful military commanders of history have not relied on the town-meeting method of arriving at a decision. In the words of one of them: "If the commander, after consultation with his authorized advisor, feels the need of asking others what to do, the command is in weak hands."

The True Mission of the General Staff

The military history of our own and foreign countries appears to establish the fact that the true mission of the General Staff is *not* to command the supply and technical services; that on the contrary the General Staff is a technical service in itself and its true mission is to furnish detailed assistance in its own specialty of troop leadership.

Even the G-1 and G-4 branches of the General Staff, which deal with matters other than tactics, deal with them from the tactical and strategical points of view. They are in existence merely to keep personnel and supply matters closely in touch with the details of the strategical, tactical, and training plans. The training prescribed in order to qualify for detail in any section of the General Staff is based primarily on handling of line troops.

The Basis of Staff Organization

Having considered what a General Staff is, and what it is for, let us now take up the second point brought up by the author of that article, as to how it should be organized, whether along functional lines or on the basis of direct responsibility and command.

Major Young's excellent article on the "Fundamentals

Digitized by Google

of Staff Control" in the same issue of THE MILITARY ENGINEER as that in which Major Lee's article appeared has covered so well the necessity of organization along functional lines for the General Staff that I merely wish to put his rule for staff control into slightly different words. His rule is "non-interference except when questions concern two or more bureaus or services." I would prefer to say "except when the decision on the question directly affects the tactical situation." This amounts to the same practical criterion as that given by Major Young, but it brings out a little more clearly the basic mission of the General Staff as expressed in the first part of this article.

For instance, Major Young cites an example where a decision is needed as to which one will have the use of certain transportation—the division engineer or the division quartermaster. As he says, this would be decided by G-1 who thinks "in terms of transportation questions." The additional words "with respect to the tactical situation" are of course understood.

This rule covers the extent of General Staff control fairly well if we are sure that we are all speaking the same language. However, since some General Staff officers apparently operated on this rule during the World War and still succeeded in missing the whole point, let us go a little further into detail as to exactly what we mean.

It is believed that many of the mistakes made by General Staff officers in the World War were due to lack of comprehension of one of the simplest and most fundamental principles of management that apply to both military and civil work. This is, when you give a man a mission, you must also give him the means to accomplish it. "Means" consist of many different things, but to illustrate the point let us consider the example used above by Major Young—transportation.

A division commander has a certain amount of transportation at his disposal. He has a number of officers under him whose work requires transportation. He can not give each of these officers all the transportation needed for any task that may be assigned them, yet if he assigns a task he must also assign the means necessary to perform the task. The proper distribution of transportation is then to give each officer requiring transportation such an amount as will enable him to accomplish his average amount of work or even his minimum amount of work if transportation is very limited. The rest of the transportation should be kept in such a flexible state of control that it may readily be diverted from one activity to another, according to the need for it, and a staff officer put in charge.

This staff officer in charge of transportation is not there in a negative role to "interfere," nor yet to refrain from interfering; he is there to help by positive action whenever help is needed. If things are moving along smoothly and his assistance is not required, the less he has to say the better it will be for all concerned. Since the time when help is most needed is in a crisis, let us consider the case of a division about to attack over ground cut up with trenches and shell holes. A number of officers have to prepare to meet a crisis demanding transportation and they all apply for help. The division quartermaster and the division ordnance officer want to be ready to rush supplies forward; the division surgeon anticipates more wounded than his transportation will handle; the division engineer says he can't build his road through without extra trucks, etc. All the transportation of the division, plus all it can get from the corps, would not be sufficient to hand over on demand to each of these officers all that he needs, yet each must receive the means necessary to carry out his task. It is not a question of relative importance of the tasks. They are all essential and all must be carried out. I believe a case like this illustrates fairly well what the General Staff officer in charge of transportation is there for. It is not a case of interfering or deciding between two men who both ask for the same transportation. It is a case of G-1 furnishing, if he possibly can, such help as will let both or all of them carry out their missions.

It is fortunate that even in an emergency like the case under consideration, the crises of the various activities occur at different times and can, to some extent, be foreseen and the curve plotted in advance. For instance, in this case the crisis of the division engineer unquestionably comes first in point of time. He should have immediately all available transportation to enable him to get his road through promptly. Incidentally, the division engineer should be given the exclusive control of the road for a certain number of hours. After the staff has arranged to help the division engineer with his mission, then they may arrange to help the others in the proper order, according to circumstances, as to the quartermaster and ordnance officers getting supplies forward and the division surgeon getting his wounded back. It would be poor staff work to allow the division quartermaster to keep supply trucks loaded ready to rush forward. The daily radius of action of a truck is such that he can get his supplies forward much more promptly by unloading the supply train and letting the division engineer use these trucks for road material. The trucks can come back and be reloaded and still reach the troops more promptly than if they had remained loaded readv to start.

Thus G-1 does not really "interfere" with anybody, but does help all by so using his limited transportation that each officer is furnished sufficient means to perform his allotted task.

Now let us consider a case where it is impossible to assign sufficient means to carry out an order: If the division engineer is given a task that requires more transportation than that normally allotted to him, he must also be given the necessary extra transportation by the authority assigning the task—that is, the division commander. In the example cited by Major Young, both the division quartermaster and the division engineer evidently need the use of certain transportation to carry out orders given them. It is not enough for G-1 to decide who shall have it by thinking in terms of transportation, and deciding who has the greater need of the limited amount available. Suppose both need this transportation at the same time, and it has been decided that the division quartermaster's work should be given priority over that assigned the division engineer, and G-1 assigns the transportation to the division quartermaster. The matter is not settled yet. G-1 must see that the mission assigned the division engineer is changed to correspond to the reduced means given him to accomplish it. The mission and the means are inseparably bound together.

For instance, the division engineer is ordered to build within a certain time two bridges, which are to be used simultaneously by two columns of troops, and he states that he needs a certain amount of transportation to do it, which is more than he has. If G-1 finds that he can only furnish enough to make up half the amount of transportation needed, he must see that the orders issued the division engineer are changed so as to allow him to double the time or else

Digitized by Google

require only one bridge to be built within the time limit. Of course, if the division engineer habitually makes wrong estimates and insists on more transportation than he needs, that is a different matter. The remedy in that case is to get a new division engineer. If G-1 takes the stand that the division engineer can perform his mission with less transportation than the division engineer claims is the minimum needed, then the division engineer is no longer responsible for results. G-1 has assumed responsibility for the results of the mission given the division engineer. In fact, G-1 has done even more harm. He has taken the prerogative of making a tactical decision, affecting the division as a whole, away from the division commander and given it to the division engineer. If there is not time to go over G-1's head to the Chief of Staff or the division commander, the division engineer now has to decide what he had best do with the means available, whether to carry material to both bridge sites, and thus take double the time allowed, or to construct first the bridge that he (the division engineer) considers the more important and then start on the other. The decision must be made by someone. If the division commander doesn't do it, the division engineer must.

The General Staff officers are present for the main purpose of keeping things closely tied in with the tactical situation. G-1 must keep the Chief of Staff, and through him the Commanding General, informed as to the transportation situation, so that orders will not be issued requiring transportation not available. If it develops later that enough extra transportation can not be allotted to enable an assigned mission to be carried out, then the staff must see that the mission is changed to correspond to the means available. Otherwise, the power of making the decision passes from the officer giving the order to the one receiving it. If poor staff work allows a subordinate commander to receive conflicting orders or a mission without sufficient means to carry it out, then if time does not allow the matter to be taken up with the Commanding General, the decision must be made by the subordinate commander as to which order he will obey or what part of his mission he will not carry out, due to the lack of means. It is up to the division staff to preserve to the division commander his right to make decisions on matters affecting the division as a whole.

Major Lee, from the viewpoint of his different experiences, has come to an opposite conclusion from that of Major Young. In objecting to the functional organization of the General Staff, he says, "It is not known why Leavenworth should indoctrinate the American Army with such an impracticable framework when the simple principles of organization can be applied to the staff as well as the line." Is it true that one good system of organization will fit all cases? Because the system in force in the line works well there, does it necessarily follow that it ought also to work if applied to the staff?

Both Major Lee and Major Young appear to agree that the basic principles of General Staff organization apply to any unit having a General Staff. However, since their experience with the General Staff in different sized units has led them to different general conclusions, let us consider some of the basic principles that should apply to the General Staff regardless of the size of the unit.

Major Lee gives a list of seven "first principles of organization," and by applying them to the problem finally arrives at the conclusion that the organization of the General Staff should be along the same lines as that on which the line of the Army is organized. Let us prefix to his list of first principles one that appears to have priority over all that he mentions, viz, that the first determining factor to be considered in organizing is the object for which the organization is to be formed.

There is more than one way of subdividing almost anything, and the method of subdivision used depends on the use to which the subdivisions are to be put. For instance, water may be subdivided on at least two dissimilar bases. The city water company considers it as composed of units of the same kind as the whole, such as gallons, cubic feet, or other units of water, while the chemist considers it as composed of hydrogen and oxygen, which enter into the composition of each and all of the units. Organization of men consists of a subdivision into units so as to facilitate the handling of the whole by one man at the head; this subdivision also may be effected in more than one way, depending on the use to which the subdivisions are to be put. Before organizing we must first decide on what the subdivisions are to do. It is a little hard to generalize, but possibly it may be expressed in this way: Are the duties of the heads of the various subdivisions primarily *downward* or *upward*.

Organization for Control Downward or Assistance Upward

Downward. In this case we are organizing so that the commanding officer of any unit can be given an integral part of the mission of the next higher unit. He is given an integral part of the means available with which to accomplish his mission, and is held responsible for results. His duties are *downward*. That is, he so uses the means placed under him as to accomplish the results required. In organizing with this object of successively subdividing and distributing the missions and means of the whole *downward* we have found, by experience, that the type of organization used with line troops is the best.

Upward. If our object is to organize a force to furnish technical information, advice and assistance *upward,* that is to the chief in command, we necessarily organize by subdivisions according to nature of information and advice.

Both of the above types of organization are correct, but neither is correct for all cases. The one that is here described as "downward" is the one best adapted for the line of the Army, while the one here characterized as "upward" is found in organizations of most staffs, military and civil.

To which of these two subdivisions does the General Staff belong? As shown in the first part of this discussion, the mission of the General Staff is universally regarded as being that of furnishing technical information, advice, and assistance to the commanding general and preparing the orders necessary to give effect to his decisions—that is to say, its duties are primarily *upward.*

It may be objected, as Major Lee says, that the General Staff gives orders and exercises control *downward* and that, therefore, its organization should be like that of the line. However, why does it give orders? Is that its basic function? It is not. Take the War Department General Staff for example. It not only furnishes technical information and advice *upward,* but exercises control and command *downward.* However, the control and command exercised downward are but corrolaries to its principal reason for existence—its work upward. It amounts to just this: The Secretary of War has a great number of matters of diverse character presented for his decision. No one man, no matter how capable, can possibly give each of these matters the amount of study necessary for a proper decision. Consequently, he needs a body of assistants organized according to subject matter to prepare studies on which he may base his decision without having to dig out the facts himself. A

Digitized by Google

matter is ordinarily referred to that section of the General Staff handling subjects of the same character. The Secretary of War ordinarily does not make a decision on any subject until an expert has clearly laid out the possible decisions that may be made and effect of each decision not only on the matter in hand, but on any matter it may affect.

Many minor matters that are of too little importance to take up the time of the Secretary of War must be decided on from the viewpoint of the Army as a whole. These are handled in the name of the Secretary of War by those to whom he specifically delegates the power to give orders in his name (Chief of Staff and the Assistant Chiefs of Staff). What this amounts to is that within certain specified limits the Secretary of War approves in advance the recommendation of his adviser, who is an expert in the particular question at issue, who knows his policies, and who also knows his intentions with regard to the Army as a whole. Thus the fact that the General Staff does also give orders downward does not call for any different organization than that necessary to it for information and advice upward. The functional organization of the General Staff, therefore, appears to be suited to its duties both up and down, since its duties downward are of a secondary incidental nature and based directly on the confidence the Secretary of War has in the sound judgment of its advice upward.

Mr. Elihu Root, with his customary clarity of thought and expression, said of the General Staff: "It is not an executive body; it is not an administrative body; it acts only through the authority of others. It makes intelligent command possible by procuring and arranging information and working out plans in detail, and it makes intelligent and effective execution of commands possible by keeping all the separate agents advised of the parts they are to play in the general scheme."

The commanding general of a division, having decided on a course of action and discussed the main points with his Chief of Staff, may authorize the latter to give orders for the minor details necessary to carry his decision into effect. Just how far the Chief of Staff can go in making arrangements without presenting the case to the commanding general depends on the individual commanding general and his opinion of the capabilities of his Chief of Staff. The General Staff officers are not charged with any specific integral part of the tactical mission of the division. They are assistants to the commanding general in discharging duties that are his. If he allows his Chief of Staff to issue orders and make decisions in his name, it signifies merely that many minor points come up that must be decided from the viewpoint of the division as a whole; that the commanding general has no time to consider personally each one of these minor points, so he decides in advance that he will take the advice of his advisor, who is an expert on all such matters and who also knows his intentions with regard to the division as a whole. Therefore, the Chief of Staff gives not his own decision, but the decision of the commanding general. The Commanding General may not be personally consulted, but the Chief of Staff knows in advance what his decision should and will be. If he doesn't know, he had better take the question up with the general, or else the general will soon be asking for a new Chief of Staff.

The point I wish to bring out is that the Chief of Staff is *not* in the chain of command; that while he gives decisions and orders without consulting the commanding general in every case, these decisions and orders are always such as he believes the general himself would issue were the matter before him. These orders are with the consent of the commanding general, and only go as far as he allows. This point is important: Orders given by a General Staff officer are given only with the consent of the general commanding, either express or implied.

Organization and Assignment

After we have determined the form of organization best suited to attain our object, we next consider how we can best use the personnel available to effect this organization.

Having first drawn up our organization chart, we *then* write names of persons selected to fill the various positions.

Gen. Fox Conner points out that our staff organization should have the same subdivision of duties throughout all organizations from G. H. Q. down to the smallest unit large enough to have a staff. However, we note as we get down to the smaller units that a function which in large units may require all the time of one man plus a number of assistants, may in the small unit not have sufficient work connected with it to occupy all the time of one man really big enough to handle the job. This problem is usually solved by assigning a man of sufficient ability to do the work and utilizing his surplus time by assigning to him other duties as well. In other words, his name is written in several places on the organization chart. The point that so many persons miss is that organization and assignment are not the same thing. In some of our small Army Posts one man frequently was Post Adjutant, Post Ordnance Officer, and Post Signal Officer. No one would contend such an assignment to mean that those three branches were grouped together in one organization.

The main purpose of a study of organization is too often considered as determining the limiting lines separating the work of one man from that of another. This conception is apt to lead to a system of water-tight compartments and poor team-work. I mention it here, as the point should be stressed that it isn't a place where their work *divides*, but where it *meets*. The New York Stock Exchange is not the dividing place between buyers and sellers. On the contrary, it is the place where buyers and sellers *meet*.

Technical Staff Advisors

The commanding general of a division who has the responsibility of deciding on some project or enterprise may need engineering advice. For instance, suppose that an important part of his scheme depends on being able to get a bridge built near a certain point in a certain length of time. He very properly calls into consultation the chief engineer of the division and asks him if it can be done. The general has to make the decision, and he wants his expert advice first hand. Assume that the chief engineer says it can be done and that the general decides that he will adopt the operations plan he was considering. He informs the Chief of Staff of his decision, and the latter promulgates the same in suitable orders. He includes therein the task assigned to the divisional engineers. He allots to the latter such necessary transportation, material, and other means as may not previously have been under the control of the regimental commander. The Chief of Staff should, however, bear in mind that the orders to the chief engineer should be merely those that indicate where the work of the engineers fits into the general plan of operations decided on by the general. The chief engineer, by virtue of his close touch with the commanding general, knows the latter's aims and desires; he knows what is needed; knows the resources at his command, what can be done, and when and how. The Chief of Staff should indicate the task of engineers in rather broad, general terms and should not give de-

Digitized by Google

tailed instructions to the chief engineer on matters which are clearly within the sphere of the latter as an engineer.

Under this mode of procedure the officer commanding the engineer regiment functions in a dual capacity—that is to say, he has his name written in two places on the organization chart. In his capacity as division engineer he is the technical advisor of the commanding general on engineering matters; he also commands the engineer regiment, which is the unit that executes the engineer projects.

While with the 30th Division I had a good opportunity to observe Col. H. B. Ferguson, Corps of Engineers, who commanded the divisional engineer regiment. From him I learned a great deal on organization and how the engineers fitted into the scheme. In important matters involving engineering advice, the commanding general consulted him personally. The decision having been made by the commanding general, the regimental commander took orders from the Chief of Staff as to his part in carrying out the project.

It is admitted that the various G's have often meddled in details pertaining to the various units of a division to such an extent that they really commanded those units in fact, even though they did use the phrase "by command of." It is suggested that one remedy for this situation is to have only such a number of staff officers as are actually needed to perform their proper functions. They will then have no time to try and do someone else's job for him. A staff officer who is not actually needed for proper staff work is a positive detriment to the command. It is not only wasting a man who should be used elsewhere, but he is apt to create work for himself by meddling in someone else's work.

Functional Organization of Division Staff

Major Young's article makes it quite plain that the organization of the General Staff at G. H. Q., A. E. F., must necessarily have been along functional lines. Without going over the ground already covered so well by him, it may be stated that his contention that the General Staff should be organized on functional lines may be extended up to the War Department. The experience of the War Department since the General Staff was organized in 1903, to date, leaves no reasonable doubt that the organization of the War Department General Staff should be along functional lines rather than along the lines of organization advocated by Major Lee for the General Staff.

When it comes to extending Major Young's thesis down to include the division, I have to admit that my experience with a division has been quite limited compared to that of Major Lee. Aside from the difference in the size of the units, what is the real fundamental difference between the work of the various general staffs as we progress from the War Department down through G. H. Q. to the division? Is it not the time factor? The General Staff is primarily a planning body. Its duties of seeing that all the separate agents work together as a team and of seeing that every agent is provided with the necessary means for carrying out his mission are performed in its plans. However, we note that as we proceed downward from the War Department, each successive General Staff plans for an event less far in the future, until we sometimes find the General Staff with a division furnishing plans of action for an event only a few minutes in the future. I offer the following suggestions as a substitute for Major Young's explanation of why the theory of functional staff organization, as set forth by him, for General Headquarters did not agree with what Major Lee said about experience indicating organizational control being best for the General Staff with a division.

Major Young says in part: "I think the conclusion to be drawn is that strictly functional division of staff duty is proper at the upper end, with the supreme command of a very large force; and that as one proceeds downward through armies, corps, and divisions, its outlines become more and more blurred, until in the division an arrangement is found in effect very similar to that outlined by Major Lee, implying a combination of organizational and functional control, with the former predominating."

Much of the seeming blurring of the fundamental principles of functional organization disappears if it is recognized that the General Staff is to assist the general in his own peculiar functions of command and that there is a difference between organization and assignment. As we progress downward from the War Department to the division the successive commanders have less and less far-reaching plans and decisions to make, but their plans and decisions have to be made more quickly and the orders necessary to carry them into effect have to go into greater detail. Consequently, these successive general officers use their General Staff less and less for comprehensive studies and more and more for working out and issuing the detailed orders necessary to carry the plans and decisions of the commanding general into effect. This progressively increases the proportion of the order giving duties of the General Staff downward and decreases the volume of its advisory duties upward. However, we must not lose sight of the fact that the unit commander only allows these orders in his name because he has confidence in the staff officer as an expert in his particular specialty. Therefore, it seems that the General Staff should still be organized according to special subjects or functions. G-1 handles the details of his specialty for the whole division (but only in so far as they affect the division as a whole). His duties are more intimately connected with certain units of the division than others, but this is no reason for G-1 actually commanding those units. This would tend to incline him to meddle in details that do not concern the division as a whole, and it loses sight of why there is a G-1.

As Major Young says, "Where personal contact and personal understanding weaken, there must be an increase in system and theories of organization." In small organizations, personal contact and understanding can be used to such an extent that system and theories of organization are not needed to the same degree as in larger units. Also, organization and assignment become more or less confused, and a few capable men in the key positions will enable the commanding general to handle his unit. All this makes it difficult to formulate theories as to General Staff organization of general application, based on what worked in some one division. Possibly this is why the theory of General Staff organization based on experience with higher units will work in the division, but the theories deduced by Major Lee from what worked in a division would not be applicable to G. H. Q. or the War Department.

Basic Principles Apply to All Units

The same basic principles of General Staff organization should hold for units of all sizes. The functional organization of the General Staff has worked, does work, and will work for any unit from the War Department down to the smallest unit large enough to have a General Staff. The same can not be said of the theory of General Staff organization advanced by Major Lee.

Major Lee states that the system advocated by him has actually been tried with success. Not infrequently have capable men obtained good results in spite of, and not because of, the form of organization employed.

Popularizing R. O. T. C. Instruction

By

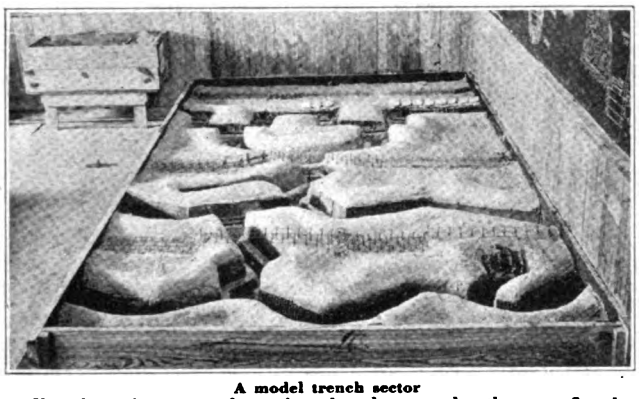
Lucius D. Clay

Captain, Corps of Engineers
Assistant Professor, Military Science and Tactics
Alabama Polytechnic Institute

[*Note.* We cannot too often remind our readers that the R. O. T. C. is the source from which our government expects to draw the trained officers to lead its forces in the next war emergency. Next to the regular army, perhaps, the R. O. T. C. is the most important element in our present military policy. It is a workable and working scheme for providing a reserve of trained officers.

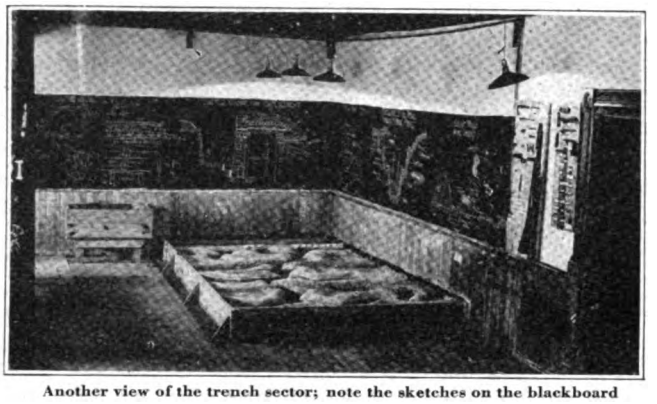
It is an important duty of the Society of American Military Engineers to support and encourage the R. O. T. C. in every possible way. And as a first step towards this it is necessary that we understand what the R. O. T. C. is, what it aims to achieve, and how it is going about its task. The best picture of the R. O. T. C. which we can present is shown in the accounts of the enthusiastic young officers, like Capt. Clay, who are giving the best that is in them to make a success of this important work.—ED.]

THE R. O. T. C. has been developed to a point where it is a vital link in the nation's chain of preparedness. To increase its value and its scope, the question for the future is how to popularize it with both students and faculty, how to emphasize its value as a part of the college curriculum. The answer to these questions lies in the methods of instruction given to the students. This instruction can no longer be the deadly routine of close order drill and physical training. It must be instruction of a broad and comprehensive nature presented always with enthusiasm and with an appeal to the interest of the students. It must carry to the student the fundamentals of all phases of military training, teaching him in the class room how to apply theoretical principles to actual conditions. It must be tangible, something that can be seen by the faculty and by the parents of the students, and at the same time, it must be instruction that is essential to prepare these youths for their place in the event of a national military crisis.



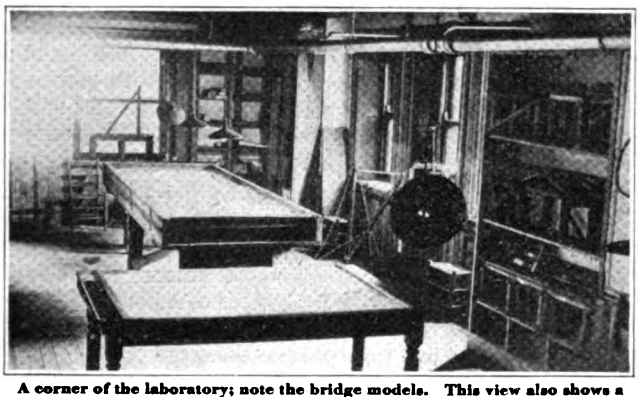
Bearing in mind this idea of training the members of the R. O. T. C. to the highest degree and, at the same time, so popularizing the work that both student and faculty will consider the military work an important and interesting part of the curriculum, the Department of Military Science and Tactics at the Alabama Polytechnic Institute has adapted several schemes of instruction. These schemes have achieved satisfactory results in that the R. O. T. C. has developed until it has an accepted place as one of the principal courses given at the institution and as one having the interest and support of both students and faculty.

The schedule requirements of the R. O. T. C. are based on a four-year course covering a total of 576 hours, and are designed to give a well-rounded knowledge of military fundamentals with special instruction in the duties of each branch of the service. To accomplish this result, work must necessarily be divided into two parts; theoretical and practical instruction. During the scholastic year, theoretical instruction predominates; it seeks to give to the student the basic knowledge which he will be able to apply to practical conditions during the summer encampment. The first requirement is to develop "esprit de corps" both for the individual unit and for the branch of service it represents. To develop this spirit, it is essential to have a period, or periods at which the entire unit can be consolidated for drill purposes. This period gives the advanced student the opportunity to prove his ability as a leader and also serves to furnish occasions for ceremonies and drills calculated to arouse the interest of the faculty and alumni of the college. It gives the opportunity for the student to apply in practice his theoretical training. Finally, it brings out the competitive spirit; everyone is working for the final goal, which is a competitive drill between all the branches of the service represented at this institution. This furnishes the incentive to work by arousing the desire to win, that spirit so essential to the salvation of any organization.



However, it is in the class room that the success and efficiency of a unit are determined. This work for the most part is theoretical and is conducted from text-books, by recitations, conferences, lectures and problems. Tactics, fortifications, mapping, map reading, bridges and range firing are examples that illustrate the variety of subjects treated. At this institution, the class room work is divided into two phases—the class room proper and the laboratory. The R. O. T. C. laboratory furnishes almost unlimited possibilities for the development of interest and enthusiasm on the part of the student. At a very low cost the instructors here have developed a laboratory useful in many courses and of such universal interest that faculty and alumni are continually bringing their friends in to examine it. The college furnished a well ventilated room, 20 by 40 feet in size. The lighting and equipment was left to the ingenuity of the instructors. The equipment now consists of chairs, blackboards, shelves, tables, desk, book cabinet, and water hydrant. As one enters the door he is confronted with a disassembled Springfield rifle, caliber .30, and a Colt automatic pistol, mounted on the wall with each part labeled. Lights are arranged to make each part plainly visible at all times to the interested students. Shelves and window sills are utilized to hold models of trestle and spar bridges, gin poles, pile drivers, revetting material, and wire entanglements. A military library containing the private library of the instructors is kept in a book cabinet in one corner, while in other corners are found machine guns, automatic rifle, Stokes mortar, and the 37-mm. gun, all so displayed as to catch the attention of the student as he enters the room, and so placed that they may be surrounded and inspected at any time. Walls are covered with blue-prints of a military nature and with pictures of R. O. T. C. activities. Blackboard spaces are reserved for lecture use or covered with sketches of various types of trenches and emplacements. Two 8-foot by 6-foot tables are equipped as terrain sand tables; another is covered by a large 12-inch war-game map; and a fourth contains the B. H. relief map. A large fortification model is built on the floor in a sand-box 14 feet by 7 feet. This box is built to represent a trench sector, and is equipped with many types of revetments, obstacles, latrines, and emplacements. These sand sets are used for such purposes as tactics, map

Digitized by Google



reading, engineer reconnaissance, sketching, fortifications, etc. They are equipped with realistic bridges, houses, rivers, and fields constructed by the non-commissioned personnel here. These tables represent a very small expenditure of money, but a large expenditure of time. However, their use has been well worth the time, as they are of continual interest to the students. In presenting subjects in the laboratory, competition is considered the first essential to success, and the instruction is given accordingly.

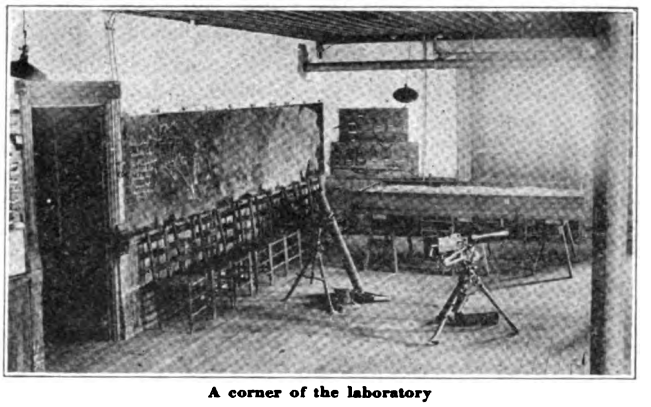
Another view of the trench sector; note the sketches on the blackboard



A corner of the laboratory; note the bridge models. This view also shows a terrain table and war-game map

Terrain sand table

The B. H. relief map

A corner of the laboratory

Tactics, for example, is a subject taught almost entirely on the war-game map and sand tables. For studying the conduct of patrols, the students are divided into two groups, representing patrols sent out by opposing bodies of troops. These patrols are sent out to work in the same area. Only one patrol is allowed in the room at a time. While this patrol is determining its movements on the sand table, the hostile patrol position is concealed until it is located by the patrol present. From the patrol problem, the tactical work is carried on to the actual engagement, where the winning side is finally developed. Throughout the entire course, competition is forcing the students to keep up their interest, to make every attempt to be on the winning side at the end. The two groups soon begin to argue the questions involved, then they become aroused and determined to win. The tactics course is now real to them. The other models are used for lectures and demonstrations. The laboratory is also used for map reproduction and photography. This same spirit of competition is carried into all branches of the work.

Inter-company athletic competitions are arranged to arouse enthusiasm for the individual organization and to keep the name R. O. T. C. continually before the students. Gallery teams are developed, and matches are fired with other colleges having R. O. T. C. units. In short, whenever

Digitized by Google

possible, the spirit of competition, that invincible asset of American youth, is fostered and encouraged and adapted to promoting the efficiency of the R. O. T. C. Now, the most difficult proposition of all is to make the classroom instruction proper prove interesting to the students. To do this several schemes have been tried with satisfactory results. The first method is the problem method. In this method, the assignment for the day is developed in the form of a problem which is given the class to solve collectively. Let this problem be one for the engineer unit—say a problem in road building. The instructor designates a student to take charge as the senior officer, the chief engineer. The class then conducts the problem. The chief assigns various phases of the work, such as map reconnaissance, traffic data, etc., to various members of the class. These men turn the report in to the chief, who consolidates it and gives it to the instructor as the class solution. The instructor is always on hand giving advice and assistance when called on. Or, for another example, suppose the problem to be in organization of the ground. The instructor gives the problem to the class and allows a few minutes for study. He then calls on a certain student A to state his analysis of the situation. The rest of the class is free to criticize and correct A's solution. At any point, the instructor stops A and calls on B to proceed with A's solution. This, of course, demands hard and long preparation for the class on the part of the instructor. At the same time, however, it is justified, as it demands concentration and real thought from the members of the class.

Another method of instruction is the collective blackboard method. In this method the instructor prepares a number of questions on the day's assignment. In the classroom he sends his class to the board. He gives out a question and allows a certain fixed time for answering it. He then gives a certain time for the student to correct this question, which he then follows with another question. The advantages of this system are that it serves as a means of emphasizing the important parts of a lesson, it teaches the student how to pick out these points; it corrects mistaken ideas about these points and, finally, it teaches him the necessity for quick thinking. It is an excellent method for one instructor to use when handling a large class.

Moreover, the class room instruction is never allowed to become a monotony. The instructor cannot sit at his desk and successfully put across a piece of instruction. He has to carry it to the students. He has to break through the natural wall of inattention that surrounds the brain after a few hours of work in the average grind of college instruction. To do this, he must keep in motion, focusing the attention of the students. He must illustrate his instruction with sketches so that brain cells fatigued by sound waves may be rested while an impression is received through the eyes. And he must relieve restlessness when any member of his class shows signs of such a condition by sending that member to the board to illustrate a point or by some other similar device. In other words, the student is in the class room and at disposal of the instructor. He is willing to learn, he wants to be interested. His brain is absorbed in concentration on various college courses. It is up to each instructor to penetrate that veil of lethargy and preoccupation and carry the instruction to him with an enthusiasm and an energy that will arouse his interest and make his work and the instructor's work a real pleasure.

However, all repetition breeds monotony. Therefore repetition must be avoided. The military departments are fortunate in this respect, for class-room work can be broken by devoting a day now and then to dismantling and assembling the infantry accessory weapons—a job which is more play than work to the average college student. Lectures on interesting subjects, accompanied by slides or motion pictures, may be given. In other words, every opportunity must be grasped to provide something new, something different, for the students and they will soon respond with enthusiasm to the instructor's overtures.

Furthermore, the instructor must be willing and must show his willingness to answer all questions of the student. When he is unable to answer a question, he must say so with the resolution that he will look up the answer. In other words, he must not attempt to "run a bluff" for the average student soon detects the bluffer and diagnoses him accordingly.

This article has attempted to show how R. O. T. C. instruction may be popularized. It has not gone into the method of popularizing the R. O. T. C. by clubs, dances, sponsors, and other social activities. It is the belief of the instructors at this institution that the truly successful way to popularize the R. O. T. C. is to make the class-room work attractive; to convince the student that he is being given something of permanent value.

The Professor of Civil Engineering does not give dances to attract students to his classes; he does not organize clubs to attract students to his subject. Neither does the Professor of History do these things. Their work speaks for itself. And to make the military course hold its place, it too must be made to speak for itself. The social side should not be neglected, for it always carries a tremendous appeal to the average college student, but the real appeal for permanent success and a proper place in the college curriculum should be made on the basis that a course in the R. O. T. C. is more than a pleasure—it is a distinct profit. Finally, it should be impressed upon the student that the fulfillment of his patriotic duty, which is to increase his value to his government, carries with it an increase in his own efficiency, a greater ability to act and think with decision and promptitude. When this viewpoint is finally given the student, the faculty, the college administrative authorities, and the parents of the boys, then and then only the R. O. T. C. will be established on a permanent basis as a course of true value in the college concerned.

Map Making in Italy

The Geographical Institute at Florence is charged by the Italian government with making all official maps of the country. The institute is a part of the Ministry of War, and its director is usually a general officer of the staff. At present, the director is General Vachelli. The personnel of the institute is either civil or military. Most of the work, of a very technical nature, such as color printing, transforming maps, etc., is done by civilians of long experience. The Geographical Institute not only make maps for the war department, but also works for the government railroads, department of the interior, and, in fact, does all the official map making in the country. Italy is very proud of this institute, which, it is claimed, is one of the best in the world.

Other maps are made by Agostini, a civilian firm, and by the Touring Club of Italy. Agostini simply reproduces the Geographical Institute maps for sale to the public. The automobile club has some men in the field who report new roads, etc., to the club, in order to keep the club maps up-to-date.

Functional Organization of Engineers

By

F. B. Wilby

Major, Corps of Engineers

[*Note.* The following talk was delivered by Maj. Wilby before the New York Post of the Society of American Military Engineers, at their meeting on March 1, 1921.—Ed.]

THE subject of the meeting to-night is "Functional Organization of Engineers." I am not sure that I understand exactly what is meant by that subject. If it is intended to convey the idea that engineers are organized into water-tight compartments, in accordance with their different specialties and functions, each different kind of an engineer being supreme in his own sphere, I am afraid I will have difficulty in discussing the subject. But if, as I believe, it was intended to call for an outline of the probable future organization of the engineer service, showing how the many different kinds of engineers can be fitted into an organization for efficiently and smoothly carrying out their manifold duties in war, I believe I can give you an outline of the general principles of the organization project now being perfected in the office of the Chief of Engineers in accordance with policies recently adopted by the War Department.

In the first place, the theory of operation for the engineer service as a whole must be based on that primary principle of sound military organization—that the commander of any military unit or area in the theater of operations is in full control of that unit or area, and is alone responsible for military results therein. This fundamental principle of military organization is the outgrowth of years of experience in war, and however much it may interfere with our theories of the most efficient organization for performing any particular duty, it must be accepted as the basis of our organization.

The commander, while responsible for results, is not expected to give his personal attention to all of the details of administration of the unit or area under his control. He is given for this purpose a certain staff, each one of which is more or less of a specialist in his line, and serves as adviser and sometimes as executive for the commanding officer in his specialty. One member of this staff is the engineer. As the assistant to the commander for the execution of engineering work, the unit engineer must have the confidence of his commander, and in accordance with the measure of that confidence he will act as the agent of the commander in carrying out the engineering work required by the unit, or in the area concerned.

In the recent war we were called upon to organize rapidly a huge army, larger than any we had ever conceived of, and it was natural that in deciding on the preliminary organization of this army we should have called upon our allies for the results of their experience. Consequently, the first organization project for the A. E. F. was modeled in large part on the British and French organizaion, and as a result contained innumerable services, arms, and special troops peculiar to the long period of stabilized warfare which had been in existence on the western front for several years.

This initial organization for the engineers included many special troops and services; among others, we find a mining service, a water-supply service, a general construction service, an engineer supply service, a survey and printing service, a road service, a light railway service, a quarry service, electrical and mechanical troops, gas troops, sound and flash-ranging troops, searchlight troops, camouflage troops, not to mention inland waterway troops, stevedore troops, and innumerable different kinds of standard-gauge railway troops whose duties differed from those performed by troops of the light railway service only in the number of inches between the rails of the railroad they were supposed to construct, maintain, or operate.

As a result of these many different kinds of special troops and services, each under the impression that it could only be called on to do one thing, but firmly convinced that it knew more about that one thing than anyone else, there resulted a constant conflict of authority between these special services and the various military commanders and their unit engineers as to whether the special service was independent of the local authority or whether the local commander and his unit engineer were in full control. All of you who served in France have vivid recollections of some of these troubles. It is our hope that in the new organization of the Army we can settle beforehand the number of necessary special services and kinds of special troops in those services and define as nearly as possible the purpose of each and its relation to the various military commanders so as to avoid in the future some of the troubles we had during the past war.

As for the number of separate services or arms, for the present this has been decided by Congress in the re-organization of the Army under the National Defense Act as amended by the Act of June 4, 1920. This Act, unless changed, fixes the number of combatant arms as seven (7): Infantry, Cavalry, Field Artillery, Coast Artillery, Air Service, Corps of Engineers, and Signal Corps. In addition to these seven (7) combatant arms there are various other staff corps and departments, including the Quartermaster Corps, Medical Department, Ordnance Department, Chemical Warfare Service, and others of a purely administrative nature. By thus fixing the basic organization, certain separate services which grew up during the war have been definitely eliminated. Among them may be mentioned the Construction Service, the Transportation Service, and the Motor Transport Corps; all three of these are now, under the law, functions of the Quartermaster Corps.

It is interesting to note that under the law as now written the Corps of Engineers will have very few duties in war other than building fortifications, mapping, and possibly some mining and demolition work. The law does not lay down the duties of the Corps of Engineers, but it does prescribe the duties of the Quartermaster Corps, and in so doing, it assigns to them most of the duties per-

Digitized by Google

formed by the engineers in France. This section reads as follows:

"The Quartermaster General . . . shall be charged with . . . the direction of all work pertaining to construction, maintenance, and repair of buildings, structures, and utilities other than fortifications connected with the Army; . . . with the operation of utilities; . . . with the transportation of the Army by land and water, including the transportation of troops and supplies by mechanical or animal means; with the furnishing of means of transportation of all classes and kinds required by the Army; etc. . . ."

Under this authority the Quartermaster Corps would do all construction in war, as well as in peace; and in the theatre of operations, as well as in the zone of the interior. This, of course, was not the intention of the law, and the law will probably be changed in the near future.

The War Department has therefore been proceeding on the principle that the engineers will have certain well-defined duties in the theatre of operations, similar to those performed by them in France at the end of the recent war. The only exceptions are sound and flash-ranging, and the operation of searchlights, which have been transferred to the artillery. The duties thus assigned to the Corps of Engineers in the theatre of operations may be briefly stated as:

Construction,
Mining and Demolitions,
Operation of Utilities,
Mapping,
Engineer supply.

As laid down in more detail in a draft of Army Regulations recently approved by the War Department, but which has not yet been published, the Corps of Engineers is charged with the following duties within the theater of military operations:

"All work of construction, and the repair and maintenance of all structures, of every character, except telephone and telegraph systems and other signal communications for the use of troops.

"Military mining, demolitions and protective measures against enemy mines.

"The operation of railways, portable and fixed electric light and power systems, water supply systems, and all other utilities of general service, except such as are specifically assigned to other services.

"The execution of surveying and mapping, including the production and distribution of maps.

"The procurement, storage, and issue of all materials for construction work, for the organization of defense systems, and for all other operations assigned to the engineer service, including all plant, tools and appliances for such work."

In order to carry out these duties, the latest approved project for the re-organization of the Army, calls for certain kinds and numbers of engineer troops. These are specified in detail in Engineer Memorandum No. 1, dated December 10, 1920, of which I have a few copies here, as well as in an article on "The Organization of the Engineer Service for Military Operations" in a recent number of THE MILITARY ENGINEER, the number for January-February, 1921.* I will not go into the details of that organization here, other than to say that the troops proposed for the engineer service in time of war are divided ino two classes, general engineer troops, and special engineer troops; the first class being ready to perform all kinds of engineering work, and the latter being recruited and trained primarily for special work.

General engineer troops constitute about 85 per cent, and special engineer troops about 15 per cent, of all engineer troops assigned to the theatre of operations. Of the 15 per cent special troops, about 9 per cent are railway operating troops, and 4 per cent are bridge and water tank trains, leaving about 2 per cent for all other special troops.

The general engineer troops include: combat engineer regiments and mounted battalions, for assignment to infantry and cavalry divisions; engineer regiments (general service), and auxiliary engineer battalions.

The special engineer troops include: topographical, camouflage, railway, lumbering, and shop troops, and bridge and water tank trains.

Some of you may be of the opinion that important special troops have been omitted, while others may think that too many special troops have been included. Possibly some might agree with my friend, Colonel Graves, who is of the opinion that there should be only one kind of engineer organization, capable of performing all kinds of engineer work. Such a consummation would certainly be ideal, but I, for one, am not quite so optimistic as to the capabilities of such a standard organization.

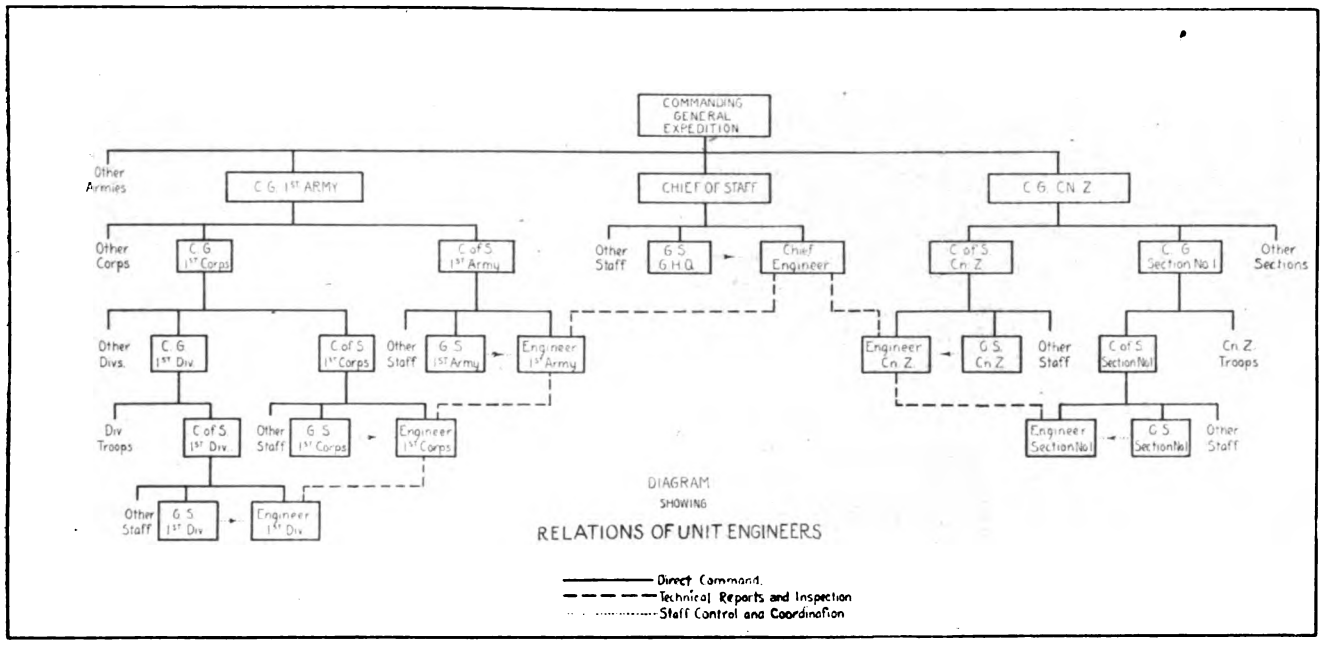
Now as to the *use* of the special engineer troops which have been authorized, as well as the various individual specialists which will be required for various purposes; if we will keep in mind the fundamental principle of military organization—namely, that the commander of each unit or area is responsible for all operations of that unit, or in that area, and that he is given an engineer as his assistant for the execution of all engineering work required by that unit or in that area, then it necessarily follows that this engineer should be given the troops and assistants needed to carry out that work. The troops, thus assigned, owe primary allegiance to the military command to which they are attached. No man can serve two masters. If every kind of special engineer organization belongs to a separate special service, reporting directly to G. H. Q. and not under the control of the local military commander, can we hold that commander responsible for military success, when that success may depend upon the work of some unit, operating in his territory, but over which he has no control? By this, I do not mean that there may not be advice and direct correspondence on technical matters of no vital interest to the commander concerned, but all *control* vests in the local commander where the responsibility necessarily lies.

There is one service which is an exception to this rule, that is the operation of railways. This service is of such a nature that it is impossible to permit local commanders to control the operatives within their respective territories without endangering the collapse of the entire service. The organization for the operation of railways will, therefore, be modeled as closely as possible after the method of operation in civil life. The Chief Engineer at G. H. Q. will act as Director of Railways for the theatre of operations. He will control and direct the operation and maintenance of all railways by means of a General Manager of Railways on his staff; a General Superintendent on the staff of each Army Engineer for handling the extension and initial operation of railways in the army area until turned over to the communications zone, and a Gen-

*Recent changes in this project have substituted an *engineer regiment (general service)* for each *corps and army regiment, construction regiment*, or *road regiment*; and *shop* troops in place of *depot* troops.

Digitized by Google

eral Superintendent on the staff of the Engineer Communications Zone, in charge of the operation of all other railways in the theatre of operations.



The Service of Military Railways cannot be entirely separated from the engineer service as it was in France, without causing an undesirable duplication of effort. If the military railway service were modeled exactly along civilian lines, all railway construction would be carried out by that service. However, the principal construction agencies of the army are organized for general construction work under the Corps of Engineers, and if a separate railway service were organized paralleling civilian practice, with its own construction organization, it would result in two construction forces in the theatre of operations, constantly competing with each other for men, material and supplies. The solution which is favored generally in the office of the Chief of Engineers, and I believe in the War Department, is to have the railway service in the theatre of operations under the Corps of Engineers, operating along civilian lines as a separate branch as far as possible, but with all large railway construction projects planned or proposed by the railway service, approved by the unit engineer, and carried out by the other construction agencies at the disposal of the engineers.

Having determined the number of separate services in the military establishment, the probable duties of the engineer service in war, and the number of different kinds of engineer troops to be organized for carrying out those duties, let us see how we can conveniently group our duties for most efficient supervision and control. The essential principle of unity of control vested in the local commander does not mean that his engineer will not have to organize the engineering work into certain more or less definite groups based on the character of the work to be performed.

The duties of engineers in war may be grouped as previously stated into five general classes:

Construction,
Mining and Demolitions,
Operation of Utilities,
Mapping,
Engineer supply.

Of these, "mining and demolitions" is almost entirely a function of combat engineers with infantry and cavalry divisions, and may be neglected so far as other units are concerned. The "operation of utilities" with the exception of the operation of railways, is usually so intimately connected with the installation, construction or repair of such utilities, that it can well be handled by the organization having charge of their construction. Our principal duties may then be regrouped for the purpose of supervision and control under four main heads:

1. A *Construction* Section in charge of all general construction, including the operation of utilities except railways.

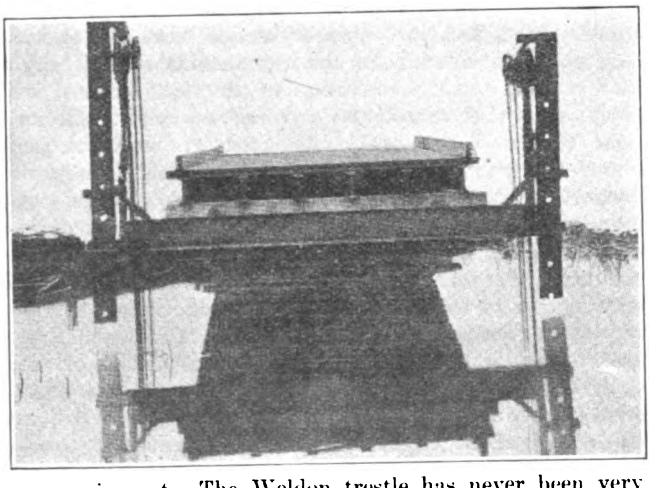
2. A *Railway* Section in charge of the operation of railways.

3. A *Mapping* Section in charge of production, reproduction, and distribution of maps.

4. A *Supply* Section in charge of engineer supply.

These four main divisions of engineer operations will appear throughout the engineer service from top to bottom, and form a basis for the organization of each engineer headquarters. In addition to the four sections just given, there will usually be required two additional sections for handling purely administrative work; a Personnel Section; and a Plans, Training, and Intelligence Section. With these six sections, it is believed the engineer service will be organized into as many separate groups as can be properly controlled and supervised by one man, the unit engineer. The Railway Section will only appear in those headquarters having control of railway operations, that is, in the headquarters of the Engineer Communications Zone, and in the headquarters of each army engineer. The Construction Section at most headquarters will be by far the largest section, and will include all general construction including railways, roads, quarries, bridges, buildings, water supply, electrical and mechanical installation, etc., as well as the operation of all utilities, except railways, and in addition certain minor related functions such as camouflage and geology. The Supply Section will include procurement by purchase, manufacture or requisition of all engineer material and supplies, including the production of lumber, as well as

Digitized by Google



the operation of cement, camouflage, or other factories. You will note that there is no separate Department of Light Railways and Roads, no separate Camouflage Service, or separate Forestry Service; each being only a branch of the larger division or function of Construction or Supply, as the case may be.

In conclusion I want to touch briefly on the relations of unit engineers to each other, and to other arms of the service. Nearly all of our problems originate with the combat division. It is the fighting unit—the unit upon which all depends. If the division fails to carry out its mission—the army fails. If the division succeeds—the army succeeds. Consequently, all engineers of higher units need only remember that 90 per cent of their job is done if they succeed in helping the unit engineer of the next lower unit to solve his problems. Everything that is done at home, in the communications zone, the army, or the corps, is done with the object of assuring the accomplishment of a tactical mission by some division, or group of divisions. The vital needs of the army develop at the front, and as a result, certain impulses which create engineer operations are transmitted all the way back. The impulse comes from the *front,* and in general the activities of the engineers of higher units are controlled by this impulse, and not the activities of lower units by the impulse from the rear.

Our relations with other arms can be covered by the one word—SERVICE. In other words, our only reason for existence is to help the infantry win the battle, or, by helping the other arms auxiliary to the infantry, to accomplish the same purpose. To do this we must have the confidence of the General Staff and of our respective commanding officers. This confidence can only be gained by producing results, and those results must be, not merely a monument to our skill as engineers, but the results desired by the General Staff, and by our commanding officers.

New trestle for British ponton equipage

As the British ponton equipment is now being re-designed to carry light, medium, and heavy loads, it is necessary to consider the question of a service trestle for use with this

new equipment. The Weldon trestle has never been very popular and does not lend itself very well for use with medium and heavy loads. A new trestle has therefore been designed and tested and is shown in the illustration.

The legs consist of 8-inch by 4-inch rolled steel joists (I-beams) and the transom is a 12-inch by 5-inch joist. The general dimensions of the trestle are the same as the Weldon trestle, but it will carry medium loads. The construction of the trestle is very simple. The transom has brackets permanently secured at each end; these brackets carry rollers through which the legs can slide. In this way the legs cannot splay or move out of line, but each leg can slide up or down independently so as to suit an uneven bottom (footing) if necessary. The legs are drilled every six inches, and after the transom has been adjusted for height, it is supported on pins passing through these holes. Two types of shoe are provided. The normal shoe is of timber and measures 10 inches by 18 inches; this shoe is suitable for rocky bottom or ground which will support a pressure of four tons per square foot. A second shoe is provided which measures 2 feet by 3 feet; this shoe can be bolted onto the normal shoe and provides a pressure of just under 1 ton per square foot. The trestle weighs 1,180 pounds, or 40 per cent more than the Weldon trestle, but will carry an 8-ton axle load. Two trestles built up side by side as a tower will carry heavy loads. The trestle can be put together and launched more rapidly than the Weldon trestle, and the legs can not jamb against the transom under any conditions. The transom is raised or lowered by means of two 2-ton Morris blocks. These blocks are a considerable improvement on the differential blocks for trestle work. The trestle has been tested with a 12-ton axle load. Further trials are to be carried out with this trestle.—*Royal Engrs. Journal.*

Petroleum production of the world, 1919-20

(*American Petroleum Inst.*)

The production of petroleum in 1920 has been estimated at 688,474,000 barrels against 514,504,000 barrels in 1919. The 1920 production represents a gain of approximately 173,970,000 barrels, or 33.7 per cent. The United States supplied 443,402,000 barrels, or 64.4 per cent of the total production in 1920, and Mexico supplied 159,800,000 barrels, or 23.2 per cent. The United States and Mexico made the greatest gains in production in 1920, the former having increased its production from 377,719,000 barrels in 1919 to 443,402,000 barrels in 1920, a gain of 65,683,000 barrels, or 17.4 per cent. The latter increased its production from 87,073,000 barrels to 159,800,000 barrels, a gain of 72,727,000 barrels, or 83.5 per cent.

The tabulation shows the estimated gain by countries:

	1919	1920	1920 in per cent of 1919
Mexico	87,073,000	159,800,000	184
Venezuela	321,000	500,000	156
United States	337,719,000	443,402,000	131
Roumania	6,518,000	7,406,300	114
Peru	2,561,000	2,790,000	109
Persia	6,290,000	6,604,700	105
Japan and Formosa	2,121,000	2,213,000	104
Dutch East Indies	15,780,000	16,000,000	101
India	8,453,000	8,500,000	101
Canada	220,000	220,000	100
Italy	38,000	38,000	100
Galacia	6,255,000	6,000,000	96
Argentina	1,504,000	1,366,900	91
Russia	34,284,000	30,000,000	88
Egypt	1,662,000	1,089,200	66
Trinidad	2,780,000	1,628,600	59
Germany	925,000	215,300	23
France	----------	700,000	----------
Total	514,504,000	688,474,000	134

Bituminous Pavement Design

By

F. S. Besson

Major, Corps of Engineers, U. S. A.
Assistant to the Engineer Commissioner, District of Columbia

(Copyright, 1921, by F. S. Besson)

THE question of Rigid Concrete Bases *versus* Flexible Ones for bituminous pavements has of late received wide attention. Two hypotheses advanced are as follows:

(*a*) A rigid smooth base is conducive to pushing and cracking of bituminous surfaces; inherently, because of the rigidity and smoothness of that base. Further, cracks develop in surfaces corresponding to whatever cracks may occur in the base.

(*b*) The measure of probable life of a pavement is load impact rather than dead load and a flexible base is accordingly a better one for a bituminous surface than a rigid base.

Having half a century of experience with bituminous pavements to its credit, the District of Columbia has adopted as its standard an asphalt surface on a 6-inch concrete base, the latter of 1:3:7 proportion using Potomac River ravel as the coarse aggregate. In view of the fact that this policy is contrary to any that might be derived from the hypotheses set forth in the preceding paragraph, it would appear that the time is ripe for a critical analysis of the paving situation in Washington in order that the relative correctness of its adopted policy may be definitely settled.

Fig. 1. This picture illustrates cracking into small lozenge-shaped patches. This type of crack appears only when a flexible base is used. It appears in bituminous surfaces even though the design of the mixture is perfect.

Trinidad, Cuban, Bermudez, Maracaibo, Montezuma, California, Aztec, and Standard asphalts have been used in paving the streets of Washington. Original surfaces on concrete bases exist in all ages up to 43 years. Traffic on the different streets varies from a negligible quantity to 1,160 tons per yard of width per day. Though a great number of "perfect" streets may be looked upon with justifiable pride, the District has its share of waved and cracked surfaces. Paralleling the history of streets with concrete bases and of even earlier origin in Washington is that of pavements with so-called flexible bases. Old granite block and cobble pavements, and macadam and gravel roads have been utilized; also bituminous bases constructed by the penetration method; and in other cases, stone premixed with bituminous cement. These latter have been laid with as great a thickness as 10 inches, underlain by 6 inches of gravel as a sub-base.

All these different asphalt paving conditions existent in the city and available for study present a most favorable situation for successful investigation: First, is the adoption of a rigid concrete base shown to be a sound policy? Then, if the use of concrete is warranted, and cracks, waves and short life are not due to the rigidity of the base, what does cause defective pavements? Further, what system of design can be followed in order to insure full value in future construction?

This last problem has a broad aspect. Not only should design preclude defects but it should also supply true economic value. Examples of all types of bituminous surfaces are available in Washington, varying in thickness from 1 to more than 3 inches. Aggregate combinations exhibiting every sieve analysis advocated in asphalt paving practice may be found. The surface adopted by the city as standard consists of a binder course 2 inches thick before compression and a topping 2½ inches prior to rolling. This is a high-priced surface. Binder stone is expensive, sand used in the topping costs 2½ times as much as concrete sand, and limestone dust mixed with the sand adds to the cost. Is this design truly economic?

It is difficult to determine the relative merits of flexible and rigid bases except through practical experience. Unsupported theory is of little use, and tests to be of value must duplicate actual conditions. Maintenance data taken in connection with service rendered affords a good basis for study, and several generations of the Highway Division of the District have thereby passed judgment in favor of concrete. Where a deep telford foundation exists or a thick richly cemented bituminous base underlain by sand and gravel, pavements compare favorably with those having concrete bases. This is because their rigidity approaches that of the latter. Such bases are not used in Washington to-day, however, because rigidity is obtained thereby only at a cost much above that for concrete.

A great many of the pavements in the city laid with a flexible base were so constructed because of price limitations written into appropriation acts by Congress. For instance, when the price per square yard was thus restricted to $2, the lowest bid received for sheet asphalt on concrete base was $2.25 per square yard. This led to the use of a bituminous base 4 inches thick, which with the 3-inch surface, gave a 7-inch pavement costing $2.00 per square yard

Digitized by Google

as compared to the standard 9-inch pavement which would have cost but 25 cents more. As to the degree of quality worked into the bituminous base pavement, its cost of $2 per square yard is a fairly good measure.

Typical of these pavements, and of all other flexible base ones in the city, is the eventual cracking of the asphalt surface into small lozenge-shaped pieces. This is illustrated in Fig. 1. The cracks are not due to sub-base failure, which is evidenced by the fact that their growth is not necessarily accompanied by the development of other defects. Instead, it is habitually found that the contour of the street surface remains true to grade. In the illustration it may be noticed that the cracks occur not only in the original pavement but also extend through repair patches of various ages and compositions. This deterioration is thus shown to be independent of the composition and type of asphalt surface. Further, it is not found where a rigid base exists.

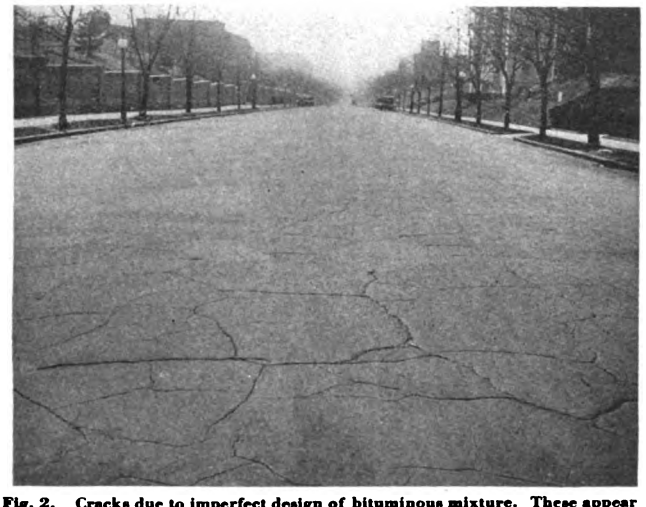

Fig. 2. Cracks due to imperfect design of bituminous mixture. These appear irrespective of the type of underlying base

Significantly different from the cracking which has just been described is that illustrated in Fig. 2. This occurs, no matter what type of base is used and is entirely due to imperfections in the asphalt surface itself. When a new surface is laid, on the old base, the asphalt mixture being correctly designed, the cracks do not appear. That cracks in bituminous pavements are not caused by cracks in the concrete base may be verified by following the work of district patching gangs. In the working season, these men approximate 500 patches daily. By watching their work of stripping the asphalt from the base, it may readily be observed that cracks in the surface have absolutely no relation to cracks in the concrete base.

Inspection during the repair of pavements also shows conclusively that pushing or rolling or waving of the surface is independent of the base, whether it be concrete or other construction, corrugated or smooth. It has been claimed that the binder course is placed between the topping and base in order to prevent waves in the surface. A certain patent calls for 2 or 3 inch stone imbedded in the base and projecting half way into the surface asphalt in order to key it to the concrete and thus prevent waves. On some bridge work it is understood that 2 by 3 inch timbers have been alternated with 2 by 4 inch, in order to form a corrugated base upon which to lay an asphalt surface. At one time the District of Columbia used ribbed rollers and special tampers in order to form ridges in the concrete. This practice was abandoned years ago and to-day asphalt is placed even on the smooth hard surface of old concrete streets; also, on level plank bridge floors newly laid.

The illustration, Fig. 3, illustrating a section of sheet asphalt actually taken from a street, shows a wave clearly independent of the base and even of the binder course. Movement has taken place completely within the topping. The conclusion is drawn that, given a rigid concrete base, causes of defects in a bituminuous surface must be searched for within the latter itself. These surfaces are in reality either concretes or mortars made with bituminous cement. While somewhat analogous to hydraulic concrete, they are, however, vastly different. A sample may be cut from a street, the bitumen extracted and the mineral aggregate obtained in a free clear state.

In seeking reasons for the wide variations that occur, a large number of specimens have recently been taken from pavements, from good ones and poor ones, the latter either cracked or waved. With the aid of personnel of the Engineer Department of the District, especially Messrs. J. C. Elbert and Vernon Cleaver, these samples have been investigated. Naturally, most attention at first was given to the extracted bitumen since this item in construction specifications is usually so minutely described and restricted. While the quantity of bitumen soluble in carbon bisulphide and the specific gravity of this amount have been obtained with a high degree of accuracy, it has been impracticable to get dependable results on other investigations relative to this bitumen. A slight trace of solvent, while having a negligible affect upon weight and specific gravity determinations, has a destructive influence on the value of results obtained in other tests, as, for instance, the penetration determination. Just how erratic these results may be is shown in many cases where original records are available made at the time of laying the surface.

Original penetration records have been studied but they show no relation to the degree of excellence of the pavements examined. While it must be realized that different penetrations are required for each of various constructions, it appears that specifying the penetration within two or three points is unnecessary refinement, placing undue hardship on the manufacturers of bituminous materials. Grade divisions with ten point ranges should certainly suffice. Pat tests have also been made from specimens brought from the streets but without useful results. It is not desired to underrate the value of penetration and pat tests as now made use of while construction of a pavement is in progress. However, investigation made along those lines subsequent to the appearance of defects leads to no discovery of the causes thereof. Bituminous cements as

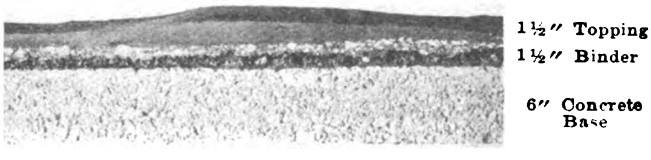

Fig. 3. Wave in the 1½-inch topping course of a sheet-asphalt pavement. This wave is clearly independent, not only of the concrete base, but also of the binder course.

Digitized by Google

marketed to-day are well stabilized products and by following recognized practice all difficulty as to quality may be precluded. Investigations of defective pavements for the purpose of aiding future work may therefore proceed along other lines.

One theory advanced for waved pavements is that they are due to the use of sand or mineral aggregates, the grains of which are round and smooth instead of angular and rough. No general relation can be discovered between the shape of the grains of aggregate and the nature of the service rendered by pavements. In fact, all sizes of aggregate retained in the 200 mesh up to and including 1 inch binder stone as taken from Washington streets, appear to be angular and rough. Examination shows that even beach sand used for polishing platinum evaporating dishes, though having no sharp cutting edges, may be very angular in shape, and it is difficult to know to what extent the term "round and smooth" would apply. While the grains of Standard Ottawa sand may be said to be round and smooth, find, dependent upon the bituminous cement and mineral aggregate, just what the voidage should be in order to guarantee perfect results. How much bitumen should be combined with any particular aggregate, it would seem, depends upon the association of various grains of sand and stone making up that aggregate as a whole. The combinations may vary in numerous ways; each used with its required amount of bitumen and resulting in a definite percentage of voids when compressed into a pavement. The problem can be solved if the association of sand and stone making up each particular aggregate can be measured.

A cubic foot block of stone may require a definite volume of bitumen to paint it. If the stone is broken into 1 inch cubes, the film thickness and other conditions remaining constant, 12 times this volume will be required in order to coat all surfaces now presented by the stone. This fact is the basis of "surface area of aggregate" theories which have always received a great deal of credence. Rela-

Per cent passing each sieve and retained on the next smaller.

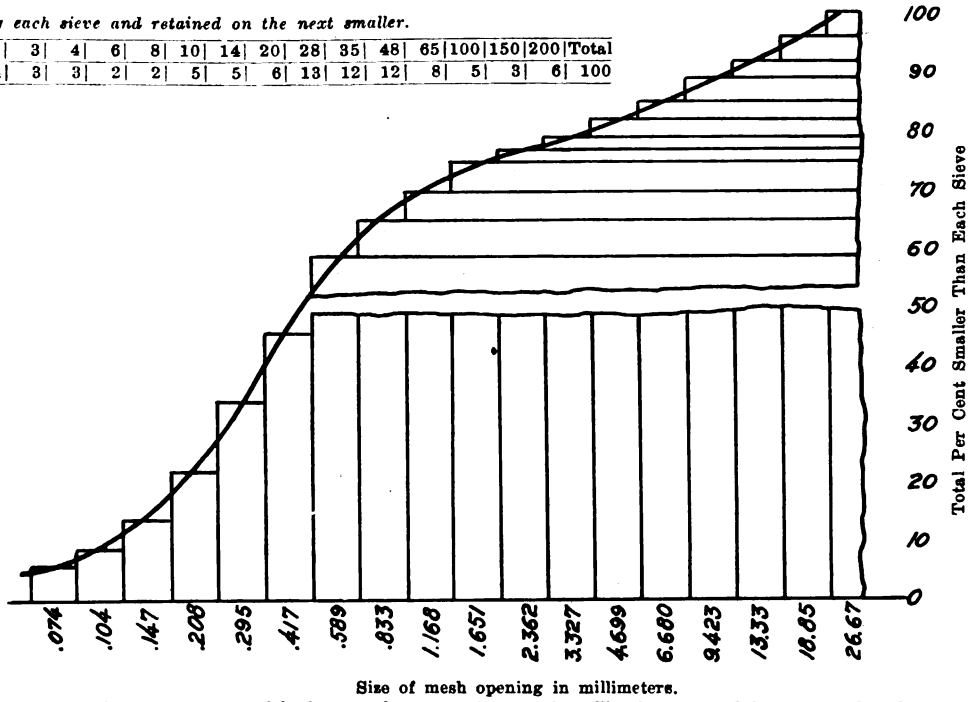

Fig. 4. The area beneath the curve may be obtained either by summation of the horizontal or vertical rectangles. The fineness modulus or sum of total percentages finer than each mesh is equivalent to weighting the percentage passing each mesh in accordance with arithmetical progression.

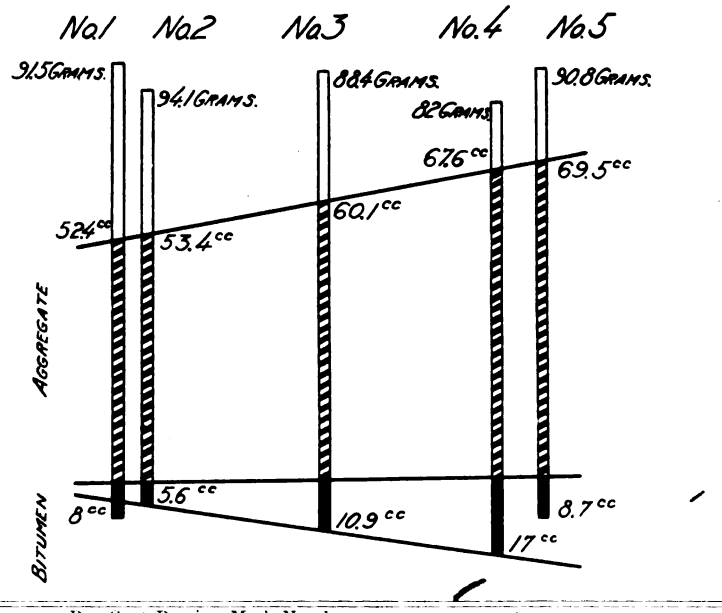
a like description can be applied to but few other sands and it seems that the shape of grains can hardly be the determining cause of a defect of such a wide general occurrence as waves in bituminous surfaces.

Much value has at times been attached to density measurements of samples taken from streets on the assumption that bitumen with mineral aggregate acts like water with sand. Too much gives mushy results or quicksand, just enough gives a smooth hard surface like a motor racing beach, and too little, a dry sand without sufficient substance to hold the grains together. To obtain a good mixture for paving it has been claimed that all voids in the compressed aggregate must be filled with bituminous cement. Tests do not establish this claim and it is found that voids exist in specimens taken from excellent streets. Even mixtures that contain too much bitumen and have waved under service conditions show a quite noticeable percentage of voids. Personally, notwithstanding this, it is felt that the question of voids does have an important bearing upon the problem. It is probably an impossible task to tive amounts of bitumen necessary to cover surface areas may be determined but having done so as with the 1 inch cubes, information is still lacking as to the quantity of bitumen necessary to add to the combination of pieces in order that they may be cemented together and compressed into a monolithic slab. If two-thirds of the cubic-foot block of stone were broken into 2-inch cubes and the remaining one-third into ½-inch cubes, it would have to be acknowledged that a different amount of bitumen would be required to cement them than the 1-inch cubes, though the surface areas would be equal.

The surface area theory is arbitrary when applied as a measure of the required bitumen content of paving mixtures. In computing surface areas, the grains of mineral aggregate are assumed to be either cubes, spheres or other shapes, in formulæ relative to which a mean diameter and certain constants enter. When a granulometric analysis has been made, the various mesh sizes are assumed to be the mean diameters. The number of grains in a net volume of matter passing through any one sieve depends

Digitized by Google

upon the volume of each grain, that is, the number varies inversely as the cube of the mesh diameter. The area of each grain varies as the square, and therefore, the total area of the volume through each sieve varies inversely as the diameter.



There are records of sands that give identical sieve analyses and, therefore, equal surface areas. Notwithstanding this, their dry loose void percentages vary from forty to fifty-five. Such a wide range of voidage shows clearly that mesh openings alone cannot be used as an indication of the particular combination of grains of mineral matter making up any specified aggregate for bituminous constructions. The inaccuracy of the surface area theory is further shown when an attempt is made to apply it to that portion of the aggregate passing the 200-sieve. This matter is habitually an impalpable powder and distinctly different than that retained on the 200, the granular component being clearly evident. In order to assign sizes to the particles passing the 200-sieve (some of which are often of a colloidal nature) the method of elutriation is used. Though the importance of dust in bituminous mixtures is acknowledged, the huge values as to bitumen requirements assigned by arbitrarily weighting the sizes inversely as their diameters, are manifestly out of all proportion.

Another representation said to compare combinations of mineral grains, sand, stone or gravel, is based on what is known variously as the mechanical analysis, cumulative plat, or fineness modulus method. In Fig. 4. using a logarithmic horizontal scale, the curve represents an aggregate with the per cent finer than each sieve platted against mesh diameters in millimeters. Using eighteen sieves, 5-5/9 per cent, passing the smallest, 11-1/9 the next and so on by equal increments to 100 per cent for the largest, gives a straight line or uniform gradation. The full value of the cumulative plat is to show the relative uniformity of aggregate siftings diagrammatically. It can not be used for the determination of bitumen requirements of aggregates.

In the fineness modulus method the cumulative plat is made use of by taking the sum of the ordinates of the curves. Its inapplicability is illustrated by the fact that there are numerous dissimilar aggregates well known as to their widely different bitumen requirements and yet having equal fineness moduli. Fig. 4 illustrates that the sum of the ordinates, or fineness modulus, can be considered as measured by the area beneath the curve. This area may also be obtained by a summation of the horizontal rectangles, thus showing that the fineness modulus method is an arbitrary one since the weight or value placed on the percentage of aggregate passing each sieve of a complete nest is made to progress arithmetically, from the largest mesh to the smallest.

Experience has shown that the amount of bitumen required is proportionate in many instances to the aggregate percentages through the 80, 100, and 200 sieves. It is this fact that has given the semblance of applicability to those systems just described which arbitrarily magnify the percentages through the smaller meshes.

In seeking a new theory it was noticed at a mixing plant that a certain weight of asphalt is used for each cubic foot of aggregate dumped into the mixer. In other words, the proportion of bitumen to aggregate, expressed in percentages by weight depends upon the weight of a cubic foot of dry loose aggregate, or what is the same thing, the volume of a unit weight. In carrying out investigations upon this basis volume measurements have been made by means of a graduated cylinder with a diameter of 62 millimeters and of sufficient capacity to hold 1,000 grams of dry loose aggregate. In order to reduce aggregate separation, specimens have been poured into the cylinder by quarters. With coarse materials, personal equation enters greatly but the method is open to refine-

Quality of Mixture	Sample Number	Per Cent Passing Mesh Number												Per Cent Aggregate	Per Cent Bitumen	Sp. Gravity Aggregate	Per Cent Voids
		1	¾	½	¼	10	20	30	40	50	80	100	200

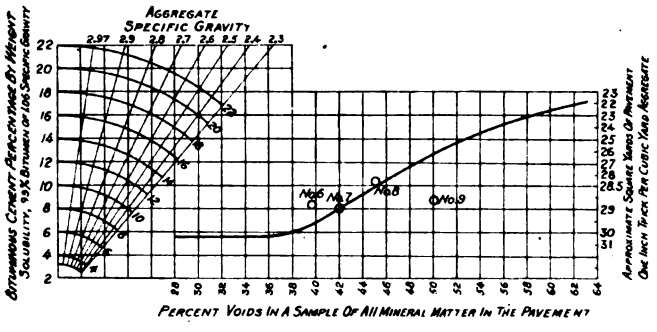
Fig. 5. Relation of aggregate weights to aggregate volumes and of bitumen volumes to aggregate volumes

Note.—Aggregate Volumes Measured Loose in a Cylinder of 6.2 c. Diameter.



Digitized by Google

ment so that such influence can be reduced to a minimum.

It has been found that, as with other theories, in many cases a relation exists as to the 80, 100 and 200 aggregate percentages. On the basis of 1,000 grams of pavement and an average of 10 per cent by weight of aggregate passing these three sieves, it is not unusual for the volume of the total aggregate to lie between 500 and 550 c. c. Similarly, if these sizes comprise 25 per cent, the total usually lies between 550 and 600 c. c., and if 35 per cent, between 600 and 650. In annual reports for the past forty years and in technical literature it is stated that dust is added to aggregates in order to lessen the voids. On the contrary the voidage is thereby often increased. Surface area, fineness modulus, per cent smaller than No. 80, all three lead to uncertainties. There are some paving mixtures whose volumes of unit weights of aggregate have no definite relation to the sand and dust smaller than the No. 80 sieve. It is in these cases that surface area and fineness modulus fail to be of service and the volume separate control and are not in reality related to the primary design of bituminous surfaces. There are but two essential elements, bitumen soluble in carbon bisulphide, and mineral aggregate. There may be traces of organic or other matter but such should be negligible. Having chosen an aggregate suitable as to quality, size, and gradation, for any particular purpose, the problem of design is to proportion the mineral matter and bitumen so as to best insure economic service.

From the results of a number of analyses, it has been possible to prepare as an aid to proper design, the diagram, Fig. 6, which has been drawn for asphalt cement, 99 per cent bitumen of 1.06 specific gravity. This permits its direct application with sufficient accuracy to a wide range of asphalts in common use. The diagram can readily be modified to answer for any asphalt.

Specimen No. 8 is an aliquot part of 150 daily samples from a contractor's plant during a working season and is, therefore, representative of present construction in Washington. No. 6 is an asphaltic concrete taken from a pavement laid in 1913, the service rendered by which has been most unfavorable as compared to sheet asphalt streets of the same age subjected to identical traffic. Such examples tend to the disparagement of certain types of pavement, whereas in this particular instance the diagram goes far in explaining the disparity. No. 9, though having not an unusual aggregate graduation, has a relatively low specific gravity and high percentage of voids. Insufficient bitumen has been used and the pavement is badly cracked. Pavement cracks are often attributed to lack of traffic, which, perhaps, may be true to a limited extent. However, in one such case where there has been no traffic for the past ten years, a specimen analysis shows up beneath the curve in Fig. 6, and the cracks are undoubtedly fully accounted for thereby.

Fig. 6. Bitumen requirements for pavements as controlled by voidage and specific gravity of mineral aggregate

method as controlled by void percentage and specific gravity of aggregate continues to be truly indicative of the bitumen required.

In Fig. 5, Nos. 2 and 3 represent specimens taken from excellent street surfaces in the city. No. 4 is platted from a mixture made up in accordance with a specification taken from a trade journal. The cross-hatched areas represent dry loose aggregate volumes which are dependent upon void percentage and specific gravity of aggregate. The solid black portions represent bitumen. Notwithstanding that the loose volume for No. 1 is less than for No. 2 the bitumen is markedly greater. Too much bitumen means a soft pavement and No. 1 actually exists as one of the waved streets of the city. Insufficient bitumen is manifestly the trouble with specimen No. 5 and the pavement which it represents is very much cracked.

Study of the aggregate siftings recorded in Fig. 5 does not afford any help in ascertaining reasons for the defects in No. 1 and No. 5. Both the Surface Area and Fineness Modulus methods place No. 1 midway of Nos. 2 and 3, and No. 5 between Numbers 1 and 3 in positions that would tend to show that their bitumen contents were exactly right. In like manner the sum of the 80, 100 and 200 siftings place the two inferior specimens between No. 2 and No. 3, permitting no inference as to the causes of their defects.

Caution is necessary when interpreting investigations of specimens cut from pavements. It has been found that in many streets constructed years ago the mixtures lack uniformity. Bitumen percentages vary; also the aggregate, as to quality, voidage, and screen analysis. In new construction these points can be properly taken care of and constancy insured by careful supervision and workmanship. Sometimes foreign influences, as for instance, illuminating gas, are very destructive. Such factors call for

In fact, well-constructed bituminous pavements are remarkably stable and free from abnormal deterioration, due either to traffic or the lack of it, and we are fortunate that this is so. Where there is no traffic to-day, there may be heavy traffic to-morrow. Almost a fourth of the total existing yardage of bituminous pavements in Washington was laid more than twenty-five years ago. Certainly at that time there was no conception of the traffic to which these pavements would be eventually subjected. It should be reiterated that "well constructed" is conceived to include a rigid base. One street carrying the heaviest traffic in the city has long been classed among our roughest and most waved surfaces. Notwithstanding the tremendous daily impact which the 6-inch base is thereby forced to sustain, the concrete in it is as good to-day as when newly laid twenty-seven years ago.

Specimen No. 7, Fig. 6, represents a remarkable pavement laid forty-two years ago. Maintenance expenditures

Digitized by Google

for it have always been noticeably low. For the past ten years they total $241.76 for its area of 1,282 square yards, or 1,88 cents per square yard per year. Present traffic amounts to 250 tons per day per yard of street width. Another exceptional point about the pavement is that it was laid without a binder-course between its concrete base and 2-inch surface. This specimen is placed between two great classes of bituminous surfaces; the one class including coarse-grain mixtures—topeka, concretes, etc., having bitumen requirements of less than 8 per cent by weight; the other class having bitumen requirements of more than 10 per cent by weight. The inclusion of this 9 per cent specimen completes the range and shows that the general worth of an aggregate is independent of its bitumen requirement. Whether or not any particular aggregate will meet specially imposed conditions can be determined only through experience. At one extreme are the coarse stone bituminous concretes, at the other, dust mixtures that can be pared with a sharp knife as if they were hard rubber; and each has its special application. Having decided upon the aggregate, its bitumen requirement can be closely approximated by means of the diagram. While the use of this diagram is fundamentally correct, it must of necessity be accompanied by practical tests of aggregates. In addition to void percentage and specific gravity there are petrographic and physical qualities of aggregates affecting results to a more or less extent. Moreover, since the data leading up to the preparation of the diagram have been brought together with little time available, by a highway construction rather than a research organization, they are undoubedly open to refinement in some respects.

Two thoughts are suggested by a consideration of the preceding facts. Can the extra cost of binder be safely eliminated? Can a natural aggregate be used instead of the expensive artificial ones of usual practice? A search through literature on the subject fails to reveal any good reason for the adoption of the binder course. That it may be successfully eliminated is substantiated by examples in Washington of various ages. The most recent instances, and directly comparable with sheet asphalt and binder practice of to-day, are several streets laid in 1911. For these, topping mixture alone was used, and to-day no surface conditions can be noted to differentiate them from streets constructed at the same time with the identical topping laid over a binder course.

In order to lessen the cost of topping mixtures, the obvious course to follow is to substitute natural sand for the usual artificial mixture. This natural sand in Washington has long been used for hydraulic concrete with good results. To be workable with bituminous cement, experience must show whether or not its dry, loose volume per unit weight is of sufficient constancy. This sand costs but 80 cents per cubic yard, as compared to $2.65 per cubic yard for the mixture of special sand and limestone dust now in use. Because of this and a reduction in the bitumen requirement a saving of from 10 to 15 cents per square yard would result. While a few experimental patches have been laid in accordance with this idea, the problem is one that can be settled only after further research. It should be of particular interest in those localities where, to-day, bituminous sheet surfaces are almost prohibited because of the high cost of those artificial aggregates habitually prescribed in current practice.

The question of the binder occupies a wholly different status, and it appears to me sufficient facts exist to warrant the elimination of this course. A three dollar and twenty cent pavement is made up of $1.62 for the 6-inch concrete base, $0.67 for the binder and $0.91 for the topping. With elimination of the binder it is believed that the opportunity should be grasped to increase the thickness of the concrete base, thereby increasing the stability of the construction; for, setting flexibility and rigidity arguments to one side, the word best describing the worth of a base is "Stability." Eight inches of concrete base at $2.16, with $0.91 for topping, gives a 9½-inch pavement, costing $3.07, as compared to $3.20, for the present 9-inch standard. The 1½-inch surface may not last as long as the 3-inch, but its replacement will cost a great deal less. It is the part of wisdom to put every possible cent into insuring for the base permanency throughout the uncertainties of the years to come.

Due to the stability of Washington's concrete-base pavements, it has thus far been unnecessary for the District authorities to put into effect any restrictions as to weights of motor vehicles and their loads. The heaviest trucks made use of in the District are 7½ tons, which, with their loads, give a gross weight of 30,000 pounds. They are equipped with 14-inch tires in rear, giving a load of 2 or 3 pounds more than 800 per inch width. Two generations, even one generation ago, in laying concrete bases no conception was had as to the loads to which they would be subjected to-day. The traffic of the future is to the present generation just as impossible of discernment; however, every practicable effort must be made to provide for it.

Highway construction must keep pace with national growth and progress. Washington has examples of all types of roads and streets. Cheap construction is warranted in some cases, but on main-travelled arteries it gives way to a more permanent type. It was a wise and economical policy which years ago adopted the concrete base as a standard. To date, this class of base has given every indication of being the one permanent part of a bituminous pavement, the outstanding feature of which is the economy with which repairs may be made and, further, the ease with which a worn-out surface may be stripped from the base and replaced with new.

Prize Map Problem

Solutions and Discussion

IN the January-February number of this journal we published a problem on the Duties of Divisional Engineers in an Advance. As prizes for the best solutions submitted we offered several subscriptions to THE MILITARY ENGINEER, paid up for a period of three years each. Much to our disappointment only six solutions were received. These were forwarded to a Board composed of three members of the faculty of The Engineer School, viz. Majs. R. C. Crawford, W. H. Holcombe and D. O. Elliott, all of the Corps of Engineers, U. S. Army. Needless to say, the names of competitors were not made known to the Board. The latter, after careful consideration, pronounced the best paper to be that submitted by Capt. Charles H. Roe, Engineer Reserve Corps (No. 68 Lake Avenue, Tarrytown, N. Y.), and the second best was that submitted by Capt. John E. Wood, Corps of Engineers (Municipal Building, Washington, D. C.).

Again, without divulging the names of the contestants, all solutions were submitted for discussion to Lieut. Col. George B. Pillsbury, Corps of Engineers (Army Staff College, Washington, D. C.).

We can not here repeat the statement* of the problem, which will be found on Page 13, Volume XIII, No. 67, of THE MILITARY ENGINEER, but we print below the winning solutions and Colonel Pillsbury's comments. As suggested in these comments, it is to be hoped that others will submit remarks on the problem and the solutions, which will assist our readers in arriving at a thorough understanding of the duties of engineer troops attached to a force of all arms making an advance in the face of the enemy. [ED.]

First Prize Winning Solution

By

Charles H. Roe
Captain, Engineer Reserve Corps

(a) *Organization and Standing Instructions.*

Colonel A has not introduced any new or novel feature in his organization. Regimental headquarters is constituted and functions exactly as is contemplated by the compilers of the organization tables. On account of his duties as Divisional Engineer requiring considerable of his time, Colonel A has left the actual work of administration of the regiment very largely to Lieutenant Colonel B. Captain M, topographical and intelligence officer, has charge of the work of correcting maps. The other staff officers are working as usual. Colonel A retains the one motor car given the regiment for his own use, and the four motorcycles are in charge of the Supply Officer, who sends them out upon order from the Adjutant. Major Y, of the 1st Battalion, has been instructed to report progress twice daily by telegraph on his work of reinforcing bridges. The company, with the advance guard, reports twice daily by runner or other convenient, expeditious method upon the following points: Condition of the road being traversed, the railroad, bridges, and any possibilities of water supply for the troops.

(b) *Results of Conferences.*

Before 6 P. M. Colonel G gives G-3 the following proposed disposition of engineer troops:

"Company F will relieve Company E with the advance guard before the march begins to-morrow. The same six detachments of engineer troops in automobiles and the ten mounted men with the cavalry, all under command of Captain M, topographical officer, who have been engaged in correcting maps, will continue on this work to-morrow. The 1st Battalion is en route to join the regiment, having been relieved by the corps troops, and the regiment will, accordingly, be intact to-morrow with the exception of the company with the advance guard. The engineer train will be with the regiment, immediately following."

Colonel A also hands G-3 a copy of the wire from the Corps Engineer relative to the relief of the 1st Battalion and the ponton equipage, and requests that he issue the necessary orders for the engineer train to move up directly in the rear of the regiment. Colonel A sees G-2 and informs him that the work of correcting maps will be continued as he requested. Before 7 P. M. Colonel A sees G-1 and hands him the following proposed plans for water supply the following day:

"Water-tank train will leave OCEANSIDE with full tanks. There may be water obtainable in ENCINITAS, and possibly from the SAN MARCOS or the ESCONDIDO creeks. If no water supply has been uncovered by the advance by noon, the water-tank train will deliver its supply to the various units during the noon halt and return at once to OCEANSIDE for a fresh supply. Upon reaching DELMAR water is obtainable there unless the enemy has cut the pipe line supplying the city, in which case water is sure to be found in the SAN DIEGUITO River which the water-tank train can carry to the division. The company of engineers with the advance guard has been instructed to report at once any wells or other possible source of water supply that they find."

G-1 approves this plan. Colonel A hands G-1 a copy of the wire from the Corps Engineer relative to the relief of the 1st Battalion and the ponton equipage. Colonel A then requests G-1 for a requisition for the entire stock of bridge timbers and railroad ties in the railroad yards at OCEANSIDE and that the necessary steps be taken to have this material loaded on flat cars and sent south by rail with the division, so as to be available for use by the engineers wherever necessary. G-1 asks the colonel to appraise this material and report to him.

(c) *Orders and Messages.*

To C. O.'s Company E and Company F; by motorcycle to Company E and by orderly to Company F."

"The division advances at 5:30 A. M. to-morrow. Com-

*In his letter of transmittal, one of the competitors remarks on the statement of the problem as follows: "The problem appears to me to be practicable and very well stated, but, on the quiet, I wish you would tell me where Colonel A. got those six autos. Also, who ever heard of an engineer regiment going into action with a well-stocked lumber dump in the back yard? It is too good to be true."

Digitized by Google

pany F will report to the officer in command of the advance guard in the morning in time to relieve Company E and to take up the march at that hour. Company E, after being relieved, will be ready to take its proper place with the regiment as it passes. In addition to other information to be reported upon by the company with the advance guard, as prescribed in Regimental Order No. __, August 25, 1920, Company F will report immediately to these headquarters any source of water supply found, its nature, and estimated quantity. By order of Colonel A, Captain N, Adjutant."

To Majors X and Y, C. O.'s Companies A, B, C, D, E, F., Engineer Train, Water-Tank Train; by orderly to Majors X and Y, Companies A, B, C, D, and F; by motorcyclist to the others:

"This division and the 10th are in contact with enemy outposts and small, retreating detachments of enemy troops. It is estimated that not over two Red divisions have landed in SAN DIEGO. We advance at 5:30 A. M. to-morrow. DELMAR is the day's objective. The regiment will be ready at all times to take up a defensive position and assist as infantry if superior enemy forces are encountered. The regiment will form as usual, the 1st Battalion leading. The 2nd Battalion will reserve road space for Company E, who will join the regiment on the march. Company F will be with the advance guard. The Engineer Train will follow directly behind the regiment. Messages will be sent to Lieutenant Colonel B at the head of the column of the leading company. By order of Colonel A, Captain N, Adjutant."

To C. O. Water-Tank Train, by orderly:

"You will leave OCEANSIDE to-morrow with all tanks filled. You will be prepared at any time to-morrow, upon receipt of orders from these headquarters, to return to OCEANSIDE and refill tanks. By order of Colonel A, Captain N, Adjutant."

Verbal instructions to Captain L, Regimental Supply Officer:

'Go at once to the railroad yard at OCEANSIDE and list and appraise all the railroad ties and bridge timbers piled there beside the tracks. Keep a copy of this appraisal yourself and give me the original for G-1 and a copy for myself. Please have this ready for me by 9 o'clock."

(d) *Proposed Action for Following Day*

Colonel A intends to find out, by any means possible, the nature of the pipe line supplying DELMAR, and if he thinks it is practicable to effect repairs in case it has been cut, to order material for that purpose immediately by wire from LOS ANGELES. He makes a mental note that he will impress upon First Lieutenant K, commanding the Engineer Train, as soon as he reports to the colonel, the imperative necessity of keeping his technical trucks and wagons instantly available for issue of material. The colonel notes that the bridge across HEDIONDA creek is intact as reported by Captain Z, and determines that Major Y and the 1st Battalion will resume the work of strengthening bridges or repairing same just as soon as any are encountered that require it, but that he will keep the regiment intact to-morrow as long as possible.

Second Prize Winning Solution

By

John E. Wood
Captain, Corps of Engineers

(a) *Organization and Standing Instructions.*

I. Organization of Regimental Headquarters.

1. Colonel assisted by Adjutant; orders, and liaison with division headquarters; and commanding troops.

2. Lieutenant Colonel: directing field functions—
Trains,
Water supply,
Roads and bridges,
Materials,
Mapping.

3. Topographical Officer: in charge of division water supply.

4. Supply Officer: commanding officer of animal trains (under Lieutenant Colonel).

5. Commander of Engineer Train: with trains.

6. One lieutenant with Headquarters Detachment.

7. Mounted Section, Headquarters Detachment, with Advance Guard.

8. (*a*) One Lieutenant, Company D, at OCEANSIDE, in touch with Corps Engineer.
(*b*) One Lieutenant, Company E, liaison with Division Headquarters.
(*c*) One Lieutenant, Company F, liaison with Artillery Brigade Headquarters.

9. Motors:
Cycle riders—
3 to Regimental Headquarters,
1 to Trains.
Car—
Regimental Headquarters.

10. Water detail of one Master Engineer, 15 men from Company F.

II. Transmission of orders.

1. All companies to receive orders through Battalion Headquarters, except when acting separately. (Two motorcycles detailed.)

2. Separate companies and trains will receive orders direct from Regimental Headquarters; charged to Lieutenant Colonel. (One motorcycle detailed.)

3. March orders to be issued before daybreak and distributed by messenger.

4. Immediately upon reaching objective, Company Commanders to report to Regimental Headquarters.

(b) *Results of Conferences.*

I. With G-1.

1. Troops will carry water:
(*a*) Canteens filled,
(*b*) Water carts filled. Necessity for conservation of water.

2. Water will be available at DELMAR in afternoon.

3. Information will be disseminated through G-1 as soon as water points shall have been established. Organization commanders to instruct troops as to water points:
Troops only,
Animals.

4. Organizations to provide headquarters signs.

5. Two motor trucks for water supply.

II. With G-3.

Position of engineers in column approved as follows:

1. Company E and 4 tool wagons (with Headquarters Mounted Section attached) with advanced guard.

2. The regiment, less Company E, and mounted section of headquarters detachment with main body, immediately following artillery.

3. Trains of engineer troops will lead their respective columns—
(*a*) Animals,
(*b*) Motor.

Reporting to Division Train Commander; but subject to orders from regiment (rights of way over all other transportation).

Digitized by Google

4. One Lieutenant, Company E, Division Headquarters liaison.

III. With Artillery Brigade Commander: one lieutenant of Company F, with Artillery Brigade headquarters.

IV. With Corps Engineer: message as to—

1. General conditions.
2. Condition of troops.
3. Availability of materials.
4. Establishment of material dumps.
5. Water supply—
   Pumps,
   Damming materials,
   Designation signs.

V. With Division Sanitary Officer: re chlorination of water.

(c) *Orders and Messages.*

I. Field Orders, Headquarters, 8th Engineers.
No. 8, Fire House, OCEANSIDE,
Map CALIFORNIA, 5-D. Sept. 29, 1921.

1. A Red force, approximately 50,000, landed at SAN DIEGO, September 25. They will probably advance inland and to the North. Red patrols have been encountered by our advance cavalry near AQUA HEDIONDA.

The advance southward will be along the OCEANSIDE-ENCINITAS-DELMAR road. The 10th Division is advancing southward along the MOOSA-ENCINITAS-MERTON road; and bivouaced last night at MOOSA.

The country to the south is generally treeless and uncultivated; water is scarce.

2. This division will proceed at 5:30 A. M. to-morrow, the 30th. DELMAR is the day's objective. Our cavalry will precede the advance guard, and establish contact with the advance units of the 10th Division inland. The division will be ready to take up a defensive position if required. Division Headquarters will be established at ENCINITAS.

All troops will carry canteens filled. Water carts will be filled before striking camp.

3. Company E, with 4 tool wagons and Mounted Section, Headquarters Detachment, will report to Lieutenant Colonel A. P. commanding Advance Guard, at 5:30 A. M., the Court House at CARLSBAD; the remaining transportation of Company E will join regimental trains in rear of main body, at CARLSBAD.

The regiment, less Company E, and headquarters mounted section will form at OCEANSIDE preparatory to moving out at 5:30 A. M. to-morrow. Our position in the column will be immediately following the 25th Field Artillery. Transportation will join trains.

4. Trains will report to Supply Officer, and will be ready to join the column at 5:30 A. M. to-morrow. The animal train will consist of

(*a*) Regimental transportation,
(*b*) Company E transportation, less tool wagons,
(*c*) Companies D and F transportation,
(*d*) Engineer Train.

Motor train will consist of

(*a*) Engineer Train,
(*b*) Water-Supply Train.

Transportation of the 1st Battalion is proceeding southward along the OCEANSIDE-ENCINITAS road; and should reach OCEANSIDE on October 1.

The animal and motor trains will lead their respective columns. The Supply Officer will report his commands to the Commander of Trains, but subject to subsequent orders from his regiment.

An Engineer Dump will be established at OCEANSIDE, Lieutenant A. Y., Company D, in charge. Trees in limited amount may be expected along the line of march; lumber or bridge materials will be available at OCEANSIDE.

5. Regimental Headquarters will be established at ENCINITAS at noon to-morrow. Company Commanders will report as soon as reaching objective.

By order of Colonel A.

W. Y. X., Captain of Engineers, Adjutant.

Copies to:
File,
Lieutenant Colonel B,
Battalion Headquarters (four each),
Supply Officer,
Topographical Officer,
Corps Engineer,
Division Headquarters,
Commander of Engineer Train,
Commander of Headquarters Detachment.

II. In view of the inexperience of junior officers, the following subjects will be discussed at officers' meeting, 8 P. M., September 29:

1. Situation.
2. Orders.
3. Security.
4. Punctuality.
5. Road discipline.
   (*a*) Troops.
   (*b*) Transportation.
6. Bivouacs.
   (*a*) Occupation.
   (*b*) Policing.
7. Initiative.
8. Food and water.
9. Contingencies.
10. Dependability.
11. The "Message to Garcia."

(d) *Proposed Action for Following Day.*

In the absence of any material change in the situation, plans will be based on an uninterrupted advance of three days longer, at any time of which, or after which, it will be necessary to organize the terrain over the division front.

Mapping will be expedited.

Adequate water supply will be provided by two trucks carrying—

Pumps, hand,
Pumps, power hose,
Dam materials,
Designation signs.

Engineer Dump will be established at ENCINITAS.

Troops will bivouac in shelter tents.

Material dumps will be established and relinquished to Corps Engineer when corps troops arrive. The officer in charge of rear material dumps will be in contact with Corps Engineer at all times.

Discussion

George B. Pillsbury

Lieutenant Colonel, Corps of Engineers

The selected solutions, as well as others not printed, are excellent. It is to be regretted that more competitors did not enter the lists, for the study of such problems will go far toward perfecting the engineer service for its field duties.

Interest and Value of Personal Experiences

A GREAT soldier once remarked that he would rather talk for 15 minutes to a man who had actually taken part in a battle, than to read all the theory on the Art of War that was ever written. Not remembering just who it was that said this, we might follow the common practice of attributing the remark to Napoleon, or perhaps to Grant, were it not that this literary liberty has been already so much abused as to border on license. So we allow the remark to stand anonymously on its own merits.

Certainly none will deny that personal experiences have a practical value and a human interest that mere theory can never possess. The few personal experiences of the Great War that we have been able to present to the readers of this magazine have aroused more interest than anything else we have published.

The interesting personal experiences of the war are not limited to the battlefront. The S. O. S. can contribute its share of them.

Our society includes several thousand former officers who served in the World War. Probably there is not a single one of these who has not enjoyed, or does not now enjoy in retrospection, many personal experiences of the great conflict. Probably also the great majority of these personal experiences would be both interesting and instructive to our readers, would help to popularize our magazine and to increase the solidarity of our society.

Yet the editor can count on his fingers the number of contributions of this kind that have been received during the life of the magazine.

We wish our members would come to a full realization of the fact that The Military Engineer is *their* magazine, that it is their contributions alone which keep it going.

Let your fellow members enjoy the narrative of some of your interesting personal experiences, in the war or out of it. Tell them through the columns of your magazine. Do not let the fact that you are not in the habit of writing deter you. Confidentially, we like to receive the contributions of those who don't know how to write, or think they don't. They possess a freshness and charming originality too often lacking in the products of the habitual writer.

Will you not contribute something along these lines—some little anecdote pointing a moral, or containing a useful hint for your fellow members? Make it brief, the shorter the better, humorous if you will, for all our members have a sense of humor, and in your own words.

Obey that impulse! Do it now!

Human Maintenance and Repair

AS soon as a piece of machinery is placed in commission, as soon as a strip of roadway begins to bear traffic, as soon as a building is exposed to the weather from without and to wear and tear from within, the engineer must take up the work of maintenance and

Digitized by Google

repair. This involves, first, inspection; second, application of well-established practice in forming a logical plan for maintenance and repair; and finally, faithful work in carrying out the plan. In this way, and only in this way, can the original construction continue to serve the needs for which it was designed and built. Mechanically, most engines and other structures having moving parts can not reach their highest efficiency until they have "found themselves"; until they have become broken in; until they have to their credit a certain amount of service. If good lubrication is maintained, if careful inspection and timely repairs are regularly made, the period of maximum efficiency is greatly prolonged. This is true economy and true efficiency, which constantly postpones the day when the machine must be replaced in its entirety.

Now what of the human machine, especially as we have it in the service? By a careful process of elimination we select our raw material. It must be sound. This we begin to develop, and, by years of training, years of experience and years of elimination, we finally obtain a product which usually reaches a maximum efficiency in the average officer between the ages of thirty and forty-five, considering not only his technical experience, but also his physical equipment and his mental balance, which depend largely upon his physical condition. As the officer grows older his experience ripens. Unfortunately, however, his physical vigor, and with it his mental strength and his will power, usually declines. What is the answer?

For some years there has been in existence an organization of prominent scientists and other well-known men whose mission it is to apply scientific knowledge to the maintenance of health. These gentlemen assert that the life of the average business or professional man can be prolonged fifteen years by the application of well-recognized principles of physiology and hygiene. It is claimed that the man who undergoes a thorough examination and follows the advice of qualified specialists, can, on the average, add fifteen years of successful effort to his professional career.

As engineers, we can appreciate the advantages of this. We can indorse the idea because we know that it is scientifically sound. Who of us wants to be retired for disability at the age of fifty when he could go on to sixty-four by the application of a few common-sense principles which medical men all grant are sound and well recognized? Perhaps the average officer, who must be in better physical condition than the average civilian, can not prolong his life on the average the full fifteen years. If only ten, if only five, who would not gladly accept this as worth while? The recent emergency was less than five years. We had many able officers ripe with experience, just the men we wanted for positions of responsibility, and positions wherein they could not only be of great service to the country but win great distinction and fame. Yet because of physical weakness, weakness which developed under the stress of the emergency, they became casuals, were left behind and had to be replaced by men of fewer years and less experience.

It is the present policy of Congress to rely on the veterans of the World War for the defense of the nation, even though they have now returned to civil vocations. If the health of the experienced officers who served during the recent emergency can be maintained unimpaired for ten, fifteen, or more years, if for that additional period they can be counted on as a potential military force, it would be economic folly not to take advantage of this great asset. "But the army has such a system," some may say. We of the service know, however, that the only examinations—which, by the way, have been called off for this year—are more or less superficial. At best the mission of the Examining Board is primarily, perhaps solely, one of elimination, of detecting the unfit, of making recommendations as to retirement. In our experience we have never known of a case where a medical examiner gave counsel and advice to the officer examined as to what repair and maintenance work his system required. The idea of "life extension" as applied to the individual officer seems never to have taken root in the army. We have made splendid strides combating scourges and diseases for the army personnel as a whole, but never have we taken up the systematic policy of individual examination as thoroughly and completely as science to-day will permit, of sound diagnosis by experienced doctors and of advice to the officer as to how he can safe-guard or improve his physical condition.

The charge made by the organization to which we have referred, for this service of life extension for its members is $20 per annum. Can not the Government afford $20 a year in order that its highly developed, specially trained commissioned personnel may be given this extra lease on life and increased period of usefulness? As an investment it would be well worth the consideration of the Government. As a matter of fact, however, such charge should not be necessary except for the occasional officer on detached service far removed from army centers. The officers of the Medical Corps of the army are competent to do this work and, while they are undoubtedly well occupied in the discharge of their ordinary duties, and are earning the pay allowed them by the Government, it is not improbable that by a proper distribution of this additional duty they could make the necessary examinations of the officers enrolled in the regular establishment. It might be possible to carry the idea even further and to extend the privilege of examination by officers of the Medical Corps of the army to the higher grades of officers enrolled in the Reserve Corps. By a comparatively small increase in the number of officers in the Medical Corps, or possibly by some arrangement with Medical Reserve officers, this privilege of examination could be extended to the officers of every grade in the entire Reserve Corps. These officers are enrolled and trained at no small cost to the Government, and economy would dictate such additional measures as may be necessary to conserve their experience and training.

Some policy of human maintenance and repair is needed in the army and should have the support of all engineers. The success of the experiment on a large scale in the army might ultimately lead to the application of "life extension" methods to our citizenry as a whole, or to such as wished to avail themselves of its benefits.

The Metric System

CONTACT with the French during the war seems to have revived to some extent the agitation in favor of adopting the metric system in the United States. We have no fear that this will ever be done, for while a number of scientists are in favor of the metric system, it finds little support amongst business men, manufacturers and practicing engineers, and certainly there is no suggestion of a popular demand for a change.

The advantages of the metric system are two—first, the decimal relation between its units, and second, the rational connection between the different units of length, weight, temperature, etc.

Digitized by Google

Our complex industries are based upon the English system, and to change to the metric system, which is incommensurable therewith, would throw our industries out of gear and require that they be made over. The perfect language, Esperanto, is admittedly better than English so far as simplicity is concerned, but its adoption is out of the question, and the same is true of the metric system.

The manufacturers of the nations using the British system greatly exceed those of the metric-system nations, and it would be much easier for them to adopt our system than for us to adopt theirs. It is not in accordance with democratic principles that the desires of a minority be forced upon an unwilling majority.

The fundamental unit of the British system is the *inch*—our industries are based upon this unit—which, while arbitrary perhaps, is no more so than the meter. Any change which involves the abandonment of the inch would be so difficult as to be out of question.

If it be desired to adopt a *decimal* system, the only practicable scheme would be one based on the *inch* as the fundamental unit. Some of our measures certainly seem irrational, notably the degree Fahrenheit, the pound, the mile, the gallon, the bushel. The foot and yard are not decimal multiples of the inch, but they have the advantage of being divisible by 2 and 3, though probably 2 and 5 would be better. All of these units could be brought into decimal relation with the inch without throwing our industries out of gear. For example, 1 foot equal 10 inches, 1 mile equal 10,000 feet, 1 pound equal the weight of 50 (or 100) cubic inches of water, 1 gallon equal 250 cubic inches (instead of 237). This would simplify calculations. But the difficulties of calculation are probably not as great as the exponents of the metric system would have us believe. It would, of course, be an advantage if the pound, gallon and bushel were decimally related to the inch, but it is comparatively seldom that the conversion from inches to gallons must be made.

In conclusion, then, the adoption of the metric system, whose unit is incommensurable with our well-established inch, would so disturb our industries that it is manifestly impracticable. The difficulties of calculation under our present system are not, after all, so very great, but if we desire to avail ourselves of the advantages of a true decimal system, quite as satisfactory as the metric system, the only practicable and possible solution for the English-speaking people is a system based on the inch as a unit.

Accordingly, we suggest giving up the futile effort to force the French metric system upon us. If its advocates are still determined that we shall, whether willing or not, enjoy all its advantages, let them see what they can do with the inch as a unit. For we can never abandon the inch.

The Survey of Personal and Material Resources—A Task for Military Engineers

MODERN war involves putting to efficient use all of a nation's resources in men and materials. The outbreak of the World War found practically all of the participants badly informed as to their resources in men having the various kinds of technical skill for which the war created an immediate large demand, in capacity for manufacturing the many kinds of things needed for equipping, supplying and maintaining modern armies, and in facilities for transporting such armies. Indeed, exact knowledge seemed to be lacking as to nearly everything required to be known before dependable plans could be formulated. In spite of the well-known difficulties of the European participants in the war, when we came in we had done little to forestall experiences similar to theirs.

Much of our trouble and confusion in 1917 and 1918 was due to a lack of basic facts stated in figures, or, in other words, statistics. While it is not the function of military engineers to originate broad military policies, they are highly trained men whose daily employment brings them in contact with matters that are of vital importance when the nation is suddenly called upon to make use of its latent military energies. For example, some 8,000 or 9,000 officers and 200,000 men were in service as military engineers engaged in tasks requiring peculiar skill and experience. Yet we had no record to enable us to select the men best fitted for the task in hand, and many men were diverted from the work they were best qualified to do. We must compile correct statistics as to the qualifications of our members and, in addition, we ought to agree upon a program for collecting and keeping currently correct other information or statistics appropriate to our war-time activities, such, for example, as the location and capacity of quarries, gravel beds and other sources of road-building material, the location of stocks of such materials as cement and lumber. It will be said that all these things are well known, but such knowledge is general, not specific, and it has never been studied from the standpoint of our possible military needs.

The above ideas are merely suggestive and might be amplified, but it is obvious that, on the outbreak of war, we shall need facts—that is, correct statistical information, suitably arranged, in regard to our resources.

To make the necessary general surveys and detailed examinations and to compile the needed statistics concerning all our resources in personnel and material, is a proper function of government, and should be included as a part of our military policy—a very important part indeed.

To foster and encourage, and to assist in the compilation of important statistics, and of working plans based upon these statistics, is part of the mission of the Society of American Military Engineers, as included in is larger mission of promoting the National Defense. Indeed, one of the specific objects of the Society is to promote the efficiency of the military engineer service of the United States.

At this stage of national preparedness what can be more important, what can more greatly contribute to engineer efficiency than an accurate detailed knowledge of our resources in men and material? It would appear that a responsibility in this matter rests directly upon us, inasmuch as the investigation of all things pertaining to supply and manufacture is a proper function of the engineer. Insofar as resources of personnel are concerned, our interest may, of course, properly be limited to the personnel engaged in manufacture or other form of production, and that available for engineering service in the event of war. But a little reflection will show that this includes a large proportion of our able-bodied male population.

Elsewhere in this issue we publish an article indicating the plans of the War Department for the formation of the Organized Reserves, for their training in time of peace, and for their mobilization in time of war. This involves the organization of various engineer units as well as the tentative establishment of groups of specialist officers for service at Corps, Army and Expeditionary Headquarters. Corps area commanders have been charged with the organization of these bodies of the Organized Reserves, and in due course will make public the information necessary to the work.

To avoid the misplacements—the misfit assignments of

Digitized by Google

valuable personnel—which caused so many disappointments during the war, provision is necessary. The information has been carded and catalogued. Every member of the Reserve Corps is card-indexed according to information furnished by himself, supplemented in certain cases by observations made by his superiors during the period of his war service, but there are many who served during the war who are not enrolled in the Reserves. There are many others graduated from our technical schools during and since the war who were too young for military service. For these there is no specific information in the files of the War Department. Furthermore, an "index" is never a complete specification and assignments by card catalogue do not approach in efficiency assignments based on a direct personal knowledge of the officer assigned. It is precisely in this work of organization and assignment that the local sections of the Society of American Military Engineers can render valuable assistance.

Attention is invited to the fact that the constitution and by-laws of the Society provide for a standing committee "on service relations and military policy." This committee is charged "with the consideration of all matters which may be properly brought before the Society or may originate within the committee itself, involving the relations between the military engineers and other arms of the military service, and between the military engineers and the engineering profession in civil life, including all questions relating to the tentative military organization of the matter, and other measures of military preparedness affecting such engineers."

The organization of the Society and its objects have been approved by the former Secretary of War, by the Chief of Staff, and by the Commander-in-Chief of the American Expeditionary Forces. There is, accordingly, ample warrant for each local branch to organize a committee with the above-indicated functions and to volunteer its assistance to local military authorities in connection with the organization of engineer units of the Organized Reserves.

The fate of the civilian engineers in time of war lies almost entirely in their own hands. At the present time there appears to be no greater field of usefulness, and no activity fraught with greater consequence, than this matter of the organization and utilization of the engineering resources of the Nation in men and material. The question is one deserving of the careful consideration of the members of the Society, and their interest should not be limited to passive contemplation and idle conversation. Let them formulate plans and specifications, let them get on the job, start the machinery and keep everlastingly at it. "Lets go" and keep going.

Military Instruction

IN this number of THE MILITARY ENGINEER we initiate a new department under the simple heading "Military Instruction." This department will be conducted by members of the Instruction Staff of The Engineer School, Camp A. A. Humphreys, Virginia, under the general direction of the Assistant Commandant, Lieut. Col. James A. Woodruff, Corps of Engineers.

The material will be presented under three general subheadings—namely, Military Art (Minor Tactics), Military Engineering, and General Subjects. The latter will include administration, law, and various other miscellaneous subjects not clearly within the scope of the sections on Tactics and Engineering.

It is the intention to cover in this department of the Journal all important military instruction essential to the training of the Reserve Officer of Engineers. The matter presented will also prove of assistance to the officer of the regular establishment, and will serve to keep him in touch with developments in the various fields. The scheme of instruction will be that known as the "applicatory system," now universally recognized in the armies of all the leading military nations as the best practicable method of teaching the art of war in time of peace.

In brief, this system includes—

First, a study of theoretical principles and practical methods applicable to the various situations that may arise in campaigns, and

Second, a series of practical problems usually laid on a map in which the application of the principles is exemplified.

The theoretical instruction will be given in a series of notes and lists of references to standard texts, and in each issue of the Journal there will be one or more practical problems whose solutions will be given in the next succeeding issue. Plans are under consideration whereby it may become practicable to review and criticise solutions submitted by officers who desire to take this advantage of the course. Needless to say, an officer who solves the various probems in accordance with instructions issued will reap far greater benefits from the course than he who merely reads the problem and the solution. The former must do constructive thinking on his own account, while the latter merely follows in a passive sort of way the thought of the instructors.

The matter will be published in solid form, without advertisements, at the back of the magazine, so that it can be detached and bound or filed by those who wish to do so. Postal regulations prevent its issue as a loose pamphlet, and also prevent the perforation of the pages for detachment. Indexes of all matter issued will be published from time to time.

It is hoped to make arrangements to issue with the magazine the maps necessary for the solution of problems. In the meantime THE MILITARY ENGINEER will furnish without charge the necessary maps to any who may desire to undertake the solution of problems.

A word as to the illustration which adorns the heading of this new department of instruction may be of interest to our readers. It is the reproduction of a bronze group entitled "Military Instruction," which flanks the statue of Maj. Gen. Baron von Steuben, erected in 1910 in Lafayette Park, Washington, D. C. The pedestal of the statue bears the following inscription, viz:

"Erected by the Congress of the United States to Frederick William Augustus Henry Ferdinand Baron von Steuben in grateful recognition of his services to the American people in their struggle for liberty.

"Born in Prussia, November 15, 1730; died in New York, November 28, 1794.

"After serving as aide-de-camp to Frederick the Great of Prussia, he offered his sword to the American Colonies and was appointed Major General and Inspector-General in the Continental Army. He gave military training and discipline to the citizen soldiers who achieved the independence of the United States."

In view of the part which von Steuben played in the establishment of our national independence, it is peculiarly fitting that we should typify the aims of this new Department of Military Instruction by this group representing sage Experience imparting counsel for the future to untutored Youth.

Petition for Amendment to By-Laws

In accordance with Paragraph No. 2 of Article XII of the By-Laws, the undersigned active members of the Society respectfully petition for an amendment to Paragraph 1, Article VIII of the By-Laws, which now reads:

"The annual meeting for the election of officers and for the transaction of other business of the Society shall be held in the City of Washington, D. C., on the Friday preceding the third Wednesday in January."

Amend by striking out the word "preceding" and substituting the word "following"—so that Paragraph No. 1 will read:

"The annual meeting for the election of officers and for the transaction of other business of the Society shall be held in the City of Washington, D. C., on the Friday following the third Wednesday in January."

The object of this proposed amendment is to bring the annual meetings of the Society of American Military Engineers and the American Society of Civil Engineers within the same week, and with only one day interval between the meetings, thus enabling those who are members of both Societies to conveniently attend both annual meetings—the annual meeting of the American Society of Civil Engineers being held on the third Wednesday in January in New York.

(Signed) F. A. MOLITOR, New York City.
J. P. HALLIHAN, New York City.
C. DAVIS, New York City.
F. G. JONAH, St. Louis, Mo.
D. C. JONES, St. Louis, Mo.
J. W. SKELLEY, St. Louis, Mo.
J. L. BUCHANAN, St. Louis, Mo.
R. P. GARRETT, St. Louis, Mo.
A. K. B. LYMAN, St. Louis, Mo.
T. B. PERRY, St. Louis, Mo.
G. C. GRAETER, St. Louis, Mo.
A. T. PERKINS, St. Louis, Mo.
J. A. LAIRD, St. Louis, Mo.

Personals

Leave of absence for three months granted to Col. THOMAS H. REES, Corps of Engineers, has been extended for three months.

Col. CHARLES L. POTTER, Corps of Engineers, has been granted leave of absence for two months.

Col. GEORGE P. HOWELL, Corps of Engineers; Maj. GORDON R. YOUNG, Corps of Engineers, and Capt. HARTWELL W. WILLIAMS, Quartermaster Corps, have been appointed to investigate the alleged damage to Silver Lake caused by débris from the Remount Station at Camp Gordon, Georgia.

Col. HARLEY B. FERGUSON, Corps of Engineers, has been relieved from his duties at the General Staff College, Washington Barracks, D. C., and ordered to report to the Assistant Secretary of War for assignment to duty in his office.

Lieut. Col. CLARENCE O. SHERRILL, Corps of Engineers, has been detailed in charge of the public buildings and grounds in the District of Columbia and as Military Aide to the President, relieving Maj. CLARENCE S. RIDLEY, Corps of Engineers. In addition to his other duties, Col. SHERRILL has been detailed by the President to act as Superintendent of State, War and Navy Department Building.

Lieut Col. W. GOFF CAPLES and Majors LAURENCE V. FRAZIER, FRANCIS B. WILBY, CLARENCE S. RIDLEY, FREDERICK B. DOWNING, CHARLES L. HALL, JOHN R. D. MATHESON, CHARLES J. TAYLOR and DAVID MCCOACH, JR., all of the Corps of Engineers, have been ordered for duty as student officers at the School of the Line for the year 1921-22.

Maj. ARTHUR R. EHRNBECK, upon the expiration of leave of absence on account of sickness, has been transferred from his station in the Hawaiian Islands to San Francisco, Calif., for assignment to duty as Assistant to the Engineer, Ninth Corps Area.

Maj. WILLIAM A. JOHNSON, Corps of Engineers, has been detailed, in addition to his other duties, to superintend the construction or repair of any aid to navigation authorized by Congress in the Nineteenth Lighthouse District, relieving Col. CLEMENT A. F. FLAGLER, Corps of Engineers.

Maj. HENRY A. FINCH, Corps of Engineers, has been granted leave of absence for three months.

Maj. JAMES G. STEESE, U. S. A., retired, in addition to his other duties, has been detailed to superintend the construction or repair of any aid to navigation authorized by Congress in the Sixteenth Lighthouse District, relieving Col. JAMES B. CAVANAUGH, Corps of Engineers,

Maj. JOHN C. H. LEE, General Staff, has been transferred from Fort Sheridan, Illinois, to Manila for duty as Assistant Chief of Staff for Military Intelligence, Philippine Department.

Maj. ROBERT C. WILLIAMS, Infantry, has been transferred to the Corps of Engineers.

Capt. HIRAM B. ELY, Corps of Engineers, has been transferred, at his own request, to the Ordnance Department, Regular Army.

Capt. EDMUND H. LEVY, Corps of Engineers, has been granted leave of absence for one month and five days.

Capt. AUBREY H. BOND, Corps of Engineers, has been ordered, at the expiration of his present leave of absence, from Camp Jackson, South Carolina, to Camp Lewis, Washington, for assignment to duty with the Fourth Engineers.

Capt. GEORGE J. NOLD, Corps of Engineers, has been granted leave of absence for one month.

Capt. RALPH E. CRUSE, Corps of Engineers, has been granted leave of absence for one month effective upon his arrival in the United States.

Capt. HENRY M. UNDERWOOD, Corps of Engineers, has been transferred from the Hawaiian Islands to Troy, N. Y., for assignment to duty as a student at the Rensselaer Polytechnic Institute.

Capt. THOMAS HAY NIXON, Corps of Engineers, has been transferred, at his own request, to the Ordnance Department, Regular Army, and assigned to the Watertown Arsenal for Duty.

Capt. MILTON HEILFRON, Engineers, has been transferred to the Coast Artillery Corps and assigned to the Thirty-first Artillery Brigade, Coast Artillery Corps, Camp Lewis, Washington.

Capt. CLIFFORD E. BLACK, Infantry, has been transferred to the Corps of Engineers.

Capt. WILLAM H. WAUGH, Quartermaster Corps, has been transferred to the Corps of Engineers.

First Lieut. JOHN C. ARROWSMITH, Corps of Engineers, has been granted leave of absence for one month.

First Lieut. WILLIAM A. CALLAWAY, Corps of Engineers, has been transferred to the Infantry.

First Lieut. CONRAD P. HARDY, Corps of Engineers, has been granted leave of absence for two months effective upon his arrival in the United States.

First Lieut. (since promoted to the grade of Captain) HAROLD J. ADAMS, Corps of Engineers, has been transferred to the Signal Corps.

List of Applicants for Membership

This list contains only those applicants from whom formal applications have been received between March 1 and April 19, 1921:

Anderson, Col. P. M., 5508 Broad Branch Road, N. W., Washington, D. C.
Andrews, Lieut. Martin Arthur, Camp Travis, Texas.
Barrows, Capt. R. G., 89 Rawson Road, Brookline, Mass.
Berliner, Richard W., 460 W. 147th Street, New York City.
Bermel, Capt. P. E., General Delivery, Tucson, Ariz.
Blackstone, Henry, 76 W. 85th Street, New York City.
Bonfils, Capt. F. W., West Point, N. Y.
Boughton, Maj. Wilfred E., 1665 Grand Concourse, New York City.
Brokaw, Lieut. Van S., 1057 Balmoral Avenue, Chicago, Ill.
Brown, Marshall W., 50 Voorhis Avenue, Nyack, N. Y.
Brunel, Louis J., Angels Camp, Calif.
Bunker, George H., Wilmington, N. C.
Burns, Lieut. Donald S., 5th Engineers, Camp Meade, Md.
Bush, Warrant Officer Peter A., 27 Hillcrest Avenue, Cranford, N. J.
Carlson, Arnold G., 427 32d Street, Paterson, N. J.
Carter, C. B., 1062 McCormick Building, Chicago, Ill.
Chadwick, Lieut. B. F., Camp Humphreys, Va.

Activities of Our Local Posts

San Francisco Post

The Activities Committee met on March 7, with the following members present:

Col. Herbert Deakyne, C. E.; Lieut. Col. John H. Skeggs, E. R. C.; Maj. U. S. Grant III, C. E.; Capt. D. W. Dodge, E. R. C.

The functions of this committee as defined in the plan of organization adopted by the Post, are:

(*a*) To arrange inspection and observation trips.
(*b*) To establish and maintain close relations between the regular establishment and the reserve.
(*c*) To initiate and support movements of interest and advantage to reserve officers.
(*d*) To serve in conjunction with courses of training and study.

The committee decided to arrange for a trip over the coast defenses about San Francisco Bay, the trip to be preceded by a description of the works and the plan of defense.

Other trips planned include the Presidio of San Francisco, parts of the State Highway, with particular reference to their military value, the Hetch Hetchy water-supply project for San Francisco, and the U. S. Disciplinary Prison on Alcatraz Island. The committee believes that not only will these trips be interesting and instructive, but also that they will serve to bring the members of the Post into close personal touch with one another, which is highly desirable.

In lieu of the April meeting a trip has been arranged to the Mare Island Navy Yard through the courtesy of Capt. Edwin L. Beach, U. S. N., Commandant. The chairman of the committee, Colonel Deakyne, has proffered the use of the U. S. Engineer boat for this trip.

Los Angeles Post

At a meeting on April 5, Mr. C. M. Cram, 725 Central Building, Los Angeles, Calif., was appointed as secretary to succeed Mr. Burt Harmon, whose resignation was accepted.

Chicago Post

The March meeting was held on the 17th at the Electric Club, where the members of the Post were the guests of Castle Post of the American Legion for dinner. The subject of the evening was Military Railways. Mr. S. M. Felton, director general of military railways during the war, introduced the speaker of the evining, Col. F. G. Jonah, chief engineer of the St. L. & S. F. Ry., who served as chief engineer of the Division of Light Railways, A. E. F. Col. Jonah gave a very interesting talk based upon his wide and successful experience in the operation of light railways in France, with many lantern-slide illustrations.

The Chicago Post is rapidly developing an extensive program of subjects to be presented at the monthly meetings and hopes to make a definite contribution to the development of military engineering.

Portland, Oregon, Post

The Portland, Oreg., Post, Society American Military Engineers, was organized June 15, 1920, and was granted a charter under date of October 4, 1920.

The following officers were elected:

President, Maj. Lyman Griswold;
Vice-President, Capt. W. H. Emrick;
Secretary, Capt. P. Hetherton;
Treasurer, Capt. J. W. Morris;
Assistant Treasurer, Capt. R. E. Kremers.

Meetings have been held on the second Tuesday of each month since July 15, 1920, the first meetings having been devoted to discussions of policies and two problems worked up by special committees in connection with land-defense matters at the mouth of the Columbia River. The meeting of August 12 was in the nature of a farewell meeting for Lieut. Col. J. R. Slattery, under whose auspices the Post was organized.

Commencing with the November meeting the program has been preceded each month by a very enjoyable dinner served in a private dining room of the Portland Chamber of Commerce, except for the February meeting, when the dinner and meeting were held at the City of Portland Municipal docks, where the members of the Post were guests of the Dock Commission. Since the inauguration of the dinner feature the meetings have been attended by as many as sixty members and as few as twenty, with an average attendance of about thirty.

Two local inspections of engineering works were made prior to attending dinner, one in February, when the extensive docks, grain elevator, flouring mill, and ore-handling plant at Municipal Terminal No. 4 were visited, and the other in April, when the electric light, power, and steam-heating plant of the Northwestern Electric Company was inspected.

It is planned to hold the next meeting at the Portland Automobile Club, and to invite the ladies, serve a buffet supper, and dance to the jazzy strains of a local orchestra.

The dinner feature contributes not a little to the interest taken by the local engineers and the very gratifying progress of the Post. You know that it is ever so much easier to get communicative and appear interested after a square meal, and a cigar will almost always last as long as a meeting ought to last, not to become boresome.

Well, after dinner is over, about 8 o'clock, the president opens up, and the items of business are rapidly disposed of. Then comes a report from the Current Events Committee, giving a summary of military events that have happened during the month that should be of permanent interest to members. After that, the Library Committee usually reports a new publication placed on the library shelf. The Program Committee suggests where to meet and what to do next month. The committee in charge of the Rifle Association work usually reports progress. Then come the fireworks. We always try to have some fireworks. In a large body of intelligent men or women there are usually found legitimate differences in viewpoints on important questions. Lately we have been discussing the proposed Department

Digitized by Google

of Public Works and the effect on the Corps of Engineers of losing the river and harbor work.

At the last meeting the opinion seemed to predominate that while a Department of Public Works ought undoubtedly to be organized to co-ordinate the engineering work of the Government, the term engineering work includes such a mass of undertakings that, unless some discriminations are made, it may rightly claim authority over things technically of an engineering nature but practically not properly to be included under a Department of Public Works. The river and harbor work is distinctly an engineering function, but it should be excepted just as certain other phases of Government work of a technical nature are bound to be excepted, for one reason or another, not just because all phases cannot be united under one head, but because there is at least one overwhelming reason for keeping river and harbor work under the Corps of Engineers, and no cogent reason for taking it away, such as prospective increase in economy and efficiency of the particular work affected.

Now, the one compelling reason why it should remain under the Corps is that through its agency, and at no extra cost, the officers of the Corps of Engineers get the engineering experience and the contact with the engineers of the country which is absolutely essential for the Corps if it is to handle successfully the engineering problems of the next war. Mr. O. Laurgaard, city engineer of Portland, presented cogent reasons for establishing a Department of Public Works, but agreed that the river and harbor work was not of such vital importance to the correct functioning of the Department of Public Works to make it a matter of great concern, whether it were included in the new department or not, but on the basis that this work was purely of a civil characer, it was only reasonable that the civil bureau should handle it. He felt that there was plenty of opportunity on fortifications and purely military work for training the military engineer. The latter assertion was rebutted by Major Park and Capt. Ben Morrow. Lieut. Col. Lewis H. Rand was a welcome guest, and he presented some well-considered reasons why the Corps of Engineers should retain the work. Mr. J. N. Teal, who has just been relieved by Senator Chamberlain on the U. S. Shipping Board, spoke strongly on behalf of continuation of the river and harbor work under the Corps of Engineers. Mr. C. L. McKesson, of the Bureau of Roads, gave some interesting side lights on the general subject.

New Local Posts being formed

Steps have been taken to establish several new local Posts of the Society. The list is given below, with the names and addresses of the temporary secretaries. All members in the vicinity of these new Posts are urged to get in touch with the secretaries, with a view to affiliation with a local Post.

The local Posts are the backbone of our Society. They provide the opportunity for personal contact and for the discussion of all matters pertaining to the maintenance of an adequate Engineer Reserve. Without such discussion, it will be difficult or impossible for the editors of the journal to keep in touch with the actual needs of the Society.

Following is a list of new Posts:

Baltimore Post—Capt. John S. Doyle, E. O. R. C., 309 Custom House, Baltimore, Md.

Boston Post—Lieut. Louis A. Armistead, Room 701, 108 Massachusetts Avenue, Boston, Mass.

Buffalo Post—Mr. Albert F. Krause, Builders Exchange, Court and Pearl Streets, Buffalo, N. Y.

Cincinnati Post—Capt. Hugh J. Krampe, E. O. R. C., 1608 First National Bank Building, Cincinnati, Ohio.

Detroit Post—Maj. Richard B. Hewitt, E. O. R. C., 712 Bord Building, Detroit, Mich.

Indianapolis Post—Capt. C. L. Harrod, E. O. R. C., Public Service Commission of Indiana, Indianapolis, Ind.

Twin Cities Post—Capt. John F. Druar, E. O. R. C., 512 Globe Building, St. Paul, Minn.

Akron Post—Lieut. Sears S. Day, E. O. R. C., Lock Box 254, East Akron, Ohio.

Suggestions for Articles

"Comments by company and platoon commanders on the engineer wagons used in France, their suitability, and changes suggested for future use."

"Military railways; their construction, maintenance and operation."

"Carrying parties; how to lessen the man-power requirements of this work in position warfare."

"The Military Capacity of a Wagon Road."

"The Service of Supply in the Next War."

"The airplane as an aid to transportation."

"A World War bibliography for the E-Officer."

"Water Supply in mobile Engineer Operations."

"Construction and maintenance of ponton bridges under battle conditions in France."

The Army Uniform

By

Aymar Embury II

Major, Engineer Reserve Corps

[*Note.* The question of a proper uniform for our Army has been under discussion since the Colonial days, and is apparently still unsettled. To be sure, the uniform appropriate for a particular epoch is not usually suitable for the next. Different uniforms are required for social and instructive purposes and for garrison and field duty, for the arctic and tropical regions, etc. Moreover, comfort and utilitarianism are not the only matters to be considered. The pride of the soldier must be stimulated, even the taste of the ladies has its influence—a very great influence, in fact.

These considerations give room for great differences of opinion, as is evident from the discussion on Major Embury's "ideal" costume for the soldier. His views, however, appear to meet the approval of the majority of the commentators.—ED.]

THE question of uniform is usually considered, especially by the civilian, as being of such minor importance that contemplated changes in uniform are regarded with the same sort of tolerant humor with which one regards the changing styles in women's hats. Unfortunately in the past the Army authorities have afforded a certain justification for this criticism, since changes in uniform have been usually proposed with a view to appearance rather than as questions of efficiency, the sole noteworthy change being that which put our Army in olive drab instead of blue. That the efficiency of an army in the field is dependent upon uniform to a considerable extent is evident when one realizes that the men usually sleep in their clothes and are frequently compelled to make long marches carrying heavy burdens. If their clothes are so uncomfortable that sleep is broken and disturbed, and if the clothes increase the difficulty of marching, reserve energy is very rapidly consumed. The extreme of comfort is therefore of the highest value in field uniform.

The original reason for putting soldiers into uniform was that they might be recognized by their comrades and their officers under all circumstances, and since the first uniformed troops were the so-called "Household Troops" attached to courts, the uniforms were designed with a view to their ceremonial use to suitably display the power and magnificence of royalty. These original uniforms were therefore made without regard to the comfort or convenience of the men inside them, and were of gaudy colors and striking design. The point of view from which a uniform to-day is regarded is considerably changed. We now regard the uniform as a suitable set of working clothes for a soldier. Unfortunately, however, the present uniform, except in color, does not fulfill the requirements of this new standard. Our campaign uniform to-day is essentially a simplified dress uniform in olive drab.

In talking over the question of uniform with older officers, suggested changes have invariably been met with the objection that they would detract from the military appearance of the men, as if to be military were to be uncomfortable, and while unquestionably it is desirable that soldiers should feel that their costumes are becoming, since the effect of clothing upon morale in either the civilian or the soldier is a definite and recognizable asset or the reverse, the very general dissatisfaction felt by the enlisted men of our Army with their uniforms from the point of view of appearance as well as of comfort, indicates that the uniform as at present designed has not fulfilled even the least of its purposes.

The defects in the present uniform are threefold: it is not easy to identify the unit to which a man belongs; the uniform is uncomfortable to a point where it is fatiguing; and it lacks the smartness necessary to good soldierly appearance.

Considering first the question of recognition, especially in the A. E. F., it will be remembered that at first the uniform was exactly alike for all branches of the service except for the small metal collar ornaments bearing the insignia of the arm and the regimental and company numbers. Since these can be read only at a distance of three or four feet it was impossible to tell at a glance to what unit any enlisted man belonged. Further, since these metal buttons were not as a rule carried in stock by the organization supply officer and as elaborate machinery is necessary for their manufacture, replacement troops ordinarily were without insignia or with incorrect insignia. A number of men in my own regiment never had correct collar ornaments during the entire time of their service, nor was it possible for me to obtain them. Further, these metal ornaments were often caught upon the shoulder straps of the packs and were detached and lost. The metal ornaments on officers' uniforms were so impractical that many officers purchased embroidered cloth badges. Some system of cloth ornaments of distinctive colors for indicating the branches of the service should be devised, just as in the A. E. F. the various divisions finally adopted shoulder badges and in some cases, as for example the 89th, the colors of these badges indicated the various branches of the service. Similarly in the First Army the capital "A" usually was combined with the badge of a branch of the service, as for example the Engineer castle or the crossed cannon of the Heavy Artillery.

In the Civil War under similar circumstances, the various army corps (which were much smaller than our divisions) adopted devices colored differently to distinguish the brigades. The men in the French and Italian Armies wore a colored badge on the collar to distinguish the branch of the service, with regimental numbers embroidered on it. The German Army used shoulder straps similarly embroidered. The English used colored divisional marks on the point of the shoulder or on the center of the back; the various units being distinguished by their metal cap badges and buttons. Our Army was the only one in which it was almost impossible to tell to what unit a man belonged, which resulted in very great confusion when troops went into action with a large number of replacements.

From head to foot there was not a feature of our uniform which was not severely and justly criticised as being uncomfortable or unsuited for field service, except the shoes. The campaign hat was withdrawn and the so-called "overseas" cap substituted for it. This cap had the sole

Digitized by Google

merit of fitting comfortably into our infinitesimal pockets. Most of them were so manufactured that the flaps would not turn down to protect the ears against cold or rain, but the crease between the flaps and the center of the cap held water like a roof gutter. The cap was not the slightest protection against either sun or rain and could not comfortably be worn under a trench helmet.

The coat which approximated an army fit, bound the shoulders so tightly that it was very difficult to hold a rifle in its proper position and grenade throwing or bayonet work without taking off the coat was like running in hobbles. The close standing collar was pulled back so tightly against the neck by the shoulder straps of the packs that if it were not unfastened it would entirely cut off the supply of air from the lungs. The pockets were too small to be useful and as ornaments were a complete failure.

The breeches were so tight at the knees that they impeded marching and the time required to put them on and take them off was far too great. Further, as it was necessary to put on the breeches before the shoes, when the men slept on the ground they generally got their feet wet before they were dressed, which caused sore feet.

The issue puttees were not spiral and in order to make them stay up they had to be pulled so tight as to impede circulation. Also when it rained they kept slipping down, causing delays in the march.

The field shoes were splendidly constructed, extremely comfortable, very durable, impervious to water, and after one became accustomed to their weight, not especially heavy in marching.

The regulation overcoat was too long and had to be reduced and as the rain coats were not big enough to go over the overcoat, a man had the choice in wet weather of wearing his raincoat, keeping his body dry and letting his overcoat get wet, adding eight or ten pounds to the weight he was carrying, or of wearing his overcoat and throwing his raincoat away. As the raincoats leaked, neither way was satisfactory, and as the overcoats were not really warm, especially in the wind, they were perhaps the least useful article of the equipment as well as the most difficult to carry.

Now if the result of all this uncomfortable equipment had been to make the men look like magnificent soldiers and give them pride in their equipment, they might perhaps have been willing to endure the discomfort without grumbling, but as a matter of fact our Army was more slovenly in appearance than most of the others. It is true that certain military policemen or orderlies of the headquarters companies, who bought their own puttees, had their uniforms fitted by the company tailors and did not have to sleep in their clothes, presented a very smart and soldierly appearance. These cases, however, were the rare exception; the average soldier was equipped with clothing which fitted him only approximately and which he had no opportunity to have recut. In the effort which has been made by the Army to provide clothing to fit every shape and size of soldier, the table of sizes shows some forty numbers of coats and more than thirty of breeches, but as the supply officers were not permitted to carry in stock more than five per cent. in excess of the number of garments required for their units, the chances were twenty to one even under favorable circumstances that a soldier would not find the sizes he needed, and in the wholesale distribution that was attempted after each action, few men managed to procure all the different items of uniform in the correct sizes. Therefore from a point of appearance alone our uniform in field service was a complete failure, and our men were constantly seen with puttees that hung around their legs like a diagonal fringe, with coat collars so big that their heads would slip through them when they were fastened and with breeches which looked like those of the New Amsterdam Light Infantry of 1650. There is no question that our men felt ashamed of the appearance which they were compelled to present (no matter how hard they tried to look well) whenever they were on pass or on duty which presupposed a smart appearance.

The remedy for these difficulties is, I think, reasonably simple. The American soldier never looks so well as when he wears a loose flannel shirt without a coat. His excellent physique and easy, careless grace in loose comfortable garments are far more soldierly than his wooden motions in the regulation tight-fitting uniform. Further, loose garments can be carried in very few sizes and are smart when properly worn, as for example the blouse worn by the United States Navy, which is, I believe, manufactured in only five sizes, but in which our sailors are the smartest uniformed men in the United States. The Russians alone among the foreign troops appeared to appreciate this fact, possibly because their military uniform was the typical peasant garment of uniform color and cut. A loose blouse, either buttoned like a coat or similar to the Russian blouse with a V-shaped neck, held in at the waist with a belt and with loose sleeves with buttoned cuffs to keep them from falling down over the hands, would be extremely comfortable. The collar should be so arranged that it could be turned up and buttoned or strapped close around the throat in cold or wet weather, to keep out the rain or to protect the throat. Ample pockets should of course be provided.

Trousers should be substituted for breeches and should be made sufficiently wide so that they could be put on after the shoes. If puttees are entirely discarded and loose half-boots used instead of shoes, the bottom of the trousers could be worn either inside or outside the upper part of the boot, according to the weather. Boots extending to the calf would be sufficient protection from the mud under all normal conditions; in the trenches or swamps nothing is satisfactory. This way of wearing trousers and half-boots has been found the most comfortable sort of foot wear by construction engineers, lumbermen and others, who are confronted with the same problems as soldiers.

Instead of the overcoat and raincoat the so-called "trench coat" authorized for overseas use by all officers should be issued. The coat and lining can be worn in combination in cold weather and since the coat is wind-proof as well as waterproof it is an extremely warm garment. Further, the lining could be issued only when required, would be much less expensive than the overcoat, and when not worn could be packed in a small space. This combination has one additional advantage in that the lining can be used as an extra blanket and with the coat itself will completely cover a man; no overcoat will do this. A better and more practical garment it would seem impossible to devise.

Like the trench coat there is a hat in common use which is perfectly adapted for military purposes. Our campaign hat is in many respects the best military headgear which has yet been discovered but it cannot be worn under a helmet nor conveniently carried except on the head, and the hard, straight brim makes it impossible to conform the hat to the variety of heads which soldiers (in common with other human beings) seem to have. Our campaign hat was apparently made for a race of bullet-headed men and when anybody with an oval head wears it, it hurts his head

Digitized by Google

until the brim turns up or down in a way which spoils the looks of the hat and the looks of a line of men wearing them. The common light felt fedora, so popular during the last few years in this country, is almost perfectly adapted to military use. The roll rim takes up any irregularity in the shape of the hat and when turned down is a perfect protection against the rain. A hat of good material can be folded up and put in the pocket if required, or the hat can be worn underneath the trench helmet more easily than the overseas cap..

It will be objected that a uniform of this kind is not sufficiently "military," but what is or is not military is largely a matter of custom. I cannot believe that the red-coated British soldier of the Revolutionary period would have thought that the British campaign uniform of 1918 had any military quality. Nor can I imagine any American soldier dressed up in a short skirt, bare knees and rolled-down stockings (like a Coney Island bathing suit) feeling as if he were in a proper uniform; yet that is exactly the uniform that the Highland troops wore, and no one thought of them as either looking or being unmilitary.

For dress occasions there seems to be no legitimate objection to a uniform of the traditional close-fitting type. The English Army has already returned to the scarlet tunic of pre-war days, believing that the men (not to mention their feminine admirers) like clothes in which they can dress up, and that this improves the discipline and the morale of the service. It seems to me that this point of view is perfectly logical. No human being likes to wear exactly the same garments on all occasions, including bed (if that is an occasion), and the old blue dress uniform of the United States Army, preferably varied to indicate the branch of the service and the organization, would unquestionably stimuate pride in its wearer. The Marine dress uniform is an excellent example of what a dress uniform will do for an organization, and the way the Engineer officer clings to his distinctive buttons is another indication of the same effect. It should not be forgotten that the purposes of dress and field uniforms are entirely different.

Discussion

George O. Squier
Major General, Chief Signal Officer

Just as one returns in an idle moment to the study of a problem that tradition implies was once solved, the solution lost, and which now apparently is unsolvable, so one takes up and reads this article on our military uniform. It is to be hoped that some one sometime will arrive at an approved solution. Until they do, the problem will remain with us.

I personally favor a smarter uniform for wear during hours off duty than our working clothes, and I would also like to see the open roll collar adopted for the field blouse.

The adoption of a blouse with a yoke, and with pockets which will hold bulky articles would, I believe, be open to criticism. A box pleat in the seams at the back of the coat just under the shoulders, and a reasonable fullness in the breast would give ample room to move the arms. Pockets similar to those generally used in civilian clothing should give room for the carrying of all articles needed when men are not equipped with the haversack or officers with the field carrying case. In other details I approve adoption of the field uniform as described in this article and illustration.

Wm. Mitchell
Brigadier General, Air Service

This article on the proper uniform for the Army has

Major Embury's Field Service Uniform

Digitized by Google

been read with great interest. I believe that the suggested changes, as shown in the illustration, would greatly conduce to the usefulness and comfort of the men. The long trousers capable of being put on after the shoes, are a distinct advantage. The looseness of the coat over the shoulders and chest would also add to the comfort of those wearing this uniform.

It is suggested that the collar letter be placed also on the reverse of the collar. This would enable men to be identified when their collars are turned up in cold weather, yet not cold enough to require overcoats. There should be some means of fastening the collar in the turned-up position.

George D. Snyder

Formerly Major, Engineers, U. S. A.;
Late Colonel 22d Engineers, N. Y. National Guard

The Army is to be congratulated on receiving such practical suggestions from one whose profession is to combine utility with appearance, for we have given little effort to the harmonizing of these elements in the past.

Formerly we blindly followed the military fashions of the dominant nations in Europe, without regard to their suitability to our climate or the physical characteristics of the men inflicted with them. The Civil War was fought with French models. After the Franco-Prussian War these were abandoned and Prussian uniforms, including a spiked helmet, were substituted. The Spanish-American War found us without clothing or equipment suitable to a tropical climate; these had to be hastily improvised and were generally not received until the war was over.

At the beginning of the World War we gave up some of the most comfortable portions of our uniform to conform to the practice of our allies. Our campaign hat for instance; although the Australians and New Zealanders did very good work in theirs.

It is believed that we should have a uniform and equipment suited to the climate in which our troops are trained and ordinarily used, making such modifications as may be necessary should they be called to any unusual climate.

The following comments are confined to engineer troops not mounted, as the suggestions of Major Embury would have to be modified materially for mounted troops.

The increasing use of motor transport is reducing the number of mounted men with an engineer regiment, but some mounted engineers, not only with cavalry divisions but with infantry divisions as well, will always be required.

The engineer is a "hog for work" and needs clothing that will give him the necessary freedom of body and limb without making him look like one. It is believed that this will be accomplished by Major Embury's suggestions providing the blouse is not ordinarily taken in the field but is left in barracks, substituting a sweater for use in the field.

The half-length laced boots are an improvement on the present shoe and wrapped puttees, which impede the circulation and freedom of movement. An ankle height shoe may be found advisable for use in barracks, office duty or on furlough when the trousers are worn over the shoe.

It will be found that the trousers will not look well over shoes after being worn inside boots, without being pressed. In garrison the soldier will probably have two pairs; old ones to tuck in the boots and a newer pair for dress and for wear outside the shoe. Officers will find these trousers a great comfort for wear outside the shoe, when on desk duty, when in quarters, at social functions and the like.

The blouse will be found to be a great comfort for men on office duty and on pass. With the rolling V-collar a white shirt and prescribed linen collar and tie should be permitted when on pass, or at social and dress occasions. Give the soldier the same comfort in dress and the same ability to vary it to meet social conditions that prevail in civil life. The officers also would appreciate the right to wear similar garments now enjoyed by their brothers in the Navy.

It is believed that the chevron should continue to point upward as at present in accordance with heraldry.

Charles E. Stodter

Colonel, Cavalry

I have read this article with a great deal of interest and I thoroughly agree with the views expressed therein. There is no question that our so-called "service uniform" is not suitable for service. The attempt to combine a dress uniform and a service uniform has resulted in failure, as the purposes of the two uniforms are so radically different that a combination cannot answer for either purpose.

The *service uniform* should fulfill the following requirements:

(a) It should be comfortable.
(b) It should be suitable for all conditions of service.
(c) It should not be injurious to health.
(d) It should be as neat and pleasing in appearance as consistent with the above requirements.

Our present service uniform does not fulfill these conditions. In the first place, it is not comfortable. Comfort has been sacrificed because those responsible for its design have been handicapped by the idea that the uniform must be "military." This word seems to convey the view to a great many officers that in order to be military the uniform must be tight and uncomfortable. This misconception of the word "military" has handicapped progress in the Army more than any other word in our language.

The unsuitability of the service uniform has been recognized by many officers, and we have gone so far at times as to practically abandon the coat and to wear the flannel shirt or a sweater as an outer garment. There can be no question as to the need of a coat. We must have it for comfort, for the carrying capacity of its pockets, and for the sake of appearance.

The service uniform described in this article fulfills all the requirements of a real service uniform. A soldier can march, dig trenches, throw grenades, or sleep in this uniform with comfort. He can not do any of these with comfort in the present service uniform.

In regard to the details of the uniform depicted in the sketch, the hat is very similar to the old campaign hat which we had in the service twenty years ago. The brim is a little narrower, perhaps, and the crown a little higher, but it is not essentially different. That old hat was the best headgear we have ever had. It was abandoned in favor of the stiff-brimmed hat because somebody thought the old hat was not "military."

In regard to the coat, I have been advocating this type of coat with open V-shaped collar for more than ten years. The pockets as shown in the illustration are rather too small. I would make them considerably larger. A noncommissioned officer should wear his chevrons on both arms. We did this before the war and until someone figured that a few cents could be saved by omitting one chevron. The company letter and regimental number should be placed on a piece of cloth of the color of the arm of the service, that is yellow for cavalry, red for artillery,

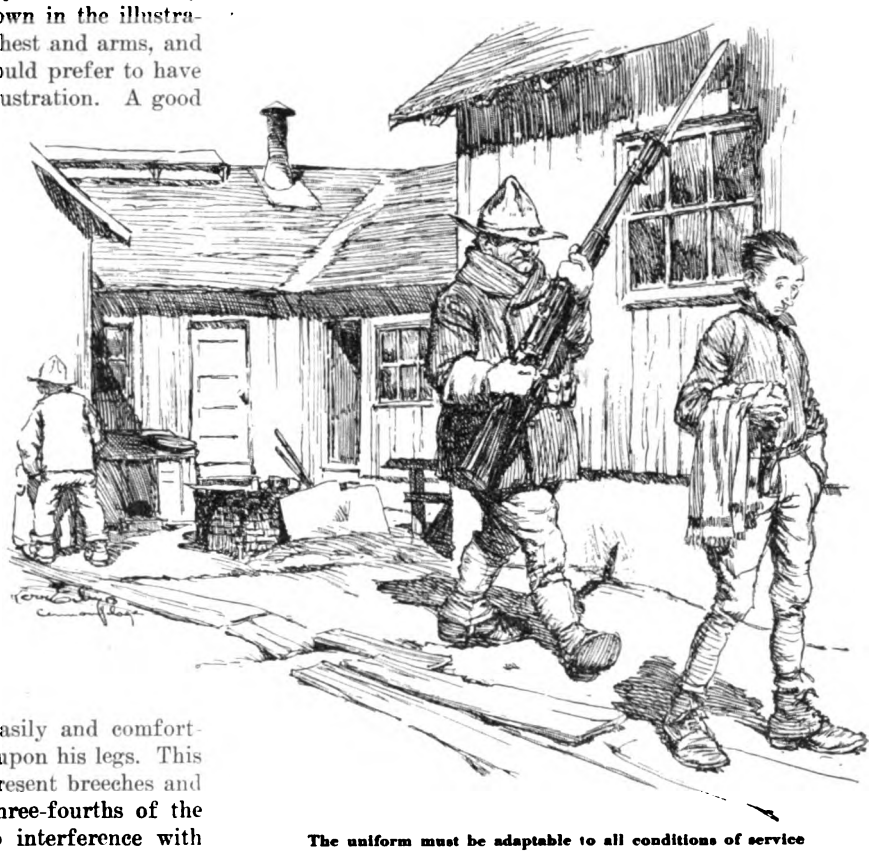
Digitized by Google

and so on. This shows at a glance the arm to which the man belongs, his company, his regiment, and with the division or corps devices absolutely identifies the soldier.

The tight cuff on the sleeve has some advantages, but it also has the disadvantage that when the soldier wears gloves, which he must do in winter, it is difficult for the glove to be tucked under the tight cuff and I believe that it is preferable for the glove to be worn under the sleeve rather than outside.

I am rather inclined to favor placing the lower pockets on the inside of the coat with only a buttoned flap showing on the outside. This presents a neater appearance and I believe is equally as useful and comfortable. The bellows can be made on the inside and the pocket can be so hung that when articles are carried in it they will not unduly bulge out the skirts of the coat. As shown in the illustration, the coat should be loose about the chest and arms, and the skirts should be rather full, and I would prefer to have them a little longer than shown in the illustration. A good tailor can make a loose garment so that it fits properly and hangs well from the shoulders. A poor tailor tries to fit a coat by drawing it tightly around the body of the wearer. The best fitting uniform I every had was one in which I could gather up at least six inches of surplus material in the chest and yet it hung properly and did not give any appearance of being too loose.

The long trousers and the high-topped shoes are excellent. They are practical. They have stood the test of years by men who spend their lives in the open. For cavalry, it might be desirable to provide breeches and the shoes should be several inches higher. For many years we wore long trousers in the cavalry service, both with boots and with leggings.



In order that a soldier may march easily and comfortably, there should be no undue pressure upon his legs. This condition cannot be obtained with our present breeches and spiral puttees. I have no doubt that three-fourths of the foot trouble among our men is due to interference with the circulation of the blood in the lower leg.

We need a dress uniform quite as much as a service uniform. The service uniform constitutes our working clothes, and no man likes to appear at social functions or on occasions of ceremony dressed in his working clothes. It would be just as appropriate for the farmer to go to church in his overalls or the business man to attend a formal social affair in his office clothes as it is for a soldier to appear on social or ceremonial occasions dressed in his service uniform. Every man likes to feel that he is properly dressed for the occasion, and the soldier cannot feel that he is properly dressed when he appears in society in his service uniform.

It has been recognized that morale is a very important factor in building up an organization and in obtaining success in war. A neat, attractive dress uniform adds greatly to the morale of our troops, and I am convinced that we would get twenty-five per cent more enlistments if our Army recruiting parties would appear as neatly and well-dressed as our Marine recruiting parties do.

I am thoroughly in favor of the trench coat as a substitute for the present overcoat and raincoat. The outer material should be of a strong, light-weight, wool material, like gabardine, and the inner lining of sufficient weight to give the necessary warmth. The coat should cost no more than the present raincoat and overcoat, would be much more convenient to carry, and, if well made, should certainly look neater than our present raincoat, and as neat as our present overcoat.

There are a considerable number of officers in the service who believe in the views expressed in this article. On the other hand, many officers have given the subject no especial thought or have been content to accept what we were given and to make the best of it. Many have the idea that we must be "military" at all costs, even to the extent of making ourselves uncomfortable. It is only by constant agitation and by keeping this matter before the Army that we can accomplish the desired changes.

The uniform must be adaptable to all conditions of service

Chas. D. Roberts
Colonel, Infantry

This article indicates a considerable grasp of the subject in general; and as a whole the suggestions for changes are well thought out, pertinent and practical.

The question of uniform is more important than it is usually thought to be. In time of war, serviceability necessarily becomes a paramount consideration. The stimulus of war is sufficient to make the service attractive, and "working clothes" only are required. The large number of men called to the colors "for the period of the emergency only," renders it highly desirable to make the uniform as simple as possible. The theatre of war is usually pretty well fixed and it is possible to adopt one kind of uniform as the standard that seems likely to be used throughout the war. Changes in the uniform during a war are not simple matters and mistakes once made can be

Digitized by Google

corrected only at great expense and after much loss of time. Similarly, when the war ends, vast stocks of uniforms are on hand which must, as a matter of economy, be used by the peace-time army as long as the articles are reasonably suitable and available.

In our army the uniform is very complicated. Our troops serve in every kind of climate and must be prepared to take the field under every conceivable condition as to terrain and weather. It is impossible to so standardize the uniform as to make one kind fit service in Alaska, in Arizona, and in Panama. After much experience we have virtually come to two kinds of uniforms, one of cotton for warm weather and the other of wool for cold, with various additional or substitutional articles added for service under certain special conditions, as in Alaska.

In peace time the war stimulus is absent and various means are sought to attract men to the service and make it possible to carry on military training and to keep alive the military spirit until the next period of mobilization. One of the chief means now being employed is that of offering to recruits the opportunity of learning trades. But we should not neglect the attractive effect of a smart uniform for dress occasions. Most soldiers are young men who have an instinctive and natural desire to appear to advantage among their fellows (male and *female*). The army can not offer pay to compete with civilian occupations, and we must take advantage of every other opportunity to make the service attractive.

In my opinion the basic mistake in our present uniform is that it attempts to combine *smartness* with working efficiency and comfort. The result is unsatisfactory from either point of view. The present drab uniform is ugly, as well as uncomfortable and unsuited to field service anywhere.

In making changes we must not be influenced too much by our experiences in France. That was abnormal service for American troops and, perhaps, may never be repeated. Our long experience in service everywhere must be given full weight. We must remember that in tropical and subtropical regions the sun replaces the rain as the chief enemy to the soldier's comfort. Imagine a man in an overseas cap or a trench helmet marching under a tropical sun.

Taking up the proposals in the article more in detail:

Ornaments and insignia on woolen coats should be of cloth or embroidery sewed on. On cotton uniform they must be detachable for washing unless made of wash material, which is almost impossible. The divisional shoulder patches have been retained, and if made in various colors, as was done in the 81st Division—the first of all American divisions to use shoulder insignia—provide sufficient means for indentification. The hat cord could be replaced by a narrow hat band of appropriate color, which would probably be more satisfactory.

It is hoped that the overseas cap is a thing of the past. The campaign hat is the best headgear we have ever had for all purposes, and should be retained as part of the field uniform.

Almost everybody in the army wants a service coat with turndown collar and bellows pockets, loose enough for comfort. The tight cuff would be good for cold weather, but entirely unsuited to warm weather when a circulation of air around the wrist is essential to comfort. A buttoned cuff should be provided in the woolen coat.

I agree emphatically with the writer that breeches are entirely unsuited for foot troops. Loose trousers should be provided. However, the high shoes are not practicable for a large army, due to expense, and especially to the amount of leather needed. The present shoes, with a low, canvas legging of gaiter style, should be worn in the field. The type of legging used by our troops during the Spanish-American War was the best ever provided and, with an improvement of the strap passing under the instep, would be suitable. On no account should the legging fit closely around the ankle or calf, since the ankle must be flexed at each step, and the calf muscles must move freely.

The trench coat could well replace the overcoat and raincoat; but a lighter grade, well ventilated and without lining, should be provided for hot climates.

To sum up: (1) Give us a really serviceable, comfortable field uniform, "working clothes" made for utility, and of woolen or cotton to suit the climate. This would be the only uniform worn in war and the only one of which large stocks should be kept on hand.

(2) Give us back our plain, but smart, blue dress uniform. Allow organizations to adopt distinctive insignia, etc., for wear with this uniform.

Let this dress uniform be replaced in the tropics, both for officers and men, by a white uniform similar to that now worn.

C. W. Exton

Colonel, Chemical Warfare Service

General Fries has requested me to answer this letter for him. We have discussed the matter together, however, and I am really expressing his views as well as my own.

So long as we have but one uniform of olive drab for both field and dress occasions, we must approach this subject with that fact in mind.

It is admitted, I think by everyone, that the two essential qualities of a uniform are smartness and serviceability. As to smartness, it is believed that our uniform, with the skirt of the coat a bit longer and with the addition of the Sam Brown belt, is the smartest field uniform worn by any army to-day. As to serviceability, in cold weather the high collar of our uniform makes it much warmer and more comfortable than an open collar, which, as worn by the British, always requires some sort of neck scarf. In warm weather, the open collar would require a clean, well-laundered shirt. This might be obtained by the officers, but for enlisted men it seems questionable.

We seem to be committed to the olive-drab shirt for field service in the tropics and during warm weather in the United States. I doubt if this can be improved upon. For garrison wear, the khaki coat with the high collar is very smart looking and reasonably comfortable, and does not require a well-laundered shirt. There are some advantages in this. As to the long trousers, they would be quite impracticable for the mounted services, and I doubt very much if they would be found more advantageous for the infantry, especially as they would require a heavy, high-topped shoe at all times. The hat, while it might be extremely comfortable, would soon assume the characteristics of the wearer, the result being little uniformity.

I believe that our present uniform if properly fitted, not tightly, as generally worn, but easy and comfortable as it should be worn, will be found to be the most satisfactory uniform yet devised.

R. H. C. Kelton

Colonel, Coast Artillery Corps

Major Embury's views on the subject of army uniform are not only well written, but the arguments as set forth are quite correct and well presented. The logical reasons for

Digitized by Google

putting soldiers into uniform are the same to-day as when this scheme was first adopted many hundreds of years ago.

The author makes as his primary point that in any uniform for campaign purposes, "The extreme of comfort is of the highest value," but, following this statement, remarks that in the history of this Government, and probably in that of all other governments (in reference to this same feature), all types of uniforms have been governed by desire for appearance rather than utility and efficiency, and that the only recent noteworthy exception to this policy as far as the United States is concerned, has been the change of color from blue to olive drab.

The author shows that the original conception of uniforms had no regard whatever for the comfort or convenience of the men inside of them, and involved only the ideas of gaudy color and striking design. At the present time, we are prone to regard the campaign uniform as "a suitable set of *working clothes* for a soldier," but, unfortunately, except in the matter of color (referred to above), the uniform does not fulfill the requirements of this standard. While we have adopted a neutral color, we have retained the constricting feature of tight-fitting clothes, and thus have produced only a simplified dress uniform in olive drab. We have sacrificed most of the characteristics which might be said to produce a soldierly or striking appearance in the public eye, but have adopted very little to add to the soldier's comfort in campaign.

In other words, we have tried to produce in a single outfit a compromise which does not accomplish either one of these two essential ideas: *First*, a good-looking, peace-time uniform, which adds to the prestige of the military man in the public mind, and to the self-esteem of the individual soldier. *Second*, a comfortable, satisfactory set of working clothes for a soldier in campaign.

If, in this effort to effect a compromise, we fail signally to achieve either of these *desired results*, it seems only logical that we should abandon the compromise and adopt a dual system of uniform which will produce the *proper effect* in time of peace and provide the necessary equipment and desired efficiency in time of war.

Personally, I am in favor of returning to the blue dress uniform for peace-time purposes, discarding, however, the military full dress and making any social or evening uniforms, authorized for the commissioned personnel, entirely optional. For purposes of campaign, the uniform shown in the author's illustration is of simple design, and evidently produces what the author of the articles calls a "comfortable set of working clothes."

If a campaign uniform is designed as such, and not diverted by any efforts to make its appearance dressy, and then a garrison uniform is designed for good appearance, we may succeed in producing something satisfactory under the head of military uniform.

The author's criticism on the various articles of the present olive-drab uniform are sound and well expressed, and his scheme for simplifying the question of sizes and fit is unquestionably a practical solution of the troublesome problem of manifold sizes.

The scheme of having one set of clothes in which to work and a wholly different set of clothes in which to take recreation or amusement, is almost universal among civilized peoples. All classes of tradesmen, artisans, skilled labor, and even a very large proportion of the unskilled labor in this country, to-day provide themselves with characteristic clothing in which they do their manual work, and yet possess some outfit of better-conditioned clothing, of distinctly different quality and design, which they put on in the evening and on Sundays and holidays.

A set of "working clothes" for the military man is recognized in the Coast Artillery, by the issue of the blue denim for general fatigue and for work around the guns; the same idea has long been recognized in the United States naval service, and there seems no reason why this idea should not be extended to include the soldier in campaign. A uniform designed to meet these three cardinal principles—(a) the maximum comfort of the soldier from a standpoint of muscular activity and protection from climatic conditions, (b) identification as to his own troop units, (c) concealment from the enemy—should solve the problem for campaign,

Field service in the winter time cannot be performed to good advantage in a social evening costume

leaving to the garrison or peace-time uniform the characteristics of color and dressy fit.

J. R. R. Hannay

Colonel, Quartermaster Corps

The question of the adoption of a uniform is necessarily influenced by three major factors, viz:

(a) Utility,
(b) Cost,
(c) Psychology.

It is believed that these are given in their order of relative importance. Unfortunately, in the adoption of a uniform for the United States Army, a futile effort has been made, by compromise, to include in a single costume these three dominating factors.

Prior to the World War, when our army had not reached its present proportions, and the total necessary outlay was comparatively small, it was deemed advisable, in an attempt to cover the requisites of utility and psychology, to provide a service uniform of olive drab for field work and a dress uniform of blue, designed to inculcate neatness and soldierly appearance by engendering pride therein. The uniforms were not entirely satisfactory, however, in obtaining the desires upon which they were predicated, inasmuch as the dress uniform was not sufficiently smart and the field

Digitized by Google

uniform not sufficiently utilitarian. Mere man is prone to point the finger of scorn at the furbelows of women's dress, but if we study human nature we find that not only in the lower animal kingdom, but throughout the evolution of man the male is still, by instinct, really the "cock of the walk." and although there is no gainsaying that "fine feathers do not make fine birds," a well-dressed, neat-appearing man does, naturally, take more pride in his demeanor than one who is carelessly or slovenly groomed. This is so particularly evidenced in the case of the soldier that it has become a truism that "A neat and orderly soldier is also the best soldier."

The need for an army of adequate size in the United States to protect our huge and growing interests has necessitated the increased army created by the Act of June 4, 1920. To properly uniform the army so created without exorbitant cost, it is necessary to limit the soldier to one uniform, and in order that the one uniform prescribed shall fulfill the two other requisites of utility and psychology insofar as possible, in view of the fact that the psychological part can not be eliminated without detriment to the efficiency of the army, a compromise is still necessary.

A decision must, therefore, be reached as to how the maximum neatness and soldierly appearance can be obtained without any grave loss to comfort and usefulness.

It is believed that the uniform as suggested by Major Embury does, in general, fulfill these principles, such a uniform to comprise a loosely fitting sack coat with large bellows pockets, open at the neck, and worn with a flannel shirt and black tie, the sleeves of the coat capable of being buttoned close to the wrist; long trousers sufficiently large to be drawn on over the shoes, worn with lace half-boots, high enough to hold the bottom of the trousers firmly within the tops thereof. It is believed that the tight-fitting breeches now prescribed for the army are, from an anatomical standpoint, a grave mistake, and do materially restrict the marching ability of foot-troops as well as produce discomfort to the wearer and require an undesirable length of time for dressing. The expense and difficulty entailed in providing a sufficient number of sizes to properly fit all men in breeches should be given the weight of consideration it deserves.

Too much attention has been given to the detail of securing low visibility and the use of the single color, olive drab, as it is believed that the evolution of camouflage has thoroughly demonstrated that through the breaking of solid colors low visibility is best secured. If this hypothesis be correct, it is not understood why it should be thought necessary to have such minor details of the uniform as buttons and ornaments of self tone. Buttons of the uniform should be of brass, and the soldier induced to emulate our army of twenty or thirty years ago in the constant use of the button stick and buffer. Shoulder straps in the distinctive colors of the various arms would add materially to the appearance of the uniform, and it is believed that the lapels could be likewise faced in color, showing on one side the division number and on the other the regiment number and company letter. The bronze ornaments at present worn are a nuisance to the wearer, too small to be read except at arms length and impossible of extemporization, such as is often necessary in the quick creation of a large army. It is therefore distinctly advisable from every standpoint that these insignia should be of colored cloth, and not less than three-quarters of an inch in height. That the principle of self tone in chevrons and insignia has been abandoned is apparent from the recent adoption of a blue back to the chevron, which is now worn only on the left arm. If coloring is added to the uniform, it should not serve, however, to plainly mark the individual for the benefit of an enemy sharpshooter. When the individual gets within such close range, visibility of the individual can not be prevented, but his rank should not be glaringly portrayed or so placed that with his rifle in the aiming position his insignia is a bull's eye covering his heart.

Major Embury's remarks relative to the overcoat are pertinent and well taken, and it is believed that the adoption of the trench coat, with waterproof shell and detachable lining, is the most serviceable garment which can be provided for the soldier, serving the dual needs for protection from rain and cold.

The soldier's headgear, however, is difficult of solution, inasmuch as it is now palpable that he must be equipped with a metal helmet. In view of the fact that it is not believed that a helmet can be devised which will be both sufficiently strong to afford casualty protection as well as that from sun, rain, and cold, and of sufficient lightness to the wearer when worn continuously, it is apparent that he must be provided with two kinds of headgear, both of which must be carried on the person. It is believed that the fedora recommended by Major Embury is too susceptible of conversion into multitudinous shapes suiting the varying idiosyncrasies of the wearers. It was because of this habit of enlisted men that the brim of the campaign hat was stiffened. Furthermore, the fedora has no material advantages over the campaign hat for use in cold weather or for stowing away while the helmet is in use, inasmuch as only the most expensive felt hats can be so folded and still retain any vestige of shape. The cost thus becomes excessive without material gain. The campaign hat as now worn is a more soldierly headgear than the fedora, but it is not a practicable war-service hat, in view of the fact that it can not be conveniently carried when the helmet is worn and does not provide winter protection. It would appear, therefore, that to provide the requisites for war service there must be prescribed a small cap which can be carried in the pocket, similar in general character to the overseas cap, but modified so that it can be pulled down over the ears and so that it will have some form of visor for sun protection. The necessity will still exist, however, for some form of smart, soldierly headgear for garrison use, and this should be either the garrison cap or the campaign hat, preferably the latter, but not both.

Admitting, in a measure, the correctness of his statements, it is believed that the writer's criticism anent the slovenly appearance of the American Army in the A. E. F. is not wholly justified. The problem involved in the supply of an army so enormously expanded, as well as the discipline and instruction so necessary thereto, did not permit securing the maximum neatness and soldierly appearance amongst the American forces in France. However, it is believed that, in general, the United States Army compared more than favorably with the troops of other nations in regard to looks, if not comfort. It is believed that the American Marine, not the "blue-jacket," is the best dressed and neatest soldier in the world, and this despite the fact that his uniform is practically identical with that of the army. The more favorable results obtained by the Marines are obtained by greater administrative attention being paid to the uniform, although it must be said in all fairness that this result is naturally more easily attained in a force so much smaller than the Army, which is, furthermore, imbued with a pride in the uniform resulting from constant affiliation with the troops of foreign power, and the very careful inspection made in regard to the appearance of men being

Digitized by Google

granted shore leave from ships when visiting foreign ports.

That our army is sorely in need of a more comfortable and suitable uniform can not be gainsaid. It is hoped that more advocates of sensible attire for the soldier will come forward to urge upon the War Department the advisability of what are believed to be essential and necessary changes, despite the well-founded argument of those individuals who oppose all change as precluding the possibility of uniformity in the soldier's attire.

Evarts Tracy

Lt. Col., Engineer Reserve Corps

Major Embury's suggestions for the uniform are extremely well studied, and, from my point of view, the illustration shows a uniform which would be military in appearance, comfortable and, with some modification for the tropics, well suited for all climates.

I have always thought that the British field uniform as worn in the tropics, consisting of light wool shirt, khaki blouse, khaki shorts, similar to our so-called athletic drawers, bare knees, spirals wound directly on the leg, and brown straw helmet, is most comfortable and suitable for such climates, and would be a Godsend to our troops who swelter in their tight breeches and heavy campaign hats.

I have spent considerable time for the past thirty years in the open country in different climates, varying from the tropics to the Arctic Circle, and have experimented to quite an extent with outdoor clothing.

I think everyone knows from personal experience the so-called fedora hat is all Major Embury claims for it, and I have never heard any officer or enlisted man who was not in favor of the open-neck and turn-down collar of the blouse.

Pockets that will hold something without tightening and spoiling the set of the blouse are absolutely essential, and the bellows pocket is the only solution. I should recommend them even larger than indicated in the illustration.

When the staff at G. H. Q. in France studied a new field uniform, they proposed, according to my recollection, larger pockets, but inside the coat, only the slit and flap appearing outside. It is obvious that the contents of such a pocket will bulge the blouse, destroy its hang, and make it tight and uncomfortable, whereas the bellows pocket simply expands on the outside and has no effect on fit or comfort.

The trousers and shoes are excellent, for the reasons Major Embury states. For the shoes, I should have a bellows tongue, and belt-lacing, instead of shoestrings, and the eyelets should be large, one-quarter of an inch at least in diameter, for the sake of quick and easy lacing.

It is very true that the idea of what is military looking or not is a contemporary state of mind, but this uniform is suitable and smart, and it would take no great period of time for either soldier or civilian to realize that it is also distinctly military.

A uniform that the wearer is proud of has a strong bearing on his morale and a distinct psychological influence on the public.

I had this psychological influence brought strongly to my attention last summer.

A powerful roughneck came on board a Yukon River boat, fighting drunk, and started to make trouble. A Royal Northwestern mounted policeman on the boat came up from behind and tapped him on the shoulder. The man, cursing, drew back his fist and turned around, then dropped his hand and went quietly to his bunk.

The next morning he said to the policeman, "By God! I'm glad this isn't Alaska, I get mean when I'm full, and I'd have been in jail with a broken head or worse. I would have licked anybody that touched me, but *I saw your uniform.*"

M. G. Martling

First Lieutenant, Corps of Engineers

The question of changes in the army uniform seems to be constantly arising, and Major Embury's article may be regarded as a more or less typical expression of the viewpoint of those who desire a change. Major Embury states his objections to the present uniform to be as follows:

1. Difficulty of identification of unit,
2. Discomfort,
3. Lack of smartness.

The difficulty of identification is fundamentally a matter of insignia and not of uniform. The difficulty in recognizing the unit to which a man belongs is important if it is proven that such identification is essential at a considerable distance. It would appear to the writer that the definite identification of the organization of an enlisted man, as a general rule, is essential only under conditions where a conversation might be carried on—that is, about the distance mentioned by Major Embury as the limit with the present insignia. The difficulty in obtaining insignia in the A. E. F. is not necessarily inherent in the prescribed insignia, but like many other deficiencies during the war, was due to the total unpreparedness of the United States. An objection to the Springfield rifle on the same basis would be equally valid.

For the identification of the branches of the service, the American forces in Germany are at the present time using small circular discs of cloth of distinctive color slightly greater than, and worn beneath, the button on the enlisted man's collar. They are readily recognized, but are of no particular value, except to add a touch of color to the uniform and are a disadvantage in that they are difficult to keep clean.

Major Embury's comments on the overseas cap would appear to be justified, but it is thought that he errs in being too temperate in his arraignment.

There is no doubt that the uniform furnished the enlisted man during the war was of exceedingly poor quality, both as to fit and material, but this again was due to lack of preparedness and not to the style of uniform in use. Major Embury may feel that "easy, careless gait" is a soldierly qualification. Many prefer that a command display what is commonly termed "military precision," or even what he calls "wooden motions." If freedom of motion is the ultimate ideal of military dress, we should adopt the "sport shirt" and be done with it.

What is or is not "military" in appearance is undoubtedly a matter of custom, but it is a singular fact that of seventy-seven figures in the Encyclopedia Brittanica (Uniforms—P. 556, et seq., Vol. XXVIII), covering army uniforms of the principal nations from 1845 to 1910, but three have low or roll collars. This would seem to indicate that the custom of wearing a high collar is fairly well established at any rate.

Major Embury's suggestion in regard to dress uniforms appears to be sound and worthy of consideration. It is suggested that three uniforms be furnished each enlisted man:

1. A suit of O. D. one or two-piece overalls as at present, for fatigue and drills other than disciplinary.

Digitized by Google

2. An O. D. uniform of the present type for disciplinary drills, retreat, etc.

3. A blue dress uniform for ceremonies, leave, etc.

A consideration of Major Embury's suggested uniform as shown by the illustration develops the following objections:

HAT—But little protection from the sun and rain; the horizontal crease collects rain and snow much the same as the overseas cap Major Embury objects to.

BLOUSE—Objections to the present blouse seem to be based chiefly on the following assumptions:

(*a*) That the collar predisposes the wearer to throat trouble.

(*b*) That the collar interferes with breathing when the pack is worn.

(*c*) That the blouse binds across the shoulders when the back and arms are used.

(*d*) That the pockets are too small.

Considering these objections in order:

(*a*) This objection could be definitely sustained or disproven by the Medical Corps. The writer's experience would seem to show that it has no such effect. At the time he was first examined for a commission the surgeon considered his case as somewhat doubtful on account of his throat, but finally passed him. Since then he has worn the uniform every day for nearly four years and has never had any further difficulty with his throat.

(*b*) Elimination of the restriction of the throat by the pack is obtained by the proper adjustment of the pack, and when a man has been taught how to make and adjust the pack properly, further difficulty is minimized.

(*c*) The uniform blouse does bind across the back when it is worn to work in, but up to the present time the writer never saw a coat which would not. Practically all good workmen remove their coats before they attempt to do any work. Contractors of long experience have been known who would not even have a man "on the job" who attempted to work in a coat. It is seriously doubted if it is possible to design a coat which is loose enough to permit free action of the back and shoulders which will not wrinkle, and chafe the back, when the pack is worn. No coat of ordinary material with which the writer is familiar provides room for exertion and is adapted to wear with a pack, and it is seriously doubted if the two features are compatible.

(*d*) Pockets are not an essential part of an enlisted man's blouse, and might well be omitted. He is provided with breeches' pockets for handkerchief, money, tobacco, knife, etc., and his other field equipment can be carried in the pack without disadvantage. Increasing the size of the pocket will not help the appearance of the wearer and will only encourage him to burden himself with additional unnecessaries which may well be thrown away or placed elsewhere. As a matter of fact the pockets in the blouse are practically inaccessible when the pack is worn anyway. The blouse in Major Embury's plate appears to be a hybrid. If pockets are placed on it at all there does not appear to be any good reason why the upper ones should be of the "Stanley" pattern and the lower ones plain patch pockets. The blouse is so loose around the waist that it would "bunch" under the belt, which, aside from its poor appearance, is exceedingly uncomfortable in hot weather. The sleeves are unique, to say the least, for any blouse that makes a pretense of smartness. Just how Major Embury planned to fasten on the buttons at the wrist is unknown but in the place they are, they would be subjected to a great many strains and would be difficult to keep sewed on, as well as extremely uncomfortable in hot weather when they would bind and chafe.

The blouse is apparently patterned after the British officer's tunic, but even its English origin does not appear to warrant copying their chevrons by putting the point down as shown.

The trousers are not as practical as breeches. The loose folds at the bottom have a bad habit of catching in every shrub or briar, and accumulate mud and moisture in large amounts with the slightest provocation. A pair of soaking-wet trousers flapping about the legs are far from comfortable. It is true that trousers have been so worn by men in civil life for years, but it is believed that this was due to the fact that it has been difficult for a civilian to procure breeches at all outside of the larger cities, and then only at a considerable cost. At the present time the tendency seems to be for men on construction work to wear breeches similar to the Army pattern. The objection to the breeches —that they cannot be put on over the shoes—seems to be a matter of taste. Personally, the writer prefers putting on trousers or breeches before muddy shoes, since dragging trousers over muddy shoes covers the inside with mud which works down inside of the sock and chafes the foot, causing more discomfort than wet feet alone do if they are clean.

The boots shown appear to be practical only for cases where a man has but the pair of boots he is wearing. With an additional pair in the haversack, the weight would be materially increased over a pair of shoes, and the soldier's pack at the present time is, if anything, too heavy. Figures are not available but it seems probable that the cost of two pairs of these boots would be considerably greater than two pairs of the present shoes, and one pair of leggings or puttees.

Officers' Reserve Corps strength since February, 1920

Following the passage of the Re-organization Act approved June 4, 1920, appointments in the Officers' Reserve Corps were suspended from June 16 to October 4, 1920. Except for the month of December, when an increase is shown due to action on applications which had accrued during the period of suspension, there has been since April, 1920, a steady decrease in the strength of the Officers' Reserve Corps.

As a result of the July and October examinations, approximately 800 Reserve Officers were appointed in the Regular Army.

By Months.

British Views on the Ponton and Other Standard Bridging Equipage

As a Result of the World War

(Reprinted from the *Royal Engineers Journal.*)

[*Note.* American Engineers will find much of interest in this excellent review of the tendencies of British opinion with reference to a proper standardized bridge equipage for the Army, based on the experiences of the World War. As for ourselves, we gained very little practical experience in the use of standard equipage during the war, for the reason that we were not in it long enough to develop any standards to a working basis. We must accordingly give the more weight to the views of our allies.

British progress in the readjustment of bridging standards since the war seems to closely parallel our own in that there has been "a great deal of discussion and a certain amount of experimental work." We need more of both. The decked ponton, characteristic of the British equipage, has never found favor in this country. Unless the boat be very shallow in proportion to its width it is extremely doubtful whether the addition of a deck will "double the available buoyancy." It is certain, moreover, that the addition of a deck will make the boat more difficult to maneuver, and will detract considerably from its usefulness as a ferry.

The French 1915 model ponton supports 11 tons with full submergence, and 8 tons with a freeboard sufficient for safety in swift streams like the Rhine or Rhone.

It would appear that the number of types of bridges might be reduced to three, by the elimination of the bridge for light wheeled transport. While the addition of a new type of bridge does not necessarily add new type equipment, it does seriously affect the problem of adjusting loads to wagons. Furthermore, changing a bridge from one type to another is almost certain to introduce complications, and to require stopping all traffic during the process of reconstruction.

A general summary of the loads to be carried and the other conditions to be fulfilled by any new type of equipage to be adopted, is certainly necessary as a preliminary to a proper design.—ED.]

1. A great deal of discussion and a certain amount of experimental work has been carried out on military bridging during the last two years, and the whole subject needs now to be reviewed.

2. Military bridging can be divided into four phases:

(*a*) The construction of a bridge to enable infantry to fight their way across an obstacle which is closely defended by the enemy.

(*b*) The construction of a bridge to enable field guns and first-line transport (light loads) to cross an obstacle which is under shell fire.

(*c*) The construction of a bridge to enable lorries (trucks) and the 6-inch howitzer and 60-pdr. gun (medium loads) to cross an obstacle.

(*d*) The construction of main-road bridges to take siege artillery and the heaviest military traffic.

It is only proposed in this paper to discuss bridging equipment and to leave out the whole question of improvised bridges. In this way we are at once reduced to two types—the service ponton equipment and stock-span girder bridges. The former will be taken first.

3. As regards (*a*) it is generally agreed that a light floating bridge (of the cork-float type) fills our requirements. The old idea of a bridge of half sections of pontons is too heavy and cumbersome for use under fire. A light floating bridge of this nature requires to be standardized. Many different types were used during the latter part of the war. Some were better than others, but they were all capable of improvement. An inferior design may cost the lives of many officers and men, and we should not be satisfied with any but the very best possible design.

4. As regards paragraphs (*b*), (*c*) and (*d*) we know at the moment that we can produce satisfactory bridges to fulfill our requirements in the following three ways:

(1) By constructing a light bridge by using decked-in pontons at 15 feet intervals and a superstructure of bridging baulks and single chessing.

(2) By constructing a medium bridge with piers which consist of six half sections of decked pontons and 21-foot steel joists with double chessings.

(3) By constructing a heavy bridge with piers which consist of eight half sections of decked pontons and 21-foot steel joists with treble chessing.

We must now discuss the methods by which we can obtain the full use from these three bridges; then when we have collected our ideas as to their correct use we can proceed to discuss the more detailed designs of these three bridges.

5. Now, the suggested method of using these bridges can best be illustrated by examples:

The infantry have forced their way across a river but are hard pressed and require field artillery support. The river is under heavy shell fire and the construction of a bridge will be a difficult undertaking. The lightest and best possible ponton equipment which will carry field guns is required. For this work a ponton equipment in its present form, or something very like it, is necessary. We will now take another example. The infantry have crossed a river and are driving the enemy back rapidly. The river is not under heavy shell fire, and will probably soon be out of range of the enemy's field guns. There is a demolished bridge on the main road across the river. In this case the river should at once be bridged at this point with a ponton bridge to carry medium loads, for it is obvious that lorries will want to cross this river at the earliest possible moment. In some cases a light bridge will be built first and converted later to a medium bridge, but, as a rule, if light bridges are built first to take the field guns they should be constructed clear of the main roads. The medium bridge can then be built without interfering with the passage of artillery wagons over the light bridge. If there should be a shortage of pontons, the light bridge can be broken up at the last moment to form the last few piers in the medium bridge. In many cases no light bridges would be built at all and the first bridge put across the river would be a medium bridge. The difference in the time required for the construction of a light and medium ponton bridge will not be great. A river such as the Aisne at Soissons may be taken as an average case, and is about 200 feet wide; and the difference in bridging this river for light and medium loads would probably not be more than one hour. It is true that much more material and transport is required to bridge such a river for medium loads than light loads, but the total amount is small in either case. Fifteen lorries with trailers would be sufficient to

Digitized by Google

bring up the equipment for a medium bridge across this river.

6. The light bridges built with ponton equipment should therefore be considered as emergency or fighting bridges. The approaches would not, as a rule, be required to be timbered or made good, because the bridge should only be in use for a short time, and the site of these bridges might often be chosen from tactical reasons rather than from a point of view of their proximity to a road, or suitability of the approaches, etc. The equipment for the construction of these bridges would be drawn from the Divisional Bridging Train; it would be taken as far as possible by lorry, but might require to be horse-drawn to the site of the bridge.

7. The equipment for the medium bridges should be sent up from the Corps Bridging Train, being supplemented, if necessary, by the Divisional pontons.

8. In colonial warfare the light bridges might be of comparatively greater importance, but the use of lorries and construction of main roads is extending rapidly to the colonies. Moreover, the field artillery and first-line transport may become tractor-drawn, in which case a bridge for light loads will probably cease to be required.

9. As regards sub par. (*d*) in par. 2, we have seen that a bridge to take heavy loads can be constructed from the service pontons (decked-in) by using piers of eight half sections and eight steel joists. In European warfare, when the siege artillery may be close up with the field army, it might be desired to build a heavy bridge straight away instead of a medium bridge. As a rule, a comparatively small number of heavy bridges would suffice; for instance, on a front of three miles we might find, say, three medium bridges and one heavy bridge, some or all of which might be replaced later with girder bridges. In colonial warfare, and even at times in a European war, the army might advance purely as a field army without siege artillery, and medium bridges might cover all requirements.

10. The present service equipment includes a bridging trestle—the Weldon Trestle. This trestle is required in connection with the ponton equipment for the following work:

(*a*) For use in tidal ramps.

(*b*) To save the risk of damaging pontons by grounding on a hard bottom near the banks.

(*c*) For use over swampy ground on the approach to the bridge.

(*d*) For crossing dry gaps or craters on roads.

In pre-war days, when the old medium bridge (present light bridge) was the main military bridge, there was every reason to retain the Weldon Trestle for the work indicated above; but now that this bridge is an emergency bridge, the necessity for the Weldon Trestle is far less apparent. If the water is shallow near the banks and the end ponton grounds, it may be damaged, but the bridge will not fail (especially with the new decked-in ponton, which is considerably stronger in this respect), and when constructing a fighting bridge the risk of damaging a ponton is of small importance compared with the loss of time in erecting a Weldon Trestle.

During the war, Weldon Trestles were used on many occasions as indicated in (*d*), but for this work it seems eminently desirable to erect a trestle which will carry medium loads.

Now, a new trestle has recently been designed of steel, which weighs 40 per cent more than the Weldon Trestle but will carry medium loads (the Weldon Trestle will only carry light loads). This trestle is quicker in erection than the Weldon Trestle, and it is now suggested that this trestle should be adopted instead of the Weldon. It would rarely be used with a light bridge, but would be of great value for medium bridges, and a tower built of two of these trestles would serve to carry heavy loads.

11. As regards girder bridges, a large number of types were evolved during the war, but with two exceptions they all aimed at carrying the heaviest loads over spans which varied in length up to some 150 feet. The two exceptions were the Inglis light and Inglis heavy pyramid bridges. Now a conference was held at Chatham in August, 1920, to consider the retention of the various bridges. The Inglis light pyramid bridge was considered worth retention to assist in the first phases of an advance. The Inglis heavy pyramid was not considered worth retention. Of the various remaining girder bridges it was found necessary to recommend the retention of five different types and the introduction of a further light girder bridge for medium loads. Since that date, a new type of girder bridge (the box girder) has been designed, which may replace all the shorter stock-span girders, and this bridge is adaptable to carry any desired load (light, medium, or heavy). In a few months' time we shall know considerably more about the possibility of girder bridging in this manner, and it is therefore not proposed to discuss girder bridges any further in this paper.

12. We can now consider the detail design of the three types of ponton bridge enumerated in the first part of par. 4. It is generally agreed that it is important to have the simplest possible type of ponton equipment in which every part is interchangeable and adaptable and which contains as few separate and different parts as possible. The decked-in ponton appears to be desirable in almost every way. By using decking the available buoyancy is almost double, and the ponton remains quite easy to row. The swamping of a ponton by the water rushing over the bows in a swift stream is rendered impossible. The additional weight is 600 pounds per complete ponton at present, but this can be reduced—probably to about 400 pounds (or even less). If this can be done, the decked-in ponton appears to be quite satisfactory for all three types of bridge. It has been pointed out that the half ponton is no longer required and that the service ponton should be made in one piece. This, however, has the following disadvantages:

(1) A pier of six half sections can not be made.

(2) If one end of a ponton is smashed, the whole ponton is rendered useless for the time being.

It would therefore appear to be desirable to retain the bipartite ponton. In fact, the present ponton, if decked-in and fitted with strengthened couplings, will provide a very satisfactory boat for every type of ponton bridge.

13. As regards the light bridge, it has been urged that the bay should be made 21 feet instead of 15 feet, so as to simplify the changing from light bridge to medium bridge. Now the light bridge carries a 2-ton axle load, and if it were a matter of strengthening this bridge to carry a 3-ton or 4-ton axle load, it might be possible to carry out the work with little or no obstruction to the traffic. We have, however, to increase the strength of the bridge four times, *i. e.*, to take an 8-ton axle load. It is, therefore, out of the question to do this without obstructing the traffic, but can we introduce any system whereby the change over will be very rapid, so as to cause the least possible obstruction to the traffic? A suggestion has been made that the light bridge should consist of 21-foot bays and piers of two pon-

Digitized by Google

tons side by side. This, however, is not recommended for the following reasons:

(1) The construction of the light bridge would become a slower operation and therefore much more difficult under fire.

(2) It is doubtful if the process of changing bay by bay from light bridge to medium bridge would be of any great advantage. On a river which was 200 feet wide the whole operation of changing from light bridge to medium bridge could be carried out in one hour by breaking up the light bridge entirely and rebuilding as a medium bridge.

(3) In most cases the light bridge (if built at all) should be constructed clear of the site for the medium bridge, and this problem would not arise.

14. A continuous girder has been designed by Major Inglis for use with the ponton equipment and will be tested in some six months' time. This will probably provide a very good main-road bridge for wide rivers, but will hardly fill our requirements for hasty ponton medium bridging over average-size rivers in a rapid advance. It is possible that the box-girder design may be satisfactory as a continuous girder in the Inglis pattern bridge. The decked-in ponton will be very suitable for use under a continuous girder.

15. In the equipment which has been tested at Christchurch the following are the only parts required for any of the three bridges:

(1) Decked-in ponton.
(2) Existing pattern ponton saddle.
(3) Existing pattern bridging baulks.
(4) Existing pattern chesses.
(5) Existing pattern ribands.
(6) New design of short baulk.
(7) New design of steel joist saddle.
(8) New design of steel joist road-bearer.
(9) New design of steel kerb.
(10) New design of trestle.
(11) The existing pattern accessories such as anchors, cables, etc.

It is thought that when certain detail improvements have been made and the weight of the decked ponton reduced, this equipment should fulfill all the requirements of the Army.

16. There remains the question as to how and where the ponton equipment should be carried. In the eventual future the transport of an army will no doubt travel on tracks, but for the moment we must keep to lorries and horses. The following is therefore suggested:

(*a*) The Divisional Bridging Train should carry light bridge equipment only (but pontons decked-in); the equipment to be carried in a strengthened type of ponton or trestle wagon towed behind a lorry, but capable of being horse-drawn when necessary. The lorries themselves to carry a bridge equipment of the cork-float bridge type. In this way the Division will be always prepared to meet any emergency with its own bridging equipment.

(*b*) The Corps Bridging Train to carry pontons and superstructure for medium bridge (this is also suitable for a shorter length of heavy bridge) and a small reserve of timber baulks for the light bridge. Also a small reserve of the cork-float type of bridge. Medium bridge ponton equipment would be sent up to Divisions as and when required.

(*c*) Army Bridging Parks and Engineer Stores would hold reserves of every form of ponton equipment, girder bridges, and bridging stores. Any girder bridges could be sent up by lorry to the Corps or Division when required.

17. To sum up, therefore, the following are the recommendations made in this paper:

(*a*) Further detail experiments to be carried out to reduce the weight of the decked ponton and, if successful, that this type of ponton should become universal.

(*b*) The ponton equipment as tested at Christchurch to be standardized after further trials (and possibly minor detail alterations) as the ponton equipment for the Army.

(*c*) That a floating bridge of the cork-float type (but not necessarily cork) be standardized.

(*d*) That the Divisional Bridging Train should carry light ponton bridge equipment in trailers behind lorries. The trailers to take the form of strengthened ponton wagons capable of being horsed. Also that these lorries should carry the standardized cork-float bridges.

(*e*) The Corps Bridging Train to carry medium bridge ponton equipment and the new type steel trestle on the same type of trailer as used in the Divisional Train. This equipment will build up into a shorter length of heavy bridge as desired.

(*f*) The question of girder bridges to be reviewed later when we know more about the possibilities of the box-girder bridge.

Bonuses on Construction Work

By

J. R. Slattery

Major, Corps of Engineers

In *Engineering and Contracting* for January 28th, 1920, there appeared an article entitled *"Application of wage bonus plan to construction operations."* The plan is based upon the establishment of a standard time for the performance of a certain amount of work, and when this set task has been accomplished, the payment of a substantial bonus for additional work done. The article describes how the plan was applied to hand excavation on a railroad cut, carpenter and concrete work on bridges. In each case those in charge of the work decided "on the method and a number of men who could work to advantage, then set the time standard." There was thus determined the number of man-days in which the job should be done. The efficiency of the working party was determined by dividing this number by the actual number of man-days in which the job was done, and a bonus paid if this efficiency was 75 per cent or higher. The following table shows the per cent of bonus paid for various efficiencies:

Efficiency per cent.	Bonus per cent.	Efficiency per cent.	Bonus per cent.
75	1.0	90	10
76	1.6	91	11
77	2.0	92	12
78	2.4	93	13
79	2.8	94	14
80	3.3	95	15
81	3.8	96	16
82	4.3	97	17
83	5.0	98	18
84	5.5	99	19
85	6.0	100	20
86	7.0	101	21
87	7.6	102	22
88	8.4	103	23
89	9.2	105	25

The plan described appears a most excellent one, but there are some irregularities in the increments in percentage of bonus to be paid that do not seem quite reasonable: for example, for an increase in efficiency from 74 per cent to 75 per cent, 1 per cent bonus is paid, but for the next 1 per cent increase in efficiency, the bonus increment is

Digitized by Google

only .6 per cent, while for the next 1 per cent (76 per cent to 77 per cent), the bonus increment is only .4 per cent. Again the increment in bonus corresponding to an increase in efficiency from 85 to 86 per cent is 1 per cent, whereas it is only .5 per cent and .6 per cent, respectively, for increases in efficiencies from 84 to 85 per cent, and 86 to 87 per cent. A more logical table would seem to be the following:

Efficiency per cent.	Bonus per cent.	Efficiency per cent.	Bonus per cent.
75	0.	90	10
76	0.4	91	11
77	1.0	92	12
78	1.6	93	13
79	2.2	94	14
80	2.8	95	15
81	3.4	96	16
82	4.0	97	17
83	4.6	98	18
84	5.2	99	19
85	6.0	100	20
86	6.8	101	21
87	7.6	102	22
88	8.4	103	23
89	9.2	104	24
		105 and up	25

The writer has in years past discussed the bonus plan with many contractors and has found them almost universally of the belief that the payment of bonuses promoted the efficiency of work. It is more difficult to find a satisfactory plan for payment of bonuses to government employees than to contractors' employees, but it is believed that the government would benefit greatly by adopting the bonus plan, wherever a reasonable basis for the payment of the same can be determined. In the case of dredging it is thought that a basis could be determined, for any given plant, as follows: Assume that a dredge works at 100 per cent efficiency when it works 20 hours out of every 24. For any given job a reasonably accurate estimate can be made as to about what yardage should be removed per month if the dredge actually worked at 100 per cent efficiency as defined above.

In any given locality the number of months of the year during which actual dredging operations can be carried on is known within close limits. Call this "n" months. The actual cost of dredging operations for the year includes not only the expenses incurred during these "n" months, but likewise the expenditures for care of plant and annual overhauling during the other months of the year. The true cost of any month's dredging, therefore, is equal to the actual operating expense (including cost of repairs, ordinary and extraordinary, during that month), plus $1/n$ of the cost of annual overhauling and care of plant during the lay-up season. At any given time, it is possible to estimate accurately an amount which should cover the monthly cost of operation (exclusive of repairs), and to approximate amounts which should cover cost of monthly repairs, ordinary and extraordinary, and cost of annual overhauling and care of plant during the lay-up season. From these figures there can be determined a monthly operating cost which should not be exceeded by $1/n$ of the total operating cost for a year, and if this monthly cost be divided by the number of yards which it is calculated the dredge should remove when working at 100 per cent efficiency there will result a unit cost that could be used as a basis for determining the efficiency of dredge operation during any month. The per cent of efficiency would be obtained by dividing this basic unit cost by the actual unit cost for the month calculated as follows:

$$\text{Unit cost for month} = \left[\text{Total operating cost per month, including cost of repairs} + \frac{\text{Cost of annual overhauling that year}}{n} + \frac{\text{Cost of care of plant during lay-up}}{n}\right] \div \text{Output for month.}$$

This may possibly appear somewhat complicated, but it is believed that if a study is made of operating costs of any given piece of plant, it will be found that the quantities involved are determined without difficulty and are reasonably convincing. It is considered essential to introduce a factor representing cost of repairs into the basic cost for use in determining efficiency, in order to guard against the danger of a crew's endeavoring to obtain output at the expense of proper care of machinery.

There might be some difficulty in determining the output to the satisfaction of all concerned, but it is believed that if the output was determined by a survey party having no interest in the bonus, and this survey party was in charge of a capable man, there would be little chance of collusion between dredge crew and survey party.

It is probable that most government engineers, who have had to do with the handling of labor during the past year have been impressed with the desirability of finding some way of stimulating labor's interest in work, and have found that neither increases in pay nor discharges accomplish that end. Perhaps an intelligent bonus system will meet the needs.

What the Ancients thought of prohibition

In a report of the Chief of Engineers, U. S. Army, dated October 12, 1814, is an account of his inspection of certain district work, in which he states that if *extra* whiskey is not allowed the troops they will not work. It appears that the "no beer no work" movement contains nothing original.

Industry's Supply of Energy

Abstract of Article by George Otis Smith, U. S. G. S.

(From *Mechanical Engineering*)

EDWARD EVERETT HALE charted the course of industrial development when he said that the extent to which the world had changed the laborer who uses his body into the workman who uses his head was the index of civilization. The true measure of industrial progress is found in the amount of mechanical power used to supplement man power. The mechanical engineer has devoted practically all of his energies to perfecting the application of power to man's use, and has given little consideration to the sources of the energy used, or to the estimation of the supply available. In the ancient days of Rome, or Greece or Egypt, hordes of slaves made use of only the simplest laws of mechanics. To-day, it is estimated that the total capacity of our prime movers is approximately 100,000,000 horsepower, or nearly one horsepower to every inhabitant in the United States. Using the equivalent of ten man-power hours to the horsepower hour, each of us now has the equivalent of ten servants to do his bidding.

The load factor, however, of all these prime movers, it is estimated, is not more than 14 per cent. The census of our energy slaves does not include the millions of automotive engines in our pleasure cars, trucks and tractors, which may in rated capacity far exceed that of the prime movers mentioned.

In contrast with the Greek civilization of the past, or even with Oriental life of to-day, we see that the Anglo-Saxon dominance of industry and commerce is founded largely on coal and iron. The invention of the steam engine gave such impulse to industrial development that the industrial scheme changed more in a few years than it had in the eighteen centuries since the boy Jesus worked at the carpenter's bench in his father's shop.

Present supply of energy and its distribution

Engineers of the U. S. Geological Survey estimate 125 billion horsepower hours as last year's output in the United States. Of this amount 82 per cent is credited to steam, a little over 15 per cent to water and the remainder, less than 3 per cent, to internal combustion engines. This power was used as follows: Public utilities, 42 per cent; manufacturing industries, 28 per cent, and steam railroads, 30 per cent.

Our per capita consumption of coal is estimated at 6 tons, which exceeds that of any other country. In order to visualize our coal consumption we may take as a unit the 1,000 tons of coal that represent the output of a mine worker in a year. This is one short train-load of 20 cars. Our industries and public utilities use 350 tons; our railroads burn 250 tons for their own use; 165 tons is used for heating and cooking in the homes of the land; 130 tons goes to coke ovens, and the remaining 105 tons goes for export and operation of coal mines and gas works.

A century ago the country's output was only 40,000 tons of coal, or less than 8 pounds per capita; even 50 years ago we used only 1,700 pounds, as against nearly 6½ tons in 1918.

The world's sources of supply

One of the by-products of our Peace Commission was an inventory of the water-power resources of the world, now being prepared for publication by the U. S. Geological Survey. It shows that only about one-twentieth of the potential power of the world's rivers has been utilized and over half of this in North America, with Europe credited with one-third and the rest divided between Asia, South America, Oceanica and Africa in the order named. In its potential resources, however, Africa ranks not last, but first; it has over 40 per cent of the world's supply of water-power and is followed in turn by Asia, North America, South America, Europe and Oceanica.

Of the better grades of coal resources, North America has more than half, Asia about one-fourth, Europe one-sixth and the rest is divided between Oceanica, Africa and South America in the order named.

Oil resources are more difficult to estimate; they appear to be evenly balanced between the eastern and western hemispheres, but the northern hemisphere appears to have at least five times as much oil as the southern. The continents in order of wealth in oil are North America, Asia, South America, Europe, Oceanica and Africa. More than half the world's oil reserves are believed to be concentrated in two inter-continental areas; one of these includes the North American and South American countries bordering the Carribean Sea and the other includes the countries of western Asia and southeastern Europe with the Caucasus as an axis. Each of these areas comprises only about 2 per cent of the earth's surface, but each is estimated to contain 30 per cent of the world's future supply of oil.

Oil shale can not be utilized as cheaply as natural petroleum but will form an important resource in the future. The United States alone is believed to possess deposits of oil shale that contain at least ten times as much oil as there is natural petroleum available in North America. No other continent is known to have resources of oil shale at all comparable with those of North America.

This rapid review of the world's source of energy shows North America taking first rank among the continents, with Asia a close second and Europe a poor third, although we should remember that Europe has a much smaller area than either of the other two.

Relative importance of coal, oil and water as sources of energy

Even in Europe and North America only about one-fifth of the potential water power has yet been developed. The further development of the use of water power will still involve the use of coal in increasing quantities, as the largest development of water power is practicable only with coal power as a dependable "standby," ever ready to meet promptly any special demand.

As sources of power, oil and natural gas present a marked contrast with water. Hydro-electric energy is more easily distributed and used, but water power development involves large capital outlay, and in any national emergency no quick response in water power is possible. However, once the large necessary investment of labor and material is made in water power, the output of energy continues for generations. Oil and gas on the contrary are

Digitized by Google

quickly developed and quickly exhausted. Natural gas, the ideal fuel, is a resource so temporary that its use forms merely an incident in industrial progress. The sorry lesson we have learned from the waste of natural gas may have its value if we apply the truth to our use of oil. Unless we check the increase in the consumption of oil, it too will be but a flash in the pan.

Looking for a moment at the power problem in our own country we see the nation's wealth in water, fuel and oil measured in millions of horse-power, thousands of billions of tons and billions of barrels, but to determine the relative position of water, coal and oil as sources of energy, we must reduce these units to a common denominator. If we take 50 million horse-power as an average figure for the potential water power of the United States, without storage, we find that if fully developed and if used at the average load factor of to-day, our rivers and streams would just about meet the country's present needs, and would supply that amount of power for all time; moreover, with storage and an improved load factor, they could provide a considerably increased output of energy to meet the growing demand.

Now if we assume that the whole power burden should be placed on our coal mines, we can get a direct comparison between our coal resources and our potential water power. There are in the United States accessible and available for future use, an aggregate of about 2,500 billion tons of coal, not including lignite; only about one-fifth of this is in the eastern states, another one-fifth is in the coal fields of the central states and nearly three-fifths is in the Rocky Mountain and western states. The most practicable unit for the conversion of these great resources of coal into power is a new one, the horse-power century, for which the equivalent in eastern coal is 250 tons, in interior coal 300 tons, and in western coal, 350 tons. By applying these h. p. centuries to our estimate of reserves we get a total of 8,161 million horse-power centuries. A million horse-power centuries is seven times the present power output of the United States, so we see that by adopting the best steam practice of to-day the present power requirements of this country could be met with coal for 57,000 years, although we know that long before the end of that period the greater depth of the coal mines and their increased distance from market would alone create power demands for mining and transportation that would considerably cut down the amount of power available for other uses.

We measure the petroleum wealth of the United States by billions of barrels—about 5 billion already produced in the last 60 years and about 7 billion left for the future; again, adopting the best steam practice of to-day in public utility stations of Texas and California—a little less than 32 barrels to the horse-power year—and trying to carry the whole power load of the country with oil alone we find that the oil reserves of the United States, although measured by billions of barrels, would last only 9 years and 3 months.

Without allowing for the fact that steam raising for power is only one of the many uses for coal, these two figures, 57,000 and 9¼ years, are sufficiently impressive to make us fairly receptive to the general truth of Mr. Eckel's statement in his recent book, Coal, Iron and Water: "We have just as much real chance of replacing coal by oil as we have of finding enough gold to use it in place of steel."

Costs of energy

In taking up the question of the relative costs in human energy in making the three kinds of energy available, engineers will appreciate the differences of labor outlay in constructing a hydro-electric plant, opening up a coal mine and drilling an oil well. Each is an engineering project that requires careful planning and the expenditure of money, skill and labor, but in widely different amounts.

Moreover, the water power plant is to last for generations and the coal mine for several decades, but the life of an oil well is measured by a few years. In operation, however, the water power plant is a labor saver, as is illustrated by the balance sheet put out by the Alabama Power Company, comparing a large steam plant with a hydro-electric plant operated under the same management and feeding into the same transmission lines. In terms of 1,000 kilowatt capacity it takes 13½ men to run the steam plant and the coal mine tributary to it. And how many does it take for the corresponding units in the hydro-electric plant? One-sixth of one man; the exact ratio is 84 to 1. Another comparison with coal is afforded by the statement that in Mexico one man can produce and transport to market the oil equivalent to the coal that it would take 10 men in the United States to mine.

Mechanical engineers should bear in mind these approximate comparisons of the labor costs of our energy slaves as they plan for the larger use of mechanical power. They should realize that the matter of full utilization of power resources goes further than material resources or energy supplies: do we not need to raise our intellectual load factor? Is there not too great a gap between our peak practice and our average load? In a word the Engineer needs to be more of a citizen, or as Herbert Hoover puts it, "Organize the engineering mind for expression in public service."

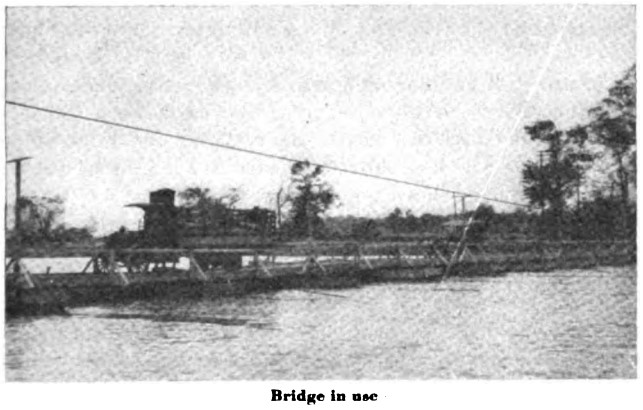
Army Ponton Equipage Meets an Emergency of Peace Time



By

J. B. La Guardia
Captain, Corps of Engineers

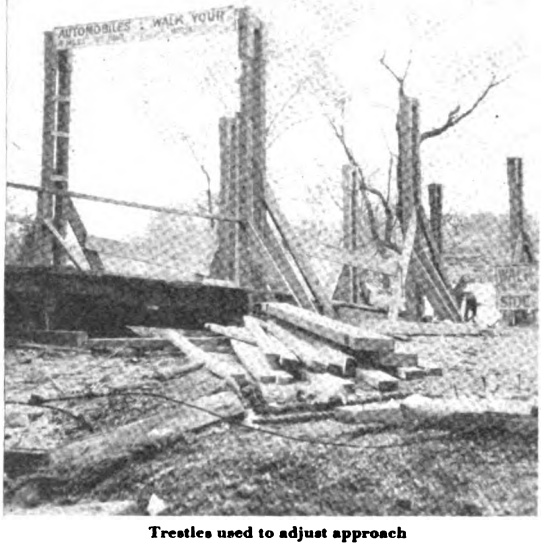
[*Note.* The ponton equipage is entitled to a prominent place amongst the devices of war which find a useful application to the needs and emergencies of peace. The following instance of the use of the equipage for the relief of a civil community in time of flood is typical of many similar instances in the past.—ED.]

THE city of West Point, Ga., is located on the Chattahoochee River about 90 miles southwest of Atlanta. It is divided into two parts by the river and the two sections of the city were connected by a 3-span steel highway bridge erected in 1890. On this bridge were carried the water main, electric, telephone and telegraph lines.

A heavy rainfall throughout the state of Georgia, total-

Bridge in use

ing 12 inches in four days, December 7-10, 1919, caused the river to rise to a stage of 31 feet above the normal, exceeding by 5 feet the record flood of 1886. This rise flooded a great portion of the city; also, a tremendous amount of drift-wood and debris came down the river, which collected against the bridge, forming an effective dam, and in the afternoon of December 9 the center and east spans were washed away. This break in the bridge left the east (residential) section of the town destitute of water, light, and any means of communication with the business section.



A detachment of 3 officers and 40 men from the 7th Engineers were ordered to West Point. This detachment guarded against looting which was in progress on a large scale, and also assisted in getting food and water to the residential section. The primary object in sending this detachment was to build a ponton bridge across the river. However, a special Act of Congress was necessary to authorize the employment of War Department Equipment for such a purpose. This caused considerable delay, and so on December 19-20 the detachment returned to Camp Gordon, Georgia.

The city of West Point is a distributing center for a large cotton mill and cotton raising section on both sides of the river. Deprived of means of communication offered by the bridge, considerable financial loss would ensue. Steps were immediately taken to construct two flying ferries, and these plied back and forth heavily loaded. At the same time efforts were continued to obtain the authority for the ponton bridge. This authority was obtained and ponton equipment began arriving January 9, 1920.

The bridge was located near the site of the flying ferries, or 800 feet upstream from the old highway bridge. The river at this point is 440 feet wide. The banks are steep and about 8 feet above normal water level. At normal stage the depth of the river varies from 6 to 15 feet. The current then is about 3 or 4 miles per hour, but as the stage rises the current increases and at a stage of 18 feet 6 inches a velocity of 15 miles per hour was measured.

The bridge as constructed varied from the normal type of military bridge in the following respects:

The number of balks used was eleven, eight of these were the usual military type, and three others, placed one on

Trestles used to adjust approach
(Pen line in illustration indicates Mooring Posts)

the middle and two on the outside, were made of 4″×6″ ×20′ notched to 5 inches. This arrangement permitted the nailing of the flooring, made up of 2-inch material, to the middle balk and of bolting side rails to the outer ones. Two wheel treads, 24 inches wide, were placed along the

The Vicksburg Campaign

(Continued from Page 196)

halted. It was a novel situation. Our pickets were inside the Confederate line and their pickets were inside of ours, but as neither side could fire on the other without giving warning, according to agreement, a parley was held and it was agreed that the two lines should be established as they stood, the Confederates taking the line occupied by our pickets and ours taking the place of the Confederates. That put the two lines about fifty feet apart, each line having the same number of men. About 10 o'clock that night a working party was established behind our picket line armed with picks and spades and before daylight the second parallel was established.

Agreements not to fire on each other were put into effect in other parts of the line and often men and officers met between the lines and settled the issues of the war in the most amicable manner. The Confederate soldiers as a rule put the blame for the war and its continuance on the politicians and women of both sides, saying that if the men of the two sides, excluding ministers of the gospel, could get together, there would be no difficulty in framing a peace that would be satisfactory to both.

The revetments on the inside of our works were sometimes made with gabions and sometimes with fascines or hurdle work, but the men did not like to make gabions, or hurdle work, and so as cracker boxes were plentiful they were more generally used for revetments. Sap rollers of the size laid down in the books, could not be used at all. They were too heavy. They had to be made lighter in order to move them over the hilly ground. This was done in various ways, sometimes they were made hollow, two empty barrels being placed end to end to form the hollow space. When our sap rollers at the railroad redoubt had reached the crest of the counterscarp and it was desired to know the width and depth of the ditch, a looking glass was procured and fastened to a long pole and raised from behind the sap roller and inclined forward. In this way a good view of the ditch could often be had.

We had no Cohorn mortars. If we had had, they would have proved very useful as they could be easily moved about from place to place, but Yankee ingenuity devised a substitute. The stump of a gum tree was bound with iron hoops and bored out to fit a six or twelve pounder shell. This was planted in the ground in rear of our lines with an inclination forward of about 45 degrees and fired as a mortar. It had a range of several hundred feet and was often good for about fifty rounds before it burst. The enemy used fire balls to destroy sap rollers when we approached too close to their ditches. The sap rollers being constructed of light material and exposed to the hot rays of a southern sun, burned readily and it was no easy job to replace them.

On the extreme right of our line, which flank was held by Sherman, the approaches were particularly difficult. His corps occupied the crest of the north and the Confederate the south side of a deep valley. This valley therefore had to be crossed in order to reach the enemy's works. On the side toward the enemy the slope was quite steep and had had a heavy growth of timber on it, but the trees having been felled, lay in a tangled mass, through which troops could not pass and maintain their formation. There was some compensation in this, however; the slope being steep the enemy's bullets passed over the men's heads when they were close up. This slope was too steep, for the most part, to enable approaches to be made in the regular way, but was favorable for mining. However, we had no more miners than we had sappers, consequently here as elsewhere along the line progress was slow.

Near the angle on McPherson's front the approaches were soon pushed up so close to the ditch that further progress could only be made by mining. A few coal miners were found in a West Virginia regiment and they, with the assistance of other men, drove a gallery in under Fort Hill (called by the troops Fort Hell); the soil being stiff, no timbering was necessary. The enemy tried to stop our work by counter-mining, but did not succeed. In a chamber at the far end of the gallery a charge of a ton of powder was placed and fired at 3:30 p. m. on June 25th; as word had been sent along the line that the explosion would take place at that time sharpshooters were stationed along the trenches to give the Confederates a volley when they were up in their trenches in surprise at what was taking place. They were completely taken by surprise and received a deadly volley from our line.

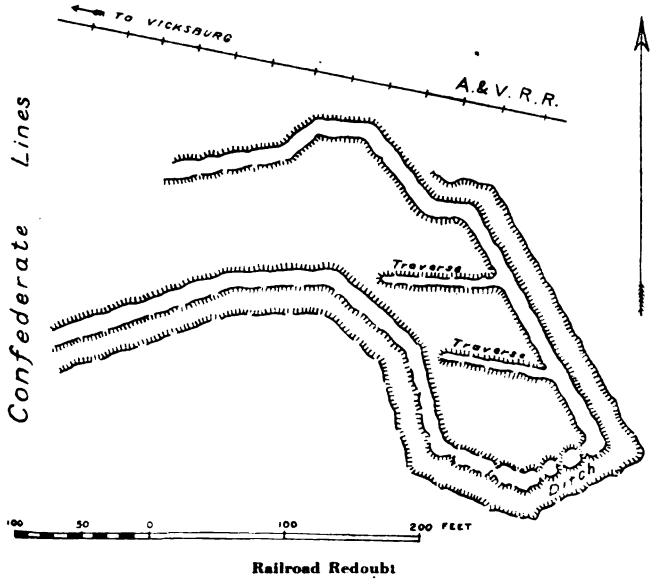
The blowing up of Fort Hill was a complete success and the crater formed was immediately occupied by our men, but the Confederates, warned by the strange noises they had heard in their counter-mines, had prepared a new line of defense some distance in the rear.

In consequence, no decisive results were accomplished, though preparations had been made to take advantage of the surprised Confederates, if a good opportunity presented itself.

On July 1st another mine was sprung at the same place, or rather a little in advance of it, blowing several Confederate soldiers and one negro laborer into our lines. The astonished negro was thrown up about a hundred feet in the air and came down not seriously hurt.

On July 1st the approaches in front of the 13th Army Corps had been advanced to the counter-scarp of the ditch at three places, viz, the Baldwins Ferry Redoubt, the Railroad Redoubt and the Square Redoubt. As further progress could not be made on the surface in the ordinary way, arrangements were made to start mining, when orders were received to suspend that work and put all labor on widening trenches so that infantry could move along in them in columns of fours. At the same time material was ordered to be prepared for filling the ditches so that infantry and artillery could pass over them without losing their formation. The ditches were to be first filled up with bags of cotton solidly pressed into them and then covered with planks and earth. Each man in the front part of the assaulting column was to carry two bags of cotton, which it was found was nearly bullet proof when prepared in this way. The assault was to take place at dawn of July 6th, but as the surrender took place on the 4th, the assault did not materialize. The plan of filling the ditch with bags of cotton was a novel one in siege operation, but cotton was plentiful, though worth about 80 cents a pound.

Grant made a mistake when, on May 22nd, he yielded his better judgment to the importunities of his subordinate, General McClernand, commanding the 13th Army Corps (in the center of the line of investment), who called for reinforcements to support an alleged capture of part of the enemy's works and requested that a diversion be made in his favor by a renewal of the attacks of Sherman and McPherson on their fronts. Grant could see fairly well from where he had taken station, near McPherson's headquarters, what was going on on McClernand's front. From what he could see he did not believe the statement of his subordinate, but the latter was nearer the scene, and it was his troops that had made the alleged capture. McClernand's assertion was so positive in a second dispatch that Grant



Digitized by Google

did not feel that he could, under the circumstances, safely ignore the request. It was necessary that action be immediate. There was no time to investigate, so he ordered Bloomer's Brigade of Quinby's Division to be sent to McClernand's assistance, and at the same time ordered the two corps commanders (Sherman and McPherson) to renew their attacks, and notified that he could use McArthur's Division then on the way up. The result was that several hundred more men were unnecessarily sacrificed.

The railroad redoubt

The works that McClernand claimed to have captured were the lunette on the Baldwin Ferry Road and the Railroad Redoubt on the left of the railroad leading into Vicksburg. Our men did get as far as the ditch of the lunette and the outer slope of the parapet of the Railroad Redoubt, but they could go no farther. We could not see the lunette from where we stood, on account of trees and the height of intervening ground, but we could see distinctly what took place at the Railroad Redoubt, for it was only about five hundred yards distant, with a clear space between us and the enemy. The writer was with General McClernand all day of May 22, being a member of his staff. He remembers that General McClernand received a piece of an envelope purporting to come from Colonel Stone of the 22d Iowa Infantry, who was at that time in the ditch of the redoubt, saying in substance that he held part of the fort and needed the support of reinforcements, or words to that effect. When we saw prisoners (about a dozen) come out of the end of the redoubt, General McClernand remarked in substance that we had possession, for there were Confederate prisoners coming into our lines. The writer remarked, in substance, "Yes, General, there are prisoners coming in sure, but we have not possession of the works," and in support of his statement, called attention to the fact that just at that moment one of our soldiers lying on the superior slope of the redoubt, rolled back in the ditch, killed by a Confederate soldier inside.

The Railroad Redoubt was three-sided; the flanks projecting forward being longer than the outer face. It was open in rear, but had two traverses nearly parallel to the outer face, reaching from one side to the other with a narrow passage of about two feet in width left for communication. The two traverses divided the redoubt into two separate compartments, so that the men in one could not communicate with those in an adjoining one except by way of the narrow passage referred to. The outer face of the redoubt being nearly parallel to our line of battle, had been battered down considerably in the bombardment that preceded the attack. Big shells had cut furrows in it three or four feet deep, leaving but little of the original parapet standing, so that a man creeping in these furrows would not be seen by the enemy. Some of our men, after reaching the ditch, succeeded in entering the outer compartment referred to. (See sketch.)

Railroad Redoubt

Among them was First Sergt. Joseph Griffith of Company I, 22d Iowan Infantry. At that time there was a Confederate lieutenant and about thirteen men in that compartment still alive, but all of them had discharged their guns. All of our men who gained entrance into this compartment were killed or got back into the ditch except Sergeant Griffith, who laid down in a gulley, or furrow, made by our artillery. As he did so he picked up a repeating rifle, which it is supposed was dropped by the first lieutenant of his company, who is said to have gone into action with such a rifle, and who was killed in that compartment. Sergeant Griffith at once levelled this rifle at the Confederate officer and ordered him to make his men lie down. The officer did so, and the men lay down on the ground. Griffith then ordered the lieutenant to make his men come out one by one, creeping past him in the furrows referred to as made by our artillery. One by one they crept out and dropped into the ditch. As the latter was full of our men they were easily taken care of until all were in the ditch. Colonel Stone then directed Griffith to take the prisoners to McClernand's Headquarters, which he did.

The slope of the hill on which the redoubt was built formed a natural glacis. About 100 feet from the ditch there was a depression in the surface like a terrace on a slope, and from this terrace the slope dropped off to the bottom of the ravine or bayou. From the terrace to the bottom of the ravine a man could, by stooping low, avoid being seen by the Confederates in their works, but from the ditch to the terrace they were in plain view; and in running this distance they came under fire. One of the prisoners was killed by their own sharpshooters in running this distance. A little later Griffith arrived at headquarters with his prisoners—one lieutenant and twelve or thirteen men—and from Griffith was learned how the Confederate prisoners were taken, and, what seemed most strange to us on the hill at first, how they happened to be coming into our lines.

When Griffith related the manner of his capturing so many prisoners, substantially as stated above, the writer turned to the Confederate officer and asked him if he had surrendered with all those men to that boy (Griffith was only 19 years old at that time). He replied in an angry tone, "What the hell could we do? My men had all discharged their guns and he had that rifle."

It may be of interest to officers of the Corps of Engineers to know that shortly after this battle Griffith was appointed first lieutenant in the 22d Iowa Volunteer Infantry by General Grant, an appointment he had no authority to make; the appointment was, however, subject to the approval of the Governor of Iowa, but he did not hesitate to approve it. In October following, Griffith was given an appointment as cadet at the Military Academy, West Point. He was graduated in 1868, and appointed second lieutenant of Engineers. He resigned from the Army in 1870 and died in 1877.

This exhibition of courage on the part of Sergeant Griffith proved to be a most unfortunate incident, for it seemed to convince General McClernand that we had actual possession of a part of the enemy's works, and *it* may have been the chief cause of his sending word to Grant to that effect. From a technical point of view, McClernand was within

Digitized by Google

the bounds of truth when he stated that we had possession of "*a part* of the enemy's works." The ditch was unquestionably a part of the enemy's redoubt, and we had possession of it for several hours, but it was because the ditch was a safer place than the outer slope of the parapet or the natural glacis in front of it. The ditch was, in fact, a trap. We could not advance, nor could we retreat. Like the man having hold of the bear's tail—we could not hold on and dared not let go.

Grant undoubtedly assumed, as he had a right to assume from the dispatches he received, that McClernand had possession of something of value. The statement in each dispatch was indefinite and liable to misconstruction. It was misconstrued by Grant; whether or not McClernand wished to convey an impression that he had gained more than the actual facts warranted is a question that can never be determined, but the important fact remains that the dispatches in question did convey the idea that McClernand had gained possession of something of such importance that support only was needed to break through the enemy's line.

These dispatches to Grant (there were two of the same tenor), which caused him to issue the unfortunate order to resume the attack on the other corps fronts, did not tend to heal the feeling of antagonism that existed between these two men.

The commander of a field army has a right to expect from his subordinate commanders intelligent and cordial support. There was no visible friction between them, but this episode was a straw that tended to break the camel's back. It undoubtedly increased the feeling of antagonism. McClernand was a disappointed man. He expected, and was given to understand that President Lincoln had selected him to command the army that was organized to undertake the task of capturing Vicksburg, so that when he found he was only a corps commander in that army he doubtless experienced keen disappointment. It would hardly fail, in such a man as McClernand, to intensify the feeling of hostility already existing in his heart. This finally led to his being relieved from his command and sent home.

It came about in this way, McClernand published a congratulatory order to the 13th Army Corps, in which he claimed that that corps, under him, had done most of the hard fighting of the campaign, and minimized the achievements of the other two corps. As a matter of fact all had done their full duty, and no one had a right to claim for one corps an undue share of the honor. Politician-like, McClernand, though brave and possessing some qualities that tend to make an efficient commander, could not apparently divest himself of the habits acquired in the political field. He did not see the difference between the politician and the soldier. He not only issued the order referred to, but had it printed in the northern newspapers in violation of the Army Regulations, which forbid that sort of thing. Grant knew nothing of the order in question until he saw it in a copy of the *St. Louis Republican*. He then sent a letter to McClernand with the copy of the order cut from the paper and asked if he, McClernand, had published it?

McClernand replied in a rather petulant way that he had, and that he was prepared to substantiate all the statements made in it. Grant then issued an order relieving him from the command of the 13th Army Corps and ordered him home, from which place he was to report to the Adjutant General of the Army. He then assigned Maj. Gen. E. O. C. Ord to the command of the 13th Corps, subject to the approval of the President. General Ord continued in that command during the remainder of the Vicksburg Campaign.

The Vicksburg Campaign, besides being the most successful, was one of the most important military events of the Civil War. Its results were far reaching and most disastrous for the Confederacy. With Lee's failure at Gettysburg at the same time, the war should have then ended, for it was evident to the people of the South, as well as the North, that a further struggle to disrupt the union of states was hopeless.

We now found that our prisoners amounted to no less than 31,600 men, including the sick. The Confederates had expended nearly all their ammunition and had reached the point of starvation. They had made a gallant defense, but there could be no fight in men who were starving and almost wholly out of ammunition. Our Commanding General, with characteristic generosity, granted liberal terms to the enemy, which, while it saved their honor, destroyed their capacity for further mischief.

Regulation of the Middle Mississippi River

(Continued from page 204)

dredge, which afterwards was named *Alpha* and was the first of the Commission dredge fleet, was non-propelling and did not differ materially in its principal details from similar dredges which were built later. The hull was of wood, 130 feet long by 36 feet wide. The machinery consisted of a centrifugal suction pump with 30-inch suction and discharge pipes, and a centrifugal jet pump with 15-inch suction and discharge. There were four Mississippi River type boilers, 38 inches diameter and 28 feet long. The material was discharged through a floating pipe line, 30 inches diameter, in sections 33 feet long, the total length varying from about 600 to 1,000 feet. The hourly capacity was about 600 cubic yards of sand. This dredge succeeded in opening a small channel in 7 days through a bar 1,600 feet long, the gain in depth being 2 to 3 feet.

In 1896 a jet dredge (*No. 1*) was built in the St. Louis District to deepen the channel over bars by directing streams of water against them, the current being depended upon to carry the agitated material away. This dredge had two 15-inch centrifugal pumps, with two Mississippi River type boilers 42 inches diameter and 28 feet long. The suction led over the side, and the discharge, which consisted of four 12-inch pipes with flattened nozzles, led over the bow, the machinery being mounted on a wooden barge. This dredge worked downstream, the boat being dropped down from the upper to the lower side of the bar, with the jets in operation. River dredges at the present time work upstream. The cost of the dredge, not including the barge on which it was mounted, was about $18,480.

In 1896 there was also begun in the St. Louis District the construction of three non-propelling suction dredges, *Nos. 2, 3* and *4*. *Dredge No. 2* was of wooden hull, 135 feet length and 28 feet beam. It had a single 20-inch pump of 450 cubic yards capacity per hour, three Mississippi River type boilers, and cost about $22,000. *Nos. 3* and *4* were of steel construction, 160 feet length and 40 feet beam. Each carried two pumps of 20-inch discharge and capacity of 600 cubic yards of sand per hour, six Mississippi River type boilers, and cost about $102,400.

Dredges *Nos. 1* and *2* have been dismantled, as with the construction of larger and more powerful dredges, these earlier forms were found to be uneconomical. In 1906 the capacity of *Nos. 3* and *4* (now called *Selma* and *Thebes*) was increased by replacing the two small pumps on each dredge with a single pump with 28-inch diameter discharge, utilizing the original engines.

Digitized by Google

In 1906-7 two steel hull, self-propelling dredges, the *Fort Gage* and *Fort Chartres,* larger and more powerful than any heretofore built in the district, were completed. They are of steel, 197 feet length and 45 feet beam. Each has a pump of 32-inch discharge and capacity of 1,500 cubic yards of sand per hour, six Mississippi River type boilers, stern wheel, 24-inch, non-condensing, high-pressure engines, and cost about $177,000.

Working in two shifts of eight hours each, the non-propelling dredge requires a crew of 9 officers and 39 men, and the propelling dredge of 11 officers and 37 men.

The gross cost per cubic yard of dredging done during 1920 varied from 18.2 cents for non-propelling dredges to 11.9 cents for the larger self-propelling type.

During the dredging season, which lasts ordinarily from July to December, with the aid of the regularization works, these four dredges maintain, with but occasional interruptions, an 8-foot channel 200 feet wide between St. Louis and the mouth of the Ohio River.

St. Louis Harbor hurdles, Pillsbury dike series. Shore end looking downstream. Drift caught by hurdles

The district obtains accurate information as to prevailing depths from soundings made by its own boats, including the snagboats, and from the lighthouse tender and commercial boats.

As the localities which are likely to become troublesome are well known, they are carefully observed, and when the river approaches a stage when depths may become insufficient, surveys are made of these localities and preparations are made for dredging.

Soundings are made on lines or ranges across the river with sufficient frequency to show accurately the condition of the bottom, which is shown on the map by contours. Ranges are ordinarily located at intervals of 1,000 feet, with such additional ranges as may be necessary in the shoalest water. Longitudinal ranges, following closely the steamer channel, are also sounded.

From the map, the proposed dredge cuts are located and indicated by buoys or shoal marks. Success or failure depends very materially on the skill with which these locations are made. The axis of the proposed channel to be dredged must coincide with the direction of the current, otherwise the channel will be quickly obliterated. It is desirable to have the initial cuts made through the bar as quickly as possible, in order to receive the assistance of the current in scouring out the artificial channel. Cuts should be made as deep as the suction head will permit, in order to augment the volume and velocity of the current, whose action is largely depended on to aid in the formation of the channel. The channel is made of requisite width by parallel cuts.

During the past season the time required to open channels varied from 3 to 8 days and from 32 to 73 hours actual dredging time.

Surveys, maps and gauge records

Complete surveys have been made throughout the district, including the entire area between the limiting bluff lines. The first of these surveys was made by the Mississippi River Commission between 1880 and 1888, and included triangulation of the secondary order and precise levels. Lithograph maps of this survey are issued in two editions, the larger scale, 1:20,000, showing soundings, with contour intervals of 5 feet in the bottom and 20 feet in the bluffs, triangulation stations and bench marks; the smaller edition scale, 1:63,360 (1 inch to 1 mile), shows topography, but omits the foregoing details. Prior to this survey three reconnaissances were made towards the end of the eighteenth century with another about 1821, and subsequently five or more surveys were made in somewhat greater detail. The Board on Examination and Survey of the Mississippi River in 1909, issued lithograph maps of the district, scale 1:20,000, from the northern city limits of St. Louis to the Ohio River, based on more complete topography than any of the foregoing.

In addition to these more complete surveys and maps, the St. Louis office has made a large number of surveys for the purpose of planning and locating improvement works and for dredging. As far as practicable, the entire district is covered annually. Bank and bar lines and improvement works are located and soundings are made. Extended topography is not taken, nor are contours drawn.

A survey party consists of about fifteen men, supplied with necessary instruments and tools and quartered on a small office boat. One or two small motor boats are used for making soundings.

Topography is usually taken with the plane table, and is mapped on the scale of 1:5,000. This is usually confined to the shore and bar lines, as the areas back of the shore lines undergo very little change from year to year. Triangulation and levels are based on the Mississippi River Commission Surveys, intermediate stations and bench-marks being established as required or to replace others lost or destroyed.

Tracings are made from field maps for locating construction maps or localities to be dredged, and in the office, reductions to scales of 1:10,000 and 1:20,000 are made for record on the permanent maps or standard sheets, of which there are thirty-seven. Note books, which are usually confined to triangulation, leveling and soundings, are indexed and filed, and the necessary computations are made.

Observations of the velocity and discharge of the river are made as required. A favorable cross-section, and the one usually utilized, is located at the Engineer Depot in St. Louis. The method by rod floats is employed.

The stages of the Mississippi are observed daily at a

Digitized by Google

number of stations. At St. Louis a gauge is maintained by the Mississippi River Commission, with continuous readings since 1861, and a second gauge is maintained by the U. S. Weather Bureau. The City of St. Louis maintains gauges at two water-works stations in the northern part of the city. The Commission also maintains gauges at Cape Girardeau and Cairo. The Weather Bureau publishes in the daily newspapers the readings of the gauges at St. Louis, Chester and Cairo. The Mississippi River Commission publishes annually in pamphlet form the readings of the St. Louis, Chester, Grand Tower, Cape Girardeau and Cairo gauges. The St. Louis Engineer Office maintains eight gauges between St. Louis and Cairo, and keeps a record of their readings, as well as those of all other gauges in the district, but does not publish them.

Removal of snags and wrecks

Before this work was inaugurated the navigation of the river was very much interfered with by numerous snags, logs, etc., which had lodged in the channel, and to which a new accession was brought down on each rise of the river, thus constantly adding new and unknown obstructions to those already there. A large number of wrecks, dangerous to navigation, also obstructed the channel. For the removal of these obstructions, appropriations were made as early as 1824, and the project adopted consisted of building boats suitable for removing the snags, etc., and operating them whenever the stage of water was favorable for the work and funds were available.

The total amount expended for this purpose can not be definitely given, as, previous to the appropriations made by act of March 3, 1879, a bulk sum was appropriated to be applied to several streams as their needs required.

Congress, by act of March 3, 1879, appropriated the first specific sum for removing snags, wrecks, etc., from the Mississippi River, and that appropriation was followed by others until 1888, when, by the act of August 11 of that year, an annual expenditure not to exceed $100,000 for this purpose was authorized. Under this act operations have been carried on annually since 1888.

At the present time snagging in the Mississippi River below the mouth of the Missouri and in the Old and Atchafalaya Rivers is performed under the St. Louis Engineer District by the snagboats *H. G. Wright* and *J. N. Macomb,* built in 1880 and 1874, respectively. The boats are of similar construction. A description of the *Macomb,* and of the general method of operation, follows:

The boat is of iron, 178 feet long and 90 feet wide over wheel guards; it has twin bows separated by an open space 12 feet wide, called a well, which extends 65 feet aft from the stems. The speed of the boat is 8½ miles per hour in water, with engines of 600 horsepower. A steel butting beam 22 feet long, 7 feet wide, and 16 inches thick spans the space between the bows near the stems at the surface of the water. The end of a snag is lifted onto this beam by means of a sweep chain, which is hung as a loop from one stem to the other, or by means of tackle hung from an A-frame support at the bow. Four steam capstans, each capable of a direct pull of 35 tons and a speed of 30 feet per minute, supply the power for operating the appliances and for pulling the snag to its inclined position upon the beam. To aid in this, there is added a powerful purchase fitted with a cast-iron drum, winding a "Samson" chain with links made of iron 2¼ inches in diameter. This chain is tested at 75 tons, but is often broken in the work to which it is subjected. The combined pulling power of this purchase and the four capstans is 215 tons; but this is quite insignificant when compared with the work accomplished by butting, using the whole boat as a hammer of 800-tons weight. The snag being drawn upon the beam and an after roller, which also bridges the well, it is sawed into logs by powerful steam saws, one working over the roller and one over the forward edge of the butting beam. The after saw reduces the body of the tree to logs that are dropped anywhere, as they will float away, but the large root, matted with clay and gravel and sometimes 20 feet in diameter by 3 or 4 feet thick, is carefully dropped into some deep hole or a place well out of the channel of the river.

In cases of great difficulty the hydraulic jet and dynamite are occasionally employed as auxiliaries in loosening the root of the snag.

For breaking up submerged wrecks or other similar obstructions, a steel hook is mounted upon an A-frame with feet hinged upon the twin bows. This hook is lowered and dragged over the obstruction, acting as a plow. There is also used in a similar manner a large steel grapnel, attached to the "Samson" chain, with from three to five flukes similar to those of an anchor. In destroying wrecks, the various pulling and lifting devices are used. Occasional work requires the services of a diver, and the use of explosives.

Drift heaps accumulating at bridge piers and similar obstructions are destroyed by pulling out key pieces or the use of explosives.

Large trees near caving banks are cut to prevent their becoming snags.

The matted masses of trees upon caving banks are usually removed by the snagboats as a preliminary to bank revetment at the particular point, but in stretches not to be revetted, these masses are left until they menace navigation.

The snagboat crew consists of from 40 to 45 officers and men. Schedules of patrol are arranged so that one boat is in the upper while the other is in the lower part of the river.

The snagging season generally extends from July to March, but at the present time, due to high costs and limited funds, it is not possible to operate both boats throughout the entire season.

During the full active season each boat will destroy about 1,500 to 2,000 snags, 8 to 10 drift heaps, and 5 to 8 wrecks, and will cut a number of trees near caving banks varying from a few hundred to 10,000. At present the practice of cutting trees is practically abandoned. In doing this work, the boat will traverse from 4,000 to 8,000 miles.

As a result of the consistent policy followed for many years in conducting this work, most of the old wrecks have been removed from the channel, the number of snags is gradually decreasing and few vessels are now wrecked through striking obstructions in the channel.

Decorations Awarded by War Department

The tabluation shows the decorations awarded by the War Deparment to officers and enlisted men of the United States Army to January 31, 1921, for service in the World War:

	Commissioned	Enlisted	Total	Per cent awarded Com.	Per cent awarded Enl.

Army Ponton Equipage Meets an Emergency of Peace Time

(Continued from Page 269)

entire length of the bridge. Wooden hand-rails were built. Also provisions were made for installation of an electric lighting system.

The bridge was built by the method of successive pontons, using saddle boats for the first and last boats. The Engineer detachment consisted of one officer and twelve men. The city furnished twenty-five laborers. Work was begun about 8 a. m. and, except for two bays, the bridge was completed by 6 p. m.

During the construction the river had risen 4 feet and it was predicted that it would rise higher. This rise in the river necessitated the lifting of the approach bay off the saddle boat. The river continued to rise and finally reached the stage of 18.6 feet, equivalent to a difference in stage of 14.0 feet.

The debris coming down the river fouled the anchors in spite of all efforts to prevent it. This forced the cutting loose of ten of the thirteen anchors in the bridge. To replace the loss of these anchors two hemp ropes were placed across the river taking turns around the mooring post and making the ends fast on shore. Later a 1-inch steel cable was added. This was undoubtedly instrumental in saving the bridge, for when work on realigning the bridge was begun there was a sag of about 30 feet in it. The bridge was straightened out by recasting the upstream anchors and moving the bridge into place by parts.

The current of the river during the first part of the work varied from 4 to 6 miles per hour. During the realigning it was estimated to be about 10 miles per hour.

A fluctuation from 6 to 10 feet in the stage of the river is a common occurrence. A rise of 6 feet will begin to overflow the banks. Because of these facts the ordinary

construction of the approach bay was found impracticable for the following reasons:

1. The inclination of the approach bay is excessive and tends to submerge the saddle boat and pull the flooring system off the abutment sill.

2. The bridge approach being in a cut soon is under water and the bridge therefore becomes inaccessible.

To obviate these difficulties it was recommended that adjustable shore trestles be used permitting raising and lowering of abutment sill, and that the approach be maintained by the use of suitable horse-trestles and sectional flooring.

Also in view of the difficulty encountered by the fouling of anchors, it was decided to do away with the up-

How some of the boats looked after the flood

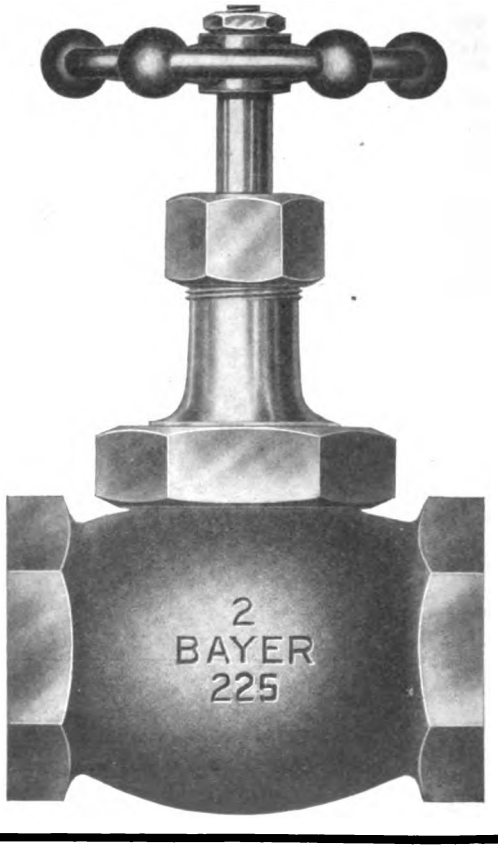
stream anchors. A steel cable was stretched across the river about 150.0 feet upstream and high enough to be clear of debris at high waters. To this the boats were tied by ½-inch steel rope.

The bridge thus constructed gave very satisfactory results, continuing in use as long as roads to it were open.

However, misfortune seemed to be pursuing the city and on March 28, 1920, it was hit by a cyclone, causing considerable damage in the city and destroying the ponton bridge. The investigation tended to show that the entire bridge was blown upstream by the wind, tearing the stern mooring post off the saddle boats and two other boats in midstream. When bridge settled back into place a number of boats were submerged, some partially, some almost

BAYER Valves

BAYER Valves are made in heavy-pattern regrinding globe, angle and check types, screw and flanged ends—all good for working pressures up to 225 lbs. Each one is guaranteed to meet the metal composition requirements of U. S. Navy Department specifications 46-B-8, June 20th, 1913, covering valve bronzes or composition "M."



Body walls are of liberal thickness, with a uniform distribution of metal. Valve seats are radial, and can be ground continually, thus prolonging the life of the valve indefinitely. Discs are made of a hard bronze composition; stems are unusually heavy with a greater number of accurately cut threads than usually found in valves of this type.

Naturally, continued satisfaction is the only logical result that can follow adherence to the BAYER standard. Send for our book "The BAYER Valve."

completely. About five boats had the bow mooring post torn out. The confusion in the town made the obtaining of help impossible. Darkness, the rising river, the tremendous amount of debris, all worked for the destruction of the bridge and during the night it broke loose and went crashing down against the piers of the old bridge. A detachment of twenty men was rushed to the scene. As soon as practicable they began to salvage what boats could be located and make such repairs as were necessary; of the twenty-six boats that were in the bridge prior to the cyclone, only nine could be used in the second bridge, the

All mooring posts gone

others being too damaged to salvage. The second bridge was built in the same manner as the first and has given service since the middle of April, 1920.

It is safe to say that the emergency which confronted this community could have been met only by a ponton bridge.

Sizing Up Your Subordinates

Have you noticed how nearly like the complex modern factory your assistant is? If he has well-selected food and good digestion, you expect him to have sufficient strength. Take that as "boiler" efficiency. If he has normal muscles, joints and senses, you expect him to move quickly, steadily and accurately. Take that as "engine" efficiency. If currents of thought flow through him as he moves through the field in which he is placed, you expect these thoughts to flow to the terminals. Take that as "generator" efficiency. If he knows signs or sounds that have meaning to you, you expect him to bring his thought to you clear, full and direct. Take that as "transmission" efficiency. If you set him to a task or approve his purpose, you expect him to cut deep and clean and feed as fast as the desired finish will permit. Take that as "tool" efficiency.

With these suggestions you get the obvious similarity. More careful examination would develop a closer relation. Now, when you write a letter of recommendation or, that bugbear of administration—an efficiency report—do you test this assistant in the usual way? Do you determine his boiler, engine, generator, transmission and tool efficiencies? Do you even guess at them as by comparison with others? If you have not done so, you will next time. And suppose you do. Will you *average* them and give him an overall *average* figure that tells no more than the average of his grades at school in mathematics and clay modeling? You will not. You will multiply them just as you always multiply efficiencies of the elements in a connected series when you want to know the overall plant efficiency.

Now, when you have made this multiplication, you see why some of your men with good points don't make good. The energy from their food never reaches the job. If you should average their ratings, the high peaks would fill up

the low places. Get the facts, get the factors, get the product, and you will see why a plugger brings home the goods. Perhaps you will see then why persistence (of a man with a good idea) so often seems to you to be obstinacy (in a man with a poor one). When effort and accuracy are involved, give each a rate and remember that a blind man can not see, no matter how hard he tries. Rate him zero on sight and rate him high on what he has. The product will show the true state of affairs. Then when you report on a man, report on *what he does*—in terms of what he might be *expected to do*. The boss can multiply *the factors that interest him* almost as well as you can, and *he can pick them out of your report* if you put them in.—R. M. Copeland, Capt. C. of E.

How far will wages fall?

The outstanding feature of the business situation at present, as contrasted with that during November and December, is the note of optimism that comes from the New England and Middle Atlantic manufacturing centers with regard to a revival of business in the early spring. Coupled with this is the feeling that the sooner contemplated wage reductions are made the sooner will industry hit the road to normality. The wage cuts of 22½ per cent in the cotton and wool industries have been followed by the opening of a number of mills in Maine, Massachusetts, and in the South.

At the moment the situation is a double deadlock between the consumer and retailer on the one hand and the wage-earner and the wage-payer on the other. The retailer having previously filled his shelves with high-priced goods, was loath to take a loss commensurate with changed market conditions, even though this would result in clearing his shelves. His maintenance of high prices, certainly over the holiday season, had an undoubted influence in the so-called consumers' strike.

The retailers are now, in many instances, adding to their stocks by purchases at present low prices, and putting all their goods on the market at a price somewhere between the former high and the present low. They are in this manner averaging their loss and pursuing the policy of the Swede, who, looking at the stream, averred that he could not cross it in one jump, but that he could in two.

The other deadlock is being met by wage cuts. These wage reductions range from 10 per cent to considerably higher. In the morocco industry in Delaware, cuts of as high as 50 per cent have been made, while in many cases the reductions are about in proportion to the decline in the cost of living; in others, they are much greater. What the wage-earner as a consumer is gaining in his struggle with the retailer, he is losing in his struggle with the wage-payer. This is about what is happening in the deadlock which the writer has indicated.

How far will wages fall? Will wages recede to the pre-war level? This is the question on everybody's tongue. Labor has generally shown a willingness to accept lower wages with the prospect of continued employment.

An English statistician seeking information on the same question, recently made a study of the movement of wages in the building trades. The building industry was chosen for study because it has existed with almost the same occupational subdivisions over a long period of time. The records of the prices paid for labor in the construction and repair of government buildings, such as Westminster Ab-

Court, and Buckingham Palace exist for about 700 years back. These records are preserved in the Public Record office, the Exchequer, the Audit Office, and the Office of Works of all sums paid out by the Royal purse. The results of this study are shown as above.

In the course of the study the rates paid to bricklayers, masons, carpenters, and joiners were found to vary only slightly and were, therefore, grouped together. Plumbers appear to have received better rates throughout than most of the allied trades. Plasterers were also paid quite well, particularly during medieval times, when their work was almost that of an artist. Prior to 1800, wage rates showed a wide range, due to variations in skill; sometimes a difference of as much as 40 per cent in the rate paid is indicated between the highest and lowest paid craftsman, same trade.

The rates indicated in the table show a general rise in wages with occasional recessions. These recessions have not necessarily been at the ends of war periods, but seem rather to have been contemporaneous with periods of lessened industrial activity. In other words, the law of supply and demand has been a governing factor.

But it is significant that such recessions as have taken place have not been permanent. In the long run the trend of wages is upward. Standards of living are rising continually. Men do not change over night, but, viewed conditions, economic conditions cannot lag long behind. Furthermore, with continuous advancements in industry national and individual wealth increases. Wages will tend to grow; the criterion is not money wages, but purchasing power.

Prices to-day as compared with those prevailing in previous centuries show marked increases. Higher prices for goods are reflected in high prices for labor, and higher prices for labor inevitably mean higher production costs, and so higher prices. It is a circle which can not be broken.

We may, therefore, say that while reductions in wages that are now taking place are tending toward industrial stability and are beneficial so long as they help to pull industry out of the mire of inactivity, neither wages nor prices will recede to their pre-war levels.—*100 Per Cent.*

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

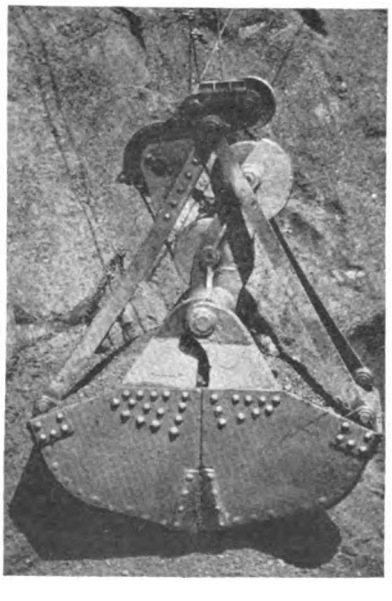
Experiences in pile driving

Col. Charles R. Gow, of Boston, Mass., recently discussed his experiences in pile driving before the Boston Society of Engineers. The Back Bay marshes near Boston are reclaimed flats, having a gravel filling 15 to 18 feet deep overlying the same thickness of mud, with blue clay underneath, into which pile must be driven in order to obtain a satisfactory bearing. The presence of the mud layer makes it necessary for piling to penetrate the underlying clay in order to obtain a satisfactory bearing. Investigation has shown that a large proportion of piles driven failed to penetrate the top gravel stratum, owing to the gathering of stones and pebbles ahead of the pile tip preventing further penetration. Some piles became broomed and mushroomed; some failed by diagonal shear or telescoping; others had their lower portions broken off and deflected laterally almost at right angles. Sharpening the tips of piles was an aid in overcoming this difficulty.

Attempts to drive wooden piles through stone riprap usually resulted in brooming the pile into a mass of pulp.

High frictional resistance in upper strata often results in stopping piles before good bottom is reached; the result is an apparently stable foundation, which later yields slowly under pressure and causes settlement. Piling driven in sandy or gravelly soil usually has better resistance than where the supporting medium is of clay, as the latter is apt to be stiffer when first encountered than at a greater depth. The application of the *Engineering News* formula to piling driven in clay in the vicinity of Boston does not give satisfactory results. Penetration at the end of the driving is frequently much greater than it is after the pile is permited to remain undisturbed for a few hours. The closing in of the clay around the pile, filling the depressions and crevices, greatly increases resistance to further penetration; for example, one 40-foot pile when driven to grade gave a 10-inch penetration, indicating a safe carrying capacity of only 4 tons; a test load, applied a considerable time after the driving, showed no settlement at 12 tons and only a slight settlement at 18 tons; so a 12-ton load was adopted. In another case, piles which gave values of not more than 2 to 3 tons by application of *Engineering News* formula, subsequently supported test loads of 10 to 12 tons without appreciable settlement. In another case, penetration into soft clay for last blows of 5 to 7 inches was reduced to ⅛ to ¾ inches after the piles had set for 24 hours. Piling subject to vibratory forces will often yield when a static load of the same amount produces no effect; deeper penetration and lighter loading are therefore necessary when vibratory forces are present.



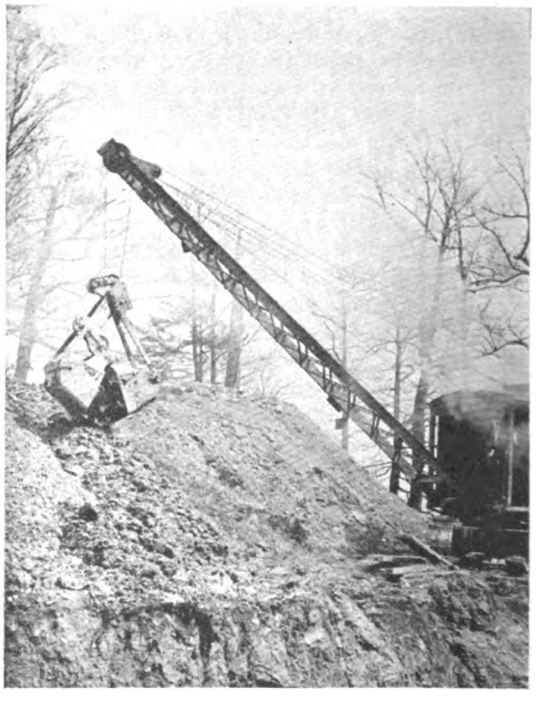
Splicing of piles may be done by the following methods: First, ordinary carpenter's splice, where the ends are halved into one another and bolted; second, metal sleeve; third, butt end spliced with outside cleats like splints; fourth, doweling the two ends together. The last method is satisfactory when deflection of the pile is improbable; in other cases the splice must be as strong as the balance of the pile.

To increase the bearing power of piling in soft material, laging the pile vertically with 2 by 4 or 4 by 6 strips is often resorted to an order to increase the surface exposed to frictional contact.

When piles must be driven through water in locations where the bottom is difficult to penetrate, they may be rendered stable by depositing riprap around them; in some cases it is desirable to remove the hard material by dredging, and to back fill the space after the piles have been driven.—*Eng. and Cont.*

ADAPTABILITY FOR ANY KIND OF WORK

WILLIAMS BUCKETS



Whether it be in loading **or** unloading and **handling** all kinds of **bulk materials**, for dredging **and excavating** work, **or for any** of the many **heavy capacities** in which **buckets** are commonly **employed**, WILLIAMS BUCKETS may be relied upon thoroughly.

Williams Buckets

"Built to Dig and Last While Digging"

They live up to their name. They are built to give constant service. Built with large bearings and with well-guarded cables. They hold their alignment and stand the gaff in all kinds of digging and handling.

International Roller Worth

The remarkable utility and all-round service worth of Austin Road Rollers has become a recognized international fact. You will find these rollers not only in every part of the United States, but also in Canada, Japan, India, Russia, France, Spain, etc. In fact, wherever there is road construction there you will find an Austin Roller.

The expert engineering foresight back of all Austin products has determined the grade of materials and element of design and construction that unfailingly obtain Maximum Life, Service and Dependability.

Write today for catalog

During the war the United States and Allied Governments purchased over 700 Austin Motor Rollers, more than ten times their combined purchases of all other rollers and at higher prices.

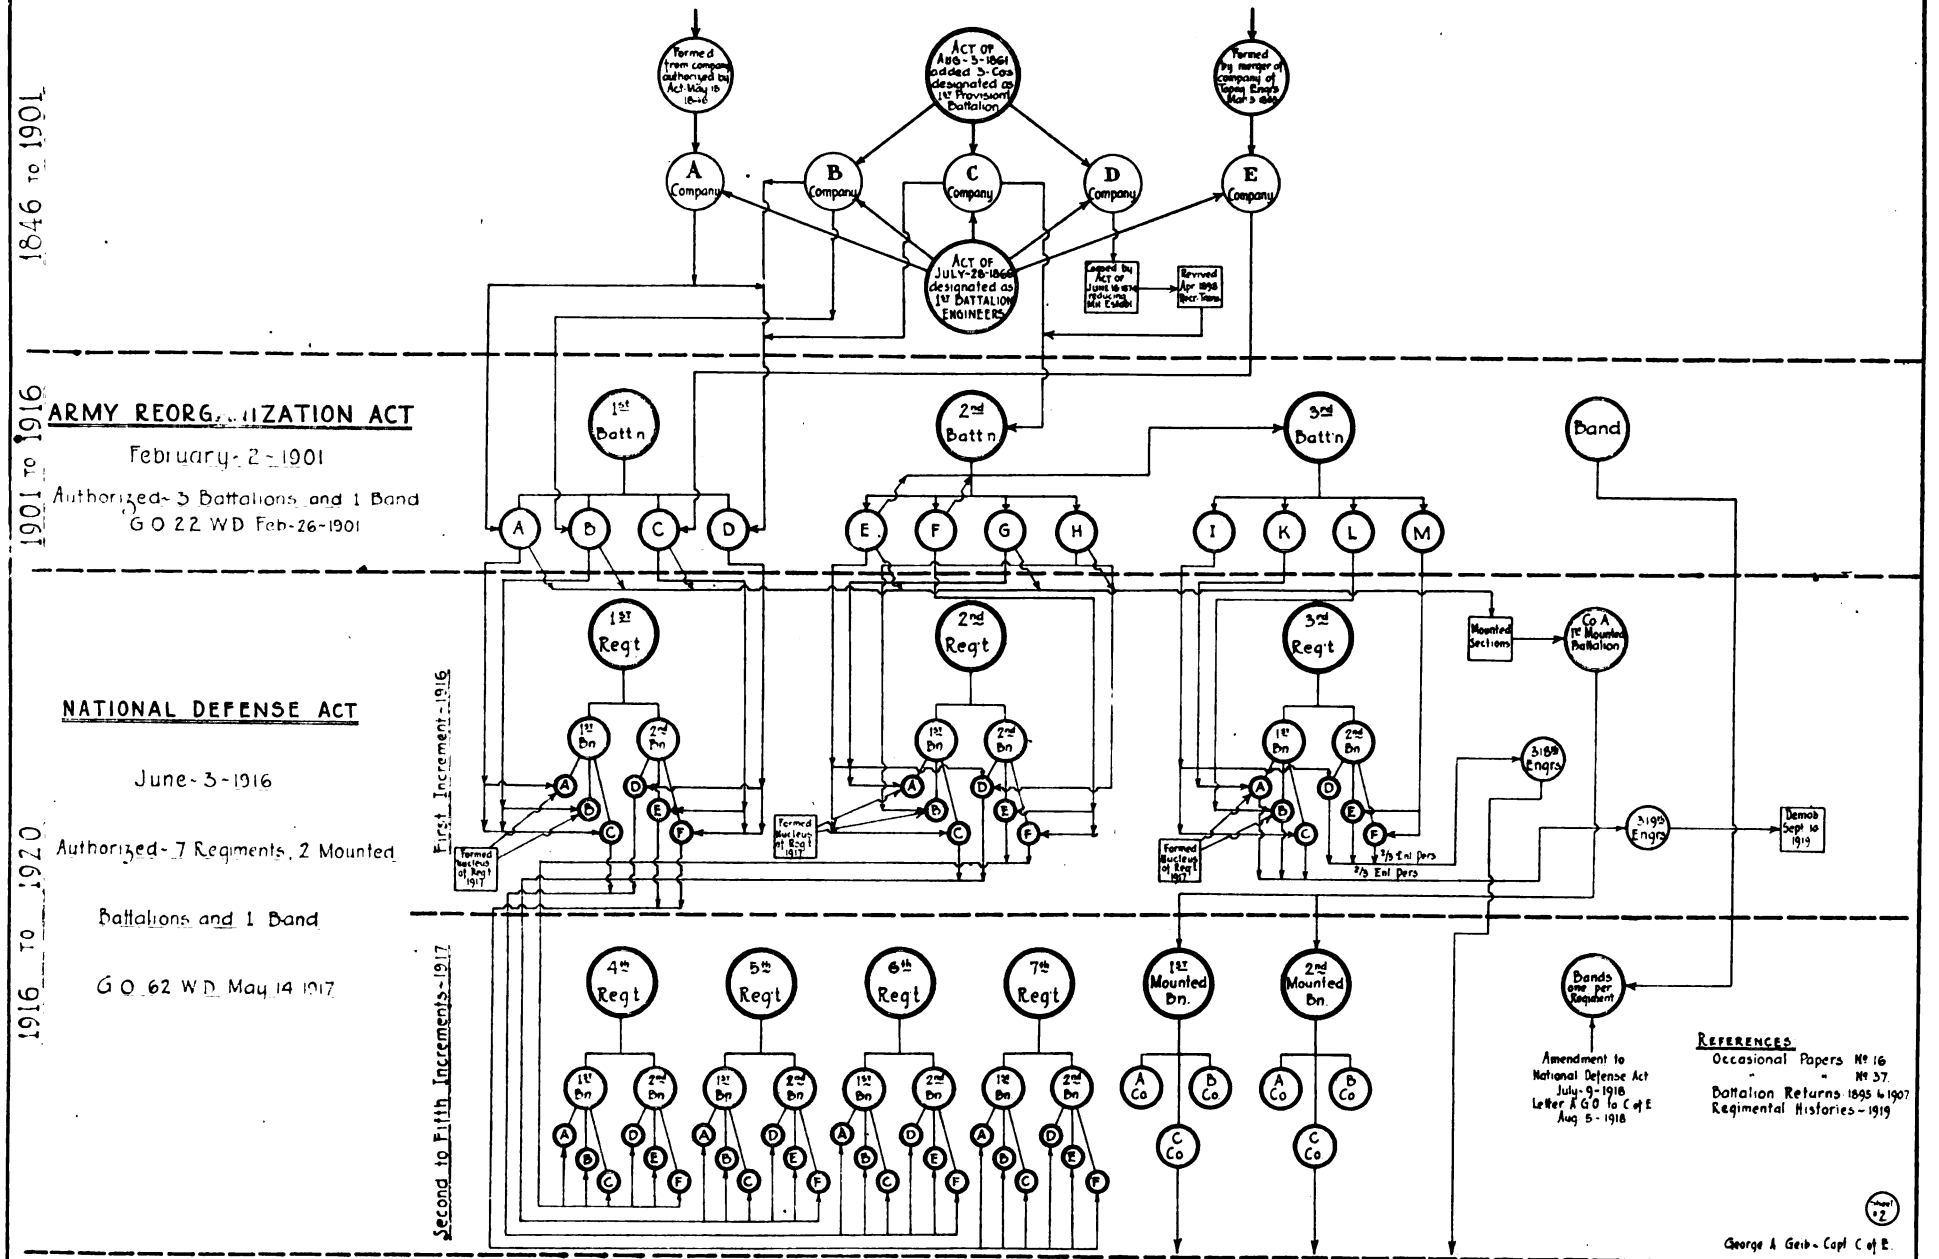
A Graphical History of Engineer Organizations

By

Geo A. Geib

Captain, Corps of Engineers

THE use of graphics in the presentation of facts, statistics, production and various other items has been so readily accepted as the most efficient method of analyzation that the writer has endeavored to present the growth, expansion and history of the Corps of Engineers from its inception to the present time by the same means.



To go into the detail of the formation of each individual company would be a difficult task on account of the incomplete records of such organizations, so an attempt has been made merely to show the formation of regiments and battalions as a whole, and the "flow" of personnel since 1901.

It will be noticed that the formation of the Corps of Engineers dates back to 1802, when, by the Act of March 16, separate Corps were formed of Artillerists and Engineers. From that period on, the Corps of Engineers, Corps of Topographical Engineers, and U. S. Military Academy were practically one, but as various acts were passed to govern the status of Topographical Engineers and the Military Academy the three departments were segregated on the chart and such Acts given that affected their status. On sheet No. 1 it will be noted that the Act of May 15, 1846, authorized one company of 100 men. This was carried along to sheet No. 2 for the sake of indicating the origin of "A" Company in the First Provisional Battalion, as the Act of August 3, 1861, authorized only three companies. The same applies to the origin of "E" Company, which was formerly the Corps of Topographical Engineers. The actual beginning of the First Provisional Battalion then really began when "A" Company

Digitized by Google

GRAPHICAL HISTORY ~ ENGINEER ORGANIZATIONS

Digitized by Google

was first formed under Act of May 15, 1846, hence the period on sheet No. 2 is designated 1846 to 1901.

Upon the formation of the three battalions under the Act of February 2, 1901, the companies of the First Battalion were organized in widely scattered localities and acted independently. However, the 2nd and 3rd Battalion companies were organized later by transfers to headquarters and then distributed to the various companies, which is shown by the flow emanating from headquarters to company.

The "flow" of personnel in the subsequent expansion of the Corps under the National Defense Act is shown from companies to companies, but there is no doubt that such flow might have been transmitted through regimental headquarters instead of as shown. The equal distribution of the personnel is assumed to have been the process of the formation and the quota assigned to each company acting as a nucleus; for instance, in the case of Companies "E" and "F" of the Second Regiment forming the Fourth Regiment.

The 1920 status of all engineer organizations is also given for reference purposes only, and which will be carried out along the same lines as soon as the authorizations of proposed units are received.

The Plattsburg Camp Idea Revived

Regulations for the Citizens' Military Training Camps, as definitely authorized by Sec. 47d of the National Defense Act, have now been issued by the War Department. To the uninitiated, the regulations are quite complicated, but may be summarized about as follows:

(*a*) There will be three types of camps—Red, White, and Blue.

(*b*) The Red Camp is for training in the duties of a private. Any able-bodied citizen, from 16 to 35, of average intelligence can secure admission.

(*c*) The White Camp is for training in the duties of a non-commissioned officer. The camp is to be attended by citizens between 19 and 35 in the following order of preference:

(1) Enlisted men of the Organized Reserves.

(2) Civilian graduates of the Red camp, or men who have had equivalent military training.

(*d*) The Blue Camp is for training in the duties of a junior officer. The camp is to be attended by citizens from 21 to 35 years of age who have the required education, technical and general, and the qualifications requisite for a commission in the Officers' Reserve Corps. This is the course which will probably be of direct personal interest to most readers of THE MILITARY ENGINEER.

The Blue student body will consist of (1st) a quota of warrant and non-commissioned officers of the Regular Army; (2nd) selected members of the National Guard for whose payment funds are available; (3d) members of the Organized Reserve for whose payment funds are available; (4th) if any vacancies exist, a quota of selected civilians. Members of the National Guard and Organized Reserves for whose payment funds are not available may attend as civilians.

The basic instruction in the Blue Camps, applicable to all arms, includes Administration, Manual of Guard Duty, Military Law, Field Service Regulations, Pistol Marksmanship, Map Reading, Sanitation and Personal Hygiene, and Physical Training.

In addition to basic instruction, the Engineer Sections of the Blue Camps will receive instruction in Engineer Equipment, Military Engineering, Engineer Reconnaissance, Technique of Engineer Weapons, and Tactics and Troop Leading. Every endeavor will be made to make the courses interesting as well as instructive.

All students receive transportation to and from camp, subsistence, clothing, and equipment. Members of the Regular Army receive their ordinary pay. Men attending as National Guardsmen or members of the Organized Reserves receive the usual active-duty pay. Civilians are not paid. On the conclusion of a camp, a student who has satisfactorily completed the course receives a certificate that he has the requisite military training for appointment as an officer in the Officers' Reserve Corps.

The training camps will be of one month's duration each. Full information on the subject can be obtained from commanding generals of corps areas, under whose command the various camps are to be.

For this summer the War Department desires to initiate the movement by special emphasis on the Red Camps. It is expected that these will appeal to boys and young men of 16 to 19 years of age. Through them and through their parents the Army hopes to get in close contact with the people and to demonstrate that military training and military environment will develop the young men physically, mentally, and morally. To this end special attention will be paid to medical supervision, to the character of food served, to the physical training, and to the recreation and amusements provided.

In general terms the programs for the Red Camps provide for basic training in infantry and demonstrations covering, in a general way, the tactics and technique of the other combat branches of the Army. The purpose of these demonstrations is to permit of the candidates gaining a conception of the duties and functions of the various branches in order that, should they enlist in the Organized Reserve or take further military training at the White and Blue Camps, they will have sufficient knowledge of the service to permit of making an intelligent decision as to the branch in which to serve.

White and Blue Camps may be held if a sufficient demand should develop for the more advanced instruction, but if such camps are conducted they will be on a rather small scale and will be frankly experimental in nature, with a view to gaining experience for future years.

It will be noted that no provision is made for the training of Reserve Officers in these camps. Nor will any Reserve Officers' Training Camps be established during the summer of 1921, due to lack of funds and other considerations. A limited number of experienced Reserve Officers will probably be needed as instructors at the Red, White, and Blue camps. No Reserve Officer will be called for such duty without his consent.

Experience as an instructor in one of these camps will be of the greatest benefit to the Reserve Officers who undertake it.

Engineer Reserve Officers who desire detail as instructors at these camps should make application to the commander of the corps area in which they reside. Those detailed will be on active duty status and will receive the pay and allowances of their grade.

Following is a list of the corps areas:

Number	Headquarters	Territory
First	Boston, Mass.	New England States.
Second	Governors Island, N. Y.	N. Y., N. J., and Del.
Third	Fort Howard, Md.	Penn., Md., Va., and D. C.
Fourth	Fort McPherson, Ga.	N. C., S. C., Ga., Fla., Tenn., Ala., Miss., and La.
Fifth	Fort Benj. Harrison, Ind.	W. Va., Ohio, Ind., and Ky.
Sixth	Fort Sheridan, Ill.	Mich., Wis., and Ill.
Seventh	Fort Crook, Nebr.	Minn., Mo., Iowa, and N. D. Neb., Kan., Ark., and S. D.
Eighth	Fort Sam Houston, Texas	Okla., Texas, Colo., N. M., and Ariz.
Ninth	The Presidio, San Francisco, Calif.	Pacific Coast and Rocky Mountain States.

The Field Artillery Journal

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bi-monthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

Address—

The Secretary
United States Field Artillery Association
War Department, Washington, D. C.

Roads in Morocco

[The following remarks are based on an article on The Construction of Roads in the French Protectorate of Morocco, written by M. Joyant, Ingenieur en chef des Ponts et Chaussées and published in the September-October (1920) number of the "Annales des Ponts et Chaussées."—ED.]

For political reasons it was impossible for the French government to commence railway construction in Morocco prior to the World War. During the war it was equally impossible for economical reasons. On the other hand, from the inauguration of the protectorate in 1912, France was privileged to construct roads; and when trade was handicapped by the outbreak of war, it became very desirable to afford as much useful employment as possible to the natives of the protectorate.

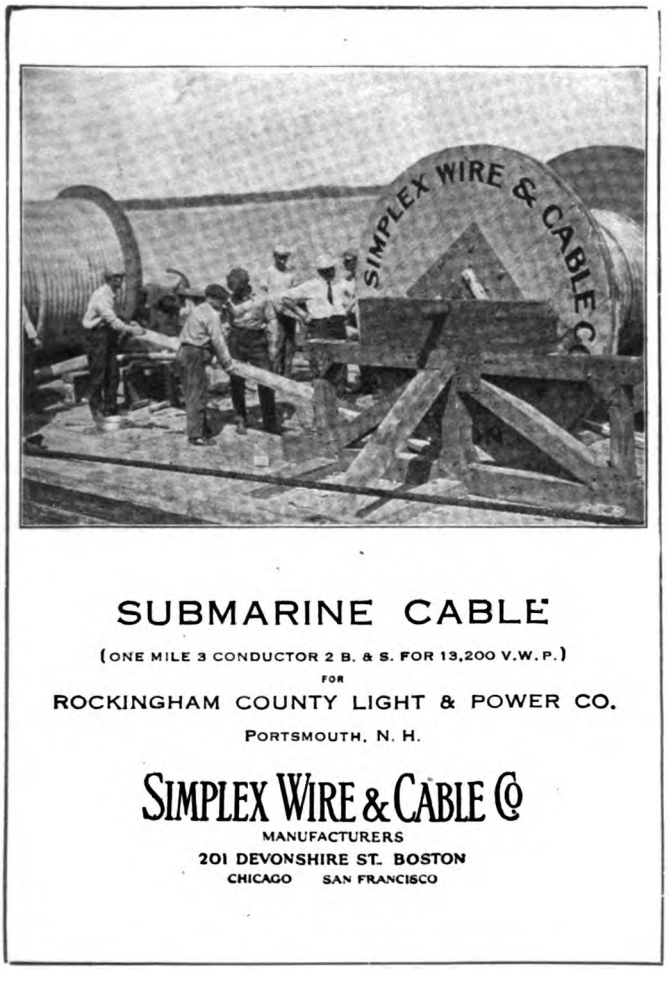
This memoir describes road work in Morocco from 1912 to 1919. The work was subject to the following conditions, rather unusual in our road work at home, but quite possible in any future Latin-American occupation:

(a) Labor was abundant, of good muscular power, and cheap; but not highly skilled.

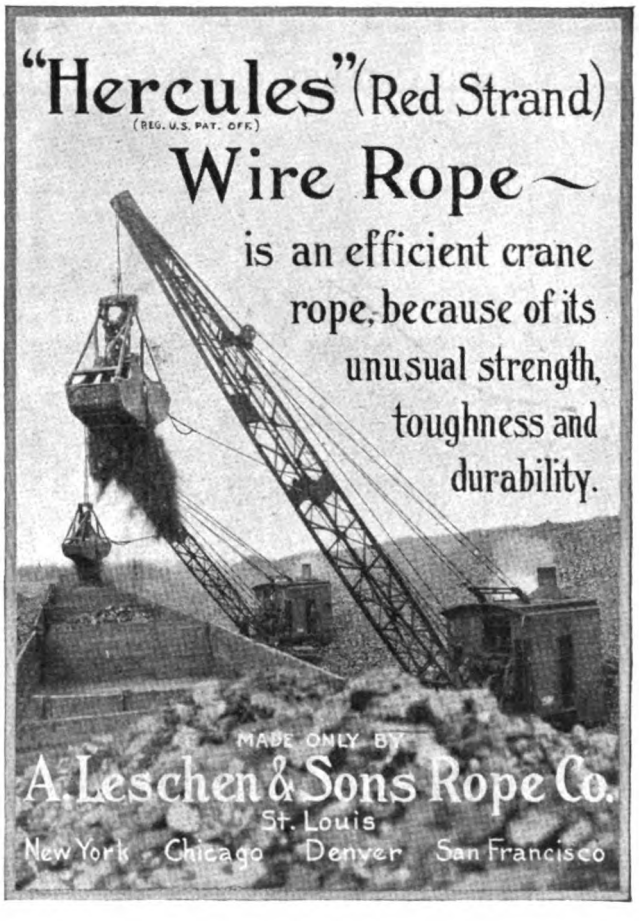
(b) Animal traction was available on very favorable terms.

(c) Road machinery and gasoline were scarce and very expensive.

The author of this article presents a graphic description of the work done, together with a defense of the system against criticisms evidently made by men at home. The following passage, which is translated almost literally, may recall some of the old criticisms which pioneer engineers have always had to face from wise men in an office building:



"Many proposed the construction of roads with re-enforced concrete; some, to reduce expense, proposed to build, with re-enforced concrete, only the tracks for the wheels; with a further effort of the imagination, they would have given a special shape to the wheel tracks and the wheel tires, and thus re-invented railways Certainly re-enforced concrete is an excellent material, but, in a new country, without means of transportation, and without industrial production, it is contrary to common sense to wish to use, on the construction of roads, great quantities of imported materials, like cement and iron, instead of rock taken from the ground in the vicinity."



The roads were built almost exactly according to the classical French system, with which so many members of the A. E. F. are familiar. Some little discussion is even given to the selection and planting of the shade trees. In the location of the roads, it was not, however, necessary to follow ancient routes, but the routes between the rather distant towns were selected so as to pass as close as possible to existing or potential rock quarries. The author of the article makes a conclusive defense, alike against those who would have selected the routes on purely topographical grounds, and those who would have preferred a greater mileage of unpaved roadway.

The article ends with the following synopsis:

1. As soon as a simple trail becomes unsatisfactory, it is necessary to build a real road, and the classical methods of construction retain their value.

2. In locating the road, not only topography, but also the ease and rapidity of construction must be considered. The transportation of rock is the most difficult part of the work,

Digitized by Google

and becomes prohibitive, in cost, when the quarries are more than 10 km. (6¼ miles) from the scene of the work.

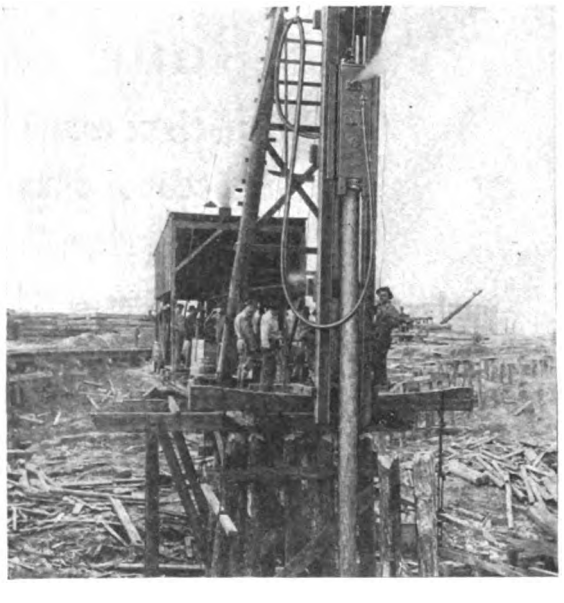
3. The construction of a road system can advantageously precede the building of a railroad (except in regions not provided with rock), when railroad work is postponed for political or economic reasons. But a road will not long be sufficient for the needs of traffic along the principal arteries of a country.

Rubber—Its Growth, Protection and Preparation

The Motor Transport Training School at Camp Holabird, Maryland, has issued a lecture on Rubber compiled by Mr. A. J. Hopkins, from which the following is extracted:

The elastic properties of rubber were early known to the natives of the jungles, but it was only after the discovery by Charles Goodyear, an American, in the fore part of the nineteenth century, of the secret of rubber vulcanizing, that rubber began to play an important part in the affairs of civilization. To-day there is scarcely an article in the world more universally used than rubber.

Early attempts to use it gave little result, because of the fact that rubber melted in summer and stiffened like stone in winter. The rubber industry was about to pass away when Charles Goodyear discovered that crude rubber mixed with certain chemical ingredients, the chief of which is sulphur, and subjected to a certain degree of heat, became pliable and unaffected by changes in temperature. This discovery was one of the most important of modern times and deserves to rank with the discovery of electricity, the invention of printing, gunpowder, and other great benefits to mankind that have advanced civilization.



Crude rubber is gathered from certain species of trees, shrubs, vines, and roots; it is not the sap of the tree, but a free chemical compound contained in the sap. Upon tapping the tree a milky fluid issues forth at the rate of about three-fourths of an ordinary teacupful at each tapping. This fluid is called latex. It is slightly alkaline and contains 58 per cent of water and 35 per cent of rubber, with traces of sugar and mineral salts. After straining and adding a weak solution of acetic acid to the latex, the rubber, a white, tough, elastic mass, coagulates and floats, when it is removed and washed and dried in long, narrow sheets called crepe. It is sometimes smoked by a process somewhat similar to the smoking of hams after being rolled into thin sheets. In 1918, the total rubber production was 296,579 tons, of which 80 per cent was cultivated and 20 per cent wild.

Cultivated rubber is obtained from the Strait settlements, southern India, Ceylon, Malay Peninsula, and Indo-China. Wild rubber comes mostly from South America and Central Africa, in a belt about ten degrees north and south of the equator. The most important wild rubbers are the Baras and Castillons of the Amazon region.

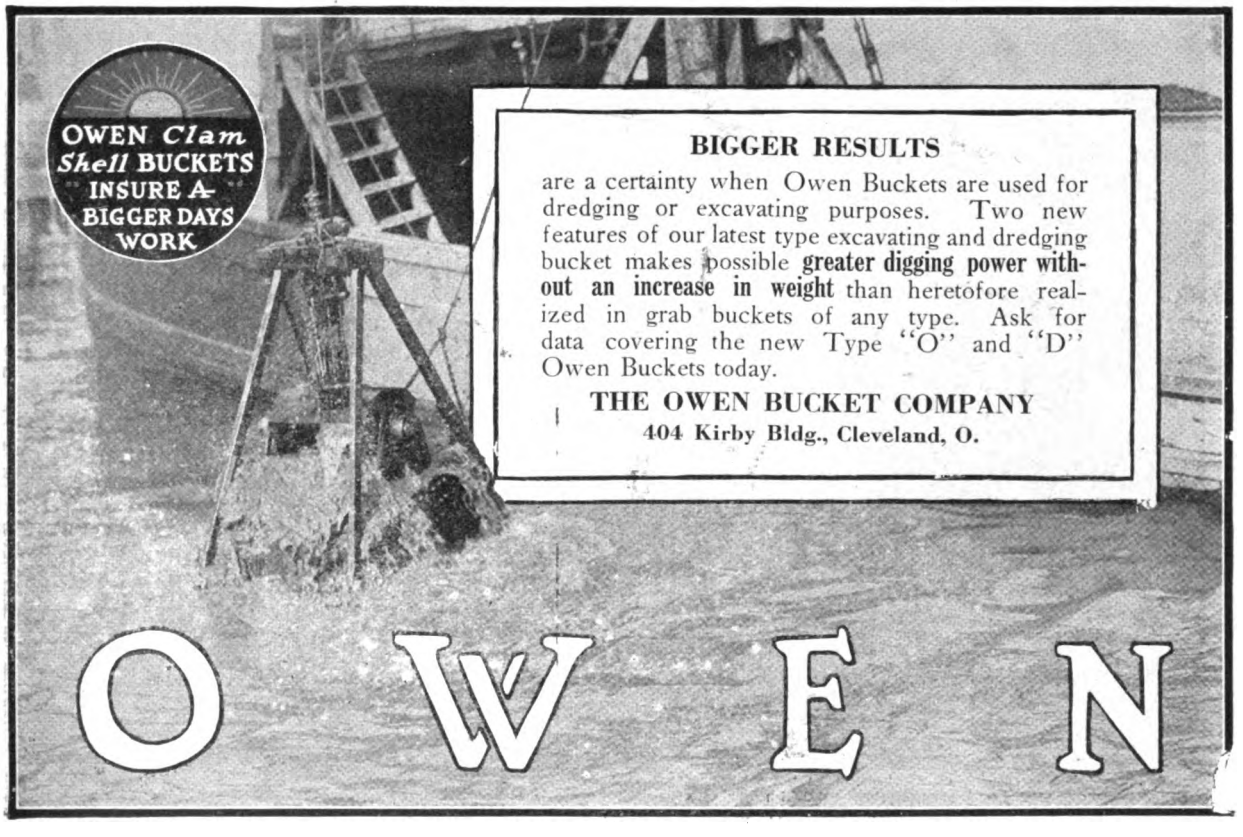
Methods of Providing Mechanical Protection for Piles

It has long been recognized that creosoting, while valuable in preventing decay and deterring marine borers, is not a long-lived preventative of damage by the latter in infested waters. Various methods of affording mechanical protection to piles are presented in an appendix to the annual report of the Committee on Wood Preservation, Amer. Ry. Assn. Bul. 233.



Cast-iron Cases have been used for many years on the coast of the Gulf of Mexico. The cast-iron sections are made in halves, to be placed and bolted together after the piles are driven and capped. As the castings of each section are bolted together, the completed casing is lowered to the mud line by the addition of other sections, if necessary, and forced into the mud. The space between casing and pile is then filled with sand and capped with cement mortar to prevent the washing out of the sand. The casing must go far enough into the mud to insure a permanent seal to retain the sand filling. As long as the casing remains intact the protection is complete. Cast iron corrodes slowly, and with heavy casings protection has been afforded by this method for 30 years in several instances. The present high cost of cast iron is the chief objection to the method.

Vitrified Pipe Cases can be used in a similar fashion when not exposed to wave action nor the pounding of drift. They have been used extensively along the Gulf and Pacific coasts. The pipe sections in one piece are placed over the pile before it is capped. The sections are cemented together, lowered into the mud, and sealed with cement mortar cases. Any serious defects are shown by escaping sand, and broken sections can be replaced by sections made in halves and joined together by special lugs, copper wire, or treated wooden plugs. Annual inspections have been found sufficient, as the borers are not able to make trouble-some headway even though breaks in the casings occur in the intervals. The weakness of the casing is the chief objection to the method.

Reinforced Concrete Cases are less fragile than vitrified pipe and less expensive than cast iron. The cases can be made in one piece for placing before the piles are capped, or in halves for placing at any time after the piles are driven. The halves may be locked by leaving reinforcing wires exposed in each half to be twisted to the wires of the other half and covered with cement mortar. In these cases the concrete covering of the reinforcement is usually thin, and experience has not fully developed the thickness necessary to insure the reinforcement against corrosion. The lack of extended tests in service is the chief objection to this method.

Concrete Jackets Cast in Place have been used lately in the harbor of Charleston, S. C., where the teredo, which is less active than in the waters of the Gulf, is successfully controlled by careful creosoting. The limnoria, however, is very active, cutting off the piles near the low-water line, but rarely working dangerously on treated piles at depths greater than 2 feet below low water. Under these conditions, protection from 3 feet below low water to 4 feet above high water is satisfactory, and for this purpose the jackets have been used. They have been applied as follows:

Six-penny nails were driven into the piles 6 inches apart in rings 8 inches apart. The nails projected 3 inches and the rings extended the length desired for the jacket. No. 10 gage iron wire, for reinforcement, was twisted around the nails and stretched longitudinally and laterally, at about 1½ inches from the pile. The forms were made by ⅛-inch wood veneering bound against the heads of the nails with wire which stretched enough to allow the mortar to cover the heads of the nails in most cases. 1:2:4 concrete, with ¾-inch stone, was used, and no great difficulty in placing it in forms 4 feet long was experienced. To keep the filling

Digitized by Google

from falling out, bagging was placed around the bottom of the form if it did not rest in the mud. Jackets placed in 1915 have shown no signs of failure except for some breaking away of the concrete at the bottom of the jackets, believed to be due to leaking of the bagging at the time of placing the concrete. On work now going on, jackets 3 inches thick of plain concrete are being placed, using No. 24 galvanized iron for the forms. The difficulty of securing good concrete for considerable depths under water are the chief objections to this method.

Gunite coatings for wooden piles were placed in Seattle in 1919, but the committee believes that it is too early to report upon the success of the work. If the coating proves durable, it will afford a rapid and cheap means of securing the protection desired.

Nails studding the exposed surfaces were used by the Romans long ago as protection against teredo, and are still used in European waters. Effective protection does not seem to require complete covering of more than one-fourth of the exposed surface. The expense of this method is its chief objection.

Sheet Metal in the form of copper or zinc sheets have been used, and afford complete protection as long as the sheets are intact. Copper is not affected by salt water, but the zinc soon corrodes. It is suggested that some of the brands of rust resisting sheet iron will withstand the effects of sea water for considerable periods, but complete data is not available. The chief objection to the method is its expense.

Coatings of Tar, Asphalt, etc., and similar materials, either alone or in combination with fabrics of various kinds, are efficient as long as they remain intact, but they are likely to be broken by handling or the pounding of drift, etc. Unreliability is the chief objection to this method.

Bark left on piles affords protection against marine borers, and the life of untreated piles is considerably prolonged in infested waters by leaving the bark on. This protection is, however, incomplete, and it precludes other treatment, to prevent decay, etc., which are its chief disadvantages.—*Engineering and Contracting.*

The Obligation of Supremacy

A reputation of "par excellence" in any trade is both an asset and a liability. It attracts business but at the same time obligates its holder to a most intense degree of concern to maintain his supremacy. This obligation operates as a guarantee as effectively as any written bond.

In laying pavements, WARREN BROTHERS COMPANY are compelled to give in their supervision and attention to detail that no engineer, regardless of his individual ability, can afford to give. The greater his skill and experience, the more the engineer realizes this and welcomes the technical supervision of detail by the specialist. Proven under every condition and climate.

Warrenite-Bitulithic

plus our expert supervision and inspection, has demonstrated its supremacy throughout the United States and Canada.

The Engineer and the English Language

"An engineer who is inarticulate," said a well-known New York engineer in speaking of the value to members of his profession of a thorough knowledge of English, "is quite as useless as one who is professionally incompetent." This is a terse and vigorous expression of a truth which all experienced engineers recognize, that the man who has not the power to give his ideas clearly to others, the man whose thoughts are locked in his brain simply because he has not the ability to communicate them, suffers under a handicap which no amount of professional knowledge can possibly overcome. The engineer is not a hermit in his profession, shut off from all intercourse with others; his work is indissolubly bound up with that of other men, and he finds himself constantly obliged to communicate with them. The men employed by an electric-light company, from the president down to the humblest clerk, are individuals each busied with his own particular task, to be sure, but each contributing toward a common end—the success of the company. and because of this common aim they are in constant communication with one another, by word of mouth, by letter. by written report. It can, then, be readily perceived that the failure on the part of any individual employee to make himself clearly understood by other employees will often affect very seriously the efficiency of the whole machine. An incomplete, indefinite, or ambiguous report from a foreman, for example, may temporarily delay the progress of an important piece of work. The more clearly and effectively the communication of ideas is carried on, the more efficiently will the common work of all be accomplished. And the employee who is best able to express himself clearly and exactly is the one who will stand the best chance, other things being equal, of advancement. The young engineer who writes the clearest, most accurate report, the foreman who can explain exactly and in a few words just what he wants done, are the men whom the superintendent is bound to notice. There is more than one instance on record of promotions which have come solely as the result of the ability to write a good report.—*Composition of Technical Papers, Prof. Homer Andrew Watt.*

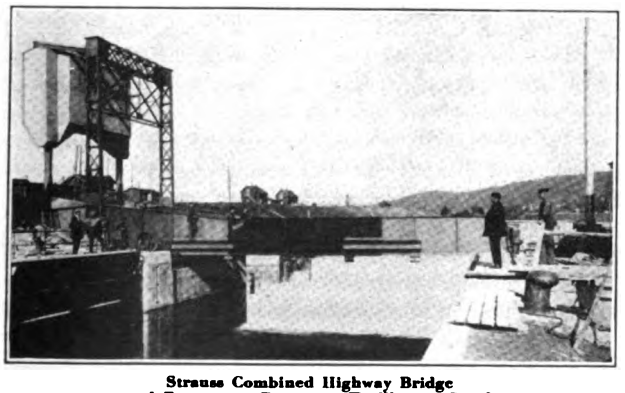
Engineers in the Italian Army

The engineer officers in the Italian army either serve with engineer troops or are assigned to engineer directing offices in the different territorial army corps districts or are on detached service, such as general staff, etc.

The service with troops includes instructing troops in fortifications, road building, bridge building, all branches of military engineering, and, in addition, much of the work done by our signal corps—for example, telegraph, telephones, and wireless. The engineer officers serving with troops, command and come in constant contact with troops of their own branch of the service.

Engineer officers assigned to the various territorial army corps engineer directing offices (Direzione di genio de corpi d'armata) have charge of the work which must be done by military engineers within their corps districts. These officers come more in contact with civilian laborers, contractors, technicians, etc., than they do with the different branches of the military service. When practicable, however, engineer troops are used under the direction of the corps engineers, especially when the work to be done is of such a nature that it will be good instruction for the troops.

Military engineers are not engaged on public works necessary to the commercial or industrial life of the nation. In Italy, the government has an organized service called the Civilian Engineers (Genio civile), which is a part of the ministry of public works. The "genio civile" attends to all works necessary to the commercial and industrial life of the nation. It also looks after the improvement of rivers, harbors, canals, railways, and highways, with the following exceptions:



(*a*) Military highways are attended to by the territorial army corps engineer directing offices.

(*b*) In case of earthquake, flood, or other calamity, many of which occur in Italy, the engineers help in every way.

(*c*) In harbors where there are naval arsenals or bases, the army engineers have charge of all constructing work which is of a purely military or secret nature. For this purpose there is stationed at each big naval arsenal, naval yards, etc., an army engineer officer who has charge of all building work for the navy, except the work of a purely naval character, such as ship building, ship repairs, and work on armament.

The territorial army corps engineer directing offices are charged with all construction required for the military establishment, including fortifications, barracks, quarters, warehouse depots, etc. This work is usually done by civilian laborers, contractors, etc., under the direction of military engineers. However, when the work is of a secret nature, such as parts of fortifications, arsenals, etc., it is usual to have engineer troops do this sort of work.

Military engineers are not connected in any way with peace-time mapping operations. The mapping is entirely done by the Instituto Geografico, which is a branch of the war department. The Geographical Institute consists of army officers on detached service and civilians. Some of these army officers, of course, are engineers, but the officers with best qualifications are chosen for the Geographical Institute, no matter to what branch of the service they belong.

Alaska Railroad Location Surveys Through Broad Pass

[In March, 1914, Congress authorized the President to acquire or construct, and to operate, a system of railways in Alaska. The estimated cost of the proposed system was $35,000,000. The work has been carried on under the Secretary of the Interior. Surveys were begun in the early spring of that year, and construction began in the spring of 1915. The route adopted extends from Seward to Fairbanks, approximately 470 miles, with a branch about 40 miles long to the Matanuska Coal Field. The Alaska Northern Railroad Company, a private enterprise started in 1904 and abandoned in 1909, when it had been built about 70 miles from Seward, was purchased for $1,500,000 and rehabilitated at an additional cost of about $1,800,000. The section through Broad Pass is expected to be completed this year, and will complete the project, for which the total appropriations have amounted to $52,000,000.—ED.]

The Broad Pass District on the route of the Alaskan Government Railroad lies between Indian River and Jack River, 61 miles (from mile 266 to 327), and includes the main divide, Broad Pass, between the Pacific Coast and the interior rivers, as well as the minor summit, Chulitna Pass, between the Susitana and Chulitna Rivers. Broad Pass is nearly 8 miles wide, and attains an elevation of 2,362 feet above sea level. It is flanked by high mountains to the east and west with low rolling ridges, partly timbered and partly covered with heavy arctic and reindeer moss, in the pass itself. Small lakes and muskeg swamps abound.

After crossing the Susitna (mile 264) the line follows the Indian River canon, crosses Chulitna Pass (mile 274), leaving Indian River to the east, climbs on a compensated grade, maximum 1.75 per cent, to the high benches east of the Chulitna River, and crosses Hurricane Gulch (mile 284) on a steel bridge 700 feet long and about 300 feet high, with a main arch span of 284 feet. It then descends on a 1.5 per cent grade to the Chulitna valley bottoms, crosses the East Fork of the Chulitna (mile 292), climbs on a 1.75 per cent grade to the benches between the East and Middle Forks and crosses the latter at mile 306. It then climbs on a 1 per cent grade to Broad Pass summit (mile 310), descends on a 1 per cent grade to the crossings of the Cantwell River (mile 317) and Windy Creek (mile 323), and follows Jack River to its confluence with the Nenana River at mile 327.

The working season for survey parties extends from about June 1 to October 1. A locating party usually consisted of a locating engineer, assistant engineer, transitman, topographer, levelman, draftsman, office man, two rodmen, four chainmen, one rear flagman, two cooks, ten axemen, four packers, one hunter, and a pioneer crew of six men to build trails. From Indian River (mile 266), pack transportation was employed requiring four packers with 36 horses and mules. Trails were heavy, and there were many difficult fords, so that the pack trains averaged from ten to twelve miles per day with a load of 200 pounds per animal. Each animal was fed 10 pounds of oats daily, and foraged on native grass until it was killed by the September frosts. The animals suffered from mosquitos and flies in spite of all protection that could be devised, the most effective being the application of grease around ears, eyes and nostrils, and the building of smoky fires ("smudges"), in the smoke of which the animals could stand when not grazing at night. The pack rigging consisted of saw-buck pack saddles with Humboldt rigging.

The equipment and personal effects of the party were held to a minimum. The tonnage included one 16 by 24 foot dining tent, one 14 by 16 foot cook tent, one 14 by 16 foot office tent, and a 9-foot square mosquito-proof sleeping tent of light-weight duck or silk with cloth floor and draw-string cloth door for each three men. Two sheet-iron coal stoves weighing 125 pounds each, a sibley stove for the office tent, granite-ware cooking utensils, a knock-down drafting table, and two stationary boxes carried on a single pack animal, were the principal items of camp equipment. The individual equipment of each man was limited to 50 pounds. Subsistence consisted of ordinary staples from the United States, supplemented by fresh meat, bear, caribou, mountain sheep, supplied by the hunter, fresh fish, and native blueberries in the late fall. The instrumental equipment was of the ordinary kind.

A reconnaissance by the locating engineer was made to fix the preliminary line to follow as nearly as possible the probable final location. The preliminary line was accurately run. Hand-levels and plumb-bobs were used in chaining, and all angles were doubled. The leveler took elevations at every 50-foot station and at all breaks necessary for an accurate profile. The topographer followed with a rodman, two chainmen, and an axeman, taking actual 5 or 10 foot contours and slope notes, except where sufficient information could be given by a few side notes. No attempt was made to make an elaborate topographical map of the country. As the final location usually followed the preliminary line closely, accurate local topography within a short distance of the preliminary line was all that was required.

On the located line, well-made stakes were set at 50-foot intervals, substantial hubs were set at points of curvature and at necessary instrument points on tangents. The draftsman made all maps and kept traverse books of the courses of all preliminary and the located lines. His computations were checked by the office man, who also kept complete profiles showing alignment, instrument points, grade, grade points, bench marks, side slopes, and timber and vegetation notes.

Much of the topography was very rugged, timber was frequently, and underbrush usually, rather dense, and about two-thirds of the days were rainy, so that progress was slow, though work was done daily in rain, sunshine or snow. Progress on preliminary lines and levels varied from 2,000 feet to 2 miles, and on location lines and levels from 1,500 feet to 1 mile daily.—*Engrg. News-Record.*

R. O. T. C. Enrollment

On February 1, 1921, the total number of units and student enrollment therein amongst the colleges was as follows:

		Students
101	Infantry units with	33,649
20	Field Artillery units with	5,513
19	Coast Artillery	2,696
19	Corps of Engineers	2,827
11	Cavalry	1,810
11	Signal Corps	1,307
8	Motor Transport	670
6	Air Service	253
5	Dental Corps	215
5	Medical Corps	109
3	Ordnance	354
3	Veterinary	94
211	Units; total enrollment	49,497

Accurate measurements were recently taken of 273 students under military training in one R. O. T. C. unit, and again after an interval of three months. The average results were as follows: Gain in weight, 8.84 pounds; gain in chest expansion, 1.24 inches; loss in waist measurement, 2.08 inches; gain in height, ½ inch.

Prize Map Problem

(Continued from Page 245)

The following comments are presented in the hope of provoking discussion.

Form of Orders. In one of the selected solutions the required instructions to the engineer troops are given as a field order. It is believed that this is the correct procedure, the desirability of which can not be overemphasized. The engineer troops in a division are usually so scattered, in the field, that the officers can not be assembled to receive verbal instructions. In the haste of arranging the next day's operations the division engineer is tempted to issue separate instructions to the various fractions, with the consequence that no one knows what the other is doing, and co-operation is lost. A field order is in a form which gives the whole program in the simplest manner, and its use should be habitual. Each detached unit of the regiment should regularly send a runner to the next higher unit, at a fixed hour every evening, to receive the orders for the following day.

The distribution of the order should not be limited to engineer troops. The Chief of Staff, certain of his assistants, and the infantry and artillery brigade commanders have a vital interest in the proposed activities of the engineers, and each should receive his copy. These must, of course, be distributed by cyclists or runners furnished by engineer headquarters.

Mission. To check up the substance of the order, it is necessary to consider the mission of the engineers, for the order announces the decisions made to insure the accomplishment of the mission. The general mission of the engineers is to assist, by all means at their disposal, the other arms in the accomplishment of the intentions of the commander. It is not therefore generally necessary for the higher command to prescribe a definite mission for the engineers, but it will often specify particular tasks which it regards of especial importance. The conference which the division engineer attended was for the purpose of outlining to-morrow's operations to the staff, in order that the latter might begin immediately the arrangements for its execution. The division field order will follow, and will prescribe the details of the execution.

After learning at the conference the general plan of operations, the division engineer can decide the detailed mission of the engineers. In to-morrow's advance, the 16th Infantry Brigade will lead. It will undoubtedly be assigned some artillery to deal with any enemy strong points that may be encountered. While the infantry and machine guns will not probably need any assistance from the engineers, the artillery will probably need help in crossing some of the streams, if the enemy detachments have been at all active in demolition.

No need for assisting the cavalry is foreseen.

Bridges and Roads. It is probable that there will be considerable work in repairing or reconstructing bridges before the divisional transport can pass. The mission of the engineers in this regard must, it is important to note, be considered as that of getting the transport through, rather than of constructing the bridges as a strictly engineer task. We need not expect to find any road craters of importance, for the enemy has scarcely had time to prepare them; but he may well have left delayed action mines in bridge abutments and along the railroad.

Water. The most pressing question is water. The water-tank train at hand is of insufficient capacity to supply even the men, unless it makes two or three round

Wickes Blueprint System

FOR DISTINCTNESS

Above all else a blueprint must be distinct—a single decimal point or figure misinterpreted may result in a catastrophe.
Protect your job, your workmen and yourself by getting absolutely distinct Prints.
Use the WICKES SYSTEM. It is consistently reliable in accuracy, distinctness and clearness. No blotches or faded lines, to mar its strength of tone.

trips per day. The division engineer must try to get more tank trucks and must also arrange for a systematic search for every possible source of local supply, for developing the supply when found, and for facilitating its distribution by placing signs, by improving approaches, and by controlling traffic blocks and jambs at such places. It is possible that the cavalry will organize its own search for water in the upper reaches of the streams, but it will be well to arrange for co-operation in this important matter.

The Railroad. It is a safe bet that the enemy has destroyed the railroad to the limit of his ability, and it can not be counted on for the delivery of material until it is repaired. It is very possible, however, that from lack of time and means this destruction has not been so thorough but that it can be speedily repaired. Every mile that the railroad can be operated south of Oceanside will be so much clear gain for the division. It is true that the telegram which the division engineer has received from the corps engineer indicates the latter's intention to see to the repair, but it is not clear that the corps engineer is in a position to undertake the work to-morrow. The division engineer can not dismiss the subject with the thought that it is not his business to repair the railroad. It is his business to assist his commander in every possible way. He should call up the corps engineer, and if the latter has not the work immediately in hand, arrange for its undertaking with divisional personnel. In any case, the line will be thoroughly examined by an officer or competent master sergeant.

The Engineer Train. The decision of the commander to organize a defensive position, if superior enemy forces are encountered, requires that the entrenching tools and material in the engineer train be ready for prompt issue. Wagons carrying this material will not, therefore, be available for any other use.

Marking Roads. In addition to correcting the road maps, arrangements must be made for marking roads and places so that messengers and troops can quickly and easily find the way. The main highway needs no marking, but reliable sign posts should be placed on the cross-roads connecting with the interior highway, which may become of supreme importance to the division; and signs should be placed to show plainly the names of towns, etc. As the tanks are coming up, warning signs should be placed at bridges which they, or other extra-heavy vehicles, cannot safely pass.

Summary. The detailed mission of the engineers includes:

(a) Preparation of any necessary stream crossings for the artillery with the leading brigade, with such promptness that the brigade will not lose its artillery support.

(b) Repair of any bridges that have been destroyed, or the substitution of emergency crossings. The handling of traffic at these and other critical points until it can be taken over by the military police.

(c) An organized search for delayed-action mines wherever they are likely to be found.

(d) An organized search for all sources of water, its prompt development where found and the provision of facilities for its distribution.

(e) A thorough examination of the railroad and, if so indicated after conference with the corps engineer, its repair as far south as possible.

(f) The provision of entrenching tools and material promptly when needed.

(g) The correction of road maps, and the thorough "signboarding" of roads and places.

(h) The meeting of any unforeseen emergencies.

Means. The means at the disposal of the division engineer are his regiment, one battalion of which will, however, be without its tool wagons and other transport tomorrow; the material and tools with his engineer train; the local resources at Oceanside, those which he can find along the route, and such additional material as he can secure, by train or truck, from Los Angeles. He will not get his ponton train for several days unless he can arrange to have it shipped by rail, or to have it towed by motor trucks. In the latter case the wagons are likely to arrive in wrecked condition.

Decision. His decision must include the disposition of his troops and transport, subject to the approval of the higher command in its features affecting the other units; the specific missions to be assigned to any engineer units; alterations in the material carried in his transport, and additional material and transport to be secured from the division staff, or from the corps engineer.

As the details of the work required are largely unknown, he must, as indicated in the selected solutions, keep detachments to a minimum and hold the bulk of his force in hand to meet developments. On the other hand, he should designate in advance all necessary detachments, in order that the subordinate commanders may fully plan and organize the execution of their duties. Obviously, there must be one fraction with the advanced troops, to execute the first emergency work and send back early warning of further work required. As indicated in most of the solutions, one company will be appropriate for this purpose. Correct organization would seem to require that it be attached to the leading infantry brigade, and be under the orders of that commander, but its mission should be clearly stated in division orders.

It is thought that a platoon should be left at Oceanside, to take care of the procurement, care and loading of any supplies that may be sent for. One company will probably be all that can be spared for railroad repair, if that duty falls to the division troops.

Relations with Higher Authorities. The higher command will be interested only in the assignment of the company to the leading brigade, and in the position of the bulk of the regiment, and its transport, in the column. For the latter, it is thought that a position immediately following the leading brigade and its attached artillery will be appropriate.

The division engineer will give G-3 a draft of the necessary paragraphs in the division order covering these dispositions, and secure his approval of the proposed use of the engineer troops. The point is well brought out in one of the selected solutions that he would at the same time inform him of the contents of the corps engineer's telegram.

Next, I think, he would call up the corps engineer, settle the railroad repair question, ask for additional water-tank trucks, request that a carload of road plank be sent to Oceanside, and see what could be done toward hastening the arrival of the bridge train.

Drafting the Orders. He would then give directions to his supply officer for unloading from the trucks and wagons material not needed for the following day, and the loading of such material as road plank. I think he would put at least one truck, loaded with plank, at the disposal of the company commander with the leading brigade.

The field order for the regiment would next be drawn up. This would include so much information concerning the

Digitized by Google

enemy, our own troops, and the plan of action as may safely be distributed, always bearing in mind that a copy is likely to fall into enemy hands through the capture of its holder; it would outline the disposition of engineer troops, following the draft given to G-3, and would give the mission of each fraction, so far as assignable at the time. Certain missions are assignable, and the officers concerned should be informed of them at the earliest possible hour, so that they may make their own arrangements. Thus the mission of fully developing local water resources, of reporting on the condition of the railroad, of searching for mines, etc., might be assigned to the 2nd Battalion (less its detached company). If thought necessary, the reservation might be made that, say, one complete company of this battalion would be held ready for bridging or other work to be later indicated by the division engineer.

The order would include a statement of the special material to be carried by the engineer train, dispositions for furnishing the 1st Battalion with tools, etc., and would, of course, end with instructions where messages should be sent.

As the order would probably be issued prior to the receipt of the division order, it would specify that the time of departure of the main fraction of the regiment, and possibly other details, would be announced later.

Sufficient copies would be prepared so that battalion commanders would have only to transmit them to company commanders with a supplementary memorandum assigning the duties between these units.

Supply Question. The division engineer has then to confer with G-4, the assistant chief of staff for supply, presenting to him the plan for water supply, informing him of the measures taken, and requesting the necessary assistance in extra truck assignment. I doubt whether he would be justified, in view of the uncertain requirements, in asking for extra trucks at this time; but he should arrive at a definite arrangement for getting additional trucks if bridge and road material in considerable quantity must be sent up in order to allow the divisional transport to proceed.

Organization. I think it very clear that the division engineer must have a well organized and well-trained staff to attend to all these details in the limited time available. The best organization is, I think, a matter worthy of considerable discussion.

Questions for Discussion

(Continued from Page 252)

within the limits of the various corps areas, and few, if any, competitions between engineer units have been staged. It is believed that it would be beneficial to organize a competition between the engineer units, and to make this competition an annual event. In connection therewith some trophy would be necessary, to be contested for each year, and to have engraved thereon the name of the team winning the event annually. In addition, it would be highly desirable to give medals to the members of the winning teams. There are no funds in the hands of the Government available for this purpose, and it would be highly fitting if the Society of American Military Engineers were to donate a trophy, to be known by the name of the Society. However, the Society treasury has no funds for this purpose, and will have to depend upon the efforts of the local sections or of individuals to defray the costs.

It is desired that this matter be brought to the attention of the local branches and of individuals with a view to getting an expression of opinion which may form the basis of further action early next fall, when Society activities are resumed. Medals may possibly be provided by local branches, each medal to bear the name of the branch, but this would necessitate arrangements to "endow" the medal or, by other means, to insure that it will be available annually. The following questions should, therefore, be decided, viz:

(*a*) Shall the Society establish a marksmanship trophy to be competed for annually by engineer units of the R. O. T. C?

(*b*) How shall funds be raised for the purpose?

(*c*) To what extent can you or your branch contribute?

(*d*) Does your branch wish to make provision for a medal for an individual contestant in addition to contributing its share of the team trophy?

II. *Student branches.*—In connection with R. O. T. C. units, and in connection with other institutions where there are no engineer units of the R. O. T. C., it appears advisable to undertake the establishment of student branches somewhat after the manner of other engineering societies. This can be done under the present constitution and by-laws, inasmuch as students pursuing engineering courses can be elected to associate membership. These students, however, can rarely afford to pay the full membership price, and it has been suggested that the executive committee of the Society may authorize reduced fees—about one dollar ($1.00) per student—with the understanding that the journal shall be issued only on the basis of present subscription price—that is to say, one journal to be issued for each five members in the student branch. Is there any objection to such procedure?

III. *Society ribbon and medallion.*—The Society emblem has met with a very favorable reception, but it has been pointed out that a number of the members will prefer to wear the Victory Button or some other emblem. It has been suggested that a narrow ribbon—to be passed through the button-hole out across the lapel and fastened in the back—would be desirable. It has also been suggested that a badge, to be suspended from a ribbon somewhat after the matter of a Victory Medal or the badges of the various military societies, might be adopted by the Society. For this ribbon, the engineer colors have been suggested—that is to say, a scarlet ribbon with white edges. However, to conform to heraldic practice and "tie in" the emblem with the World War, it has been proposed to place along the extreme outer edges a narrow black thread and a similar narrow black thread down the center of the scarlet stripe. The black being taken from the colors of the former German Empire will tie the emblem in with the World War, will distinguish the ribbon from a great many others in existence, and the black on the extreme edges of the white will serve to define the ribbon when produced in lithographic form on a white page. For the pendant medallion, it is proposed to use the emblem recently adopted, but enlarged to the diameter of the Victory Medal. The ribbo for the lapel will not exceed three-sixteenths of an inch in width, and may be slightly narrower.

Certain objections have been raised to this scheme. They are based on the fact that a ribbon thus worn often signifies an official decoration, as the Legion of Honor and various other foreign decorations. Certain members of the Society feel that an unofficial body, such as The Society of American Military Engineers, should not adopt a device of the same general nature. Do you advocate a ribbon? Do you advocate a badge as described?

IV. It has also been suggested that a diploma or certificate of membership be prepared to conform to the practice of the more prominent engineering and scientific societies.

Digitized by Google

The engraving of a suitable plate would involve a considerable expense, and the cost of preparing each diploma thereafter will add to the total cost. It is roughly estimated that diplomas of this kind may cost anywhere from sixty-five cents to a dollar each. How many members would probably desire diplomas of this kind?

It is desired that these matters be considered by the members, that they be discussed by the local posts, and that the opinions, either of individuals or of local posts, be forwarded to the Secretary of the Society not later than June 15, in order that action may be taken in accordance with the censensus of opinion.

Philadelphia Post

Maj. Gen. Charles P. Summerall, Commanding General, 1st Division, Camp Dix, N. J., was the speaker of the evening at the meeting of the Philadelphia Post on March 24, 1921. His subject was "The relation of the Engineers to the Infantry." General Summerall reviewed the work of the engineers at the front with combatant units in the recen war. He reviewed in some deail the work of the engineers with the 1st and 2d Divisions, and paid high tribute to the efficiency and valor of the engineer troops.

Before the meeting, General Summerall was the guest of the Post at a small informal dinner served at The Engineers Club of Philadelphia.

Col. W. B. Ladue, Corps of Engineers, commanding the 1st Engineers at Camp Dix, and the Commander of the Philadelphia Post, presided at the meeting.

Maj. Gen. W. C. Langfitt, retired, formerly Chief Engineer, A. E. F., addressed the April meeting on the work of the American railway troops with the British in France. General Langfitt's address was both instructive and entertaining. He compared the work of the American, Britisn and French railway units, both standard and light railways, in France, and pointed out wherein each excelled. General Langfitt's address covered the staff organization, the equipment, and the operation of standard and light railway work at the front in France. General Langfitt is commander of the New York Post of the Society of American Military Engineers, and discussed the plans which the New York Post has under consideration for keeping alive the interest of its members in military matters, and instructing them in the duties which they will be called upon to perform in case of war. It was suggested, that as the cities of New York and Philadelphia are not very far apart, and as communication is very good between the two cities, possibly the members of the two Posts might find it instructive and beneficial to co-operate to a certain extent, and to attend each other's meetings from time to time.

Prior to the meeting, General Langfitt was entertained at dinner by the Post at The Engineers Club of Philadelphia.

Col. W. B. Ladue, Corps of Engineers, commanding the 1st Engineers at Camp Dix, and the Commander of the Philadlphia Post, presided at the meeting.

St. Louis Post

On April 21 a dinner was held at the Missouri Athletic Club. The following were present:

Colonel Jonah, Major Jones, Colonel Perkins, Colonel Abbott, Lieutenant Frost, Major Skelly, Major Lockwood. Lieutenant Thorburn, Mr. Perry, Mr. Porter, Mr. White, Mr. Hastain, Mr. Moynhan, Mr. Buchanan.

Immediately following dinner, Colonel Jonah opened the meeting, introducing Colonel Burgess, Corps of Engineers, U. S. Army, who gave a very interesting talk on the subject of "A Volunteer Regiment of Railway Engineers." Following Colonel Burgess' talk there was an informal discussion between Colonel Burgess, Colonel Abbott, Colonel Perkins and others in connection with ways and means to make the St. Louis Post useful to the Regular Army plant.

Boston Post

On March 11 the first steps were taken toward the formation of a local Post of the Society. The following officers were elected:

President, Col. T. H. Dillon; Vice-President, Col. W. H. Root; Secretary-Treasurer, Lewis A. Armistead.

The board of directors consists of the following, in addition to the three officers of the Post:

Col. D. C. Jackson, Col. J. F. Osborn, Col. S. D. Grigham, Maj. Alexander Macomber, and Maj. M. F. La Croix.

There are several hundred engineers residing in this vicinity who are eligible for membership in the Post, and it is expected that a large number of them will affiliate.

Silver Button Winners

The enthusiastic efforts put forth by members to win silver buttons has been most gratifying and has resulted in nearly 100 new members within the past four weeks. The time limit of sixty days does not expire until June 1, and all members are urged to put forth every effort the last four weeks of our "drive." Twelve members have already secured three or more paid members; four have secured two paid members, and forty have secured one paid member. Following is a list of Silver Button winners, with total number of members secured by each:

L. R. Lohr, Camp Humphreys, Va.	8
J. D. Schmidt, Custom House, New Orleans, La.	4
R. C. White, 1022 Railway Exch. Bldg., St. Louis, Mo.	4
Frank J. Clark, 42 Cedar St., Dobbs Ferry, N. Y.	3
W. H. Peters, Fort Jay, Governors Island, N. Y.	3
Wm. P. Cowles, 3237 Portland Ave., Minneapolis, Minn.	3
F. B. Wieners, March Field, Calif.	3
E. B. Murray, Camp Travis, Texas	3
B. B. Browne, Camp Grant, Ill.	3
F. W. Green, 6203 Washington Ave., St. Louis, Mo.	3
L. J. Canfield, Missoula, Mont.	3
L. E. Atkins, Urbana, Ill.	3

Silver Button winners who have not already notified us of the character of emblem desired—that is, pin, button or brooch-pin—should do so without delay.

The Engineer R. O. T. C. Unit at Virginia Polytechnic Institute

The V. P. I. Engineer Unit was among the first Engineer Units established, and due to its most excellent record among the other seventeen units assembled at Camp Humphreys in 1920, is rated very high. The enrollment in the Advanced Course of the Engineer Unit of Va. Tech is the largest in the United States. At the summer camp for Engineer Units in 1920, the V. P. I. contingent carried off a lion's share of the military honors and held its own with larger technical schools in the solution of technical problems of various kinds that are a part of the summer camp curricula.

While the work of the Unit at college is planned so as to utilize the academic training that the student receives in his college course, it is not a repetition of the college work, but often calls for thorough training and ingenuity. In addition to the application of academic subjects, many purely military engineering subjects are taught. These subjects are as follows:

Military Topography and Map Reading

This is based on a mechanical method not used in the college work, but very useful for certain life problems met by the engineer. A thorough course is given in this during the junior and senior years and at the summer camp, where more time is available. This method, which requires only a simple sketching board, properly understood and executed, enables the student to make a map of any terrain with such accuracy that it will compare very favorably with that made by the transit and level.

Military Bridges

In this course the academic work on bridge construction is utilized in solving military bridging problems. It also includes a study of the purely military bridges, such as ponton, spar, and improvised bridges.

Military Roads

In this course the student is not concerned with the design of any particular road, but rather with the necessity of having good roads in military operations; their upkeep under the heaviest traffic known, and the proper regulation of roads during operations of troops.

The remainder of the junior year is spent in studying organization of engineers, demolition of explosives, field fortifications, and minor tactics.

The work of the unit during the senior year includes a short review of the work of the junior year and a study of the following subjects:

General Construction

This includes all forms of construction from cantonments, warehouses, wharves, and depots to water supply, electrical power, sewage disposal, refrigeration, etc. These subjects are covered by having the students prepare papers on them, which papers are discussed in class.

Army Organization and Mechanical Equipment and Ordnance

In the ordnance course, the problems involve a knowledge of statics, dynamics, hydraulics, thermo-dynamics, and strength of materials. These problems prove interesting, impart a knowledge of ordnance material, and serve as a review on the subjects involved in the solution of the problems.

Eligibility to join the Engineer Unit depends on the academic course that the student is pursuing, all engineering courses being approved for entrance into the unit. The work of the unit as outlined above is of practical value to all students of engineering not alone for military but for civilian pursuits, and the successful completion of the unit course entitles the student to a commission in the Engineer Officers' Reserve Corps and membership in the American Society of Military Engineers, which has at present 4,000 members, over 3,000 of whom are engineers in civil life and most of whom belong to the Engineer Officers' Reserve Corps in grades of rank from brigadier general to second lieutenant.—*Special R. O. T. C. Edition of "The Virginia Tech."*

Weaver, Capt. Theron DeW., 608 Army Building, 39 Whitehall Street, New York City.
Weeks, Maj. F. R., Fort Crook, Nebr.
Wheeler, Lieut Wm. H., 4th Engineers, Camp Lewis, Wash.
Whipple, Capt. Stephen C., Camp Lewis, Wash.
Whitehurst, Capt. H. C., Norfolk General Intermediate Depot, Norfolk, Va.
Wisewell, Capt. Francis H., Jr., 500 Clinton Street, Hudson, N. Y.
Wood, Capt. John Elliott, District Building, Washington, D. C.
Wood, Lieut. W. A., Jr., 8th Engineers, Mounted, Fort Bliss, Texas.

Addresses Wanted

The Secretary of the Society would be pleased to receive any information concerning the present addresses of the following named members, whose mail has been returned unclaimed:

Lieut. W. E. Badden, Lakehurst Proving Ground, Lakehurst, N. J.
Capt. H. L. Baker, Woolwich, Me.
Capt. William A. Bassett, Mill Basin Inn, Mill Basin, Brooklyn, N. Y.
Capt. W. G. Baxter, 53 Eddy Street, Providence, R. I.
Mr. C. M. Binford, Riley, W. Va.
Capt. P. E. Borchers, 29 Aluminum Terrace, Dayton, Ohio.
Capt. B. R. Butt, Clarksburg, W. Va.
Capt. G. B. Byam, 1600 Q Street, Washington, D. C.
Lieut. R. W. Cabell, Lakehurst Proving Ground, Lakehurst, N. J.
Lieut. Col. Ralph E. Cameron, 435 Woodward Avenue, Detroit, Mich.
C. L. Catlin, 728 S. Denver Street, Tulsa, Okla.
Capt. J. L. Church, Montana Club, Helena, Mont.
Lieut. E. S. Cloud, 1751 19th Street, Cleveland, Ohio.
Capt. Harry M. Crawford, 500 Pearl Street, S. Brownsville, Pa.
Lieut. W. E. D'Evelyn, El Paso University Club, El Paso, Texas.
Capt. John H. Devine, 1st U. S. Engineers, Camp Knox, Ky.
Mr. J. D. Dixon, Chico, Calif.
D. J. Donovan, 316 19th Street, Milwaukee, Wis.
J. L. Doyle, Box 732, Johnstown, Pa.
Mr. N. E. Emmons, 27 Lewis Street, Hartford, Conn.
Mr. J. H. Feehan, 207 S. 45th Street, Philadelphia, Pa.
J. J. Flynn, Lakehurst Proving Ground, Lakehurst, N. J.
Mr. Everett L. Fornyou, B. & O. Building, Baltimore, Md.
N. C. Frith, care of A. W. Shaw Co., 299 Madison Avenue, New York City.
Mr. E. C. Garvin, Court House Building, Brunswick, Ga.
Lieut. N. Gerten, 41 Elmhurst Avenue, Long Island, N. Y.
Capt. F. M. Gibson, 2273 83d Street, New York City.
E. L. Gonyou, 907 Delaware Avenue, Wilmington, Del.
H. K. Graf, 708 A. O. U. W. Building, Little Rock, Ark.
Mr. G. T. Granger, 1609 Cadiz, Dallas, Texas.
D. L. Greenleaf, 5463 Blackstone Avenue, Chicago, Ill.
Mr. B. C. Grey, Columbus, Ohio.
Lieut. R. R. Hetz, 1401 Forest Street, Carthogue, Mo.
Col. G. E. Humphrey, 107 Armistead Bridge Court, NorFolk, Va.
Mr. Guy S. Hynes, Cheyenne Hotel, Tulsa, Okla.
Capt. C. V. Imeson, Construction Quartermaster, Eagle Pass, Texas.
F. L. Johnston, 1131 Chapala Street, Santa Barbara, Calif.
G. W. Kidney, 81 E. McFarland Street, Dover, Mass.
S. L. Kuhn, 103 Real Estate Exchange Building, Detroit, Mich.
Capt. Joseph C. Letts, Engineers Utilities Officer, General Hospital No. 41, Fox Hill, Staten Island, N. Y.
H. Loveridge, 1333 21st Street, N. W., Washington, D. C.
Mr. Edward Lyndon, 136 W. 16th Street, New York City.
H. H. Martindale, 337 Hastings Street, Pittsburgh, Pa.
P. D. Mackie, Zona, La.
Mr. J. W. MacNaul, Wilmington, Del.
F. J. Ohara, 1010 Balboa Building, San Francisco, Calif.

Capt. J. M. Young, care of District Engineer, New York City, N. Y.

Personals

The monthly dinner-dance given by the Twelfth Engineers at Camp Grant, Illinois, on the evening of April 5 was one of a series of enjoyable entertainments given by this popular regiment.

Decorations in red and white, the colors of the corps, were prettily displayed in the Jewish Welfare Hostess House, where the affair took place.

Covers were laid for 51 guests. Those present were: Gen. and Mrs. George Bell, Jr., Col. and Mrs. T. H. Jackson, Maj. and Mrs. Trippe, Capt. and Mrs. Alva H. Perkins, Capt and Mrs. Fred T. Bass, Capt. and Mrs. Hastie, Capt. and Mrs. Leroy W. Cummings, Col. and Mrs. Tanner, Col. and Mrs. Gillem, Maj. and Mrs. Hauser, Maj. and Mrs. Alcott, Capt. and Mrs. Stork, Major Olmstead, the Misses Gillem, Col. and Mrs. Reichman, Miss Reichman, Colonel Game, Capt. and Mrs. Hall, Lieut. and Mrs. Smith, Maj. and Mrs. Wood, Judge and Mrs. Early, Maj. and Mrs. Abraham, Colonel Parker, Miss de Witt, Maj. Short, Lieutenants Lambert, Knappen, Joslyn, Seybold, Robinson, and Hannis.

Dancing was enjoyed until 11:30 p. m. Music was furnished by the Twelfth Engineer orchestra.

Preparations have begun for the annual training hike of the regiment, which will begin about June 1. Supplies are being requisitioned and stored, transportation vehicles overhauled, and individual equipment replenished. Camp Douglas, Wisconsin, has been selected as the site of the encampment.

Every phase of military engineering activity forms part of the outlined schedule of exercises. It is anticipated the maneuvres will consume a period of two months.

Participation with National Guard units at Camp Douglas will enter into the daily program. Each State organization will receive ten days' training in conjunction with the regular troops.

Transfers of officers out of the command has caused some changes in the duties assigned to members. Col. T. H. Jackson, Commanding Officer of the regiment, is now Camp Engineer; Capt. Alva H. Perkins has been appointed Adjutant; and Capt. Leroy W. Cummings is performing duty as Regimental Supply Officer and Property Officer.

Facilities for the recreation of the command have been made a feature of news in the local press.

Practically all the equipment of a well-appointed club is the property of each organization. The endeavor of the officers to have their units possess the best reading and amusement rooms in the cantonment finds a desirabe reflection in the high morale of the members.

A description of the work of the topographical section of the Twelfth Engineers and an interview with the members made up an article in one of the Rockford newspapers recently.

"Engineer officers insist that all products of their corps must at least equal the highest commercial standard. To exceed that standard is the ambition of the 'Topog' men," said the author.

The Inter-Fraternity Conference, with headquarters in New York City, representing forty-six of the leading men's college fraternities of the United States, has indorsed the Reserve Officers' Training Corps and urges all its fraternities and individual members to actively support the units in their colleges.

Military Art, Note 1

The Importance of Military Art to Engineer Officers

War—fighting—is a great game, the most fascinating game in the world. You try to outguess the enemy and, by superior intellect and courage, force your will upon his. At each move human lives are at stake and the fate of the nation may depend upon the outcome of the whole game. It is said that, prior to the launching of the Union attack at Fredericksburg, Lee was standing with Jackson on the heights on the south bank of the Rappahannock, watching the assembly of the Federal troops on the north bank. Suddenly the Confederate commander turned to Jackson and said: "General, it is a good thing that war is so terrible, otherwise we should become too fond of it."

Outside of its fascination, however, the study of tactics, that is, fighting, is something that the army officer will always have with him. The Infantry Drill Regulations says: "Success in battle is the ultimate object of all military training," and this is true, not only of the infantry, but of all branches. All of your strictly engineering work; the construction of immense depots at the base ports; the docks and terminals; the railroads and storehouses; the roads leading to the front; all along the line, until small squads of resolute engineers precede the infantry to cut the hostile wire; everything is contributing to that main effort—success in battle.

Engineer officers are, broadly speaking, both staff and line and come in contact, at one time or another, with all branches of the service. The regimental commander is, ex-officio, division engineer, and lower-ranking engineer officers are generally present at division and higher headquarters as assistants to one or more of the assistant chiefs of staff. Battalion and company commanders, sometimes lieutenants, have to co-operate with infantry and artillery commanders in the matters of defensive works, roads, camouflage, etc., etc.

There is also another phase of this question. In spite of the diabolical, death-dealing devices of war which "Christian" nations have invented—the powerful and accurate artillery, the poisonous gases, the bombing planes, the murderous machine guns—in spite of all these inventions, the infantry remains the Queen of Battles. In the final analysis, it is the man with the gun in his hand, the rifle with the gleaming bayonet at the muzzle, the strong right hand at the small of the stock, and the stout heart of the infantry soldier, that wins battles.

Now engineers, in addition to their other duties, are supposed to be able to fight as infantry when the occasion arises. When the assaulting line is held up or the enemy's offensive becomes too strong, the division commander is going to throw in all troops that can fire the rifle in the effort to clinch the victory or stave off defeat, and, as engineer officers, we would not have it otherwise. Those of you who have been assigned to regular organizations which served in the hottest fighting of the World War and have talked with the old non-coms., may have noticed what were the operations of their units in which they took the greatest pride and of which they delighted to tell, over and over again. Not the store-houses and roads they built, nor yet the bridges they constructed, sometimes under fire, for the other troops to advance, creditable as all these performances were. No, they love to tell of the time when, the infantry being sorely pressed, the "Old Man" threw in the sapper regiment, and they took the enemy's strong point and held it against all counter-attacks, with the orginary rifle as their only weapon. And, much as we might, from an impartial standpoint, deprecate such use of technical troops, we glory in their deeds and take a just pride in recounting them.

So you see from numerous standpoints how important the study of Military Art is to the engineer officer. And this importance is emphasized by the persistence with which it sticks to you and by the increasing proportion of your time which it occupies as you ascend the army educational scale. In the Basic Course at the Engineer School it occupies about one-quarter of the total time allowed (exclusive of the exempted subjects). We attempt to teach only the tactics and administration of a single company, acting alone or as part of a battalion, to have the student "learn the tune" of these tactical exercises. In the Company Officers' Course, more than half the total time is allotted to Military Art and we take up the tactics of all branches, with emphasis on the infantry regiment. In the Field Officers' Course more than two-thirds of the total time is devoted to Military Art and we study the tactics, administration and supply of units as large as the division. At the School of the Line and the Staff School at Fort Leavenworth and at the General Staff College at Washington Barracks, all the time, properly speaking, is devoted to Military Art.

It is recommended that the reader begin at once to cultivate an interest in this tactical game. Learn the rules and play the game for all it is worth. Develop your imagination and your powers of visualization. You will find such

Digitized by Google

assets a source of pleasure and of profit even if you are never called to an active military career.

Problems in Minor Tactics

The map problems published in THE MILITARY ENGINEER will be based upon those used in the Basic Course at the Engineer School at Camp Humphreys. Solutions will appear in the succeeding number, but it is earnestly recommended that readers solve these problems upon receipt of the journal, and compare their solutions later with the approved solution published. It should be borne in mind that the approved solutions published do not purport to be the *only* correct solutions of these problems. Your solution may differ widely in form from the approved solution, and still be equally as reasonable, provided you have conformed to the tactical principles involved.

MAPS—

All problems will be laid upon the Gettysburg maps, published by the General Service Schools. The "General Map" will be needed for all problems; in addition, each problem will call for certain individual sheets of the detail map, on a scale of three inches to the mile.

These maps will be supplied without charge by THE MILITARY ENGINEER upon application.

ORGANIZATION—

The troops involved in these problems are presumed to be organized as shown below:

Infantry Battalion:

Hdqrs.
Co. "A" (Rifle Company).
Co. "B" (Rifle Company).
Co. "C" (Rifle Company).
Co. "D" (Machine Gun Company); 2 platoons; each platoon, two sections; each section, 2 guns.

Infantry Rifle Company:

1 Captain,
2 First Lieutenants,
2 Second Lieutenants,
200 enlisted, including 8 privates, replacements, organized as follows:

Captain, in command.

Co. Hdqrs. (1-21):	First Platoon: Each 1 officer and 57 enlisted.	Sec. Platoon: Same as first except 2d Lt.	Third Platoon: Same as second.
First Lieut.	Platoon Hdqrs.:		
First Sgt.	First Lieut.		
Gas Sgt. (s)	1 Sgt. (1)		
Mess Sgt. (s)	4 Pvts. (r)		
Supply Sgt. (s)			
2 Cpls. (1 clk.)	First Section:		
(1 agent)	1 Sgt. (2)		
2 Buglers (p)	4 Cpls. (3)		
4 Cooks (p)	21 Pvts. (4)		
3 Mechs. (p)			
3 Shopmen (p)	Second Section:		
4 Privates (r)	Same		

Notes:

(s) Pay-roll designation, "sergeant."

(p) Privates and privates first class, several with specialists' ratings.

(r) Runners and agents.

(1) Platoon sergeant.

(2) Section leader.

(3) Includes 1 one section guide and 3 squad leaders.

(4) Grouped, with 3 corporals, into 3 squads; one private in each squad armed with automatic rifle and one with grenade discharger.

For diagram of formations of the platoon see p. 48, Infantry Drill Regulations, 1919.

ADDITIONAL DATA—

(1) The commanding officer of an infantry company (both rifle and machine gun) is mounted and has a mounted orderly.

(2) The wheeled transportation of a rifle company consists of:

(a) Two ration-and-baggage wagons (escort type), containing raw rations, forage and the company office equipment and records. These loads would be distributed between the two vehicles in accordance with considerations of weight and bulk. When fully loaded, raw rations for the entire company for two days and forage for all company animals for two days are on hand in these two wagons.

(b) Rolling kitchen, capable of carrying one day's rations for the entire company and two days' grain for its animals.

(c) Water cart, capable of carrying 160 gallons of water (ordinarily sufficient to replenish the canteens and to supply water for two or possibly three meals) and grain for its animals for two days.

(3) Each individual man, when fully equipped, carries reserve (canned) rations for two days and each man armed with the rifle or automatic rifle, 100 rounds of ammunition (in his belt).

(4) The battalion combat train consists of four escort wagons, carrying small arms ammunition placed in bandoliers (60 rounds to a bandolier) and packed in boxes which are easily opened without tools; 120 rounds per rifleman and a corresponding amount for each automatic rifle and machine gun will be assumed to be carried in these wagons.

(5) The road length of a rifle company (column of squads, without elongation) complete with train is 160 yards; without wagons 85 yards.

(6) When the term "camp" is used it will mean a shelter-tent camp, two enlisted men or one lieutenant to each tent, and one small pyramidal tent for the company commander and the company office.

(7) The Gettysburg maps, general and 3-inch, are distributed to each officer but not to the non-commissioned officers.

ESTIMATE OF SITUATION—

Whenever an "estimate of the situation" is required in the solution of map problems, students will follow the form below, omitting such points as are not applicable to the particular case in hand.

(A) MISSION.
(B) THE ENEMY FORCE:
1. Strength and Composition
2. Position
3. Movements
4. Probable intentions
(C) OUR OWN FORCE:
1. Strength and Composition
2. Position
3. Supporting troops
(D) PLANS OF ACTION.
(E) THE DECISION.

Influence of: Terrain, Weather, Climate, Soil, Morale, etc.

This form is intended merely as a reminder of the points to be considered in making the estimate. *It is not a blank form*, to be filled out with the data presented in the problem.

Digitized by Google

In forming his estimate, the commander must first of all *determine his mission* and thereafter he must *keep it constantly before him.*

In considering the "Enemy" and "Our Own Forces" the commander should eliminate those factors which do not affect his Mission. Some factors, usually those presented in the General Situation, may be ignored entirely. Others are dismissed with a brief statement showing why they do not affect the Mission. The remaining factors should be *discussed,* frankly and impartially.

Having determined, in a general way, how the strength, position, etc., of the "Enemy" and "Our Own Forces" affect his Mission, the commander next considers the various Plans of Action by which he might carry out his Mission. Here the terrain, weather, etc., will usually begin to have considerable influence on the MISSION. The influence of such factors, when appreciable, should be discussed. If, however, they are normal they may ordinarily be ignored.

Oftentimes an analysis of the Plan of Action will show that it consists of certain well defined elements. These should be set forth and then decided, either separately or interdependently, as circumstances require.

The advantages and disadvantages of the different Plans of Action should be discussed and one set off against the other. The further influence of enemy, our own forces, weather, terrain. when applicable, should likewise be considered. From this discussion the commander decides which Plan to adopt.

Occasionally a Plan of Action may be decided in toto. Usually, however, a certain predominating element is first decided, leaving one or more subsidiary questions still to be considered. A much briefer discussion will generally decide them.

Having determined upon the important elements of the Plan of Action, the final step in the Estimate of the Situation is to summarize them and set them forth in the DECISION, showing how the commander purposes to carry out his Mission. The Decision should be brief but complete—leaving minor details to be shown in the Orders. (A mere paraphrase of the Mission is in no sense a Decision.) As a rough guide for the requisite amount of detail, it may be stated that a Decision should be such that a competent staff officer, thoroughly conversant with the command and acquainted with the personality of the commander, can take it and write out an order for the commander's approval.

Map Problem No. 1. A March

Maps: Gettysburg General Map.
Gettysburg 3-inch map, Kingsdale and Taneytown sheets.

General Situation.

Alloway Creek and the Monocacy River, south of the mouth of the creek (near Harney) divide two small hostile states on the verge of war.

The Blue main forces are assembling at Westminster. The 1st Infantry (the only regulars possessed by the Blues) has been started toward the border.

The main Red forces (all reserves) are assembling at Waynesboro. Little is known definitely about their border troops, but they are believed (by the Blues) to be weak and poorly organized.

Special Situation.

On June 1st the Blue regular troops reached the localities shown below, with instructions to remain there until further orders:

1st Infantry (less 1st Bn.) at Littlestown.
1st Bn. 1st Inf. (less Co. "A") at Taneytown.
Co. "A" 1st Inf. at Silver Run (near center of eastern boundary Kingsdale sheet).

At 10:30 p. m., June 3d, Captain A, commanding Co. "A," receives the following message by motorcycle:

Hdqrs. 1st Bn. 1st Inf.,
TANEYTOWN, 3d June, ——, 9:45 p. m.

C. O. Co. "A,"
SILVER RUN.

1. The Red government declared war late this afternoon.
2. Our secret service reports that the enemy has assembled one battalion of infantry at GETTYSBURG and about one hundred (100) cavalry at EMMITSBURG. Civilians say that Red mounted patrols, ten to fifteen men, were at BRIDGEPORT and HANEY this afternoon.
3. Our forces at LITTLESTOWN and here are ordered to remain in their present locations.
4. March your company to TANEYTOWN to-morrow, the 4th instant, arriving at the school house, in the center of town, not later than 11 a. m.
5. Please acknowledge receipt.

M——
Major, 1st Inf.

The season is June. Weather has been rainy but is now clear. Roads are slightly muddy. Streams are full. Crops are just beginning to come up and leaves on the trees are about half size. Average temperatures: maximum, 80 degrees; minimum, 60 degrees. Sunrise, 4:40 a. m.; sunset, 7:20 p. m.

Required.

1. Captain A's estimate of the situation.
2. His orders, as given.
3. His message, if any.

NOTE.—The company is camped in the open field southwest of the road-fork and northeast of hill 744. Present orders provide for reveille at 5:30 a. m. on the 4th.

References.

The following lesson assignments are suggested for reading, prior to the solution of a problem similar to the foregoing. Texts marked with an asterisk are War Department publications; the others can be purchased from the General Service Schools:

(a) Technique of Modern Tactics, pp. 5-9 and 19-28.
Estimate of the Situation (General Service Schools pamphlet).
The Commander—Decisions (General Service Schools pamphlet).
(b) Technique of Modern Tactics, Chap. II.
Combat Orders (G. S. S.) Pars. 1-65; 77, 78, 84, 98, 104, 116, 118, 122-129.
*Field Service Regulations, Part II, Article III.
Mechanism of Solving Problems (General Service Schools pamphlet).
(c) Technique of Modern Tactics, pp. 56-65, p. 229, F. S. R. pars, 37-49 inc.
(d) Technique of Modern Tactics Chap. VI, F. S. R. pars. 96-114, inc.

Whatever one attempts he should be familiar with the methods which have characterized good practice in that particular line of endeavor. When confronted with a specific case the individual searches for the underlying principles which find application therein, and it is here that his resourcefulness and originality are called into play.—*Technique of Modern Tactics.*

General Subjects, Note 1

Scope

This Course is proposed to cover the following subjects:

Military Administration, Military Courtesy, and Customs of the Service; Organization; Military Law; Military Hygiene; Infantry Drill Regulations; Interior Guard Duty; Rules of Land Warfare; Theoretical Instruction in Target Practice and Combat Exercises; and Hippology.

In order to give Reserve Officers an idea of the scope of the subjects to be covered, it is proposed to publish test questions in these subjects from time to time, with references to the texts to be studied in connection therewith. The following number of THE MILITARY ENGINEER will contain an approved solution of the tests published.

A test in one or more of these subjects will be published in each number of THE MILITARY ENGINEER. The tests will be designed to enable each Reserve Officer who so desires to determine for himself whether or not he has a general working knowledge of the subject, rather than an intimate detailed knowledge such as might be expected upon completion of a school course of a course of study.

The following is a list of references on which the tests will be based:

Subject.	Text.
Administration, Military Courtesy, and Customs of the Service.	A. R. pars. 49-67, 265-300, 316-321, 327-330, 355-364, 378-392½, 775-790, 922-943, 1024-1036, 1057, 1115½, 1128, 1136, 1273-1307½, 1493 and W. D. Doc. 864 (all inclusive).
Organization.	Charts prepared at The Engineer School.
Military Law.	Manual for Courts-Martial, 1921.
Military Hygiene.	Elements of Military Hygiene —Ashburn; Spec. Regs. No. 28.
Infantry Drill Regulations.	Infantry Drill Regulations, 1919, Pars. 101 to 296; emphasis on extended order.
Interior Guard Duty.	Manual of Interior Guard Duty (complete).
Rules of Land Warfare.	Rules of Land Warfare (complete).
Theoretical Instruction in Target Practice and Combat Exercises.	Small Arms Firing Manual (complete).
Hippology.	Elements of Hippology, Marshall (complete). Cavalry Drill Regulations, Pars 965 to 977 and 987 incl. Engineer Field Manual, Part VI, Pars. 1 to 21 incl.

Questions on Military Administration

No.	Wt.	Question.
1.	16.	By whom are company non-commissioned officers appointed in the following cases: (a) In a company of engineers serving as part of a regiment? (b) In units not organized into regiments or separate battalions?
2.	8.	By what authorities may company non-commissioned officers be reduced to the ranks?
3.	14.	(a) What officers constitute the company council of administration? (b) What are the duties of this council?
4.	6.	What is a roster?
5.	18.	You are a Captain in command of a company marching at route step, what should you do— (a) When you pass an officer of junior grade? (b) When you pass an officer of senior grade? (c) When you meet a platoon commander by a lieutenant?
6.	18.	(a) How (by what procedure) is an officer placed in arrest? (b) What should an officer do when placed in arrest? (c) What determines whether an enlisted man charged with an offense shall be placed in arrest or in confinement?
7.	20.	What are the general duties of the Corps of Engineers in time of peace and in time of actual or threatened hostilities?

Questions on Military Law

(Pages 1-153, Appendices 3-27. Manual for Courts-Martial, 1921.)

No.	Wt.	Question.
1.	9.	Name the three general classes into which military jurisdiction is divided.
2.	9.	How many members has each of the following: (a) General Court-Martial, (b) Special Court-Martial, (c) Summary Court-Martial.
3.	8.	What are the limits of punishment of a summary court-martial as regards— (a) Confinement, (b) Restriction to limits, (c) Forfeiture of pay, (d) Detention of pay.
4.	6.	Who may prefer charges?
5.	5.	May military authorities force an officer to pay a personal debt?
6.	6.	Under what circumstances may an offense ordinarily capital be tried by a special court-martial?
7.	12.	Show by a simple tabulation how questions arising in open court are decided, the law member being present.
8.	10.	What proportion of votes of the members present is required for each of the following (answer by tabulation, as [a] ⅗): (a) Conviction of absence without leave, (b) Sentence to death, (c) Conviction of crime which may involve not more than 20 years' confinement, (d) Sentence to 10 years' confinement, (e) Sentence to life imprisonment.
9.	6.	What is a peremptory challenge?
10.	12.	Name the four classes of pleas likely to be met with in court-martial procedure.
11.	5.	Upon whom is placed the duty of summoning civilian witnesses?
12.	6.	What is a warrant of attachment?
13.	6.	How early in a trial may the court arrive at a finding of not guilty?

The Monongahela

A Successful River Improvement

By

J. Franklin Bell

Major, Corps of Engineers

[NOTE.—A failure to appreciate the economic conditions which make for a successful waterway improvement has resulted in many disappointments and the waste of many millions of dollars both in our own and in other lands.

There are three principal avenues of transportation employed by man, which are the highway, the railway, and the waterway. Each of these has its proper field, and when one of them attempts to invade the proper field of the other, an economic waste is the inevitable result.

Somebody once made a statement to the effect that a ton of goods could be moved a given distance by water more cheaply than by any other method. This usually true statement has probably been the cause of much waste. It is true, so far as the mere cost of movement is concerned.

But there are many items which go to make up the cost of water transportation. Some of these are:

(1) The cost of the waterway itself, and of its maintenance. When the route is provided by nature it is free of charge. When it is a purely artificial route, such as a canal, every foot of which must be built, the investment of money in the route must be reckoned with. The cost of a water route may vary from nothing at all to very much more than the cost of the most expensive railroad.

(2) The cost of transhipment. If the places from which the goods or commodities come and those to which they are delivered are not on the waterways it is necessary to tranship to rail, at one or both ends, and this transfer of goods is a very expensive process. The fact that it is too frequently overlooked is one of the chief reasons why the waterways have so often proved economic failures.

(3) The capacity of the waterway. Deep-draft vessels are more economical than shallow-draft vessels for the large-scale operations. If the waterway is very shallow, so that large vessels cannot be used, if it is very narrow and crooked, so that it limits the size of vessels, limits their speed, and causes expensive accidents and delays from grounding, etc., the cost of movement is greatly increased. Locks in a canal or canalized river naturally cause delay and restrict capacity.

(4) There are certain other considerations which affect the cost of movement by water, such as storms at sea or on the lakes increasing the cost of insurance, fogs and darkness which railroads do not have to worry about, freezing up for several months in the winter, during which time the floating plant earns no return, varying depths and widths, which make it impossible to devise any one type of vessel suitable to all parts of the waterway, etc.

When conditions are such that the total cost of water transport is only the cost of actually moving the freight by water, then water transport is usually cheaper than any other form, provided the route has a sufficient capacity. If we can approach very close to this ideal condition our waterway will be a success. If the conditions are such that we cannot even approximate to this ideal, and that has too often been the case, then the waterway is certain to be an economic failure. It should always be possible to foresee this.

It is usually a question of the length of haul by water. As a rule, under even moderately favorable conditions, the cost of moving freight by water *is* less than by rail. So every mile that we move by water we save money. But if we have an expensive transhipment to rail at each end we may eat up all this saving and find that it would have been better to have made the whole trip by rail, since the railroad car can usually reach both the mine and the factory direct, and no transfer of its contents is necessary. Thus suppose, for example, that we have a trip of 1,000 miles to make, either all rail (as is always possible) or partly by rail and partly by water. Let us assume that it costs 1 cent to move a ton of goods one mile by rail and ½ cent to move it one mile by water, and that it costs 50 cents a ton to tranship from rail to boat or from boat to rail. Then if we move part of the way by water it will cost us a dollar for two transhipments, at the two ends of the water route. Every mile we move by water we save ½ cent. So if we move 100 miles we just pay the cost of transhipment. If the water haul be less than 100 miles it would be cheaper to make the entire journey by rail. If the water haul be several hundred miles, the saving effected by using it would be considerable.

These economic principles and their application are illustrated in the case of the Monongahela River, and are well brought out in the article following.—ED.]

THE Monongahela River is one of the busiest waterways in the world. It is formed by the junction of the Tygarts Valley and West Fork Rivers about a mile south of Fairmont, West Virginia, and flows in a northerly direction 128 miles to a junction with the Allegheny River at Pittsburgh, Pa., and is now canalized throughout its entire length by means of 15 locks and dams. The drainage area is about 7,400 square miles in extent, and the discharge at its mouth varies from 160 to about 200,000 second feet, a very wide range. In its natural condition the river was navigable at moderate stages only as far as Brownsville, Pa., 56 miles above the mouth, but there was in early days a considerable traffic of flat boats and rafts which could be floated from near the headwaters down the river for several months annually. It was on this river that the early settlers loaded the supplies necessary to take with them on their flat boats to the "far west" of those days, viz: Ohio, Kentucky and Indiana.

History of the Improvement

The history of the improvement of this stream is as follows: Under authority from the State of Pennsylvania, March, 1836, a private corporation—the Monongahela Navigation Company—constructed 7 locks and dams, which extended navigation from Pittsburgh, Pa., to a point near the Mason and Dixon Line, about 85 miles above the mouth of the river. The first locks were small—50 by about 160 feet, with available depth of about 6 feet on the sills.

Under the project adopted in 1872 and completed in 1899, two additional locks and dams, Numbers 8 and 9, were built by the United States, with practically the same dimensions as those of the Navigation Company, thus extending slackwater navigation to Morgantown, W. Va., 101 miles above Pittsburg. In 1897, the 7 locks and dams built by the Navigation Company were acquired by the United States by condemnation proceedings. Since that time, in order to meet the growing needs of a demand for coal, the system has been enlarged and extended as follows: Twin locks of standard dimensions, viz, 56 by 360 feet, with depths on miter sill of 8 feet, were built at the following dams in the years indicated:

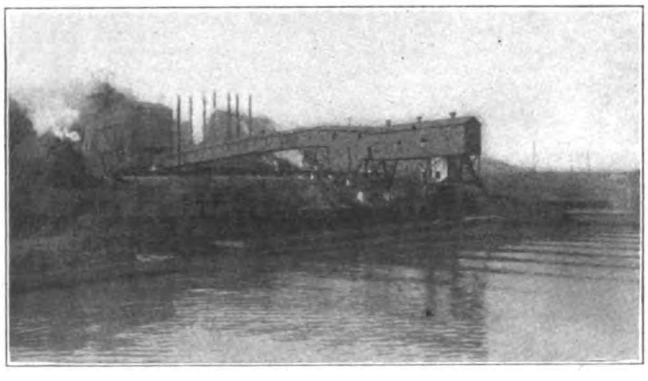
No. 2 in 1906	No. 1 in 1915
No. 3 in 1907	No. 4 in 1917
No. 5 in 1910	

and a single standard lock added at No. 6 in 1916.

The construction in 1903 of six additional locks and dams above Morgantown, W. Va., 56 by 182 feet available area, with 7-foot depths on miter sills, extended slackwater navigation from Morgantown, W. Va. to a point on the West Fork River, about 4 miles above Fairmont, W. Va., making a total distance of 133 miles from the mouth of the river at Pittsburgh, Pa.

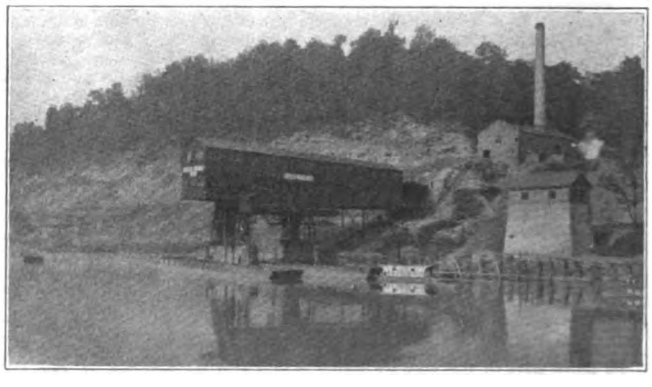
To date no enlargements of Locks 7, 8 and 9 have been made, but by reason of new coal fields being developed in these pools, a survey of the river was authorized by the River and Harbor Acts of 1919 and 1920. There is under consideration the reconstruction of No. 7 and No. 8, both

Digitized by Google



at new sites, with the elimination of present Dam 9 in connection with a new and extensive project under which an 8-foot depth will be available up to Dam 10 at Morgantown, W. Va., 101 miles above Pittsburgh. Such plan, if adopted, will provide pools from Pittsburgh to Morgantown, with lengths as follows:

Pool	Length in miles	Pool	Length in miles
1	9.2	5	11.9
2	12.6	6	16.2
3	17.4	7	6.8
4	15.5	8	9.9



Development of Traffic

Soon after the Navigation Company's property was taken over by the United States, reconstruction of the more important locks and dams was begun, as stated above, under a plan which contemplated affording the greatest possible convenience to the coal traffic then, as now, the principal business transacted along the river. At that time the movement of coal on the river was from mines situated in Pools 3, 4 and 5, to industries on both sides of the river below those pools, some being below Lock No. 1, and others a distance down the Ohio River or up the Allegheny. With a view to permitting comparatively large tows to be locked through without being divided, the new locks were made 56 feet by 360 feet in available dimensions with a minimum depth of 8 feet of water on the sills, and the plans provided for twin locks to be constructed at the busier localities as the need arose. As a result of this project, at the present time, as stated, twin locks of these standard dimensions exist at Dams 1 to 5, inclusive, with a single standard lock at No. 6, and these have been able to accommodate the coal and other traffic hitherto developed. In recent years, the readily accessible coal in Pools 3 to 5 has been opened up, and, due to the growth of the by-product coke industry especially, there has been a steady and rapidly increasing development of coal lands in the pools above, particularly in Pool 6. As is well known, all manufacturing industry in this vicinity has been expanding at a rapid rate, and this has, during the past ten years or so, caused a correspondingly marked increase in the coal traffic of the Monongahela River. Without attempting to go back further than 1898, reports show in that year a coal traffic of about 5,700,000 tons; in 1903 it was 10,000,000; in 1908, due to the then existing business depression, it had fallen to slightly over 8,000,000. From the latter date, a steady growth has manifested itself, so that in 1913 the traffic was 10,300,000 tons, in 1918 about 12,900,000 tons, and in 1919 it was 14,700,000 tons, while during the first 6 months of the calendar year 1920, the traffic through the locks at Dam 3 was approximately 11,000,000 tons, of which 9,500,000 tons was coal.

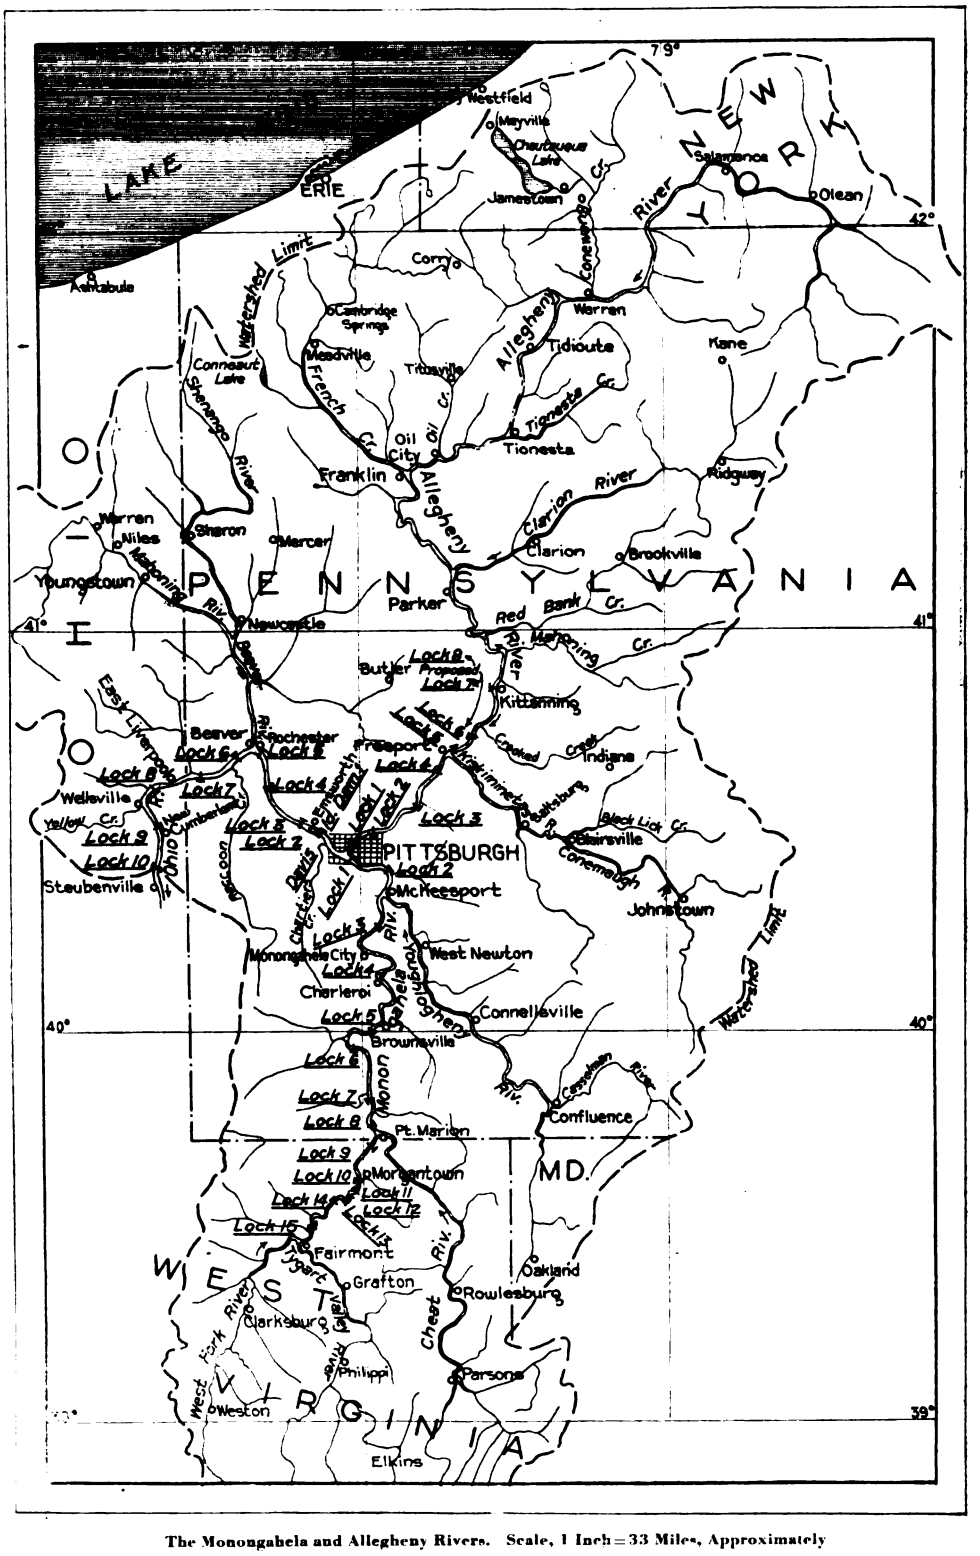
The importance of this traffic is so obvious as to render it unnecessary to enlarge upon it. It might be said, however, that many of the great steel plants in the country are located on the Monongahela, Allegheny and upper Ohio Rivers, and that some of these depend exclusively upon the Monongahela River for their coal. It is estimated by the District Engineer at Pittsburgh that out of the total length of 454 miles on both banks of the three rivers, the Allegheny, the Monongahela and the Ohio above Steubenville, Ohio, centering at Pittsburgh, 84 miles, or about 20 per cent, are now occupied by industrial plants, largely engaged in the manufacture of steel or of some of its products. Since many of these plants have been designed with a view to using river coal, they do not have the necessary space for the railroad yards and other railroad facilities to permit them to use coal carried by rail. It was assured by the manager of a very large concern that fully one-third of the entire area occupied by his plant would have to be devoted to railroad yards to enable it to operate on rail coal.

Loading coal. A washer, conveyor and tipple. The coal is crushed, washed, carried by belt conveyor to the tipple and loaded into barges. Capacity, 2,000 tons daily

Loading coal. A characteristic coal-loading plant or tipple. Capacity, 3,500 tons daily

A breakdown in the river service might readily lead to almost unendurable inconvenience for the industries that now depend on river coal, and this inconvenience would ramify and affect a very large fraction of our entire population, dependent as it is upon steel and its varied products. Accordingly, it is a matter of grave concern that every reasonable provision be made against the interruption of this traffic, and this is the purpose of a report recently called for by Congress.

The principal coal traffic on the river is carried on by the larger steel companies. The barges used are quite definitely standardized, being 175 by 26 by 11 feet depth of gunwale, with 1,200 tons maximum capacity on 8½ feet draft, and 1,000 tons on 7½ feet. To show the magnitude of their operations, it may be said that one large steel corporation owns 216 steel barges and 11 steamboats, and another 133 barges and 8 steamboats. Six barges are usually combined in a single tow, three in length, two abreast, and the towboat aft. Thus the standard tow, including the steamer, is about 700 feet long, and at present the tow must be divided to permit it to pass through even the larger locks, those at Dams 1 to 6, inclusive (twin locks at 1 to 5, inclusive), which, as above stated, have 360 by 56 feet available areas.



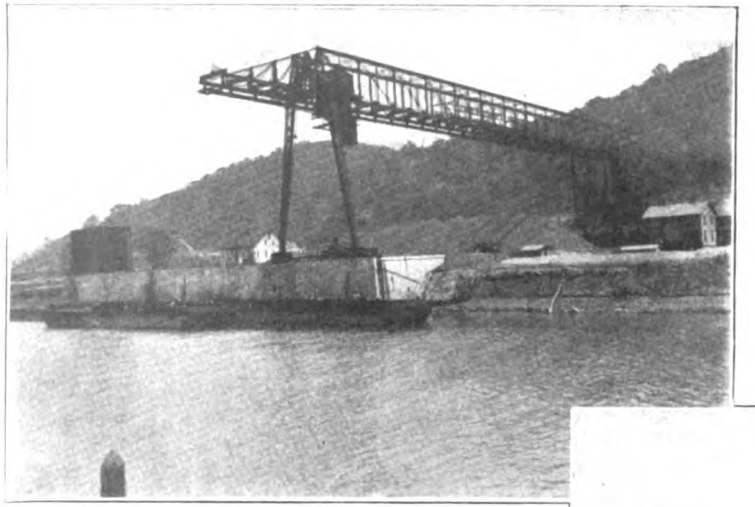
The rapid development of the traffic in coal, reaching in

Digitized by Google

1920 at Locks 3 and 4 a maximum of from 90,000 to 100,000 tons per diem, with indications of further increase by extensions already planned by the larger industrial interests and the growing demand for coal by the general public, has led to serious consideration of greatly enlarged facilities to meet coming needs. Representatives of individual concerns and others interested laid this matter before Congress with the result that the survey above referred to was authorized. The recommendations of the report naturally are based upon the volume and character of the traffic, its past rate of growth, the rate of increase hereafter to be expected, and the manner that the ruling commodity—coal—is carried.

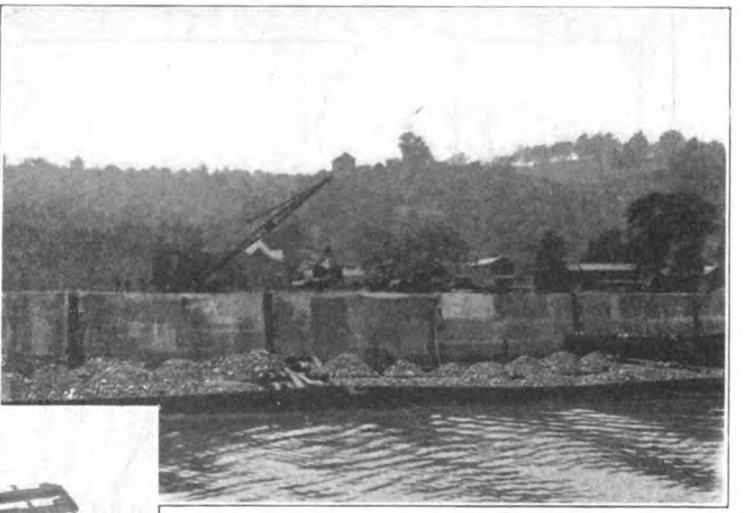
Contemplated Improvement

Accordingly, the plan under consideration contemplates minimizing delays, and the probability of accidents at locks and dams by providing adequate guard and guide walls both above and below the locks, the construction of new lock chambers of standard width of 56 feet, and 720 feet in length at the busier localities, Dams 3 and 4, and at others as needed, thereby obviating the dividing of tows to utilize both locks, or a single lock twice, and the reassembling of the tow above or below, an operation requiring time during which no other boats can use the lock. Also, there is contemplated the progressive replacement of the small locks above Dam 6, by new structures having the standard width and at least 360 feet available length. Evidently the completion of these new works should keep well in advance of the development of additional coal-shipping facilities and of the opening of new mines in the fields tributary to the pools above Dam 6. The correct program and time of doing the work are naturally dependent upon the demand for coal and its probable growth, all of which are susceptible of being more or less confidently predicted by those who are engaged in the management of the industries most concerned. Of course, a practical limit on the ultimate traffic of the waterway is imposed by the location and amount of coal deposits in the territory tributary to the river transportation, but for the immediate future, say for the next twenty to twenty-five years, it seems safe to assume that the traffic will continue to grow, and that the capacity of the locks at the busiest localities must therefore be carefully studied and increased to keep pace with demonstrated needs.



The Monongahela and Allegheny Rivers. Scale, 1 Inch = 33 Miles, Approximately

With respect to the actual traffic capacity of the Monongahela River locks there are given below figures derived from past experiences which may be accepted as a safe guide. The following are from the report of the District Engineer (1920):



Capacity of Locks.

In January, February and March, 1919, at Lock No. 3, the entire

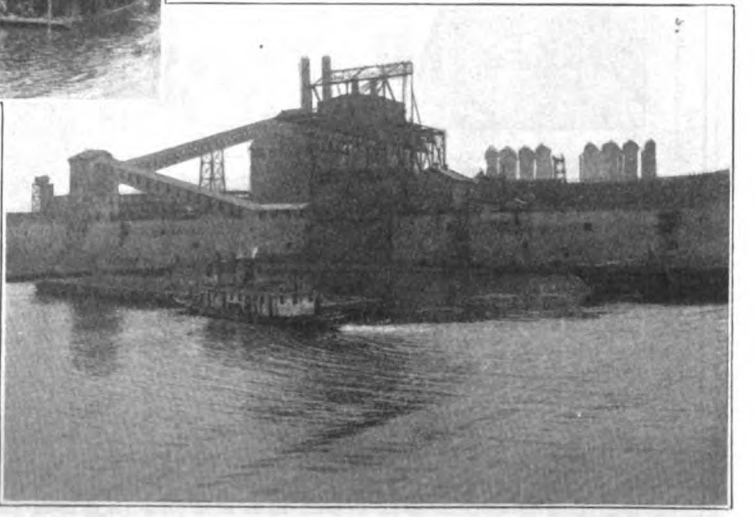
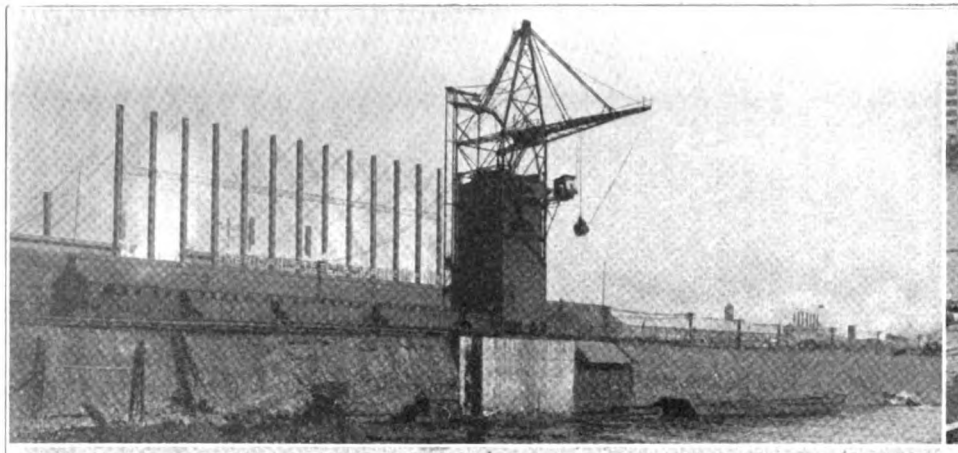
Unloading coal. Gantry crane and storage yard. The coal is hoisted from the barges and loaded on cars or stored in piles. Capacity, 1,000 tons daily



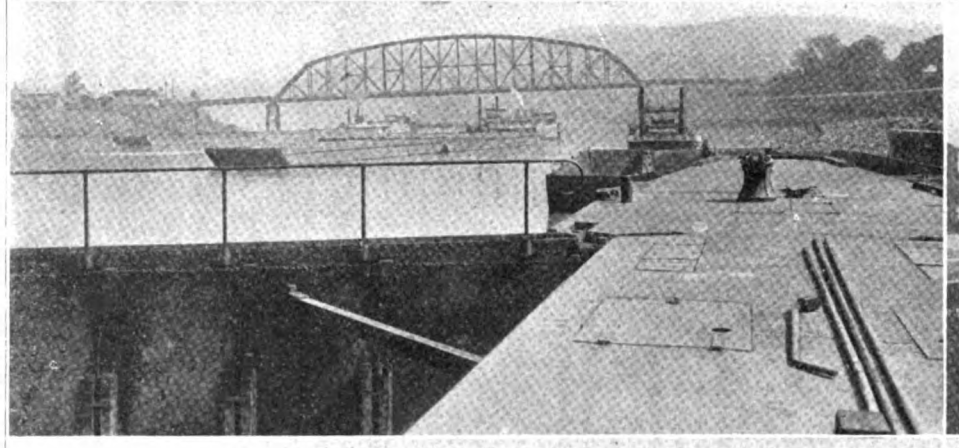
Unloading coal. Locomotive hoist and storage pile. Capacity, 1,000 tons daily

Unloading coal. Bucket hoist, crusher and car loader. Capacity, 5,000 tons daily

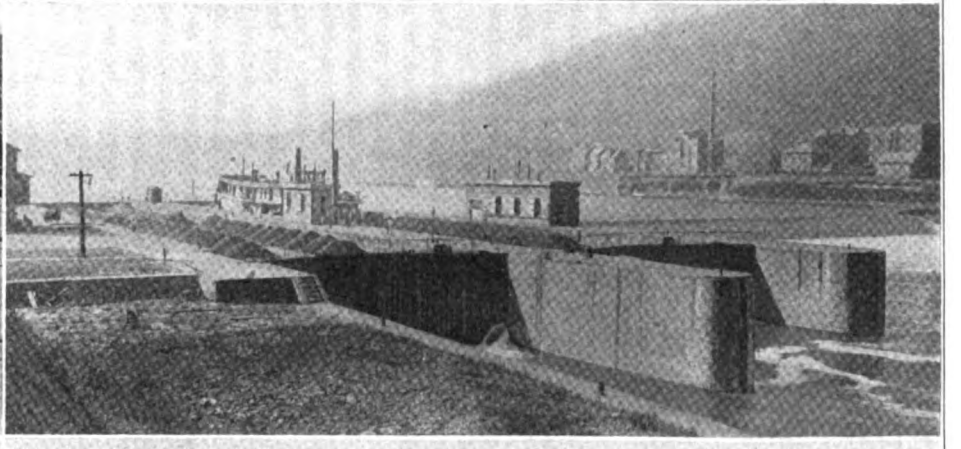


Unloading coal. Bucket ladder hoist and conveyor. Capacity, 10,000 tons daily

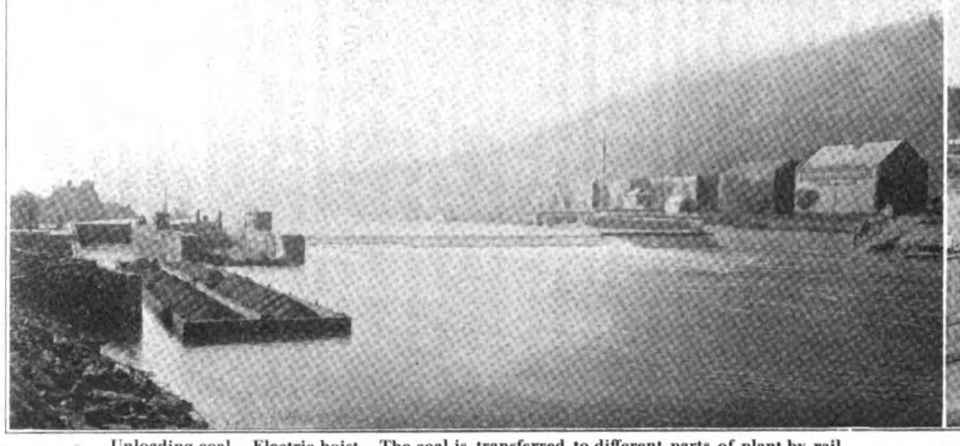
Unloading coal. Hoist and conveyor. Capacity 10,000 tons daily. Coke ovens in background. The coal is transferred to the ovens by belt conveyor



Digitized by Google



Unloading coal. Electric hoist. The coal is transferred to different parts of plant by rail. Capacity, 2,000 tons daily.



Barges loaded with steel products in Monongahela River, Pittsburgh harbor. The outer barge carries a cargo of 2,300 tons of pipe. Dimensions 42 x 269 feet, 7-foot draft.

Lock No. 5. Towboats and empty barges approaching the lower entrance.

A double lockage. Towboat and 6 barges, each carrying 1,000 tons of coal, in Lock No. 5.

Towboat and 6 barges leaving the double locks.

The tow made up and moving down the river after passing the lock.

Digitized by Google

traffic of the river was confined to one chamber. The table below exhibits the traffic *first* for one lock in use, and *second* for the remaining nine months with both locks in use.

LOCK No. 3, MONONGAHELA RIVER TRAFFIC DURING 1919

One Lock in Use.

1919	Lockages		Total traffic, tons
	Up	Down	
January	454	497	1,107,118
February	451	471	1,017,278
March	524	498	1,136,788
3 months, average per month			1,087,061

	Lockages		
	Up	Down	Tons
Maximum for one day, single lock	21	25	51,600

Two Locks in Use.

1919	Lockages		Total traffic, tons
	Up	Down	
April	442	446	1,002,640
May	407	429	956,396
June	543	547	1,242,716
July	619	601	1,470,944
August	681	698	1,650,416
September	629	620	1,454,582
October	648	661	1,611,408
November	276	290	628,398
December	396	411	888,953
9 months, average per month			1,211,628

During the busiest of the 3 months' period with one lock in use, down lockages averaged about 17½ daily and up lockages 16 daily, with an average time between down lockages of 1 hour and 20 minutes. As a matter of fact, double this number of up and down lockages have been frequently made in said time. In March of the present year a record of the time was taken of approaching and clearing of the locks by 38 coal fleets in such manner that upward-bound fleets might have been passed without mutual interference through the locks. The time averaged about 37 minutes for a complete up and down turn of the lock.

* * * * * * *

With both lock chambers in operation there were in several days passed at Lock 3, Elizabeth, Pa., and Lock 4, West Monessen, Pa., from 95,000 to 100,000 tons of coal per day in addition to empty barges moving upstream. Number of up and down lockages, from 60 to 70. Total time locks were in operation was about 18 hours.

On June 30, 1920, there passed Lock No. 6, through a single lock, 47,825 tons. The actual time used in locking and boats clearing the lock was 11 hours and 5 minutes. The tows were made up as follows:

5 tows with single lockings down,
5 tows with double lockings down,
5 tows with single lockings up,
4 tows with double lockings up.

At the above rate there would pass this single lock in 24 hours, 101,485 tons, or for two locks 202,970 tons per day.

On the basis of the foregoing performances, assuming an average of 40 down lockages in 24 hours, passing 5,000 tons per lockage, and continuing at that rate for 300 days per year, a double lock with chambers 360 feet by 56 feet by 8½ feet would show a theoretical annual capacity of approximately 60,000,000 tons.

However, such results cannot be obtained in practice. Tows do not reach the locks in the order of maximum theoretical lock capacity; also they are likely the year round more nearly 3,000 than 5,000 tons each; again, a 300-day year allows for deductions of Sundays and holidays only, making no allowance for high water, fog, ice, accidents to vessels, etc. Moreover, such a maximum capacity is based upon the further assumption that the locks can be kept in continuous operation without machinery breakages or any time allowance for repairs, such as frequently become necessary on such structures. Taking all of these things into account, it is believed that approximately 30,000,000 tons per year for a double lock represents a more reasonable estimate.

Future Traffic Demands

In making provision for the future growth of traffic, it is necessary to assume that, due to floods, severe winter weather, and other similar causes, there will be considerable losses of time. A fair allowance for these losses might be two months, leaving the average working season as 10 months. This corresponds to the experience of the winter of 1917-1918.

The demand for coal from the Monongahela Valley, both by rail and by river, is now growing at an unprecedented rate and has almost reached the limit of the capacity of the facilities for its movement to the markets along the rivers and by the railways extending to the interior of several northwestern states. For years past several hundred manufacturing plants and hundreds of thousands of private homes have been served by natural gas for steam making and household heating. As, however, the supply of natural gas is failing rapidly, and must within a few years fail entirely, great financial losses and suffering will soon be experienced unless means to supply coal to take place of gas fuel can speedily be provided. The welfare of the great manufacturing districts of Pennsylvania, West Virginia, and Eastern Ohio is therefore concerned in a problem vital to their welfare and through them vital to the prosperity of our entire country.

The contingency here referred to has arisen so recently as to have left but little time to prepare to meet the demands sure to come within the next two or three years. So far as the possibilities of the Monongahela River are concerned, it has been shown that practically all of its coal movement, great as it is, is consumed in the Pittsburgh district, and without very considerable enlargement of its present lockage facilities it cannot be relied upon to come to the relief of the railways. That it can be made to serve a vastly greater traffic is merely a matter of the enlargement of certain of its locks and the extension of its navigable depth to mining fields as yet almost virgin territory, with heavier veins of excellent coal than ever existed in the Pennsylvania counties from which the coal now comes. Adjacent to the upper Monongahela River the state geologists of West Virginia, upon a conservative basis of calculation, report that there are 2,100 square miles of workable coal of high grade, which will yield 10,000 tons per acre, much of which is contiguous to the upper reaches of the improved river.

While the present system of locks has an apparent dependable capacity of 30,000,000 tons annually for the business as now conducted in large fleets of 4,000 to 6,000 tons, the opening up of new mining fields for individual, or small company developments, promises to greatly increase the number of lockages for smaller fleets and thus in a manner encroach upon the capacity of the present locks. For this reason, and others not necessary to recite, a greater capacity at the locks is important, for even where there are duplicate locks, as at Dams 1 to 5, inclusive, one chamber may be closed for repairs, so the other chamber for the time being should have capacity sufficient to do all the business which may be offered it. The topography of the Pittsburgh district is such that not many manufacturing establishments can store much coal to meet emergencies, and, in a sense,

Digitized by Google

their coal yards are "afloat" in barges, hence the continuous service demanded of the Monongahela locks.

The increase in traffic is due almost exclusively to the growth in coal and coke tonnage. During the last four years this has grown at the rate of nearly 2,000,000 tons annually, and for the single year 1920, the rate appears to be about 4,000,000 tons. It is evident that, should the present rate of increase continue, the enlarged locks will soon be taxed to accommodate the business.

The problem involved is similar to that at the Soo, but the locality affords far less opportunity for the easy expansion of navigation facilities, and the question arises whether, in rebuilding such locks as 7 and 8, we ought not now to make them 720 feet long and count the excess cost as insurance against the certain growth of traffic in the near future. In any event, the second lock of any new pair should probably be made 720 feet long.

As showing the importance of the Monongahela River traffic, it may be interesting to note that it is exceeded in volume by only four of the great seaports—New York, Norfolk, Boston, and Philadelphia, and by the ore and coal movement on the Great Lakes.

It has already been stated that the coal traffic has increased from 5,700,000 tons in 1898 to an actual total of 14,700,000 tons in 1919, and that it will probably be about 19,000,000 tons during the present calendar year. The increase in 22 years has thus been about 200 per cent, while the present yearly increase in coal tonnage may perhaps be put at half to two-thirds of the traffic in 1898.

Why the Monongahela Improvements are a Success

The improvements made in aid of navigation on the Monongahela have been most successful. The reasons why are not difficult to find. In fact, to mention them is merely to draw attention to the obvious. In general, no *short* waterway can compete successfully with parallel railroads unless there exists, either immediately on its banks or so close to them as to eliminate relatively expensive rail hauls and transfers, an abundant supply of raw material, such as coal, iron ore or timber which can be handled in bulk, and, at the terminus of the water haul, cheaply transferred to industries also situated close to the banks of the waterway. As the water haul becomes longer, the economic possibility of absorbing the costs due to transfer from rail to water at the one end and from water to rail at the other increases, and eventually we arrive at the condition, illustrated by the familiar example of the ore, coal and grain traffic on the Great Lakes, in which a combined haul involving rail transportation for a considerable distance at both ends of the water portion of the route with the two accompanying transfers is very considerably cheaper than the through rail haul would be. In other words, water transportation is, in general, preferable to rail transportation only when the waterway is sufficiently capacious and well organized and of sufficient length to enable the cost of additional handling and transfers to be overcome by the greater economy of the water portion of the haul. The average haul on the Monongahela is only 50 miles, and even though the ton-mile cost of river transportation is considerably less than that of carriage by rail, it is clear the case is one in which extra terminal costs must be kept at a minimum, in order that this advantage of the waterway may be retained. This has actually been rendered possible through the fact that the Monongahela flows through the heart of a very rich coal region where there are many mines that can as conveniently ship by water as by rail, thereby virtually eliminating one extra transfer expense, and the coal is consigned to and used by industries so large that they can afford to install modern terminal facilities of the most economical kind. As a consequence, the economic advantage of the waterway is maintained and it has the further advantage that the traffic possesses greater certainty and ease of control, and, as already noted, the industrial plants can be constructed without the necessity of making provision for railroad yards of large area.

At present the total coal production of the seams near the Monongahela River is over 100,000,000 tons annually. The river is carrying from 15 to 20 per cent of this output, and in all likelihood gets all that can now be carried by water more advantageously than by rail. As the distance from the coal fields to Pittsburgh increases, the advantage of the waterway will also increase, and accordingly the width of coal areas tributary to the river will also increase.

Lo, the Poor Indian

They very much fear in the office of the Quartermaster General at Washington that some Western wag has been trying to have a little fun with the Army. If he is spoofing the War Department, Charley Stepinthemudd certainly has succeeded, for half a dozen veteran clerks of the Quartermaster Corps have been methodically searching files of the last hundred years in the hope of finding some record that Charley served as an Indian scout from 1812 almost to date.

Charley wants some compensation for his century of service, now that he is retired at the age of 130, and he plaintively asks if he must "waight another 100 years," which rather indicates that his financial difficulties are not very pressing.

And, poor Lo's story runs thus:

"Thorp, Wash.

"First, you will haf to excuse my Riting as I onley learned to Rite after I waz 100 years ago. I am now 130. I am a Onida and Senica Indian the Reason ov me riting to you iz this. I Have fol lowed the American Army near on too 85 years az an Indian Scout scouting and spying for the Army and I have never drawn any Pay for my services On account ov some ov them army officers not turning in my name for my services.

"My first service waz with General Jackson at New Orlens. Fiting the British Redcoats then scouting in Middle West after Bad Indians. I was with General Scott in the O'd Mexican War than scouting on the Plains. I was with A. J. Smith thru the sivil warr then Back West on the Plains and Rocky Mountains after Bad Indians. I went to Cuba with Colol Rosefent as a scout with them Ruff Riders and done my Part to help whip the spanyards.

"Rosefelt did not get me my transportation home soe I Had to goe and work in cane fields and suggar mill untill I could get enough to build me a good tight canue in whitch I cam back to the Missipia River and up to St. Louis and on up the Misurie River to great Falls Montana where I Procured too Horses and came on over to this Place to my old time white Firends House Where I stay most ov the time his great grandfather and I were boys together.

"Can not you Bring it to Pass soe I can gett just Recompence for my services to this out Belovid country for all the years ov toil and Hardships I have passed through in my countrys service? or must I waight another 100 years,

Respectively

CHARLEY STEPINTHEMUDD,
Thorp, Wash."

An ethnological expert with a side line of etymological training might gather from internal evidence that this letter was possibly written by a Caucasian of considerable education.—*Office of the Quartermaster General.*

The Instruction of Engineer Troops in Ponton Bridge Construction

By

Mason J. Young

Major, Corps of Engineers

ALL engineer officers should realize the importance of thorough instruction of all combat engineer units in the construction of ponton bridges, but, perhaps, some officers have overlooked, or lightly considered, this particular engineer activity. Of all duties that engineer troops are expected to perform none is more completely an engineer function than the construction of ponton bridges. Infantry and artillery can dig in, in fact, they actually did a large part of the field fortification work during the World War. An engineer is supposed to build a little better trench or dug-out than an infantryman, and that is all. It is much the same with reference to road work. But when it comes to a river crossing, even if the river is little more than a creek, all branches of the service have from time immemorial down to the end of the World War, waited on the engineers, and if the engineers failed at the job, that water course was not crossed.

Bringing a heavy ponton into position

As the crossing of rivers, which usually means building ponton bridges, is so solely and completely a function of engineer troops, it then becomes a very great obligation upon all engineer officers to train their organizations very thoroughly in the use of the ponton equipment. Perhaps it will not be purposeless to mention a few important military operations in the Mexican and Civil Wars and the World War which were dependent upon ponton bridges for their success, or which failed to materialize because of the lack of a bridge train.

It is a historic fact that General Taylor's army was prevented from invading Mexico for a considerable time because it had no ponton equipment and could not cross the Rio Grande River. Napoleon himself records at least one similar failure.

Nearly every advance by the northern armies during the Civil War was across broad rivers that were bridged by the ponton equipage, practically the same equipage that we have to-day.

The engineer troops with the Army of the Potomac consisted of two regiments of New York Volunteers and a battalion of regulars. This battalion of regulars later became the First Battalion of Engineers, then the First Regiment of Engineers, and was in 1917 expanded into the First, Sixth and Seventh Engineers. These two volunteer regiments, and particularly the Battalion of Engineers, were continually building ponton bridges during the Peninsular Campaign, before the battle of Fredericksburg, for General Meade's army to cross over the Potomac, when it marched north to the battle of Gettysburg, and then again when it marched south, throughout all the maneuvers in Virginia and when Grant finally marched to Richmond.

When General Sherman marched north from Savannah he crossed the Savannah River about twenty miles north of the city on bridges of canvas boats. The river at that point was wide and swift.

Engineer officers should read Occasional Papers No. 44, entitled "The Engineer Battalion in the Civil War," and the introduction to the ponton manual. The authors of those papers speak of bridges, some 2,000 feet long and others built in currents so swift that the boats had to be held in place by ship anchors.

The rivers along the western front during the World War were narrow and had gentle currents. They offered comparatively few engineering difficulties when contrasted with American rivers. Many ponton bridges were constructed in the presence of the enemy, and a very considerable per cent of the American divisional engineer regiments used ponton equipment at one time or another. Of course, the most important river crossings effected by American troops were those of the Marne and the Meuse. The Seventh Engineers, for example, constructed improvised canvas ponton foot bridges, standard ponton bridges, and one heavy ponton bridge across the Meuse River.

In discussing the experience of the World War it must be remembered that the rivers in Europe were easy to cross, and from an engineer's point of view presented few real difficulties, whereas many of the rivers of the United States are broad and swift. Because of these conditions I believe the Civil War experience furnishes a much truer guide as to what should be the degree of proficiency of engineer troops in this specialty than does the experience of the recent war.

Another point that emphasizes the necessity of thorough ponton drill in peace times is that practically every ponton bridge built by American troops in Europe was built under the immediate direction and supervision of an officer or noncommissioned officer who had had long service as an enlisted man in the engineers before the war.

Digitized by Google

Considering then the fact that the construction of ponton bridges can only be undertaken by engineer troops, and that rivers have had to be crossed as a result of nearly every military advance in the past, it is evident that ponton drill should occupy a very important place in every engineer training schedule. It is my belief that every engineer unit should each year have a ponton season set aside for this training alone, so that a high degree of proficiency can be obtained in this specialty. Furthermore, I believe that the importance of this training to an engineer soldier is analogous to the importance of the target season to all soldiers armed with the rifle, that it should proceed along much the same lines, and that it should occupy approximately the same proportion of the engineer soldier's time.

The ponton drill is practically the only engineer drill that has been standardized and for which there is a manual. Consequently it becomes an important disciplinary exercise and teaches officers and men alike the organization and co-ordination of engineer work.

Preparing a raft

First lessons in rowing and paddling

The following fundamentals should govern ponton training:

(a) The company is the bridge-building unit, and it builds bridges under the immediate direction of its captain. Consequently each company commander should have his entire company for ponton drill at one time, and he should personally supervise the drill.

(b) All noncommissioned officers should be trained in all details of ponton-bridge construction. The most difficult and most important thing for them to learn is the duties of chief of ponton.

(c) Every private should become a good oarsman.

(d) The ponton manual should be followed absolutely. This rule should not need statement, but it has not always been followed.

(e) Flotilla drill should be held if the current is moderate. I know of only two ways to develop proficient boatmen. One is to put them in the middle of a swift stream and the other is to give them flotilla drill.

(f) All knots and lashings should be made absolutely as prescribed in the manual.

(g) A trained company should build a bridge by successive pontons, under exhibition conditions, at a rate of ten feet per minute, or better.

In applying the above rules, the most important consideration is the development of good boatmen in every company. Under difficult conditions, and particularly in swift streams, only skilled boatmen can handle the boats, whereas the other operations of building a bridge present few difficulties. Speed in constructing bridges under exhibition conditions is a secondary consideration to the development of oarsmen. Under conditions which usually prevail when brides are built in war time, the engineer companies have not had ponton drill for months, and their personnel has often been largely changed by reason of replacements since having any such drill. Consequently there must be many trained boatmen at the end of the drill season, in order to have enough trained men available when an emergency arises months afterwards.

Under the conditions prevailing in the service to-day it is hard for a company commander to get enough men at one time to conduct ponton drill with his company as a properly organized unit. My only suggestion is that one company in a battalion at a time be relieved from all special duties and fatigue, and enough privates be attached to it as balk and chess carriers so that the company commander can construct a bridge by successive pontons with the prescribed details.

The training given the First Battalion of the 604th Engineers during July and August, 1918, just before the regiment went overseas, will serve to illustrate these ideas. Each company in the First Battalion of the 604th Engineers had nine (9) full days of ponton work. Half a company had ponton drill in the morning and the other half in the afternoon. It must be remembered that the companies were at war strength, and could turn out about two hundred (200) men for drill. Morning and afternoon drill periods were three and three-quarters (3¾) hours long. Thus a pontonier could have a maximum of thirty-three and three-fourths (33¾) hours' ponton drill, divided into nine drill periods.

The drill was conducted by the company commander or his lieutenants. Actually company commanders spent about half the morning and afternoon drill periods at ponton drill. The drill was discussed at officers' call in a general way. Each company commander used the drill period to instruct his men as he saw fit, and was alone responsible for the results attained.

The material available consisted of one ponton division of heavy equipage and four ponton wagons of light equipage. It was sufficient to drill half a company at a time. Drill was conducted on a broad shallow tidal stream flowing into Chesapeake Bay. There was only one experienced engineer soldier in the entire battalion. He was a sergeant, first class, and thoroughly understood ponton work. He was put on special duty at the ponton grounds, and used by the three company commanders as they saw fit. The company commanders were graduates of the engineer training camps, and all they knew about ponton work they had gathered at those camps. It was unfortunate that there was not more equipment and that the companies had to be divided for this drill. This condition necessarily distracted the attention of the company commanders and reduced the rate of progress of the men. On the other hand, the men

Digitized by Google

were of a very high type, and they worked under the stimulus of preparation for movement overseas.

During the middle of the ponton drill season it was decided to terminate it by a competition drill and the memorandum quoted hereafter was published:

HEADQUARTERS, 604TH ENGINEERS

Camp Glenburnie, Maryland, *August 5, 1918.*

Memorandum No. 57.

* * * * * * *

II. 1. The ponton drill season will be completed Monday, August 12, 1918. August 9, 10 and 12 will be devoted to competitive work between A, B and C companies. The winning company will receive Saturday forenoon, August 17, as a half holiday.

2. The judges will be the regimental and battalion commanders and regimental adjutant.

3. The competition will consist of the following tests:

(a) Building bridge by successive pontons from present drill site to old landing—distance approximately 240 feet; weight, 60.

Materials will be piled at places habitually used, and oars, anchors and lashings in boats. Bridge will consist of one trestle, eight heavy and two light pontons. Six heavy pontons and two light pontons will be moored above bridge site and two heavy pontons below. The second, third, fourth, sixth, seventh, eighth, ninth and tenth boats will be moored upstream and the fourth and eighth boats downstream. The first ponton will be moored to bank. Building detail will be divided into sections and formed on bank in double rank. Sections will be as prescribed in Ponton Manual, except that there may be fifteen (15) lashers. Long balk will be used between trestle and first ponton. Time will be taken from time command "Construct the Bridge" is given until last man is off bridge on far side. The bridge must be dismant'ed and bridge equipage properly piled or secured in the same time it took for constructing, after a short rest is given competition details. In figuring time of construction in each case a penalty of one (1) minute will be given for each defective balk lashing, mooring knot, or improperly placed anchor, and a penalty of thirty (30) seconds for each defective side-rail lashing. Other defects will be penalized on a similar basis. After penalties have been awarded, the company which has the best record will be given a rating of sixty (60) and the other two companies will be rated on the basis of a deduction of four (4) points from the total of 60 for each minute they are behind the winner. Only the time of construction after penalties are awarded will be considered. However, if it takes longer to dismantle than it did to construct the bridge, the excess time will be added to the constructing time in figuring the final rating. The abutment section must not enter water when launching the trestle.

(b) Flotilla drill; weight, 15.

Competition will consist of a race over a previously laid-out course of approximately one-half (½) mile. Each company flotilla will consist of four (4) four-oared boats, and will perform specified movements in the School of the Flotilla at designated points on course to be covered. Penalties will be awarded if movements are not cleanly and properly executed and position in flotilla kept. After penalties are awarded, the company having the best total time will be awarded fifteen (15) points, the company having the poorest time nothing, and the intermediate company a prorated number of points.

(c) Six-oar boat race; weight, 15.

Race to be over a course approximately one-eighth of a mile, turn around a stake and back again, the total distance to be one-fourth of a mile. Rating to be computed as for flotilla competition.

(d) Assembling of light ponton; weight, 10.

Detail will consist of eight (8) men, who will be formed in line beside chest near water. Time will be taken from time signal to commence work is given until boat strikes water in launching. Penalties will be imposed and rating computed as for flotilla competition.

4. Final rating will be determined by adding ratings in each competition.

It is believed that these rules are fairly clear. The importance of rowing was emphasized by the flotilla drill and the boat races, which made up thirty (30) out of one hundred (100) points.

The manner in which the flotilla drill was conducted needs further explanation. Actually it was both a race and a maneuver by flotillas consisting of four (4) four-oared ponton boats. As has already been explained, the drill was held on a broad shallow tidal stream. Five light piles, painted white at the top and numbered consecutively, were set in the water so as to mark out a closed course slightly less than one-half mile in length. The flotilla rowed around this course, executing one of the following movements as it passed each pile or as it passed from one pile to the next: Left by ponton, left oblique and forward, pontons left (twice), right front into line, flotilla left and flotilla right. The flotilla was in line at the start and finish. A sketch showing the shore line, the positions of the piles and the movements to be executed at each pile, or between consecutive piles, was prepared several days before the competition, and blue-prints of it distributed. It would have been impracticable to hold the competition with a larger flotilla, or to have two flotillas maneuvering at once, because of the restricted water space.

The results of this competition were as follows:

	A Company			B Company			C Company		
	Time	Penalties	Rating	Time	Penalties	Rating	Time	Penalties	Rating
	′ ″	′ ″		′ ″	′		′ ″	′ ″	
		(1)			(2)			(3)	
Bridge	26 19	3	46.7	24	2	60	26 40	4	41.3
						(4)		(5)	
Flotilla	12 38	0	15	13 28	0	10	Disqualified		0
		(6)						(7)	
Light Ponton	3 25	10	0	2 40	0	10	2 51	10	6
Race	5 11	0	0	5 7	0	3	4 50	0	15
Total			61.7			83			62.3

(1) Poor mooring knot, 1 minute. Locker lids open and general untrimness, 2 minutes.

(2) Poor alignment, chess laid raggedly, locker lids open, 2 minutes.

(3) Poor mooring knot, 1 minute. Poor balk lashing, 1 minute. Poorly laid chess, trestle not vertical and balk in water, 2 minutes.

(4) Due to the disqualifications of "C" Co., "B" Co. was given an arbitrary rating of 10.

(5) Disqualified for not covering entire course.

(6) Five defective knots and loose canvas, 10 seconds.

(7) A defective knot and loose canvas, 10 seconds.

The bridge was dismantled by A Company in 16 minutes 5 seconds, by B Company in 13 minutes 13 seconds, and by C Company in 20 minutes.

Company B, the winning company, was commanded by Capt. Louis A. Barton, later promoted to the grade of major.

The results of the nine-day training period and the competition may be summarized as follows:

(a) Company spirit was developed and companies trained as bridge-building units. Furthermore, the regimental and battalion commanders had an opportunity to judge to a certain extent of the capabilities of the company commanders.

(b) All the noncommissioned officers got a good general idea of ponton-bridge construction, but only a few of them really became proficient in all its details.

(c) Sixteen (16) oarsmen and four (4) chiefs of ponton attained a considerable degree of proficiency in each company.

(d) The entire battalion was taught to build bridges as prescribed in the manual.

(e) Flotilla drill was held.

(f) Knots and lashings were usually well made.

(g) The fastest company built the bridge at the rate of ten (10) feet per minute. Faster work has, of course, been done. The bridge was a short one—one trestle had to be put in position without the detail entering the water, and two canvas boats, with short balks, had to be used. All of these conditions constituted slight handicaps.

A Science of Infantry Tactics

By

Captain B. H. Liddell Hart, K. O. Y. L. I.

(Reprinted from *The Royal Engineers Journal.*)

"SIMPLICITY is the key to victory." This vital truth has scarcely been fully valued in the tactical teaching of the infantry leader. Too many text-books on tactics dealt with war in a series of water-tight compartments, explaining the points of difference rather than the points of similarity. The junior Infantry commander was taught many excellent precepts dealing with each phase of action, but his path was not smoothed for him by any framework of fundamental principles, upon which he could build as he acquired practical experience of ground and weapons. To simplify the task of the junior commander we require to establish the essential principles of tactics and their relation to the varying phases of battle. We must then fit them into their correct place, both in chronological and tactical sequence, in order to form a simple and truly scientific theory.

The family tree is an ancient institution and yet graphically clear as a chart of the various degrees of kinship. Let us endeavor to establish a simple and scientific tactical tree which will clearly convey to the military student the essential principles and their broad application to the phases of war. To understand these principles of tactics we must simplify and reduce it to the essential elements which are true of any fighting whether between two individual men, two platoons, or two armies. We will examine the simplest form of combat, that between two individuals. From their correct course of action we can deduce the essential principles, and can then apply them to the conduct of war.

But it may be argued that the conditions of war are entirely different from those of a straightforward fight between two men; that in war the enemy's movements and location are hidden from us until we are actually at grips with him.

Certainly, we agree, but the situation in war will resemble that of two men fighting under similar conditions, such as in the dark wherein a man can only locate and reconnoitre his enemy by actually touching and feeling him. Thus the man in the dark resembles the commander in modern war. Let us examine the correct principles of action which a man seeking to attack an enemy in the dark would naturally adopt.

"The Man Fighting in the Dark"

I. In the first place he must seek his enemy. Therefore the man stretches out one arm to grope for his enemy, keeping it supple and ready to guard himself from surprise.

This may be termed the principle of "protective formation."

II. When his outstretched arm touches his enemy, he would rapidly feel his way to a highly vulnerable spot, such as the latter's throat.

This is the principle of "reconnaissance."

III. The man will then seize his adversary firmly by the throat, holding him at arm's length so that the latter can neither strike back effectively, nor wriggle away to avoid or parry the decisive blow.

This is the principle of "fixing."

IV. Then while his enemy's whole attention is absorbed by the menacing hand at his throat, with his other fist the man strikes his opponent from an unexpected direction in an unguarded spot, delivering out of the dark a decisive knock-out blow.

This is the principle of "decisive manœuvre."

V. Before his enemy can recover the man instantly follows up his advantage by taking steps to render him finally powerless.

This is the principle of full and immediate "exploitation" of success.

To follow these principles is the only sure path to victory. We can only neglect the fixing phase, if our enemy commits some mistake, such as the neglect of his own security, by which he fixes himself without our intervention and so exposes himself to our decisive blow.

Digitized by Google

Now the whole action of our man-in-the-dark can be simplified into two categories:

Guarding and Hitting

It will be noted that the man guards against two dangers: Firstly, that of personal injury from the enemy's blows; secondly, that the enemy may avoid his knock-out blow and thus cause him to overbalance. The man guards against these two dangers by extending one arm in front of him ready to parry and take the sting out of the blow aimed at his body; by using this arm to grope for and feel the enemy; and finally when he has located the enemy by seizing the enemy so firmly at a spot (the throat) so vital that he will be forced to concentrate all his energy on its defence.

All these objects have a common object, and therefore may be grouped under one principle termed "Security."

When the man has fixed his enemy, he delivers a decisive knock-out blow. It will be obvious that the harder this blow, the more likely it is to be decisive. Hence the man must put his maximum possible force into it, while he only uses the necessary minimum of strength to carry out the preparatory operations. This is the principle of "Economy of Force."

But the man can increase the effect of his available strength by surprising the enemy, by his speed, by the momentum or "follow through" behind his blows; by striking his opponent's most vulnerable spots; by full exploitation of every opening or advantage; by husbanding his energy; and by moving his limbs and muscles in harmony like the parts of a well oiled machine. All these are means to promote economy of force, and therefore can be grouped under that principle.

Thus we see that there are two, and only two, supreme governing principles—Security and Economy of Force. These two principles govern the execution of the five battle principles, and may be said to cut laterally across them.

A diagram may simplify the idea.

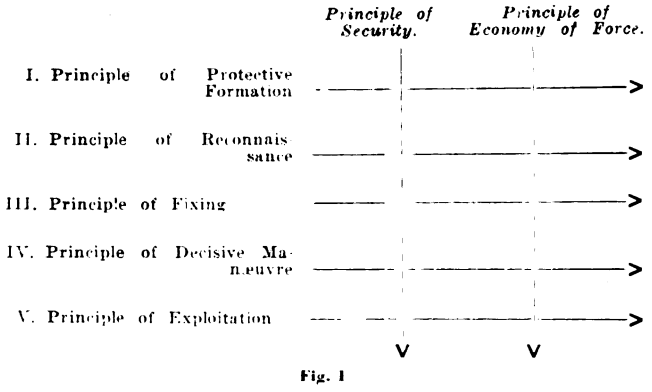

Fig. 1

Application to Infantry Tactics of the two Governing Principles Deduced from the "Man Fighting in the Dark"

A. Security. In war, as in individual combat, there are two kinds of security: Material and Tactical. The former is security against direct loss, such as casualties inflicted by the actual blows of the enemy; the latter is security against the indirect damage which we suffer if the enemy is able to avoid or parry our decisive blow, so that we weaken and expose ourselves to his counter-blow.

How does one obtain security? Exactly as did the man-in-the-dark. He pushed out one arm, which in war means adopting a *formation of security.* He used his outstretched arm to grope for and feel the enemy, which in war means *reconnaissance.* When the enemy is located, we *fix* him so firmly by an attack from one direction that he is unable to avoid or turn to meet our decisive attack delivered from another direction—usually a flank.

It will be seen that these three means to security correspond to the first three battle principles. Hence for convenience we will consider them in detail when we discuss the phase of preparation which comprises the three battle principles. The commander of any unit entrusted with the *role* of decisive manœuvre or exploitation must however remember that it is equally necessary for him to carry out these three "security" principles in the course of his own action.

B. Economy of Force. Now let us consider the principle of economy of force as applied to Infantry. One must use the minimum strength for the phase of preparation, essential though it is. One must devote the maximum possible force to the decisive blow and its exploitation. In strategy or grand tactics the distribution of our available forces is a complex problem, but in infantry tactics it is comparatively simple. Each infantry commander, platoon, company, battalion or brigade, has only four fighting sub-units under his command, apart from certain auxiliary fire weapons such as machine guns or mortars.

Hence he has only three possible ways in which he can distribute them, and these are:

i. *One sub-unit forward for reconnaissance and fixing and three for decisive manoeuvre.* This distribution will normally be best when advancing against an unlocated enemy as in the approach march or encounter attack. Thus he retains the bulk of his strength in hand until the position of the enemy has been discovered, so ensuring better results when the decisive manœuvre is carried out.

ii. *Two sub-units forward and two for manoeuvre.* This distribution will usually be advisable in a definite attack against an enemy whose positions have been located, in order to secure that the whole front of the enemy position in his sector is tested thoroughly so that a soft spot may be found. Moreover, it is imperative that the forward body shall not be held up before it has firmly fixed the main resistance of the enemy, otherwise the manœuvre body may have to be used before the decisive moment—which would be the antithesis of economy of force.

iii. *Three sub-units forward and one for manoeuvre.* This distribution may be advisable when following a creeping barrage—which reduces the need or possibility of manœuvre. This will ensure that the whole frontage is cleared directly the barrage lifts and so enable the forward sub-units to keep close behind the barrage. Further reasons for this distribution are that in such a case the strongest opposition will probably come early, and that a counter-barrage is likely, in which event the bulk of the unit will escape it.

It may also be advisable to adopt this distribution when allotted an unusually broad frontage, in order to cover it with fire. It entails the risk, however, of limiting the force of your manœuvre.

It must be remembered that while the decisive attack is made by the maximum force, its success depends upon the enemy being really fixed. *Manoeuvre is useless unless the enemy is first fixed in another direction.* Hence the manœuvre body is not necessarily the largest. The "last straw which breaks the camel's back" is a great truth in battle tactics.

It will be noticed that the author uses the words "forward body" and "manœuvre body," instead of the recognized terms "firing line" and "supports." This is because

Digitized by Google

these terms are no longer applicable to modern infantry tactics. In order to instil a correct doctrine into the minds of the average officer and N.C.O. it is advisable to eschew misleading terms, and not to try to reconcile modern ideas with out-of-date phraseology.

The term "firing line" does not convey the idea of the outstretched arm or of distribution in depth. It suggests a broad frontal attack with no attempt to make use of covered ways of approach or to find the soft spots.

In the case of "supports" both the word and the idea are dangerous. It does not inculcate the essential idea of manœuvre, but rather the obsolete and unsound idea of reinforcing frontally troops who are held up, which means piling the dead in front of the enemy's strongest points.

Reinforcement of units which are held up causes confusion owing to the mixing of units, nor does it produce so great a moral effect as a diversion from a flank, either on the enemy or on the troops reinforced. As long as obsolete terms persist, there is a danger of a wrong idea lingering in the mind of the average leader. It is contended on the other hand that the terms "forward body" and "manœuvre body" instinctively suggest the true principles. *Even if we retain the old terms, however, the action of these respective bodies still holds good.*

When one speaks of weight or force in modern war it is essential to remember that it is weight of fire and not of mere numbers of men. An army composed of highly trained fire units capable of manœuvre can defeat far larger armies who rely on mere masses of men. Thus highly fortified enemy defences must be countered by an increase of mechanical fire power, and not by reducing the intervals, and so increasing the casualties, of the infantry.

The infantry commander must not, however, delude himself with the idea that he has fulfilled the principle of economy of force when he has correctly distributed his sub-units.

He must use every means to increase the effect of his available numbers. How? By following the same sub-principles as did the man in the dark, which were:

i. *Surprise.* Striking the enemy from an unexpected direction, at an unexpected moment, in an unguarded spot. It is the duty of every commander before and during the attack to use instinctively this, and the following, means to economy of force. He should ask himself subconsciously at every stage of the fight: *How can I surprise the enemy? Is there a covered approach by which I can get closer to the enemy or round his flank? Is the smoke or fire of other units or arms affording me a momentary chance to get forward or to assault the enemy?*

ii. *Speed* of movement, fire, and eye. Opportunities in battle are fleeting and must be constantly noticed and seized.

iii. *Momentum. How can I keep up the pace of the advance? Is this a suitable moment to use the expanding torrent system?* We will discuss this matter later.

iv. *Soft Spot,* seeking and striking the enemy's weakest spots, instead of dashing out the lives of one's men in front of his strongest points.

Where does there appear to be a weak spot or where is the enemy beginning to give way?

v. *Husbanding* one's men by the aid of correct tactics and covered approaches instead of massed frontal attacks in line.

How can I get my men over that exposed stretch with the least loss?

vi. *Mutual support,* whether of brigades or sections, all working together like the muscles of the body or the members of a football team.

Can I help the units on my flanks to get forward by bringing cross-fire to bear on the enemy opposing them?

vii. *Exploitation* to the full of every advantage gained.

How can I best exploit the soft spot which I have found or the fire position which I have gained?

Before going on to deal with the execution of the five battle principles, let us consider certain

New Characteristics of the Infantry Fight

Infantry tactics have been thrown into the melting pot by the realization, which has been forced upon us, that our former methods are inapplicable and wasteful of force under modern conditions. The outstanding change has been the realization that the weight, or force, of an attack does not increase in proportion to the numbers of men thrown in; that progress can only be made by intelligent manœuvre of fire power.

Increasing numbers beyond a certain density adds nothing to the effectiveness of the attack or defence, but only results in greater casualties. Instead of dense lines of bayonet men in attack, or crowded position, in defence, one must use widely dispersed combat groups containing comparatively few men, but well equipped with fire and smoke weapons. These must be allowed ample frontage to manœuvre and find the enemy's soft spots. Thus the exact intervals will depend on whether the ground is open or close.

It is necessary at this point to remember that, in any large action, each of the infantry units will be restricted to a definite sector of the front. At first sight, therefore, it will be confined to a purely frontal attack. But modern destructive weapons have enforced a wide dispersion of the combatants on the battlefield. This dispersion has rendered possible penetration by the fire units—the sections—between the enemy defence posts. It is the *role* of the section, platoon, and company commander in turn by exploiting this penetration to change their sector of the battle from a mere bludgeon fight into a manœuvre combat, thus fulfilling the principle of economy of force by striking "from an unexpected direction against an unguarded spot."

Infantry in Attack

We now turn to consider the application of our man-in-the-dark theory to practical tactics. The ideal infantry battalion, company, or platoon, should resemble a human tank, comprising both offensive power and protective armour. Its offensive power rests in its arms and legs, or in other words its weapons and manœuvring power. The protective armour is represented by an open formation, such as a diamond or square, which prevents more than one of the sub-units being surprised by the enemy, and so affords time for the remainder to manœuvre to take the enemy in flank.

A. Preparation (Security).

"The man extends one arm to grope for, feel, and seize his enemy by the throat."

1. Protective Formation.

We deduce from our study of the man-in-the-dark that each unit should move with an advanced guard or forward

Digitized by Google

body—the outstretched arm—pushed out in the probable direction of the enemy, whilst the main, or manœuvre body, follows in rear. The latter will thus be ready to manœuvre against any enemy which the forward body encounters, and by its mere presence will protect the flanks of the forward body. In modern war the defenders can only be definitely located bit by bit by actual attack. Hence the danger of a surprise counter-attack is ever present.

An open formation of security is therefore just as vital during the attack as during the approach.

a. The Advance or Attack against an unlocated enemy.

Maxim i. The best formation for any body advancing against an unlocated enemy will usually be that of the diamond (see Figs. 2 and 3). Whichever point of the diamond encounters the enemy first has the duty of fixing him whilst the other three manœuvre to take the enemy in flank.

Maxim ii. Until a unit is committed to attack on a definite point its commander should move with his forward body in order best to direct the movements of his unit and keep in touch with the situation in front. The diamond, with its solitary leading point, facilitates this direction by the commander, and enables him to make the best use of any covered approaches.

Maxim iii. Hence it should also be used for all manœuvre bodies and units in rear until they are committed to a definite *role.*

Maxim iv. Security is the first essential. Hence each unit should move *by bounds.* In this method each body advances alternately, while the other is halted in a position from which it can cover with fire the moving body. The manœuvre body, in an advance, will only bound as far as a position in rear of the forward body, from which it can cover the next advance of the latter.

When not in the neighborhood of the enemy speed is more important than security. Therefore, units should move in column of route along roads, with only the actual head of the forward body deployed. Thus in the case of a company serving as advanced guard or forward body to a battalion, only the forward platoon would be deployed in

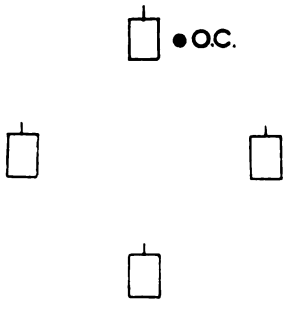

Fig. 2. Diamond Formation

diamond formation, whilst the three manœuvre platoons move in fours along the road, until in the neighborhood of the enemy.

b. The attack against a located enemy.

Maxim i. You will normally have two sub-units forward and two for manœuvre. The formation will usually be a modified square (see Fig. 4). The two forward sub-units should be well apart in order to cover the whole extent of your frontage with fire and to thoroughly explore it for soft spots. The two manœuvre sub-units should move as close together as the enemy's fire allows, in order to be under quicker control for manœuvre.

Maxim ii. Speed is the first essential, and therefore continuous progress must be aimed at, instead of movement by bounds.

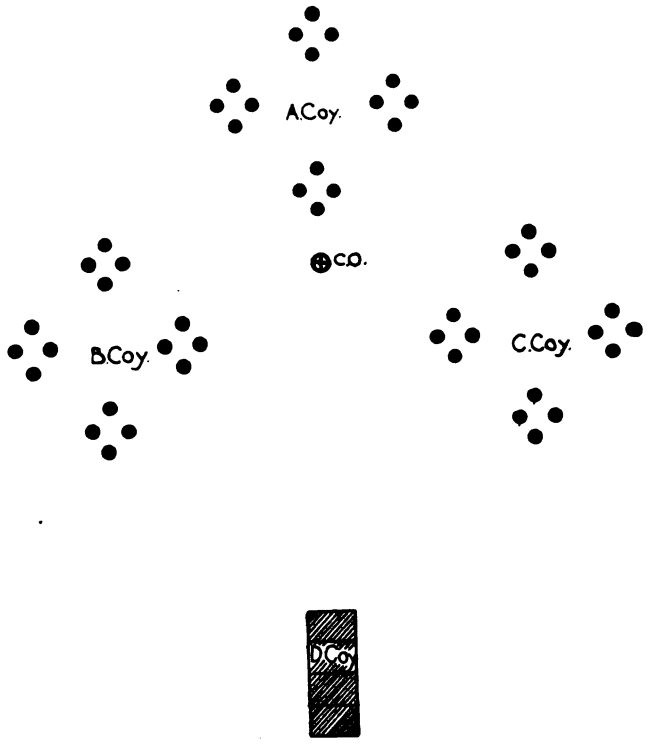

Fig. 3. A Battalion in the Approach March Against Unlocated Enemy

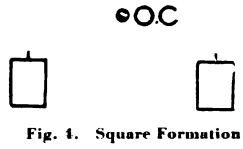

Fig. 4. Square Formation

SECTION FORMATIONS.

We now turn to consider the formation of the actual fire, or fighting, units which are the sections. The extended line is not a formation of security; it is not under the instant control and direction of the section commander and thus it prevents full advantage being taken of covered approaches and reduces the power of manœuvre.

The very idea of a line presupposes a wasteful frontal attack instead of a manœuvre combat. Hence it should be abandoned in favor of a formation such as arrowhead (see Fig. 5), with the section commander as the point of the arrow. Arrowhead is no more vulnerable to frontal fire than an extended line, whilst against enfilade fire it is even less vulnerable. It gives the section commander far greater powers of control and manœuvre, and is capable of firing in any direction. Thus it forms our ideal of a human tank or moving strong point.

Digitized by Google

When advancing through defiles or through woods and thick bush, the arrowhead can be closed into worm formation, in file or single file.

Maxim i. Arrowhead will therefore be the usual formation for both fire and movement.

Maxim ii. Worm will be the alternative formation for movement.

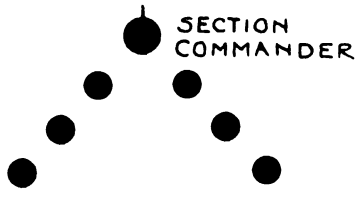

Fig. 5. Arrowhead Formation

Maxim iii. During the advance the section commander must use his intelligence and change from one formation to the other as the ground dictates.

II. RECONNAISSANCE.

Reconnaissance may be divided into two classes, "previous to battle" and "during battle."

a. Previous Reconnaissance.

This is carried out by three methods:

i. The commander of each infantry unit studies all information regarding the enemy and the ground, which his superiors or the other arms, such as cavalry and aircraft, have been able to obtain.

ii. He carries out a personal survey of the ground ahead before committing his unit to an attack on a definite objective or to the defence of a definite position. In this survey he should be accompanied by his sub-unit commanders and any *liaison* officers.

iii. Sending forward specially trained company scouts to carry out long-distance reconnaissance to obtain information on definite points.

b. Battle Reconnaissance.

This is carried out by observation and fighting:

i. Observation is achieved mainly by section scouts or patrols moving ahead of, but in touch with, the sections or higher units, respectively, which they are covering.

Maxim i. Each section when it has shaken out from the platoon should send a pair of scouts ahead to insure protection. Section scouts should move ahead of, but within view of their sections. It is their *role* to discover the most covered ways of approach and to give warning of defence posts or parties of the enemy, and thus prevent the section coming under heavy surprise fire. They should move by bounds, and at the end of each bound one scout should signal back for the section to come on or the reverse, whilst the other remains observing. When held up by the enemy's fire the section scouts should take up a position from which they can cover the section, as it moves up. The section should always move to rejoin its scouts in order that it may become an intact fighting organization once more.

Maxim ii. Patrols, which should consist of a complete section, or platoon, will be used to afford close protection to large units. They should move in touch with the unit which they are covering, but considerably beyond the radius of action of the section scouts. Like larger units also they should move in a formation of security, such as the diamond.

ii. Reconnaissance by fighting will be carried out by the advance of the forward bodies which by actually attacking the enemy's position will feel and test it at all points, and so endeavor to discover or make a breach at some weak spot. Hence it may be best considered as part of the phase of fixing.

III. FIXING.

Each forward body should advance direct on the enemy in order to reconnoiter him by fighting, discover and penetrate his weak spots and so continue its advance until it has gained the objective. If no soft spots can be found in the frontage allotted to it, it should fix him firmly, so that the manœuvre body can work round his flank and deliver a decisive surprise blow.

Maxim i. Thus when the fire of the enemy holds up a forward body, its duty will be to keep the enemy immediately opposing it *fixed* to his ground and to absorb his attention by maintaining a vigorous fire and working its way closer at every opportunity provided by the fire or smoke of neighboring units or of the auxiliary arms.

Any slackening of pressure by the forward body will only result in the defence being able to turn and meet the flanking attack. There is a danger that during this flanking movement, the manœuvre body may be exposed to cross-fire or counter-attack from other enemy posts. This can only be averted by the neighboring forward bodies really fixing their own immediate enemy. To insure this mutual support every forward body must be determined to close with, and fix the whole attention of, the enemy opposed to them.

Maxim ii. The leading sections must not delay the advance by halting to fire until no further progress can be made without beating down the hostile fire.

Maxim iii. The action of the forward infantry in attack must consist of a constant pressing forward to close with the enemy in order to find the weak spots in his defences.

Maxim iv. To this end they must seize every available cover afforded by the ground, fire, or smoke.

Maxim v. The speed of advance will be vastly quickened if tanks working with the infantry are used to carry the equipment and extra ammunition of the infantry.

Maxim vi. The forward sections can often fix the enemy defence posts opposed to them far more effectively by firing smoke to windward of them than by rifle or Lewis gun fire. The smoke drifting down over the enemy blinds them and so enables the manœuvre sections to work round their flank unseen to assault them. Moreover this method economizes ammunition.

Maxim vii. To enable him to take instant advantage of any soft spots which are found by the forward companies or platoons, every battalion and company commander should detail an officer or specially selected N. C. O. with runners to move with each of the forward companies or platoons, and to send back word to him the instant a gap is found or made.

Maxim viii. Commanders should keep touch with the units on their flanks by observation or by sending out a patrol or special scout when the necessity for information or communication arises.

B. DECISIVE MANŒUVRE.

iv. "The man delivers a decisive blow from an unexpected direction against an unguarded spot."

Each manoeuvre body will move close behind. Its normal purpose will be to assist, by means of manœuvre, the

Digitized by Google

forward body to advance and gain the objective. If the fire of the enemy holds up the former body it will be the *role* of the manœuvre body to turn the flank of and enfilade the enemy resistance which is opposing the forward body.

Maxim i. To achieve this a manœuvre body may have to quit its own sector and follow in the wake of a neighboring unit which is still advancing. It will pass through the gap thus made, and come in on the flank of the enemy, against which it will deliver an immediate blow.

As soon as this manœuvre has achieved its aim the forward and manœuvre bodies will mop up, reorganize and continue the advance until the objective has been gained. They will then consolidate the ground won in the most suitable tactical positions in the vicinity.

Maxim ii. If the enemy counter-attack during the advance the manœuvre body will be at hand and ready to counter-manœuvre against them.

Maxim iii. The commander of the unit must not, however, hold back or hesitate to throw in his manœuvre body to turn the enemy's flank directly it is clear that the forward body has fixed him.

Maxim iv. To guard against the danger of counter-attack during its flanking movement, the manœuvre body must itself be distributed in depth.

Maxim v. Company and platoon commanders should always move with their manœuvre platoons, or sections, directly they have committed their forward body to a definite attack.

Maxim vi. Battalion and brigade commanders should also move with their manœuvre companies, or battalions, but only until they commit them to a definite *role*. They should subsequently move with their reserve. Thus every infantry commander will be able to keep control of the course of the attack and influence it without delay at the decisive moments.

Maxim vii. It must be clearly understood that the assault is not necessarily carried out by the manœuvre body. If the enemy turn to meet the latter, it will be the duty of the forward body to seize the opportunity to rush in and assault the enemy.

Maxim viii. In the case of the platoon the Lewis gun sections may often be used for manœuvre. They are less mobile and present a larger target than the rifle sections, but if covered approaches are available, they are more valuable for manœuvre, because of the greater surprise and enfilade effect of Lewis gun fire.

It is highly desirable that infantry should be systematically trained in deployment and changing direction *by signal*. These will not only be of great advantage during the approach march, but could be used on many occasions during the actual attack to quicken manœuvre and direct subunits to take advantage of covered ways of approach. If thoroughly ingrained in the troops, signals can be used *at suitable moments* instead of the slower methods of messages.

C. Exploitation.

v. "The man instantly follows up his advantage and renders his enemy finally powerless."

a. The limited or unlimited objective in attack?

In battle *the only true objective is the enemy*. But his actual strength and dispositions can only be ascertained by fighting. Hence certain topographical objectives must be allotted beforehand in order to serve as stepping stones by means of which the artillery can co-operate with and support the infantry advance. On the other hand it is a direct violation of economy of force to limit the advance of unexhausted units which find soft spots and can press on with little opposition. One should only replace those units whose momentum is checked by fatigue and severe opposition. Therefore these stepping stones—termed objectives—should be restricted to the battalion or higher formations. The companies, platoons, and sections of each battalion should press on to gain the battalion objective, their objective being the only true one—*the enemy*, wherever they find him in their path.

Hence the battalion will be the smallest unit which needs to carry out pursuit beyond the objective.

b. The pursuit.

Companies and platoons need only be distributed into two bodies, forward and manœuvre, but battalions when

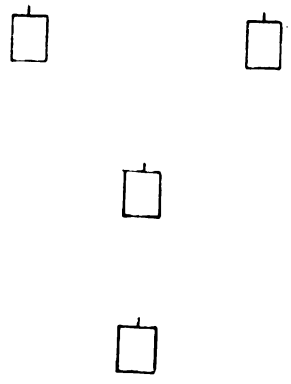

Fig. 6. Battalion in a Definite Attack

carrying out a definite attack should be divided into three bodies: forward, manœuvre, and reserve. (See Fig. 6.)

The reserve body is the means whereby the battalion or higher commander exploits success or retrieves failure. At the moment the battalion objective is taken, the enemy will be disorganized and probably demoralized, but if the attacking unit halts on the objective and is content to send out a few patrols only, the golden opportunity of exploiting the enemy's local reverse will be lost. If the troops which carried out the assault have to be reorganized for pursuit precious minutes will be lost. If a separate unit under a different commander is used for pursuit, delay is bound to occur, and the pressure on the enemy be relaxed, thus affording him a chance to recover.

Hence a fresh body, but one which is under the control of the commander who has taken the objective, should be used for pursuit.

Maxim i. The normal purpose of the battalion reserve therefore will be to exploit the success and continue pursuit until such time as fast-moving tanks or other mobile troops have caught up and passed through them. In this way a relentless pressure on the yielding enemy will be maintained, so that his retreat may rapidly spread and gain momentum, thus resembling a snowball rolling downhill.

Maxim ii. If the forward and manœuvre companies fail to gain the objective, the battalion commander may use his reserve to relieve them or to meet counter-attacks.

Conversion of Hachures to Contours

The preparation of the Chateau-Thierry battle map

By

L. B. Roberts

Major, Engineer Reserve Corps; Assoc. M. Am. Soc. C. E.

[NOTE.—Before the invention of that useful device known as the *contour*, the usual method of representing ground forms was by means of *hachures*, or hill and valley shading, as shown on Fig. 1 of this article. As many American officers know, the majority of European maps which pretend to represent ground forms, do so by means of hachures.

Hachures are unsatisfactory for several reasons. First, they give only a very general impression of the contour of the terrain and are not sufficiently accurate or rather definite to allow the solution of problems in map reading, such as the grade of a road, or the visibility of one point from another, etc. Second, hachures clutter the map and confuse the other necessary features. Third, the making of hachures is a slow and painful operation, requiring great skill on the part of the draftsman to produce even tolerable results.

Major Roberts well expresses the attitude of the American towards the hachured map, and entertainingly describes the novel and interesting experiment of converting a hachured into a contoured map.—ED.]

AT the beginning of the World War there was in existence a complete topographical map of France on a published scale of 1:80,000, or about 4/5 inch = 1 mile. This map is called the *carte de l'etat major* or general staff map. Its preparation was undertaken at the beginning of the nineteenth century, and its completion required about sixty years. Starting about the year 1810, maps of each commune (the smallest French political division) were made, to accompany the registers of property used by the authorities as a basis for taxation. These property or cadastral plans were drawn on different scales (usually 1:2,500) with varying degrees of accuracy. The general staff map was compiled from the cadastral plans; in this compilation they were superimposed upon the accurate control skeleton of triangulation started by Cassini in 1750, so that the proper positions of the important features, such as churches, cross-roads, etc., were well established.

In addition to the general staff map, scale 1:80,000, various engineering units of the French Army, as a part of their field training, had mapped disconnected areas around certain fortresses, on a scale of 1:20,000, or about 3 inches =1 mile.

During the war, due largely to the demands of the artillery, the production of large scale maps was carried on by British and French engineers, so that there was available, when American troops arrived in France, a narrow band covering the battle zone of that period on the western front.

Generally, these large scale maps were also compiled from the cadastral plans, were produced rapidly under great pressure, and were not as accurate as those of the fortress areas published to the same scale. The fact that a system of 1:20,000 scale maps did not cover the entire area of France was not generally known or appreciated by the A. E. F.

In the American forces the preparation and reproduction of nearly all maps in the army zone was one of the functions of G-2-c, or the topographical division, intelligence section, General Staff. Until the American base printing plant was completed (June 15, 1918), American troops were supplied with available French and British maps.

During offensive operations there were times when the opposing forces broke through the limits of the band of large scale maps along the battle zone, and maps on a smaller scale would necessarily be distributed. This was the case during the third German offensive of 1918, when the drive starting May 27, between the Oise Canal and Berry-au-Bac, broke the allied front. The French reserves were successful in limiting the exploitation of the initial German success; American troops definitely stopped the advance in the vicinity of Chateau-Thierry.

The German drive completely overran the limits of the existing large scale maps, and all that was available for distribution was the general staff map, scale 1:80,000.

The American divisions at Chateau-Thierry, under the 3d French Corps, looked to the French for their supply of maps; the general staff map, which was the only map the French were able to supply, was never satisfactory to our troops. The relief, or contour of the terrain, on this system is shown by means of hachures instead of contours. This method of hill shading is generalized and misleading, and was particularly confusing to the Americans, whose entire training in map reading had been gained through a study of the ground forms as shown by contours. While the map situation during the early part of the war was such that it was necessary to plan and conduct the first battle of the Marne on the 1:80,000 scale map, and we know that the French were able to use it and use it well at that time, the Americans had not been trained in the use of such a map and would have none of it. Complaints in regard to it were emphatic and vividly expressed; it seemed to be as difficult to issue proper orders for troops to take certain positions as it was to obtain proper reports of troop locations.

To meet this situation it was necessary to furnish a better map for operations at once; the quickest thing to do was to enlarge the 1:80,000 scale map to a scale of 1:20,000 by photography. This, of course, introduced errors; any errors in position on the original were amplified four times, and the enlargement of the hachure lines made them still more difficult to read. This enlargement to 1:20,000 was issued to the troops and was not satisfactory; it was, in fact, the first step in a military engineering expedient, and should have been valued as such, and nothing more (see Fig. 1).

The second step in the preparation of the Chateau-Thierry map was to eliminate the hachures and substitute contours. Accordingly, by direction of Col. R. G. Alexander, Chief, G-2-c (Topography), G. H. Q., the writer undertook to make this change.

It is difficult for those whose work has never brought them in contact with the actual making of a map to realize, when using a good one, either the time required for the various necessary operations or the difficulties that existed in each case. The most important question in the production of a map is usually one of relative accuracy. For instance, the time necessary to produce a sheet of either the 1:50,000 or the 1:80,000 scale maps at the *Service Geographique* is given as from sixteen to eighteen months. In this country, an average fifteen-minute quadrangle on

Digitized by Google

a scale of 1:62,500, or about 1 inch=1 mile, is produced in about a year by the U. S. Geological Survey. In both of the services mentioned the work is extremely accurate, and is carefully checked in every detail. On the other hand, the writer has seen an Indian produce a perfectly clear and readable map in a very few minutes by drawing in the sand with his fingers, and between these two extremes every gradation in accuracy can and does exist.

The problem in this case was to produce a large scale map the size of which was 32 by 42 inches, as rapidly as was possible. The work was started at 10 a. m. June 21. Two engineer sergeants immediately started a tracing on linen of the roads, timber and cultured features on the 1:20,000 scale map, which had been photographically enlarged from the 1:80,000. It was evident that one difficulty would be caused by the fact that very few men could work on the tracing at the same time. Another draftsman, however, who had been trained to letter backwards and upside down (a useful accomplishment where zinc plates need correction) was able to speed up the work by working from the top of the tracing.

G-2 had been collecting picture post cards of France, and the writer first had a look at the collection around Chateau-Thierry to see if an idea of the shapes of the hills could be obtained. The cards were not of much assistance. The next step was to draw form lines, without any regard to actual elevations, directly upon the photographically enlarged 1:20,000 map. These form lines showed, as closely as the hachure edges indicated, the outlines of the drainage net and of the ridges and plateaus.

An examination of any sheet of the staff map will show a number of elevations scattered over the area; these elevations were fixed trigonometrically before any modern system of leveling had been adopted, and were known to be considerably in error. From the elevations shown as the crests of ridges or high points on hills and plateaus, it was possible to change the form lines of the ridges into contours of the tops; in a similar manner from the elevations given near water courses the bottom contours were crossed on the drainage net. There now existed the main elements of a contour system, and by interpolation all the contours were drawn between the upper and lower limits of elevation. The work of drawing and tracing the contours was completed in six hours.

The tracing of the woods and planimetry was not yet complete. However, it was possible to make immediate use of the tracing of the contours by taking off prints direct from the enlarged hachure map as a base. One hundred copies of this map were made in four hours by the Dorel process (in which all the work of reproduction, including registration, is done by hand), and were immediately sent forward by courier. (See Fig 2.)

After the arrival of these maps at the front the following telegram was received at G.H.Q. "Hq. 2nd Div, June 22, 1918, Col. Alexander, G-2, G. H. Q. Contoured maps Chateau-Thierry one to twenty thousand very valuable to us. If possible send additional copies."

The entire force available continued the work on the tracing of the planimetry and woods. This tracing was completed at 1:10 a. m., June 23rd. Together with the tracing of the sketched contours, it was sent to the base printing plant at Langres-Marne, by motorcycle.

The base printing plant, operated by the 29th Engineers, had been in operation only five days. It was known that this job was coming down and everyone was set to turn it out quickly. In spite of many difficulties, 1,000 copies of the map in its final form were sent to the 2nd Division at 6:30 a. m., June 23rd. (See Fig. 3.)

The French battle map of the same area made its first appearance in Paris on June 29th. (See Fig. 4.)

Ever since the break through, the French mapping services had been working on a 1:20,000 scale map of this region; it was made according to the excellent methods adopted by the French Army, and conformed to high standards of accuracy and draftsmanship. It was a compilation from such cadastral surveys and original information as existed at the *Service Geographique*, and also from the restitution of aerial photographs. Since the sources of information were more accurate and especially on account of the aerial photographic restitution, the issue of the French edition, with necessary over-prints, to combatant troops was continued.

It is interesting to note that on this first French issue, the Bois de Belleau, as shown on the staff map, had already officially become the Bois de la Brigade Marine.

It is believed that a comparison of Figs. 3 and 4, with regard to the accuracy obtained by the rather novel method of production will be of interest to military map makers and users.

Decline in Cost of Footwear

The high cost of footwear is bound to fall sharply, if figures given out recently by the Quartermaster Corps are any indication of readjustment in prices.

When bids for 500,000 pairs of shoes for the army were opened in April, 1920, the average price was found to be $6.73 a pair. Today, with bids calling for 250.000 pairs, the contracts have just been awarded at an average price of $3.43 per pair, a cut of practically fifty per cent within twelve months.

Such prices will save the taxpayers millions of dollars in shoes for the troops.—*Office of the Q. M. Gen.*

Better Care of Disabled Veterans

First fruits of Congressional action to provide better and more ample facilities for the care of disabled veterans of the great war were announced recently. By authority of Congress, the Treasury Department was recently directed to transfer to the War Department $750,000 for the enlargement of the Fitzsimons General Hospital, Denver, Colorado, to enable it to take care of tubercular cases among veterans of the late war.

These funds were turned over to the War Department on April 20 last, and an immediate start was made by the Construction Service of the Quartermaster Corps, in the preparation of plans and specifications for enlarging this hospital by approximately 600 beds. This work includes the remodeling and completion of six large ward buildings of about 100 beds each, the construction of a new storehouse, some additions to existing storehouses, the erection of quarters for eight officers and six non-commissioned officers, an administration building, additions to the laundry, refrigerating plant, and bakery. It also involves the extension of water, sewer and electric lighting systems and roads, and the enlargement of the heating plant.

Major General H. L. Rogers, the Quartermaster General, has sent an officer of the Construction Service from Washington to Denver with the complete plans and specifications, and work will be started shortly.—*Office of the Q. M. Gen.*

The Voyage of the "Gwalia"

By

Francis Rotch, Jr.

Formerly Lieutenant, 57th Engineers

[NOTE.—Engineers have made good on so many different kinds of work on land that a new one occasions little surprise. But here is a story of how an officer and a bunch of men from the 57th Engineers tackled a job on the briny deep, heretofore the exclusive domain of our rollicking rivals, and got away with it.—ED.]

THIS is the story of how twenty-nine soldiers of the American Expeditionary Forces navigated a 400-ton tug from St. Nazaire, France, to New York, and were lost only once during the entire trip.

To start at the beginning, as all stories should, we will have to go back to the "good old days." The 57th Engineers was organized to take over the transportation on the inland waterways of France. As this service would take the men, more or less—it happened to be mostly less—near the lines, it appealed to a lot of seamen, both of salt and fresh water, who thought this branch offered more excitement than the Navy.

After the Armistice, many of these men were sent to the base ports, attached to the transportation corps, and assigned on tugs and barges about the harbor, the writer being assigned as Assistant Marine Superintendent at St. Nazaire, under Capt. Bertrand Fay.

Along in July, 1919, the closing of the port of St. Nazaire left the Army Transport Service with several large ocean tugs on their hands, tugs that had been commandeered by the Army from their owners in the States, and it was the wish of the Government to return them to their original owners. Two of these tugs were the *Cadmus* and the *Gwalia*, belonging to the New England Fuel and Transportation Company of Boston.

Captain Fay assigned to me the task of picking the crews to take the tugs back. As one of the other tugs, the *Penguin*, was manned by a civilian crew, her enlisted personnel having returned to the States, her crew was transferred to the *Cadmus* under Capt. Fred Kornick, but to man the *Gwalia* was a different matter. No civilian crews were obtainable, and it was impracticable to send her home with a French crew, so Captain Fay decided to send the *Gwalia* back with a crew of officers and enlisted men from the personnel at St. Nazaire. I was told off as her skipper, with a crew of soldiers of the American Expeditionary Forces, all of them members, prior to the Armistice, of the 57th Engineers.

There was no trouble to pick a crew, as my office was besieged with men only too glad to get a chance to work their way back to "God's Country" (even a "Y" secretary offered his services!). The 57th was full of good men, and it was only a matter of a few minutes to pick my crew and have the list sent in to headquarters.

Lieut. C. S. Appleby, Q. M. C., an old-time salt-water chief engineer, was assigned as chief, and he immediately put on a pair of overalls, grabbed a chunk of waste, and went to work; what he did to the old girl's engines is history. In a week they were running like a watch, and a happy man was the chief.

The crew was soon aboard, and we were hard at work cleaning ship and putting her in shape for the long trip ahead of us. A turtle-deck was built over forward, and as far aft as the fireroom door, extra guys were put on the stack, and everything put in shape for sea.

There is enough trouble and confusion in getting a merchant vessel ready for sea, but to sail from a French port with a soldier crew is another story. One has all the forms and procedure incident to a merchant ship, added to that of the passenger list of an army transport. There were a thousand and one little things to do, from making out a passenger list down to a field return, and with the added job of getting stores and supplies, I surely had my hands full. The hardest part was to convince the supply officer that as many navigation instruments were necessary to navigate the *Gwalia* as for the *Leviathan*. According to that gentleman, all that I had to do was to steer due west, and I would strike the coast of the U. S. A. some place between Florida and Maine.

At last the red tape was all unwound, all papers made out to suit the gentlemen at the embarkation camp, and we were ready for our final inspection. Then came another rub. According to instructions for returning troops, they were to take back with them only a limited amount of clothing. As our trip would take at least a month, and the men —particularly the fireroom gang—would be working all of the time, I made request for additional clothing. Long and loud was the wail put up by the embarkation people, but through the good offices of a captain inspector, who had a very good idea of the sea and its peculiarities, we were given all we asked for. He was a fine little man, that captain, and I only wish I could remember his name.

Then for the final inspection and physical examination, and again army and sea customs clashed. We marched to the camp for our final examination, and, of course, some of the men were left aboard, as steam was up. When the roll was called, naturally, some of the gang were missing, and long and lengthy explanations were the order of the day. Luckily, the inspecting officer and our surgeon (some title we handed Nick!) patched things up, we were "decootied" and passed as pure and shining examples of the American Army.

While on duty with the Army Transport Service at St. Nazaire, a captain of the Medical Corps had the nerve to tack a sign on the office of the Marine Superintendent, and to get even with him I invited him to act as ship's doctor for the trip, and so the name of Capt. J. C. Nicholson, M. C., was added to our crew, and we all can say that through the entire trip Nick never lost his smile.

On the afternoon of the 10th of July we pulled out of the inner basin and tied up at the outer dock. The next day a French compass adjuster from Nantes came down and made a few passes over the compass, mumbled a few secret words and informed me in all good faith that the compasses were adjusted. We afterwards found out that he was right, within at least 20 degrees, most of the time.

Digitized by Google

The next day some son-of-a-sea-cook wished about ten tons of lachrymatory gas on us with instructions to dump it overboard not less than 200 miles from shore. That afternoon a gentle breeze was blowing from aft and soon the engine and firerooms were chock-a-block with gas. While the gas is harmless, still it brings tears to the eyes by the bucketful, and in no time at all the engine-room crew was on deck and loud in their lamentations. It rested with one tearful soldier "black squadder" to solve the proposition. "Soldiers are issued gas masks to use, so why not make use of them?" And in a jiffy the entire crew donned their masks, and the good people of St. Nazaire were treated to a sight that we think was the first in history—a ship putting to sea with her entire crew wearing gas masks. The *Cadmus*, ahead with the pilot, pulled out from the dock and headed out through the breakwater and we followed, leaving behind a various collection of *petites mam'selles* belonging to various members of the crew, and also the famous wheelbarrow belonging to Kirkland.

We had no more than dropped the pilot than, looking astern, one saw a long line of boxes bobbing in our wake—the boys had lost no time in ridding the ship of her tear-bringing cargo! While we were supposed to dump the stuff 200 miles out to sea, one could not blame the boys for doing the "Jonah and the whale" act with our unwelcome cargo, as by this time the fire-room must have been uninhabitable.

Once clear of the last buoy, our course was set for Ponta del Gada, Azores, and the usual ship's routine set in.

Toward evening it started to blow up from the northeast, and before dark a nasty, typical Bay of Biscay chop started up, and the old girl began to tumble about. Around eight that evening the chief came into the wheel-house with the cheerful information that the ash-gun was leaking and the water was then above the plates in the fire-room, and the only way the leak could be stopped was to plug the ash-gun from the outboard side. The tug was brought up into the wind, and we lowered the old chief over the side; then the fun began; between rolls the old boy would ram a wad of oakum in the discharge pipe, and the next moment he would be 6 feet under water. The pipe was at last plugged, and a weary, dripping chief stumbled to his room, knowing that a dangerous leak had been stopped. The fire-room by this time was in bad shape, as we had jammed the bunkers full of coal, and there was more or less coal on the plates; the bilges being full of water, every time she rolled the force of the water in the bilges forced the fire-room plates up, causing the loose coal to go in the bilges; this in time had clogged the pumps. It did not take the boys long to clear the pumps, and soon we were on our way once more.

The next day showed no let-up in the gale, and both tugs were shipping lots of water. The turtle-decks built over forward kept most of it off the decks, though it was impossible to go aft.

The morning of the 14th there was considerable sea running, though the wind had gone down a little; the *Cadmus*, just off our starboard bow, was making very heavy weather of it; she appeared sluggish and was rolling very badly. About 8 a. m. she signaled that she was unable to proceed, and would have to heave to to make repairs to her engine and steering gear. Running close to her, we asked if they wanted a tow, but on receiving a reply that she would be all right in an hour or so, we stood by. In a couple of hours she signalled that she was going to put into Vigo Bay. As the wind and sea was on our starboard quarter, the two tugs were making fairly good weather; the moment the *Cadmus* headed into them, she began to dive like a duck. It did not take Captain Kornick long to decide that the lesser of the two evils was to continue on his way—so we squared away on our original course.

Our ship's surgeon, to give him his official title, had his bunk in the chart-house; that evening while getting his forty winks, the ship gave a particularly deep dive—doctor, bunk, trunk, charts and everything that was not fastened down, all piled in one corner of the chart-room. It took the united efforts of the mate and two men to sort the Doc out from the rest of the junk. At last he arose triumphant, still wearing his famous grin.

Meals were a serious proposition, and our soldier cooks were having a merry game of tag with the pots and pans on the galley stove. Grover, chief cook and steward, was nearly drowned when the crew's slum got the better of the galley gang and capsized all over him. It was a case of washing down both Grover and the galley.

It takes more than a blow to dampen the spirits of the average Yank engineer, and by night things were running like clockwork. Our crew being old hands at the game, soon adjusted themselves to their conditions, and the usual sea routine was the order of the day.

Sergt. Lawrence Kirkland, Company B, 9th U. S. Infantry, who went through the entire war with that historic outfit and was wounded, acted as chief mate. Kirk, in civil life, is a New York tow-boat captain, and after I had made several attempts to handle the tug in a crowded harbor, I turned the job of harbor pilot over to Kirk, and he sure was a dandy. He, like the rest of the mates, was shy in navigation, but for all that he was an A No. 1 man.

Master Engineer Jorgen J. Jorgensen, Company B, 57th Engineers, held down the second mate's billet. Jorg was an old deep-water man and was at home with his job. No better man could be found than this quiet Dane.

Master Engineer Roger W. Cook, Company B, 57th Engineers, was the third mate, and got away with the job in a splendid manner, and, with the exception of striking eight bells while I was still shooting the sun at noon, covered himself with glory.

In the engine room Chief Appleby had three good men in Greene, Blackwell and Anderson. And, like the deck officers, they gave all they had in them.

By the morning of the 16th the gale had broken, and as we were well out of the Bay, the short choppy sea that has made that place famous, or rather infamous, with seamen since the days when the Phœnicians sailed across on their way to Britain for tin, had gone down, the sun came out, and soon the rigging was full of clothing, drying. From then on, until we reached Ponta Del Gada, the trip was no different from a thousand others before and since.

On the morning of the 18th high land was sighted ahead, and at 3 that afternoon the ship was safely moored at the coaling station in the beautiful little harbor of Ponta Del Gada. The *Cadmus* was in bad shape from the buffeting she had received in the Bay, and her decks had opened up and needed to be caulked. Boiler and engine trouble had developed, so we reported to the admiral commanding the American forces that we were in need of repairs. He immediately had mechanics from the station ship. *Buffalo*, come aboard and set to work.

The *Gwalia* was in good shape, so we started to coal, and soon the ship was covered with the well-known dust of Cardiff coal. Coaling at Ponta Del Gada is carried on in the manner usual to tropical coaling stations; that is, with baskets. Gangways are rigged and the coal carried aboard by the natives in baskets, averaging 50 pounds to the basket. Coaling started at seven and finished at noon, by which time we had 80 tons aboard. We cleaned ship and pulled on the outside of the *Cadmus*.

Digitized by Google

We were ready for sea, but the *Cadmus* still had extensive repairs before she would be in shape to continue the voyage. Shore leave was given the men, and they soon made themselves at home in that pretty little semi-tropical town. Several trips were taken by the boys about the island, the most popular being to Furnas Lake, the boiling springs situated on top of one of the mountains.

Just before leaving Ponta Del Gada a colored soldier, who had been left behind from a transport and sent to the hospital, was assigned to us for transportation home. John was put to work in the galley, and held his own with the best of the bunch.

On the afternoon of the 26th we pulled out on our second leg of the trip to Bermuda, and soon had the hospitable island of St. Michael only a blue haze on the horizon. I think the crew will be a long time forgetting the week we spent at Ponta Del Gada, especially the wonderful strawberries and green corn, two things that are not on the army ration. The first four days out were uneventful, fine weather, calm sea, and a warm sun.

The glass began to drop the evening of the fourth day out, and by midnight it was blowing pretty hard from the southwest. By morning a fairly heavy sea was runni and both tugs were making heavy weather of it. This kept up for two days more. On the afternoon of the seventh day out, every indication pointed to a big blow, and it looked like the tail-end of a West India hurricane, though the wind held steady from one quarter. About 3 that afternoon we ran into a queer red haze, as though we had entered into a huge red inverted bowl. The visibility was about one-half mile, and the whole sky, from horizon to zenith, was one reddish haze. It looked bad to me, and being only an amateur navigator at the best, I got sort o' worried, but we kept plugging along as the wind still held from the same direction. About 8 that evening the wind began to box the compass, and the glass was taken down with St. Vitus' dance. Then I was worried! Soon the wind held steady in the northwest, and I knew we were out of the path of the storm, so held our course. Then the rain came, and how it did rain—it came in solid sheets, nearly horizontal, and driven ahead of that wind it was impossible to get out of the wheel-house.

The morning of August 3 the wind and sea had gone down, but it was still very thick and there were frequent rain squalls. I had reckoned that we would raise the Island of Bermuda at noon, and knew that we were not far off, so I slowed down. At noon no land could be seen—in fact, one could not see over half a mile, and then only between squalls, so I stopped the tug, as I did not want to pile up on a nice hard coral reef at that stage of the game. About 3 that afternoon it began to clear, and I got a good sight, and discovered that we were 12 miles to the north'ard and a little to the westward of the island. We soon had the tug on her course, and in a couple of hours sighted the island, but too late to enter the harbor that night, so cruised up and down all night, and at daylight headed for the entrance and picked up the pilot. Soon we were winding our way among the coral reefs that fringe the Island of Bermuda.

After passing quarantine we were ordered by Captain Menner, the American Naval Commander, to Ireland Island, where we tied up alongside of the coal dock, receiving in the meanwhile the jeers and chaff of the crew of the *Cadmus*, which had arrived the night before.

As our next run was to be only a short one, only enough coal was taken aboard to carry us to New York, but we stocked up with a large supply of green stuff and fruit There had been more or less friction between the negro and white population of the islands before we arrived, especially with the Americans, and shore liberty was denied the crew, except about the dock-yard.

At the request of Captain Menner of the U. S. S. *Tallahassee*, three time-expired men were sent home on the *Gwalia* and four on the *Cadmus*. On the morning of the 8th we pulled out from Ireland Island on our last leg to Hoboken. It was a fine bright day as we slipped by the last harlequin-striped buoy off St. George and shaped our course for the last run. Quite a ground swell was running and our three sailor passengers began to lose interest in the world at large and the *Gwalia* in particular. After a year's voyage, tied up to the dock at Ireland Island, on the old "Flat Iron," as the *Tallahassee* was called by her disrespectful crew, the lively jumping about of the *Gwalia* was too much for the representatives of the Navy. And for once the Army had the best of the Navy on the Navy's home ground.

The day before arriving at Hoboken we lost the *Cadmus*. Not liking the ground swell on her beam, she had hauled to the south'ard early in the morning, just before daylight. When day broke she was nowhere in sight, and fearing an accident we turned and went back to look for her. After cruising about until noon, we decided that she had given us the slip, so we came back on our original course. A heavy fog shut down that evening and held all night; by noon the next day it was still thick, so we decided we had better get a sounding. As we had no sounding machine aboard, Jorgensen bent a couple of extra log lines together and with an extra grate-bar for a lead, got bottom in 30 fathoms, which showed that we were near the entrance to New York Harbor. Soon after we heard a fog-horn dead ahead. According to the light list it should have been *Ambrose Light Vessel*, so we proceeded ahead dead slow, and shortly she appeared through the fog, as welcome a sight as one could wish for. Soon the *New Yorker*, with the pilot aboard, came alongside and we were mighty glad to see him. He reported the *Cadmus* one hour ahead of us. And from that we decided that she gave us the slip that night so she could be the first in. After passing quarantine we proceeded up the bay, the crew giving a hearty cheer when passing the Statue of Liberty, and shortly afterward we tied up to the dock at Hoboken.

Next day the crew were taken to Camp Merritt, and from there sent to the various army camps to be discharged. The sight of the boys whom I had been with for over a year, and who were willing to trust to my navigation to bring them home, hiking up the dock, led me to think that if every ship master was blessed with as willing and loyal a crew as I had, his lot would be a happy one.

And so ended the "Voyage of the *Gwalia*," the first vessel in history to cross the Atlantic Ocean manned by a crew of officers and enlisted men of the American Army.

Motor Vehicles in U. S. A.

At least 8,500,000 automobiles, passenger cars, and motor trucks are in use in the United States. There are, in addition, nearly 400,000 farm tractors, more than 1,000,000 stationary engines of the internal-combustion type, and probably over 200,000 motor boats. These machines consume a large percentage of the 100,000,000 barrels of gasoline, more or less, produced annually, and a large quantity of kerosene. In 1923 there will be in use probably more than 9,000,000 passenger cars, close to 2,000,000 motor trucks, more than 1,000,000 farm tractors, and 1,500,000 stationary internal-combustion engines. This means, without counting aircraft, over 13,000,000 machines of the various types mentioned.—*Proc. Am. Soc. C. E.*

Principles Governing the Use of Combat Engineers

With Illustrative Examples

By

W. A. Mitchell

Major, Corps of Engineers

IN this article it is desired to show the application in the field of a few of the principles which have been brought out in studies of combat engineers. Naturally, the application of these principles is somewhat modified in many cases by the requirements of the particular situation. For example: the division may need the engineers for work in the advance, and at the same time may need them for keeping up the roads in rear of the division because the corps and army engineers have been unable to do this work: in such case, the engineers may not be used exactly as required by the principles.

The examples available of division engineer work are somewhat limited. The records and official reports are not at all complete. As a result of a special visit to the War Department, it became evident that the reports were made in a hurry and did not bring out essential points. Therefore, the examples given are limited principally to the operations of the regiments which made complete reports.

A combat engineer regiment should not be composed entirely of laborers nor should it be composed entirely of technical men. No cases are known where a combat regiment did not possess enough technical men to do its work properly. On the other extreme, cases are known where the personnel of a regiment was composed almost entirely of technical men, with the result that they were unable to do real and effective work and a further result that much inherent good officer material was not available for development.

Principle. *A Combat Engineer Regiment should be trained in combat work as infantry, in bridge work of all kinds, in quickly laying out lines of trenches and constructing observation posts, wire entanglements and all kinds of obstacles.* If there is a great deal of road work to be done around the camp or if there are a great many barracks to be constructed around the camp, the division commander must calmly decide whether he wants to have untrained a proportionate number of his infantry, artillery and engineers, or whether he wants his engineers to be more untrained than his infantry and artillery. It is thought that road work or barrack construction does a combat engineer regiment about as much good for its work with a combat division as feeding horses does an artillery regiment, or as greasing a rifle does an infantry regiment. This comparison appears to be unfair because in actual combat operations a combat engineer regiment spends more time in fixing roads than an artillery regiment spends in feeding horses or an infantry regiment spends in greasing guns. But the comparison is actually correct: for training purposes, the combat regiment gets no real profit from road work and should preferably be made to do none at all. If there is a lot of road work to be done in a division camp, the construction troops should do it; and if there are not enough construction troops for this work, the division commander has to decide, as stated above, what troops shall acquire least training or whether all shall be proportionally untrained because of the fact that a lot of road work must be done.

The training of combat regiments is a matter which has received very little attention. Invariably, it has been found that when the matter has been carefully considered by those in charge, the training has been excellent. At General Headquarters, A. E. F., the circulars issued on engineer training were all that could be desired; but in the various divisions, especially in the United States, the training was often not very effective. Cases have been known where the division commanders believed that building of wooden barracks and roads and little culverts around the division camp were excellent training for engineers; others made their engineers devote all of their time solely to digging fortifications; and one case was reported where the engineers spent a month in sodding the ground around division headquarters. In this last case, it is known that the engineer regiment did not make a good showing in field operations.

There was one occasion where an engineer regiment was sent to an old French camp which possessed a target range, or rather it possessed a field which had three or four old trenches and target butts which were to be used for a target range. Unfortunately the range did not fit any of the American systems of target practice and consequently it was necessary to build a real range. Possibly, it was intended that the engineers dig the ditch in accordance with the mistaken impression that this is good engineer training for a combat regiment; but there were about 4,000 infantry and machine gun men in the same camp and the camp commander proportioned the work out among all the troops in camp. By using three reliefs and working from before day-break to after dark, a 40-target range was completed in two days and an 80 target range was completed in 5 days. In the 17 days that this camp was occupied practically all of the division came to the camp and went through a short course of target practice. It is believed that this is the only case on record where a whole division went through a course of target practice during active operations. No such results could have been attained if the engineer regiment had worked alone.

Even during active service, opportunities arose for training in quick marking of a fortification line. While the 2d Engineers (2d Division) was at Camp Bois L'Eveque,

Digitized by Google

rumors became prevalent that the St. Mihiel operation would soon take place. As nearly all thought that it was either St. Mihiel or Verdun, and it was evident in either case the engineers might have to rush to a front and lay out a fortification line, two whole days were spent in training the regiment for this work. The regiment was given limiting points in its firing line and was required to stretch a line connecting these two lines or points. At first the line was short, and later it was much longer, so that each man of the line represented a squad or 2 squads or a platoon. The officer then went along the line and settled arguments between the men, as few would agree to take poor positions in order to help out the men on their right and left. This is the same argument that is seen today in practical problems in field fortification in which the one concerned insists on terminating his line at some point other than the one assigned to him, because it is better for him, regardless of his neighbor.

Principle. *Construction work does not train a Combat Engineer Regiment for its proper work.* The official report of the 2d Engineers (2d Division) concerning the battle of Chateau Thierry, states: "The prevalent opinion that sapper engineer regiments acquire adequate training from construction and road work is erroneous. A sapper regiment has certain duties to do in war time, and it is very little more trained in its war duties by construction and road work than an infantry regiment would be trained in its war duties by construction and road work. The 2d Engineers was not a trained engineer regiment when it went into battle at Chateau Thierry; far from it; though many of its men had been trained in camp before the World War. In later operations, the regiment spent a day here and a few days there in training, while the other regiments of the 2d Division were resting during the pauses in the operations. The regiment could never rest; it had not been given a fair chance to train because military necessity required that it spend its time in construction work, so it had to seize every opportunity to improve. It was supposed to know certain things, and yet it had never been taught these things. Before its first battle, it had never laid out a quick fortification line, never built a standard trestle bridge, foot bridge, or ponton bridge, yet during active operations of the next six months it had to do and did things after previous drill in every case except that of the ponton bridge.

Principle. *In movements by rail or water, engineers should be sent to entraining and detraining points to facilitate the loading and unloading.* In the movement of the 4th and 89th Divisions from the Rhine to the coast, enroute to the United States, one company of engineers was sent to each of the three entraining points to facilitate the movement, with the result that the movements were made with a speed and ease almost unequalled.

Principle. *Engineer detachments should accompany the advance guard in any sustained march through new country. This is necessary in order to make certain hasty repairs, and to get the necessary information to other engineers for more difficult repairs.*

In the advance to the Rhine, nearly every division marched in two columns; and one company of engineers was sent with the advance guard of each column. These engineers repaired the roads for the advance. The remainder of the regiment followed in the reserve of one column. This organization was maintained practically throughout the entire march to the Rhine.

In the march to the Rhine, the map platoon of the 314th and 315th Engineers (89th and 90th Division) reconnoitered the roads at least one day in advance, and issued before each day's march a map showing the day's march, the turning point of each unit, and the stopping places of each unit for the night.

Principle. *In any operation involving engineer work, the engineers should be consulted and given every opportunity to make preparations.*

In the plans for crossing the Aisne River the 2d Engineers (with 36th Division) were given every opportunity to make preparations for the crossing; in fact, the engineers concluded that they were given too much opportunity to do the crossing, the general plan made by headquarters higher than 36th Division, being that the engineers were to build the bridge before the infantry got across, this being contrary to the books. The engineers were to build two foot-bridges in the face of the enemy, one bridge across canal, then one across the river. The first would have been easy, provided the enemy was surprised; but the engineers were very much afraid that they could not build two foot-bridges in immediate succession because the enemy could not be surprised two times in the same place at the same time.

However, every assistance was given the engineers, and all possible preparations were made. Six double sets of foot-bridges were prepared and laid out in the fields and the engineers were drilled in special work with these foot-bridges.

While waiting for orders to cross, the engineers also built a heavy bridge to carry trucks and tanks and this was also set up in the field, awaiting the orders to cross. However, the order to cross was not given until after the Americans had left that area. Consequently there were left in the fields, near the River Aisne, one extra heavy type highway bridge and 12 hasty foot-bridges.

In the St. Mihiel attack, one division engineer made special preparations to cross "No-Man's Land," loaded bridges on trucks and wagons and placed the greater part of his engineers on one particular road while a smaller number was placed on another road. The particular road was completed across "No-Man's Land" in about one hour, being almost 24 hours before some other divisions got across; but the adjacent division took over the road and used it at once, without having worked on it at all and the division engineer learned upon going to his division headquarters that G-4 and G-1 the night before had kindly given this road to the adjacent division, but had not thought it necessary to notify the division engineer.

The best known instance showing the advantages of preparation by engineers for work ahead, is the case of the 110th Engineers (35th Division) at Consenvoye. The division chief of staff notified the engineers about two weeks ahead of time that the Meuse River must be crossed sooner or later and arranged so that the engineers could bring up the necessary bridge material. The result was that, when the order was received to cross the river, the engineers made a foot-bridge in a very short time and are reported to have made the heavy wagon bridge in the incredibly short time of five hours for a length of about 185 feet. In the St. Mihiel the 1st Division engineers built and carried forward three bridges for crossing the Ruft de Mad, well behind the German lines. The size of the bridges was figured from airplane photographs and actually fitted the requirements quite well. In spite of their weight they were carried at least a mile by hand, this being necessary because of the road conditions.

Principle. *Engineers should thoroughly reconnoiter the roads and railroads; in an advance, engineer reconnoitering parties should accompany the infantry advance elements or at least the support.* This principle seems to have

Digitized by Google

been thoroughly understood by nearly every engineer regiment. These reconnoitering parties secured information as to the necessary work for putting into shape the roads, bridges, water points, etc. The only difficulty with the reconnoitering parties lay in their inability to determine just how much work was necessary, this being a matter requiring such a varied experience that few of the inexperienced reconnoitering engineers could perform this work in an entirely satisfactory manner.

Principle. *In a retreat the engineers should destroy the railroads and railroad bridges.* It is well known how the Belgians failed to destroy the railroad bridge at Liege. This failure on the part of the engineer officer or of the one general who controlled this engineer officer was worth the lives of some 50,000 or may be 200,000 men. If this bridge had been destroyed, the Germans would not have brought forward their supplies and especially their ammunition in such large quantities; consequently the advance against Calais and the first fighting around Ypres would have been much more unfavorable to the Germans. It would have taken at least three months to rebuild that bridge. Meanwhile, all supplies must have been transferred from one train across the river to another train, which would have very materially reduced the quantities of the supplies which were received by the German army on the front.

It is not a settled theory as to just who should order the destruction of bridges. The general rule before the war was that only a general officer should order the destruction of a bridge. This rule sounds reasonable if the enemy will adopt the same rule. For example, at St. Mihiel, the 2d Division rushed into Thiaucourt and captured the town. They found a German engineer company calmly and peacefully awaiting orders from some general officer, but the orders never came and the Germans never blew up the bridge. "We had been considerably worried over that bridge because it was a large one, and it was with great pleasure that we unloaded in 'No-Man's Land' the trucks which were carrying out our own bridges to put across in place of this bridge at Thiaucourt, which we thought would surely be blown up." The arguments as to who should give the orders regarding the blowing up of a bridge, are like the arguments as to whether we should blow up the Panama Canal locks in case the enemy is going to capture Panama. The argument against blowing them up is that we can use the canal after we recapture it; meanwhile let the enemy use it. The argument for blowing up the locks is that the enemy might not see it our way; they might not decide that they would ever need the canal again and after they had used it and saw we were going to recapture it, they would blow it up to prevent our using it when we recaptured it. In the French army in most cases, the bridges were prepared for destruction, and standing orders were given, probably by a general, that they would be blown up when it was certain that the enemy would capture it. The man on the spot was the man to decide whether the enemy would surely capture the bridge or not. This seems a proper solution if we can anticipate the enemy operations, as is generally possible. Otherwise, it appears that division engineers should be able to decide for themselves the steps suitable to the operations, in accordance with an approved policy of the general.

It is known that two companies of the 6th Engineers and parts of the 11th, 12th and 14th Railway Engineers, greatly assisted in covering the retreat of the British after the German offensive of March 21, 1918. No other U. S. troops were concerned in any retreat, consequently the lessons drawn from engineers in retreat are obtained mostly from text-books or from the work of the Germans in retreat.

In their retreat from Blanc Mont, the Germans seemed to have had two different division engineers in the American front. The engineers in front of our right destroyed their bridges effectively, broke all the steel rails on the 60-centimeter railway and on the broad-gauge track. The engineers in front of our left burned the supply depots, but did not destroy the broad-gauge tracks to any great extent. They broke only every tenth rail and a few frogs on the 60-centimeter; consequently, in two days two engineer companies rebuilt 12 miles of 60-centimeter track and were ready to connect up to the front and to the rear.

Principle. *In a retreat, the engineers should surely destroy the roads and bridges.* The Germans attempted to destroy the roads, but as a rule they showed poor judgment in the places selected, and the results were not effective. At Varennes we found a large crater. This crater was in a very convenient place for us. The Germans could have put it in a more convenient place, but they could have easily found a place more inconvenient for us. For example, they might have put it where the road ran between a ridge and low marshy ground, as at Juvigny, or in a cut, or in a high ground between marshy places.

At Blanc Mont they had two large craters in the road. These two large craters were very conveniently located for us; we built dirt roads around the craters and went on our way. Later we surfaced these dirt roads with lumber or stone.

At Landree-et-St. George there were two bridges over a small creek. We considered these bridges so important that the engineers were ordered to follow the infantry support line into the town and get to work on those bridges immediately. They did so, and lost 24 men in that operation, but they found that the bridges had not been destroyed, for which we were duly grateful.

At Beaumont and Pouilly the Germans had various ponton equipment. They sank some of it, but did not sink all of it. As a result, some of the boats were used to help build a ponton bridge near Beaumont, and an infantry colonel established a ferry with the other German ponton equipment east of Pouilly.

It is not known just what was the matter with the German engineers in some of these divisions, but it is probable that some of their commanding officers made them waste so much time on absurd traps that they were diverted from their proper work. It is a very simple matter to destroy a road and render it impassable for days by trucks. It is a still simpler matter to destroy a railroad. Consequently, it is surprising that the Germans failed so greatly in this respect.

The French at Pont-a-Mousson blew out one bay of the stone bridge. The Germans in 24 hours built up this bay and used the bridge without any further trouble during the short time they were in Pont-a-Mousson.

At Jaulgonne the 103d Engineers (28th Division) built a ponton bridge with boats which the Germans had allowed to float down the river. They put a sign on this bridge reading: "Made in Germany, but reconstructed by the 103d Engineers."

Principle. *There is not much use in sending engineers to consolidate an infantry line. They should not, generally, dig infantry trenches. They cannot possibly be expected to erect wire entanglements in front of a firing line which is in active operation; consequently, sending engineers to consolidate a trench is generally another way of sending engineers to reinforce the infantry.*

In the battle of Soissons the 2d Engineers (2d Division)

Digitized by Google

and the Division Machine-Gun Battalion formed the division reserve. At the end of the first day they were very close to the front line, and when dark came the regimental commander ordered the engineers into front lines to consolidate the trenches of the infantry. They stayed there as part of the front lines, and were there until the division was moved from the front lines. Actually, they did not do much consolidating of trenches, but dug the trenches of one of the regiments in the front line. This was a very rare case, and even in this case it really amounted to reinforcing the infantry.

In the Meuse-Argonne the 6th Engineers (3d Division) were sent forward to consolidate a position. Most of their work consisted of fighting.

In their attacks against Verdun the Germans sent engineers just behind the infantry to consolidate the positions taken. This was really trench warfare; and the consolidation consisted principally in reversing captured trenches. The engineers carried sandbags, wire, etc. Such consolidation is possible, but not very practicable; and even in such cases the engineers spend most of their time as infantry.

Principle. *When a position becomes stabilized, the engineers should lay out the second and third positions and these positions should be dug by the engineers, assisted by the troops not in the front line.* At Chateau Thierry the second position was made quite strong and was dug by engineers and infantry. No attempt was made to build up or to strengthen the front lines except where they were changed as a result of heavy enemy fire. In the Argonne, two engineer regiments did some work on second lines, but none on real second positions.

Principle. *The building of wire entanglements in front of the front lines can be efficiently carried on only at night.* This is not exactly a lesson of the war, because it was never tried in the day time. We used to reconnoiter each day and make preparations for the night work, but no one presumed or expected that we were going to do any wire entanglement work in front of the fire trenches in the day time.

In only one case was there any real staking out of position, viz, by 1st Engineers in the Meuse-Argonne, and this position was not attacked. (To be continued.)

Tidal Phenomena and their Reduction

Tidal phenomena directly affect the work of most engineers practicing their profession on the seaboard. They are of particular concern to officers of the Corps of Engineers engaged in river and harbor work. All such engineers are more or less constantly in need of authoritative reference works on the subject, and Junior Engineer Floyd C. Bedell, Engineer Department at Large, has made a study of the bibliography bearing on this manifestation of natural laws.

From the large number of references relating to the theory of the tides and reduction of tidal observations, it becomes necessary for one who is not fully informed on the subject to choose a few volumes and turn to the larger lists only for information bearing on special problems as these may occur from time to time. Such a restricted list Mr. Bedell calls "A Working Library Pertaining to Tidal Phenomena and their Reduction," and is here presented for the guidance and information of all concerned. This list is not intended to be exhaustive, and it can be improved, without doubt. It is intended to represent merely a list of books that may be used by anyone who desires to gain a good working knowledge of the subject.

"Tides and Kindred Phenomena in the Solar System," by Geo. H. Darwin; an excellent popular, though scientific, treatment of the whole field.

"Practical Manual of Tides and Waves," by W. H. Wheeler; a non-mathematical discussion containing also a bibliography in the appendix.

"The Tides"—in Encyclopedia Brittanica, 11th Edition.

"Manual of Tides," by Dr. Rollin A. Harris; a description and theory of tides.

"Hydrodynamics," by Horace Lamb; an exceedingly difficult subject, and, although scholarly, the mathematics is difficult for the ordinary practicing engineer.

"The ABC of Hydrodynamics," by R. de Villamili; recommended as an introduction to Lamb's text.

"Theorie des Marees," by Maurice Levy; a text on the solution of the differential equations involved in the passage of a tidal wave up a canal with a certain slope to its bed.

"Recherches Experimentales sur la Propagation des Ondes," by Bazin; experimental results on the propagation of waves similar to the tidal wave.

"Tidal Rivers," by W. H. Wheeler.

"Canal and River Engineering," by David Stevenson; information on practical results obtained by engineers in "training" tidal rivers and estuaries.

In the related subjects of Astronomy, Hydraulics and Mathematics the following will be found of great interest and value:

"General Astronomy," by Young.

"Hydraulics," by Ballasis (Rivington-London).

"Graphical Mechanical Computation," by Lipka.

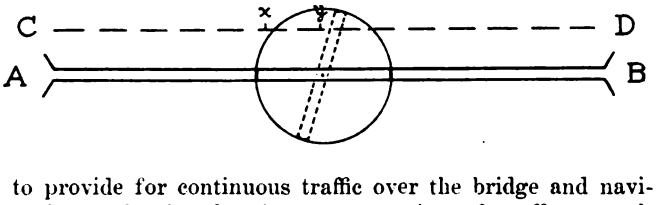
"Fournier's Series and Spherical Harmonics," by Byerly.

"Hydrology," by Mead.

For those who may be assigned on work requiring a general knowledge and who can give only a limited amount of time to the subject the following volumes and articles are recommended as a short reading course:

"Tides," by Darwin; in Encyclopedia Brittanica.

"Tides and Kindred Phenomena," by Darwin.



"Manual of Tides," by Harris; Part I, Chapter I.

"Tidal Rivers," by Wheeler.

"Canal and River Engineering," by Stevenson.

A Little Puzzle in Bridge Erection

A problem was presented of replacing an old bridge with a center-swing draw by a new bridge with a single-lift draw span, parallel to the old bridge. The new bridge was so close that when completed it would prevent the opening of the draw of the old bridge (see figure). It was necessary

to provide for continuous traffic over the bridge and navigation under it—that is, no suspension of traffic was allowed. The fixed span of the new bridge (C-x) was first erected. The draw span (x-y) was then erected in its closed position, the old draw opening meanwhile into the space y-D. Upon completion of the new draw span it was raised to the open position and the old draw opened into the new draw opening while the span y-D was placed. Traffic was then shifted to the new bridge. The cantilever ends of the old swing span were then cut off until it could be opened without touching the new bridge.

A New Mobile Water Purification Unit

From data supplied by the Design and Development Branch, Engineer Section, Schenectady General Reserve Depot

IN the A. E. F., special engineer troops (water supply) were responsible for the supply of adequate quantities of water at water points located as conveniently for the troops as service conditions would permit. About 40 water purification trucks of two types were used in this work. Since the war, development work has been carried out, along lines indicated by the A. E. F. experience, by the

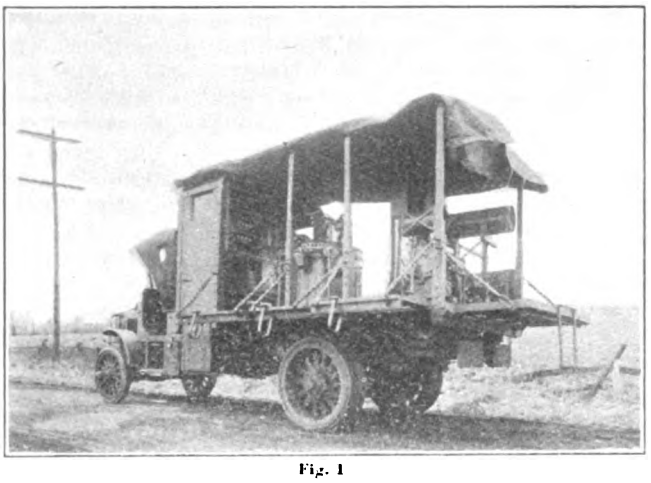

Fig. 1

Office, Chief of Engineers, in conjunction with the Wallace Tiernan Company, Inc., of New York, manufacturers of this type of equipment, who constructed much equipment of this kind for the A. E. F. A water purification unit has been developed that can be mounted on a 3½-ton, class B, army truck, which has considerable more mobility than the 5-ton truck. This will enable it to reach difficult places near water sources where the heavier truck would not be able to go. The body of the truck is the standard type, with bows and canvas cover, except that a small laboratory is built in at the front behind the seat and the sides are cut so that they can be dropped and held by chains at the level of the floor, thus increasing the available floor space. Figs. 1 and 2 show the general features of the equipment. By disconnecting the filter, the body and equipment can readily be removed from the chassis.

The equipment consists essentially of a single centrifugal pump delivering 100 gallons per minute against a 75-foot head at 1,150 revolutions per minute; a direct-connected 4-cylinder gasoline engine, delivering about 25 horsepower at 1,150 r. p. m.; a 42-inch pressure mechanical filter with a hand agitator; a five-way control valve; a combination direct dry feed and solution feed chlorinator, with a capacity of 1/10 to 12 pounds of chlorine per 24 hours; an alum pot and a soda ash tank, with appropriate feeds; a venturi meter and a water meter; and a simple laboratory for making acidity, alkalinity, color, turbidity and free chlorine tests.

The diagrammatic sketch, Fig. 3, with its accompanying key, shows the general operation of the plant. It may be operated as a simple pumping unit, as a pumping and chlorinating unit, or as a pumping and filter unit with or without chlorination. In selecting the source of supply it is desirable to secure running water, up stream from any source of pollution and with the maximum accessibility for the pumping unit and the tank trucks. Normally, the first operation is to wash the filter until the discharge is clear. The cleaning water should be chlorinated to prevent bacterial contamination of the filter sand; then the 5-way valve is turned to filter to waste and operated for a few minutes until a clear effluent is obtained. Alum must be added during this process. When alum is added to alkaline water it forms a flocculent precipitate which coagulates in a layer or blanket on top of the filter sand, permitting the passage of the water but removing most of the sediment. An alum pot containing crystal alum is connected around the pump so that a small stream of water is pumped through the pot, thereby dissolving the alum and feeding it into the suction line. The supply line has a calibrated needle valve to control the flow.

Water of low alkalinity, neutral or acid waters will not precipitate the alum, and it will pass through the filter and render the water unpalatable. To secure proper coagulation it is therefore necessary to raise the alkalinity of the water to the proper point. To accomplish this a 3 per cent solution of soda ash and water is placed in the soda ash tank, from which it flows to an automatically controlled constant level tank and then through a special graduated hard rubber orifice into the suction line. The advantage of feeding the chlorine, alum and soda ash into the suction line lies in the thorough mixing in the pump, allowing the maximum time for the chemical reactions to take place before the water reaches the filter.

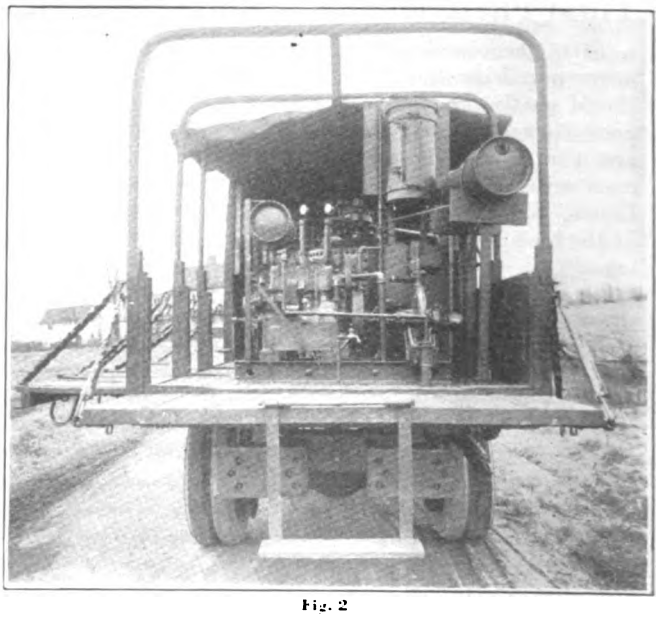

Fig. 2

Digitized by Google

Gauges are provided at the pump and on each side of the filter. In normal operations the pump gauge registers from 32 to 36 pounds per square inch, and the filter gauges register a pressure difference depending upon the cleanness of the filter. A calibrated venturi meter is placed in the discharge line. From readings of the different gauges an idea may be obtained of the condition and efficiency of the operation of the filter.

A road test of the truck over 200 miles of mountain roads showed 3.6 miles per gallon of gasoline and 28.6 miles per quart of oil.

As a result of laboratory tests of the purification unit it was found necessary to increase the size of some of the piping, change the situation of the alum pot and eliminate one of the meters. After these changes a capacity of 80 to 85 gallons per minute of filtered water of low or negligible turbidity was obtained against a head of 75 feet above the pump. In order to test the ability of the filter to handle very muddy water, a 350-gallon tank of water was made as muddy as possible by constant agitation with an excess of mud and sand, and this was pumped through the filter; the effluent was clear and palatable, but the capacity of the filter rapidly diminished, so that in about 25 minutes the flow practically stopped. Three to five minutes' washing with clear water restored the filter to perfect operation. Certain field tests are planned for the summer months. It is believed that the piping can be simplified, and it may prove desirable to use a pump of the same capacity as the present one, but capable of operating against a head of 100 to 150 feet.

The equipment, which is still in the development stage, is a marked improvement over that used in the A. E. F., being lighter and simpler, with increased capacity. Definite figures for capacity can not be given, owing to the wide range of conditions under which the plant will have to operate. The maximum capacity would be obtained when pumping clear water, requiring chlorinating but not filtering, and the minimum when handling very muddy water, necessitating frequent cleaning of the filter. Limitations imposed by weight obviously preclude the installation of a filter capable of handling the full capacity of the pump.

Under the proposed new organization of the engineer service, water supply will be handled by a special engineer organization called the Engineer Water Tank Train. The following quotation from the new staff manual shows the organization and capacity of this unit:

(a) One engineer water tank train is normally assigned to each army, and one to G. H. Q. reserve for each army in the expedition. This assignment may vary considerably with the character of the theater of operations, especially as regards the available sources of water.

(b) Each water tank train consists of three companies and one headquarters and service platoon. Each company is equipped with 50 water tank trucks with the necessary auxiliary trucks, such as gasoline tank trucks, repair trucks, etc., so as to provide two independent units of 25 tank trucks each. Each tank truck has a capacity of 500 gallons, giving a capacity of 12,500 gallons for each unit, 25,000 gallons per company, and 75,000 gallons for the water tank train. The headquarters and service platoon includes 12 purification trucks, each containing the necessary apparatus for purifying water at the rate of about 6,000 gallons per hour for chlorination only, and about 3,000 gallons per hour for chlorination and filtration. The train will also be supplied with a small quantity of canvas water tanks, water troughs, pumps, and other water-supply equipment.

(c) The engineer tank train is intended to provide the special equipment necessary for installing and carrying out water-supply activities in forward areas. It will always operate under the appropriate unit engineer, and personnel necessary for water-supply installation work will be drawn from general engineer troops.

Map Reading

Some Instances Showing the Necessity for Proficiency

By

L. M. Adams

Major, Corps of Engineers

TO point out, at this late date, mistakes that were made in training officers for the World War may seem a useless expenditure of paper and ink, but since we are now engaged, in the Officers' Reserve Corps and in the R. O. T. C., in training officers for the next emergency, advantage should be taken of the opportunity for correcting such deficiencies as the test of actual field service developed.

The observation of the writer in France in 1918 led him to the conclusion that there was a serious lack of ability to read maps among all ranks and branches in the A. E. F. A few instances will be cited to illustrate this point.

In July, 1918, I was at the Reg. P. C. ——— Inf. at *Nicholas Inferieur, Anould Sector* (Vosges), to consult with the Reg. C. O. in regard to camping an engineer battalion in his sub-sector for work on the French "Blue Line" Resistance Position. Three infantry lieutenants at the R. P. C. were about to join their platoons in the front line, and one was directed to guide me as far as the Resistance Position. The four of us started off together, and after we had gone about 500 yards via circuitous paths along the heavily wooded mountain slopes which characterize this sector, we came upon a group of French engineers putting in high wire entanglement. I asked the "guide" if this was not part of the Resistance Position I was looking for; he replied "No, it is still a long way to G. C. 5" (Group de combat No. 5). I replied, "But I am not going to G. C. 5, I wish to locate the Resistance Position—the 'Blue Line.'" I then produced the official French military map of the sector—scale 1:20,000—and asked the three officers to indicate on it where their G. C.'s were and where their Company Command Post "P. A." was. None could point out on the map, even approximately, these locations, each stating that he knew the route only to his own G. C. I then asked them to point out on the map where we then were—none could do this, although we were only some 500 yards from the starting point, which was clearly shown on the map.

On returning to the Reg. P. C. I asked by what route the companies should march from the Brigade P. C. The Reg. C. O. and his intelligence officer stated that French guides would be furnished and the men should march by a certain short cut over the mountain and that the transportation should come by the main road. I asked them to indicate the routes on the map, so that there would be some check on the French guides. Neither officer could indicate the routes on the map, and, later, at Brigade Headquarters, neither the Brigade Commander nor his adjutant could indicate the routes that would have to be followed. We later found that one of the engineer companies had marched several extra miles to reach its camp, this extra distance being very evident from the map.

In this same sector, and in the St. Die sector also, I found many miles of main roads near the front which had to be camouflaged with a screen to hide the day-time traffic from direct view of German observation posts or "sausage" balloons. Along these roads, which were considerably winding, there were several instances where the screen was erected on the wrong side of the road, due to a failure to use a compass and map correctly.

In the St. Die sector, August 16, 1918, twenty trucks of the 5th Division Supply Train were to report to the engineer division dump at Le Bihay at 6:30 p. m. to haul barbed wire by night to an advanced dump for use in an operation. These trucks started empty on this journey of about twelve miles from Raon-L'Etape at 530 p. m., but nothing was heard of them at the divisional dump until after 9 p. m., when I found them halted in the main street of St. Die. The officer in charge, a captain, had a good map with him, which showed both his starting point and his destination, but he had led his truck train over practically all roads in the sector, except the right one, and had even driven his trucks over one road so near the front that the noise of the trucks must have been clearly heard in the German lines. Why his train did not draw artillery fire will never be known except to the Germans.

A certain major of engineers, an electrical engineer by profession, could not point out on the map, even approximately, where two French batteries were which he had just visited and which I desired to visit. They proved to be only a mile away from where we were at the time and close to a main road clearly shown on the map.

On September 13, in the St. Mihiel attack, I found a lieutenant of engineers with his platoon at work on a wood road at least a kilometer away from the main route he was supposed to be at work on. He could not show me on my map where he was or what road he and his company were supposed to be improving. This same date, I found an engineer reserve captain with his labor company on road work, who did not know which way it was towards the German lines, although the place he was working at was under direct observation of German balloons and was frequently shelled.

Before the St. Mihiel attack, excellent military maps, scales 1:50,000 and 1:20,000, were issued to practically all officers, and yet I frequently found officers, even company commanders, who carried no map with them at all, attaching so little importance to them. These officers would accept detailed verbal instructions given from the exceptionally clear and accurate French military maps, of which they possessed a copy, and never offer to open and mark their own until told the importance of doing so.

For forty-eight hours after the infantry attack of the 5th Division at St. Mihiel had been launched, it was unknown whether the most advanced companies had reached

Digitized by Google

the "exploitation line" or not and whether the 5th Division's right and the 9th Division's left connected, left a gap, or were in echelon. The most conflicting reports were received as to map location of adjoining companies of the same battalion. Each company officer, prior to the battle, had a sheaf of report blanks with an excellent map printed on the back of each blank. It would seem easy under this system to get accurate and early information as to exact map location of all units. This did not prove to be the case, as few of the company officers had any exact idea of where they were on the map, or how to go about locating themselves, if the stress of battle had, for a time, caused them to lose their bearings.

As another and more serious instance; on September 16, work on the main resistance position across the 5th Divisional front (St. Mihiel Salient) was well under way. A new brigade had just moved up to hold the front, and the question arose as to where the friendly artillery barrage should be laid down in case of an enemy attack. The new brigade commander's aide was acting as brigade adjutant and was formulating a demand on the artillery as to laying down this friendly barrage. His map showed the approximate extreme front line of G. C.'s (outguards), P. A.'s (supports) and C. R.'s (reserves) of the Resistance Position. The "main line of resistance" was shown on the map as a single curved line connecting the C. R.'s. This young officer had planned to call for a friendly barrage to be laid down in case of attack just in front of this curved line marked on the map by the corps headquarters before the attack began, and in no way agreeing with the actual disposition of various elements on the ground. The barrage he was going to ask for would have fallen entirely on the area occupied by our own troops.

Many similar instances of the general inability of our officers to read maps could be cited. The existence of excellent maps of the entire American front made it possible for staff officers to formulate orders from these maps, often to the entire exclusion of personal reconnaissance. The carrying out of such orders naturally required a fair degree of ability to read maps on the part of all ranks and branches.

The development during and since the war of facilities for the making of maps will result in their being used in future campaigns to even a greater extent than during the late war, and the importance of map reading, in connection with the training of reserve officers and of the R. O. T. C., cannot be emphasized too highly.

(Continued on page 369)

Reserve Officers and Citizens' Military Training Camps

It is the earnest desire of the War Department to establish a cordial relation and mutual understanding between all elements of the United States Army and to further their training and instruction. Due to lack of appropriations and personnel the Department is now, and may continue to be for some time, unable to cause the citizen officers of the Officers' Reserve Corps, and to some extent of the National Guard, to be placed on active duty enabling them to be instructed and to foster the desired mutual cordiality between the personnel of the Regular Army and of the other components. However, there will be many opportunities of bringing about the desired relationship other than by placing reserve officers on active duty. Department and Corps Areas Commanders are charged with the duty of making full use of any existing opportunities within their jurisdiction which will enable officers of the citizen army to become acquainted with the regular establishment and to receive any benefit or instruction that facilities available permit. Accordingly, such officers, especially those of the Officers' Reserve Corps, will be informed of events of interest taking place in the regular establishment and will be invited and encouraged to attend, when practicable. When practicable, reserve officers will, if they desire instruction at their own expense, be attached to organizations or establishments of the Regular Army for instruction, target practice, field exercise, etc. In such cases the legal inability to exercise command will be observed. All proper steps will be taken to reduce to the minimum the expense of officers who seek instruction at their own expense and to give them the maximum of instruction in a minimum of time.

Inquiries have been received at the War Department indicating that, in some instances, officers of the Officers' Reserve Corps are making applications to attend, for the purpose of securing some training, the Citizens' Military Training Camps. In some instances it is indicated that the officers desire to attend at their own expense.

The mission of the Citizens' Military Training Camps is to train civilians to become privates, non-commissioned officers and second lieutenants of the Reserve Corps. The training courses have been designed accordingly. In view of the limited funds appropriated by Congress for this purpose, the number of persons who may be accommodated at the training camps is limited. In view of the fact that the courses of instruction are not suited to the further training of persons who are already reserve officers, and in view of the further fact that the attendance of such officers would prevent the attendance of an equal number of civilians who have had no training, applications of reserve officers to attend Citizens' Miitary Training Camps can not be approved, even though the officers desire to attend at their own expense.

The facilities and personnel are not available to establish separate camps or course this year for reserve officers who might be willing or desire to attend a training camp at their own expense without being ordered to active duty. The funds appropriated for pay of reserve officers set the limits within which the War Department may order officers to active duty. There are certain purposes for which, under the National Defense Act, reserve officers must be placed on active duty and paid. There are certain other duties for which reserve officers should be placed on active duty to insure the organization and development of the citizen soldiery. An allotment of the limited amount of funds for the following purposes is contemplated:

(a) For pay of reserve officers on duty with the War Department General Staff;

(b) For pay of reserve officers as instructors at the Citizens' Military Training Camps;

(c) For pay of reserve officers receiving instruction at the Special Service Schools of their arm. These will then be qualified to act as instructors within their units;

(d) For pay of a limited number of reserve officers of each division of the Organized Reserves to be called for a 15-day period of information and instruction in the missions of the three components of the Army of the United States and the plan and procedure of organization and administration of the units of the Organized Reserves.

Unless the amount of funds appropriated exceeds what it now appears may be expected, there will be little, if any, remaining after the above allotments are made. The War Department will not, therefore, in general, be able to provide a short training period for other reserve officers, either in camps or otherwise.—*Office of the Adjutant General.*

Taming the Yellow River

By

Charles K. Edmunds

[NOTE.—Chas. K. Edmunds is President of Canton Christian College, China. Dr. Edmunds, an engineer and scientist, has been much concerned during many years' residence in China with problems of irrigation and flood control.—ED.]

(Courtesy of *Asia*, the American Magazine on the Orient)

"I WANT to be Emperor of China."

He was an American of middle age, compactly and powerfully built, with friendly eyes and quiet voice. He was conversing in a Washington club and his hearers perceptibly leaned forward. It was evident that he had a real idea.

"Emperor of China for five years," he continued. "And I want the job in order to do just one thing—to tame the Yellow River."

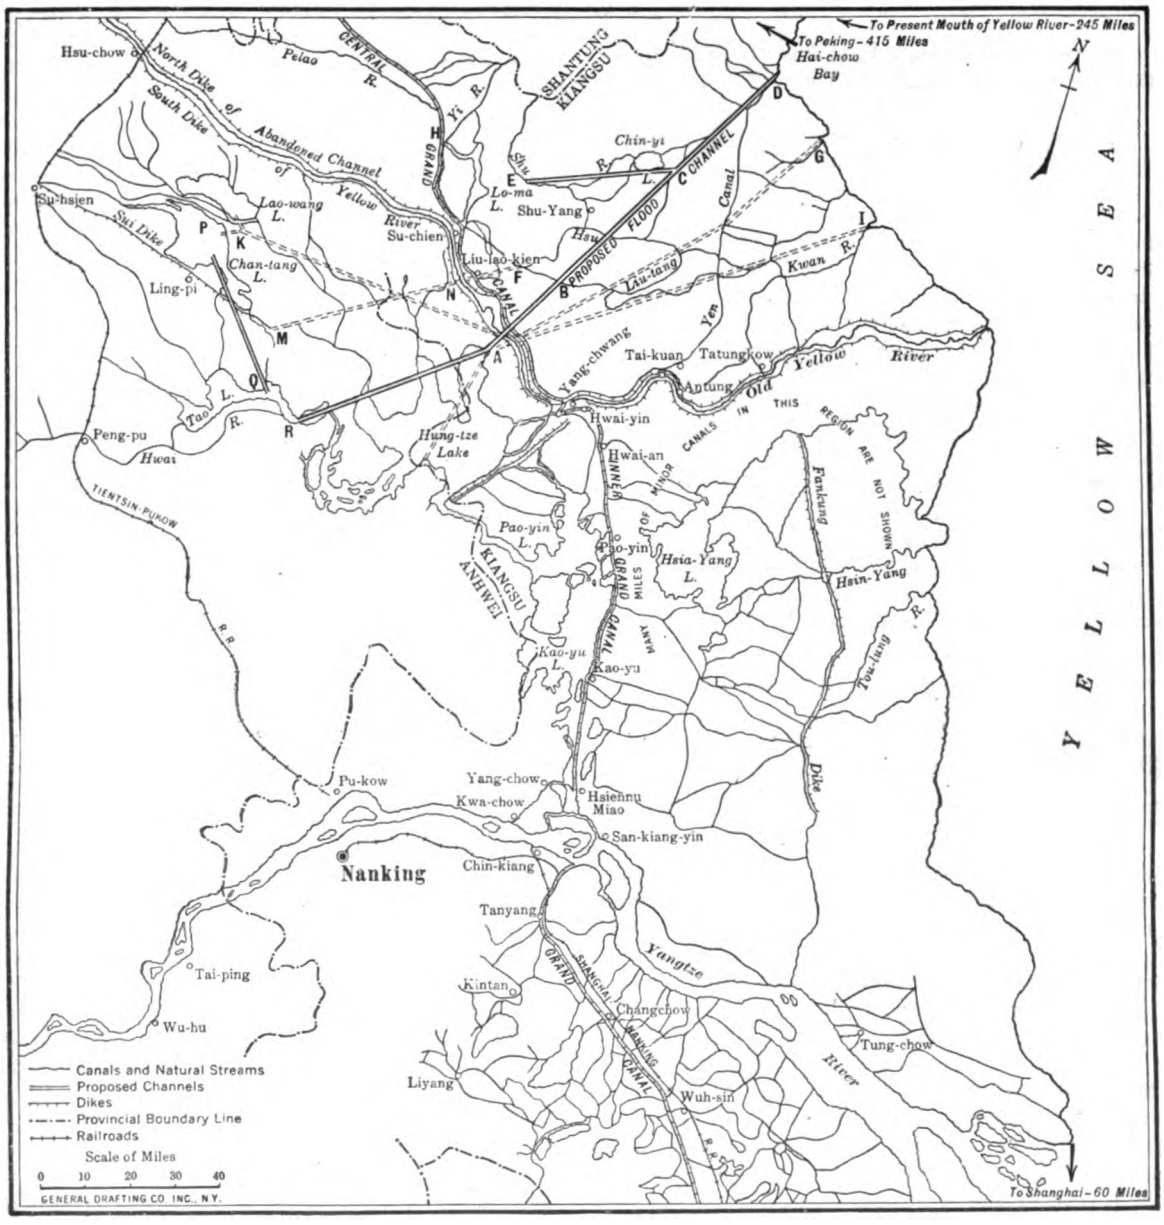
He smiled. But there was little doubt in the minds of his hearers that he knew what he was talking about in the matter of taming rivers. This sentence or two in the gossip of a club opened a vision of a great service America could render China. "To tame the Yellow River," would mean, as this American outlined the main scheme and accessory plans, to convert the Yellow River from "China's Sorrow" to a beneficient stream watering a very "Upper Valley of the Nile." It would reclaim a strip of waste land 5 miles wide by 250 miles long, sufficient for more than a hundred thousand fertile Chinese farms, and would forever prevent such outbreaks of the river through its dikes as that which in 1887 is said to have killed by flood and famine more than a million people.

John R. Freeman, of Providence, is the man who would control the Yellow River. He is probably America's foremost water engineer, final consultant on many of the country's greatest projects, including the water supply systems of New York City, Los Angeles, and San Francisco, some of the chief problems of the Panama Canal and some of America's largest water-power developments. The foundation of his interest in the control of the Yellow River is his regard for the Chinese people and his respect for their civilization and culture. As consulting engineer for the American International Corporation and the Chinese government, he went to China to improve the Grand Canal. The Yellow River crosses the Grand Canal. It was therefore necessary for him to study the Yellow River. While he was thus engaged, Chang Chien, the Chinese industrial and philanthropic leader who has gained fame through his model city, invited him to criticize the report of the Kiang-Hwai body of Chinese engineers. Since 1911, when Chang Chien organized this body and undertook its support at his own expense, these young Chinese engineers have been studying the flood and famine regions of Shantung and Kiangsu, with an eye to permanent measures of relief. The invitation to Mr. Freeman resulted in the preliminary report he has recently completed on flood control for Kiangsu.

His study of the problem of flood relief in China may lead to a work larger than the Panama Canal and greater in immediate humanitarian results. For it may point the way to saving hundreds of thousands of people from death by famine and insure them prosperity in fertile lands. The total cost will be small for a work of such magnitude. It now seems probable that all of the construction costs can be recovered in the increased value of the lands reclaimed. The total necessary expenditure is less than the amount necessary for the adequate relief of one great famine. But how can any man tame a stream that has many times broken out of its bed, devastated hundreds of square miles and found its way to the sea 250 miles from its former mouth?

Mr. Freeman's answer is so simple that it seems almost obvious after the discoveries on the relation of swiftness of current to erosion and silt transportation made by the engineers working under his supervision during the past two years. He would make the river dig its own channel, from which it could not escape—a work which, if done by dredging machines would cost over $100,000,000. He has found that, in flood times of the river, the greater its volume and the faster its flow, the deeper it digs its channel. Therefore, he says, increase its velocity to the rate which his researches show will dig up the silt and transport it to the sea, by confining it to the requisite narrowness of channel for from 250 to 300 miles. Furthermore, shorten its course by confining it to a series of straight-line channels from 10 to 20 miles in length between necessary bends. The new banks would be protected against undermining by spur dikes of stone riprap built much as the Chinese have built them for a thousand years, or by a modern device of concrete sheet piling reinforced with bamboo, instead of steel. Then the river will dig its own deep channel to the sea, and in this it will securely confine itself.

This dangerous part of the Yellow River flows through a vast delta plain of sediment hundreds of feet deep, easily cut into by a swift current. Geologists say that for fifty million years, since the second geological period, fine dust from the dry regions to the north has been blowing down on the lands that are now Shensi, Shansi, Chihli and western Shantung and forming yellow, powdery loess, which, during heavy rains, is easily washed away into the rivers by rushing torrents from denuded hills. The Yellow River has been carrying this fine silt to the Yellow Sea. But, as Mr. Freeman's figures show, despite the fact that the river carries more than 99 per cent of its mud to the ocean, the small fraction it drops along its course has raised the river bed about 10 or 15 feet above the surrounding plain, and in floods the water surface inside the dike is 25 or 30 feet above the plain outside. At the peak of floods more than 5 per cent in weight of the total flow is silt, carried by a velocity of 8 or 10 feet per second, but, when the mean velocity falls to less than 5 feet per second, the silt burden decreases rapidly. At velocities of more than 5 feet the river digs its bed deeper. After the flood, as the velocity

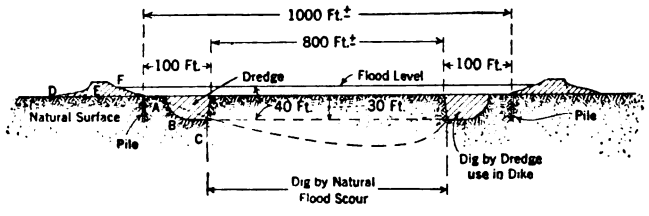


Digitized by Google

slackens, it refills the bed to the former depth. It is this ability of the river to carry off so much silt to the sea, also to leave part of it along its course, that Mr. Freeman proposes to utilize in turning the cause of hundreds of thousands of deaths into a source of new life.

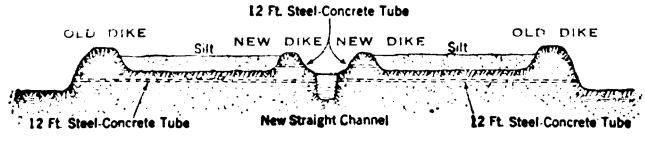
The river now curves and wanders at will out of its main channel, whenever swollen by floods, over a territory 5 to 6 miles wide between its inner dikes for 250 to 300 miles of its final course to the sea. Along this course and within these present inner dikes, Mr. Freeman would dig two very deep parallel ditches, each about 70 feet wide, leaving between them a strip of land about a quarter of a mile wide and 250 to 300 miles long. The earth thus excavated would form new dikes about 25 feet high. The outer sides of the two ditches he would reinforce with concrete piles and stone rip-rap, for these would be the ultimate sides of the river. The material excavated by shovels and by hand he would pile at the edges of the ditches, to make new dikes, about 2,000 feet apart. The sloping sides of the dikes, above normal stream-level, he would plant with willows to give resistance against floods. These new dikes would mark the edges of the new course of the river, running in straight lines 10 to 20 miles.

Into the new straight channels he would turn the river. Its own scour would eat away the 1,800 feet of land lying between and make the main channel. (See Fig. 1.) Mr. Freeman would then proceed to train the river to fill with silt the area 2 to 3 miles wide on each bank between the new and the old dike. Huge concrete pipes, 12 feet in diameter, built through the new dikes from the river, below flood-level, would permit the silt-laden river water to be drawn off in flood seasons to overflow the country between the new dikes and the old. (See Fig. 2.) Silt thus deposited would in time fill up this space, making the new walls of the river eventually 2 to 3 miles thick, and imprisoning it for all time. Furthermore, China would have along the Yellow River an area of new, fertile, river-bottom lands, 5 miles wide and 200 to 300 miles long, fully protected from flood.



One of the unique elements of the plan is the conversion of the Yellow River from a flood menace, by reason of its height above the plain, to an irrigating stream, by virtue of that fact. Mr. Freeman would build irrigation canals across from the new dikes to the area beyond the old dikes, at favorable places across the plains on each side of the

Digitized by Google



river, in such a way as to pierce the present inner dikes. If the river were tapped below low water-level, these tubes could irrigate the country outside the present dikes. The tubes would be fitted with dependable sluices at the river. Such work would have to be done with the utmost engineering skill, for the danger from botching would be great.

Such is one part of the plan. But this whole low, flat, delta region of Shantung and Kiangsu is a network of rivers, lakes, and streams. Frequently floods spread over hundreds of square miles, spoiling the crops, drowning the farm animals and starving the people. At present, most of the streams drain into the Grand Canal and thence an undue portion flows into the Yangtze. Freeman would apply

his Yellow River method to drain these directly to sea to the east, rather than to the Yangtze. He would dig a new channel—a straight line 85 miles long from the Hungtze Lake to Haichow on the Yellow Sea—100 miles south of Tsingtao. He would use the same scheme of digging parallel deep ditches, barely large enough to give material for the new dikes. in straight lines. He would turn the waters of the lakes and the Hwai, the Yi and the Shu rivers into these ditches and make their flood waters do four-fifths of the required excavation. He would spend only $6,000,000 in man and machine labor and as the result make the waters do $24,000,000 worth of dredging and scouring. He would dam up the lakes at different levels as successive reservoirs to hold flood waters and from these reservoirs he would build irrigation ditches carrying water to the surrounding country during drought.

The combined projects in Kiangsu Province could be completed in ten years. They would create 1,700,000 acres of new land, some of it reclaimed swamp lands of the lake and river region. The Yellow River and the new channel would be made navigable streams. China would be given a new port, Haichow, the sea terminus of a system of water

transportation into the interior.

Surveys for this Hwai River conservation work in Kiangsu Province were originally undertaken by C. D. Jameson, engineer, under the auspices of the American Red Cross ten years ago. Another survey by Gen. W. L. Sibert, of the United States Army, under the auspices of the Red Cross, followed four years later. The Kiang-Hwai body of Chinese engineers, organized and supported by Chang Chien, have added their work since 1911. The plan now presented by Freeman is the result of two tours of inspection and study during the past four years and much more surveying and test boring is required to perfect its details, and make precise estimates of cost.

The American International Corporation has temporarily withdrawn its engineers from the work of reconstructing the Grand Canal, and the opportunity for further surveys necessary to complete the Freeman plan of conservation is, for the time, cut off. For these surveys, only a few tens of thousands of dollars are necessary.

Here is a constructive piece of work to prevent recurring famines, an opportunity for Americans to initiate and back financially—with the possible co-operation of a public increasingly interested in China and its government—a great humanitarian plan, which could be undertaken either by a corporation that could guarantee sound construction and a reasonably good investment return, or by a semi-official public body such as the Red Cross, or by the Chinese government itself, under suitable engineering counsel and management, with the financial aid of the new consortium.

Shoot!

A rifle competition among teams representing all cavalry and engineer regiments and separate battalions will be held at Fort Bliss, Texas, beginning on July 1.

The teams from the different organizations have been selected by means of regimental competitions held at the headquarters of the different organizations.

Practically all cavalry and engineer officers of the regular establishment have generously subscribed the money necessary to obtain the trophies which will be awarded the winners.

These trophies are to be given to the team making the highest score in open competition between engineer and cavalry teams; to the engineer team making the highest score in a competition limited to engineer organizations, and to the cavalry team winning the highest score in a competition limited to cavalry organizations. Trophies will likewise be given to individuals of both services competing in individual matches under similar conditions.

The trophies will remain in the custody of the winners for one year, when they will be competed for again.

In order that individuals may retain some memento of their victories, medals will be provided for 1st, 2d and 3d places in the individual contests and for members of winning teams.

The next issue of the journal will contain an account of the shoot and the names of the winners, with scores.

From the results of this competition between the cavalry and the engineers, a squad of twenty-four of the best shots in both services will be sent to Camp Perry to prepare for the National Rifle Matches. A team of ten men and two alternates will be selected to represent the combined cavalry and engineers in these matches.

Concrete Truss Span Erected Without Falsework

In erecting the six 66-foot truss spans of a reinforced concrete highway bridge at Wichita Falls, Texas, the contractor used a scheme of construction that eliminated the necessity for falsework. In place of the usual falsework a pair of steel trusses, supported by the piers for the permanent structure, carried the weight of the concrete during erection. The concrete trusses were cast in a horizontal position on a temporary floor carried by the steel trusses, and after hardening were raised to their final vertical position by tackle slung from the top of the steel trusses.

When the work on one span was finished, the steel trusses were moved forward to the next span, first on rollers resting on the top chords of the concrete trusses, and later, after the trusses were half way across the new span, on another set of rollers underneath the bottom chord of the concrete trusses, the steel span acting as a cantilever during the process.—*Engrg. News-Record.*

Reorganization of the Engineer Service in the French Army

From data furnished by the French Embassy

A MORE or less thorough reorganization of the army is the usual aftermath of every great war. Such reorganization takes place not only in the armies that have participated in the struggle, but often in those of other nations endeavoring to profit by its lessons. Such a process is now going on in all the Allied armies.

The reorganization of the French army is not yet completed, but the lessons of the war have been carefully studied by the staff, and the principles which should govern the organization of the engineers, from the French point of view, have been enunciated. The following is a brief outline of these principles. They are of special interest at this time, inasmuch as we also are passing through a similar period of reorganization.

In the French army the engineers perform the functions which in our own army are performed by the engineers and the signal corps. The following remarks are limited to the engineer service proper, as understood in our own and most other armies.

Duties of Engineers in the Field

These include:

1. Transportation of troops and materiel.
2. Organization of the ground. (a) Communications; (b) Fortifications; (c) Demolitions.
3. Shelter for troops.
4. Supply of engineer tools and materials for troops of all arms.

The engineers are both a combat arm and a supply service. Their chief duties are transportation, construction and supply.

Engineer Troops of a Large Unit

These will include a chief engineer, an engineer staff, the engineer troops belonging to or temporarily assigned to the unit, and military and civilian labor units.

The chief engineer is a member of the staff of the commander of a large unit. He commands the engineer troops, both permanently and temporarily with that unit, and acts as technical supervisor of engineer troops of the smaller component units.

Classes of Engineer Troops

These include:

1. Army, corps, or divisional engineer units.
(a) Standard engineer units of the corps and division.
(b) Cyclist engineer units with cavalry divisions.
(c) Army engineer companies (regular or territorial), similar to the companies of the standard division or corps troops.
(d) Mining companies. These will perform the following duties: Use of explosives on a large scale, mine warfare, important shelters, use of mechanical digging plant, locating mines and traps laid by the enemy.
(e) Bridging companies, for the construction of position bridges under difficult conditions (swift currents, heavy loads, etc.).
2. Communications or transport units.
(a) Standard gauge railroad regiments.
(b) Narrow gauge (cableway or mono-rail) railroad regiments.
(c) Heavy bridge units.
(d) Motor transport battalions.
(e) Animal transport battalions.
(f) Inland waterway operating units.
Note. The last three (d, e and f) are classed as "engineer trains."
3. Special units. These include several classes of specially skilled troops and non-combatant units.
(a) Electrical companies.
(b) Water-supply companies.
(c) Forestry and hut construction companies.
(d) Road companies.
(e) Labor units of various classes, etc., etc.
4. Engineer trains and depots.
(a) Army engineer trains (tools).
(b) Army ponton trains.
(c) Motor and animal transport trains, with repair units.
(d) Depots—gasoline, engineer tools and devices, materiel, explosives, etc. (Depots include what are commonly known as dumps.)

Remarks

These troops will be in general either permanently assigned to the larger units, including, of course, their component units, or to the general engineer reserve, at the disposal of the commander in chief of the armies. A very large general reserve is regarded as essential because of the great variety and vast amount of engineer work to be done, and the objections to detaching from the larger units the troops properly belonging to them.

As a general rule, engineer works in wartime require only a few skilled specialists, but a very large number of common laborers. Accordingly, the end to be sought in engineer organization is:

1. A few engineer units with a large proportion of officers and non-commissioned officers and plenty of skilled artisans.
2. A large number of labor units.

Man Power is the only kind that can be relied upon under all conditions, especially in the forward part of the combat zone. During the late war many classes of mechanical devices, designed to save man power, were employed. Such

CITIZENS' MILITARY TRAINING CAMPS

I. Crab-apples or Pippins

UNIVERSAL training to a common and a high standard of citizenship is what our country most needs today. A democracy, or government by the people, can be completely successful only when the people are intelligent. Freemen must be intelligent; ignorant people are never free in the highest sense of the word. If we want good citizens in this country we must make them, we cannot let them grow up by chance. All the best fruits of earth are *cultivated* and this is as true of man as of the fruits of the soil. An educated cultivated gentleman is as much superior to an uncultivated clod as the splendid pippins we see on our tables at breakfast (if we are lucky) are superior to the crab apples which were their progenitors. Yet crab apples become pippins under cultivation, and in like manner the clod with proper training becomes a gentleman and the highest type of citizen. We would nearly all be clods if we had no opportunities for training, and we would nearly all be good citizens if properly trained.

This is, of course, the greatest reason for universal education—to raise our standard of citizenship. There is another aspect, the military. National security in such a world as we live in, demands readiness to defend ourselves, and one of the elements of such preparedness is that our citizens generally must be: first, patriotic, loyal and dependable, that is to say, *disciplined* in the highest sense; second, physically fit; and third, trained to bear arms. No arguments as to the correctness of these contentions will be necessary with most of our readers; they are already convinced.

Shall we ever have in this country a universal education which will at once improve our standard of citizenship and insure the national defense? Perhaps, if our citizens as a whole ever become convinced that universal education will produce these results without producing militarism such as we have seen in Prussia. One would have supposed that the beneficial effects of the training given to our men who went to war would have convinced everybody. They certainly did convince the great majority of those who received the training. But these are only a small proportion of our citizens, and daily growing smaller.

We need further demonstrations to convince America of the benefits to be derived from education under the supervision of the Federal government. Such demonstrations will be given this year, and on an increasing scale in coming years, by the Citizens' Military (Volunteer) Training Camps.

A summary of the regulations governing these camps was published in our last number, under the title, "The Plattsburg Camp Idea Revived."

On page 335 of this issue we publish a memorandum from the office of the Adjutant General on "Reserve Offi-

Digitized by Google

cers and Citizens' Military Training Camps." It is to be regretted that limitation of funds does not permit establishment this year of camps for the further training of Reserve officers, but it is hoped that all Reserve officers will exert their influence to the end that the best possible class of citizens may be secured for the Citizens' Military Training Camps.

II. The Acid Test

MUCH depends upon the outcome of these camps. The World War was fought under the policy of universal military service, which was adopted by all participants. For over one hundred and forty years we had managed our various wars under the volunteer system, wherein a few men of higher ideals or nobler spirit sacrificed themselves for the many, and yet, when we entered the World War, we recognized the inherent weaknesses of the system. Without a tremor we adopted a compulsory service law founded on the truly democratic principle that citizenship has its obligations no less than its privileges. Under this law we produced an army whose determination, whose ability, and whose general efficiency had never been equaled in our own history, nor, everything considered, was it surpassed even by those gallant allied hosts who held the front at the Marne, at Ypres, and at Verdun.

At the close of the war that army, approximating 4,000,000 men, was demobilized and absorbed in the civilian body-politic without a thought of a military coup d'etat—without the slightest jar to the orderly processes of government.

Notwithstanding the success of this experiment in raising armies, notwithstanding the demonstrated value of military training and right living, we have elected to discard the principle of universal obligation to defend the state and have reverted to the volunteer principle, which has proven so costly in men and in money. But, no longer a nation of squirrel hunters, we have made reluctant concession to the notion of preparedness; we admit that it is both a costly and a dangerous folly to seek to extemporize an adequate war force after the incidence of the emergency. Though we have abandoned the policy of universal military training, we have yet gone so far as to countenance a brief training in military fundamentals for those inclined to avail themselves of the opportunity. The new defense law contemplates a national force—the Army of the United States—to consist of a small professional army, a national guard and an organized reserve, all to be raised by the volunteer system.

A year has elapsed since the law received the approval of the President and it is now about to undergo its first real test. The progressive series of military training camps announced by the War Department furnish the young manhood of the country the opportunity to fit itself for that stern duty which it must perform when peaceful measures fail to secure the national safety. Corps area commanders are now engaged in arousing the interest of those who in the discharge of their citizenship should attend these camps and the President has recently issued a statement to encourage those to whom, under an enlightened practical idea of patriotism, no such appeal should be necessary.

By playing his part in this movement a young man will increase his value to his state and to the nation and reap a direct personal benefit as well, but failing to present himself for training, he not only rejects an opportunity of great value to himself but his indifference endangers the national defense. By his inactivity he denies the soundness of the military policy enacted by his representatives in Congress and leaves the nation virtually without recourse. While he continues to enjoy the protection of the state he takes no personal part in assuring its continued existence.

The success of our new military policy depends directly upon the organization of a reserve composed in the main of young men voluntarily subjecting themselves to military training and sacrificing time and pleasure to a sense of patriotic duty.

Are we wise to deny the greatest lesson of the World War? Are we right in discarding the idea of compulsory universal military training? Can we rely on the volunteer spirit to maintain the nation in an adequate state of preparedness?

The citizens' military training camps will put our national military policy to the acid test. Will it reveal a manhood conscious of the high obligations of democratic citizenship? Will it give us the assurance of a future—peaceful and secure?

The Local Post and Its Mission

THE best indication of the fact that our Society has grown in the course of a year and a half from infancy to healthy, vigorous youth is to be found in the splendid development of active interest on the part of our numerous local posts. This development is our best assurance of success in the future.

Something more than the reading of THE MILITARY ENGINEER is required to bring about the accomplishment of the aims for which the Society was founded. No institution devised by man can succeed if it ignores the human equation. The human equation, in order to affect an institution, requires human contact on a considerable scale. The only feasible means of securing this contact is by means of local posts. There the contact of minds reduces abstract problems to concrete forms and facilitates their solution, taking the human equation into consideration.

The number of posts and the number of members affiliated with them are steadily increasing. Many of the posts have fully emerged from the formative stage and have entered upon programs that are not only interesting and instructive to their members, but that will eventually contribute something well worth while to the War Department's plans for the national defense. The detailed report in this issue of the program evolved by the Montgomery Post is an excellent example of real progress. Many others are working along similar lines.

The Officers' Reserve Corps is still rather a nebulous organization, but there is no doubt that progress is being made toward the attainment of the end that the War Deparment has in view, which is, that Captain Z of the Engineer Officers' Reserve Corps will be Captain Z, Commanding Company B, Nth Engineers; his lieutenants will be assigned, and he will know them and their capabilities; he will even have a "top kick" and a mess sergeant; he will be conversant with the idiosyncrasies of his battalion and regimental commanders. Mobilization for active duty in an emergency will merely mean that he will change his clothes, and repair to a locality that he already knows, to take up work with which he is familiar, among fellow engineers whom he knows and can rely upon. Compare the mental attitude of Captain Z under such conditions with his attitude were he merely an unassigned officer, whose organization and duties would be determined, in haste and confusion, only after the emergency was upon us, with the result that the electrical engineer might find himself in a railroad unit, and even those whose assignments accorded with their train-

Digitized by Google

ing and ability would certainly find themselves amongst strangers.

The possibilities for interesting and valuable programs in the posts will be enormously increased when the War Department plans are carried to the point where the bulk of the members of each post have definite assignments to organizations. Each officer will then have a known objective. and problems can be studied in the posts that will afford each member an opportunity to develop himself along the lines that he will follow if called to active duty.

The War Department has taken steps to institute summer camps for the military instruction of young citizens who voluntarily enroll themselves for this purpose. Local posts should support the movement. They can and should do much toward bringing out the right material for these camps.

In many places close relations have been established between local posts and nearby engineer units of the Reserve Officers' Training Corps. The contact of R. O. T. C. students with the activities of local posts will have far-reaching effects; it will enhance the value of military training in the eyes of the student who sees practising engineers giving serious thought to it and to other phases of national defense; it will make it natural for the engineering graduate to affiliate with the Society and its posts; and it will bring the student into contact with engineers among whom he will pass the rest of his life.

The Reserve Officers' Training Corps and the Citizens' Military Training Camps are the chief sources for reserve officer material in the future. They are fundamental elements in our policy of national defense. Their growth and efficiency should be fostered by all possible means. In their cultivation the local posts will find a productive field of usefulness.

It Is for the People to Decide

ON the basis of the National Defense Act the War Department has worked out an organization for the Army of the United States, the first echelon of which will consist of six field armies, each army composed of contingents from the regular establishment, the National Guard and the Organized Reserves in the ratios of one to two to three. In other words, in the first echelon the regular army will constitute one-sixth of the whole, the National Guard one-third, and the Organized Reserves one-half. Should the emergency necessitate a greater force, the regular army will be practically submerged in the great mass of citizen soldiery.

The United States has been divided into nine corps areas, with a corps headquarters and a division of the regular army in each. Directed by the corps area headquarters, the National Guard and the Organized Reserves will form around the regular division as a nucleus, and by this means it is hoped to build up the military force directed by Congress in the National Defense Act.

Needless to say, the organization now set up can not be maintained without adequate funds. It might be possible to preserve the framework of the regular army with 170,000 or 175,000 men, but the result of recent Congressional action is to reduce the number to not more than 150,000 men by October 1, 1921. The House, in fact, was disposed to force an ultimate cut to 125,000 enlisted, with the idea of maintaining an average strength for the year of 150,000 as against the present strength of 220,000 enlisted. In brief, the regular army is a diminishing force.

What is the answer to the problem? Manifestly the plans for the regular army must be revised and the reduced personnel redistributed in such manner as best to fulfill its mission in the general scheme. The citizen-soldiery will have to assume a greater share of the burden. The various states will have to do more toward developing and training the National Guard. The officers and men enrolled in the Reserve Corps will have to depend more largely on their own efforts and less on the War Department for the acquisition of military knowledge and experience.

In the broader aspects of national defense the citizen-soldier rather than the regular army man is the leader. The individual citizen must bear the burden of making effective the military policy of the country. Congress is but the servant of the citizen-soldier, while it is the master of the regular.

Acting for the people, Congress has framed a plan for the national defense, but the realization of that plan is squarely up to the people. Preparedness will become either a living vital element in our daily life or it will become but an idle dream.

It is for the people to decide.

Death of Col. Thomas C. Clarke, E. O. R. C.

By the death, on May 25, of Col. Thomas C. Clarke, the Engineer Officers' Reserve Corps lost an officer of the highest type, the country lost a citizen who had given abundantly of his services as an engineer both in peace and in war, and the Society of American Military Engineers lost a staunch and unselfish worker in the cause of national defense.

Thomas Curtis Clarke was born in Philadelphia on December 11, 1873. He specialized in metallurgy and finished his education at the Massachusetts Institute of Technology. Years of experience with large steel and coke enterprises qualified him as one of the foremost consulting engineers of the country on the subject of by-product coke ovens. Frequent trips to Europe kept him in close touch with developments in this line and gave him a fluent command of French and German.

As early as 1895 Colonel Clarke served in the National Guard of New York. Upon the establishment of the Engineer Officers' Reserve Corps he was one of the first to give definite expression, by action, of his sense of responsibility for the defense of his country, and was commissioned captain in January, 1917. Called to active duty in May of that year, after a few months' training at Oglethorpe and Belvoir, he was promoted to lieutenant colonel and assigned to the 110th Engineers, 35th Division. He went overseas in March, 1918, succeeded to the command of the regiment in July, and in September was promoted to the rank of colonel. His part in the excellent work done by his regiment in the Meuse-Argonne offensive is described by his adjutant, Capt. E. P. Rankin, Jr., in this issue.

For participation in a trench raid by the French 69th Division that penetrated half a mile into the German lines, he was decorated with the Croix de Guerre.

Upon returning to the United States he re-entered the reserve as a colonel, and affiliated with the New York Post of the Society, of which he was one of the most enthusiastic members and one whose friends were legion. He was also a member of the American Society of Civil Engineers and of the Society of Chemical Industry.

His death was due to pneumonia, following a brief illness and operation. He leaves a widow, Mrs. Elizabeth I. Knox Clarke, of 101 East 74th Street, New York.

Activities of Our Local Posts

Montgomery Post

DWIGHT C. TREVARTHEN, P. O. Box 763, Montgomery, Ala.

At a meeting on May 14 the following plan of activities, submitted by the board of directors, was adopted without amendment, and steps were taken to put it into execution:

Purpose of the Society.

The Society of American Military Engineers was formed with the specific purpose, among others, to develop and foster, in the interests of the national defense, relations of helpful interest between the engineering profession in civil life and that in the military service. Modern military practice may be properly considered a branch of engineering science, embracing not only the operations of armies in the field, but the means and methods employed in housing, equipping, transporting and supplying these armies, requiring in some cases, as in the World War, a utilization of the entire resources of the nations involved. National defense includes not only the subject of military practice and operations, but also the questions of development and conservation of national resources, the development and utilization of transportation facilities, and other questions thereto related. This subject is therefore of vital interest to and forms the common meeting ground for the civil and the military engineer.

Proposed Special Activity.

It is therefore proposed that the Montgomery Post adopt as a subject for investigation, study and discussion the important question of national defense, limiting its consideration for the time being to the State of Alabama and that portion of Florida lying immediately south. The field of this investigation will include studies of the seaports, transportation facilities, topography, agricultural and mineral resources and development, water-power development and related subjects, having in mind the relation of such subjects to the question of national defense. These studies will be made preliminary to a subsequent adoption and solution of a more or less definite military problem involving the determination of defensive measures and military operations that should be undertaken to oppose the assumed advance northward through the State of an enemy force with an established base on the Gulf within the limits of the sector being studied.

Method.

In pursuing this special study, it is proposed to adopt a method which is here described in a general way. The time to be devoted to this problem will be approximately one year, including twelve monthly meetings of the Post. At each meeting some particular phase or element of the problem will constitute a subject for discussion at that meeting. Papers and discussions will be prepared in advance by a committee specially selected for that purpose. These papers will be read at the meeting and will be submitted for general discussion. All papers and all written discussions, including maps, will be turned over to the secretary for compilation and future reference. Efforts will be made to obtain lectures or talks on subjects of particular importance or interest, by persons having special knowledge or experience in those subjects. It is contemplated that the period of preliminary study will require about six months, and the military problem an equal period. The details of the military problem must in many respects be based upon information disclosed in the preliminary studies, so that in the beginning it will not be precisely stated. In order, however, that the preliminary studies may be properly shaped and adequate to the immediate end in view, the problem will be outlined in general, and the program of study will be initiated by a paper on this particular subject, which will be a general discussion of the possibilities in this respect, and the various problems involved. In working out the military problem effort will be made to secure the occasional assistance of military experts. It can thus be seen that all preliminary studies must be twofold in their nature; they must be made from the broad general standpoint of national defense, and they must have specific reference to and be adjusted in scope and content to the military problem to be solved.

Objects in view.

These preliminary studies and the subsequent discussion and solution of the military problem will provide a definite objective for the energies of the Post; will add interest to the meetings; will be instructive and helpful to the individual members; will lead to the crystallization of ideas, now, perhaps, more or less vague, on the questions of proper measures for national defense; will clarify and define, in our minds at least, the relation that exists or should exist between national development and national defense; will lead to the delineation and adoption of definite policies, and may be the means of bringing to the attention of the public, of officials, bureaus, and departments of the State government and of the United States Government, important features of these vital questions.

The Military Problem.

A hostile force of adequate size, to be hereafter determined, will be assumed to have effected landings and established a base or bases at one or more points on the Gulf coast, probably at Mobile or Pensacola, or at both. Information of this intention was obtained only a few days before its accomplishment, though actual hostilities had been considered a practical certainty for some time prior to that. The purpose of the enemy is to advance northward through the State of Alabama, seizing points of importance, crippling industry, capturing or destroying supplies, demoralizing inhabitants, and ultimately seizing and diverting to his own use mining and manufacturing industries in the northern part of the State. A defending force will be mobilized at a predetermined point, and will operate against the hostile army, protecting important points and resisting the advance. Final and precise details of this problem will be worked out following the completion of the preliminary studies, and thereupon will be undertaken a study and solution of the various phases and problems, particularly the engineering problems, incident to the offensive and defensive operations involved.

Preliminary Studies.

Preliminary studies must include such discussion pertinent to the subject as will form the basis for the determination and solution of the details of the military problem. The following subjects will constitute the course of preliminary study:

1. A general discussion of the military problem

Digitized by Google

2. Topographical and geographical features of the sector
3. Railways
4. Highways
5. Agricultural development and production
6. Mineral resources, mining development and production
7. Industrial development
8. Population and manpower
9. Seaports and waterways
10. Power development.

These subjects will be assigned to committees, one or more subjects to a committee, whose duty will be the collection of information on its subject or subjects, the preparation of papers and discussions and the collection of necessary maps. The chairman of the committee will be responsible that his subjects are adequately treated, assigning, as he may see fit to the different members, particular phases of the question; or the principal paper on the subject may be prepared by the chairman or some member, and submitted in advance to the other members of the committee for preparation of written discussions. The chairman will direct the discussions of his particular subject at the Post meeting, and he may also arrange for an address on that subject by an outside authority. When such an address is contemplated, advance notice should be given the secretary. The papers should be comprehensive in scope and adequate in content, having in mind the dual nature of the treatment desired; they should contain a discussion of the relation of the information contained in them to the proposed military problem, with a brief summary of conclusions. In preparation of papers, it should be borne in mind that the time available for presentation and discussion will be somewhat limited. All papers and discussions will prove more interesting and instructive if presented in connection with a map of the territory, prepared in such a way as to afford a pictorial summary of the information presented.

Grouping of Subjects.

The subjects for preliminary study are grouped for assignment as follows, each group including the subjects for consideration at a single meeting of the Post:

Group No. 1, Subject No. 1—A general discussion of the military problem.
Group No. 2, Subject No. 2—Topographical and geographical features of the sector.
Group No. 3, Subject No. 3—Railways.
Subject No. 4—Highways.
Group No. 4, Subject No. 5—Agricultural development and production.
Subject No. 6—Mineral resources, mining development and production.
Group No. 5, Subject No. 7—Industrial development.
Subject No. 8—Population and manpower.
Group No. 6, Subject No. 9—Seaports and waterways.
Subject No. 10—Power development.

It is proposed that Group No. 1 form the subject for consideration and discussion at the June meeting of the Post, and that the remaining groups be taken up at subsequent meetings in the order named. The meeting next following the completion of the last group will be given over to a discussion and formulation of a definite military problem, including the main problem and subsidiary problems. The various problems will then be discussed in detail at subsequent meetings in a manner similar to that proposed for the preliminary studies.

All papers and written discussions should be prepared far enough in advance of the meeting at which they are to be presented so that the secretary may prepare mimeograph copies for distribution among the members of the Post at the time the papers are presented. The secretary should be furnished with copies of all written and printed matter, and tracings of all maps should be furnished so that prints may be attached to mimeographed copies of papers and discussions. A file of these "Proceedings" will be kept in the files of the Post for reference at all times.

While it can not be stated definitely now just how much of the time of each meeting can be given over to the studies, it is proposed that the maximum period under any condition shall not exceed one hour.

Duties of Chairmen.

It shall be the duty of the chairman of each committee to see that the subjects assigned to his committee are adequately treated, making such assignments to the members as seem best, and preparing such synopsis as will insure covering the entire field. It is intended that the preliminary consideration and discussion of the military problem to be made at the June meeting will serve to indicate the general requirements in this respect.

Chairmen.

It is proposed that the presentation and discussion of the military problem in its preliminary aspects shall be undertaken by the board of directors acting as a special committee for this purpose. Other committees shall consist of from two to three members. The chairmen of these committees have been selected by the president, after conferring with the board of directors. The president will call a meeting of committee chairmen at an early date for the purpose of making final selection of all committees. The following members are designated as committee chairmen:

Group No. 2, Mr. G. N. Mitcham; Group No. 3, Mr. J. M. Garrett; Group No. 4, Mr. H. B. Battle; Group No. 5, Mr. A. E. Loder; Group No. 6, Mr. D. C. Trevarthen.

Tentative Schedule.

The following tentative schedule is proposed, covering the first seven months of the course:

June 11, 1921, Group No. 1; July 9, 1921, Group No. 2; August 13, 1921, Group No. 3; September 10, 1921, Group No. 4; October 8, 1921, Group No. 5; November 12, 1921, Group No. 6; December 10, 1921, formulation of definite military problem and adoption of subsequent schedule.

San Franscisco Post

DOUGLAS W. DODGE, Rialto Building, San Francisco, Calif.

The April meeting was replaced by a trip to the Mare Island Navy Yard, where the commandant, Captain Beach, received us most hospitably. A very interesting day was spent in inspecting the various activities of the yard, and the kindness of our hosts of the Navy will long be remembered.

The Activities Committee is making plans for an inspection of the coast defenses about San Francisco Bay, an observation trip over parts of the State Highway, a trip over the Hetch Hetchy water-supply project, and an inspection of the Disciplinary Barracks on Alcatraz Island.

The Program Committee, consisting of Mr. C. W. Backe, chairman; Fred C. Toklas, secretary; J. W. Williams and Raymond Salisbury, assigned to Lieut. Col. J. W. Williams and Major Grant the discussion of the subject "In what way can the interested civilian engineer be best trained in preparation for military emergency and how used to best advantage?" Col. Williams' paper on this subject received the unanimous indorsement of the Post. Major Grant and several other members discussed the various points brought out by Colonel Williams. [Colonel Williams' paper is published in full on page 351 of this issue.—ED.]

Digitized by Google

The Current Events Committee, consisting of Prof. Charles B. Wing, L. J. Corbett, Secretary, and Chester K. Smith, will undertake to gather and condense into a report, to be read at each evening meeting, all news, orders and regulations of interest, and general information pertaining to military engineering, reserve officers and the engineer reserve.

The Publicity Committee, consisting of George A. Hunt, chairman; W. B. Cunnane, Jr., secretary, and Addison N. Clark, has established a record and file of reports covering the meetings and activities of the Post. It will be their duty to forward to THE MILITARY ENGINEER such material as it is desired to publish, to secure suitable publicity in news and technical publications, and to develop a library covering the subject of military engineering.

The Membership Committee, consisting of R. P. Hastings, chairman; Don E. Tripp, secretary; E. Ronalds Foster and R. E. Childs, will pass on all applications for membership in the San Francisco Post, after investigating records and qualifications. It will maintain a list of members and will take proper steps to increase the membership roll.

The Entertainment Committee, consisting of Thomas M. Ward, chairman; Stephen Malatesta, secretary; H. S. Hahn, J. M. McCoy and L. D. Kramer, are arranging outings, hikes and excursions, rifle-range practice, etc.

The Secretary of the Post, who is an ex-officio member of all committees, has circularized the advertisers of THE MILITARY ENGINEER, requesting their literature and catalogs. These are being filed and kept up to date, and are proving of benefit both to the members of the Post and to the advertisers. A central location is being sought where a general military engineering library can be developed.

It was proposed at the May meeting by the American Association of Engineers that the San Francisco Post adopt the official publication of that Association, *The Pacific Engineer*, as the official publication of the Post. Following a discussion it was moved and carried that the offer be declined, and that the Association be advised that the official publication of the Post and the Society is THE MILITARY ENGINEER.

At a meeting of all committees on May 17 a plan was approved for closing the charter membership in the Post as it now stands. A plan was also approved for having an occasional social evening to which the wives and lady friends of members will be invited.

Steps have been taken to secure from members articles suitable for publication in THE MILITARY ENGINEER and also suggestions for articles.

Pittsburgh Post

WM. M. MCKEE, Farmers Bank Building.

The Pittsburgh Post of the Society of American Military Engineers was initiated at a meeting held June 17, 1920, in the Federal Building at Pittsburgh, Pa.

The meeting was called through the efforts of Lt. Col. H. B. Ferguson, Corps of Engineers, who at that time was in charge of the U. S. Engineer Office in Pittsburgh.

Colonel Ferguson called the meeting to order, stated the purpose of the Society, read some instructions bearing on the procedure of organization, and asked for nominations for temporary officers. The following temporary officers were elected:

President—E. A. Gibbs.
Vice-President—E. F. Archibald.
Secretary—W. M. McKee.
Treasurer—F. W. Henrici.
Asst. Treasurer—W. H. Horton.

The temporary organization was effected, notices sent to the daily papers, and application was made for a charter for the local post, which charter was issued on October 4, 1920.

A meeting to effect a permanent organization of the Pittsburgh Post was held in the Oliver Building, Pittsburgh, on the evening of February 15, 1921, the meeting having been called by temporary president, Mr. E. A. Gibbs, who presided at the meeting.

Among those present at this meeting was Maj. J. F. Bell, Corps of Engineers, who is in charge of the U. S. Engineer Office, Pittsburgh. Major Bell gave an interesting talk on the relations of regular army, national guard and reserve corps, and outlined the purpose of the Society of American Military Engineers of keeping up interest among civilian reserve in matters concerning an army of the future.

Nominations were asked for permanent officers of the Pittsburgh Post and it was decided to retain the temporary officers until the end of the year, namely October 4, 1921.

The next and most recent meeting of the local post was an informal but very successful one on board the U. S. Engineer Boat *Swan*, through the courtesy of Major Bell.

On May 14th the members of the post were again the guests of Major Bell on the *Swan*. Starting down the Ohio on a tour of inspection, the first stop was made at Emsworth, where the party went ashore and was met by W. D. Fairchild, Assistant United States District Engineer, who escorted the guests on a tour of inspection of the Emsworth Dam which is being constructed by the government.

Work on the locks has been halted on account of Congress not appropriating enough money to complete the dam across the river and install operating machinery. The next stop was made at Lock No. 2, in the Ohio River, at Coraopolis, where Major Bell demonstrated to his guests the operation of a movable dam, the opening of a bear trap and the lowering and raising of wickets on a dam. Dinner was served on the boat on the return trip and the party reached the city shortly after 7 o'clock.

Among those who made the trip were: Major Bell, Colonel Gibbs, Maj. W. M. McKee, Lieut.-Col. E. K. Hiles, Maj. J. S. Bragdon, in charge of the Engineer R. O. T. C. unit at the Carnegie Institute of Technology; J. W. Arras, Mr. Fairchild, E. F. Archibald, Wm. Donley, E. J. Ducey, L. B. Duff, G. E. A. Fairley, O. D. Foster, W. B. Hayes, F. G. Lee, H. C. McCormick, M. M. McKee, B. E. O'Hagen, J. S. Roob, F. K. Rodgers, D. S. Rodgers, Burt Sapp and Reese T. Scully.

Detroit Post

Maj. RICHARD G. HEWITT, 712 Ford Building.

A meeting was called by Maj. Richard B. Hewitt, June 1, 1921, at Detroit Athletic Club at 12 o'clock noon for the arrangement of a general call to complete the organization of the Detroit Post of the Society of American Military Engineers.

Present—

Col. E. M. Markham, C. of E.
Maj. M. S. MacDiarmid.
Maj. H. Augustus O'Dell.
Capt. A. L. Schuffert.
Lieut. J. French Paddock.
Fred M. Mason.
Maj. Richard B. Hewitt.

After an explanation of the "Mission" it was moved and seconded by Major O'Dell that Colonel Markham be made chairman and Major Hewitt secretary of the meeting. Motion carried.

Digitized by Google

Ordered by Colonel Markham that meeting be called for Monday, June 20, 1921, at 7:20 in the evening. Place of meeting, the Detroit Board of Commerce.

Instructions were given to Major Hewitt to prepare call for meeting and mail copies to all members of the society, reserve officers and ex-officers in the state, also to the Detroit members of the four national engineering societies, viz., civil, electrical, mechanical and mining; to post notices with all American Legion posts; to arrange for newspaper notices in Sunday issues 12th and 19th; to engage space at the Board of Commerce and secure speakers for the evening, both from civil and military life.

No other business coming before this meeting adjournment was taken until June 20, 1921, at 7:30 in the evening.

In preparation for the meeting of June 20th, the secretary mailed to 1600 engineers in the State of Michigan a four-page printed circular containing a notice of the meeting, an informal application for membership, and information concerning the organization and aims of the Society and its journal. The following paragraph is taken from this circular:

"Square Pegs Into Round Holes."

"If you took part in the late war or if you have talked with those who did, you will be aware that most of the discouragement, the bitter disappointment and heartburnings incident to the conflict were the result of men not finding the places in which they really belonged. Because of our stage of unpreparedness at the outbreak of the war, many engineers (and others) were assigned to duties without a knowledge of their experience and qualifications. Great numbers of them found their tasks uncongenial and suffered the chagrin of feeling that they were not permitted to render the service of which they were capable. It will be the function of our Society and especially its local posts to prevent a recurrence of such a situation in future."

A list of present members in various parts of Michigan was included in the circular and prospective members were urged to get in touch with them.

Los Angeles Post

C. M. Cram, 725 Central Building.

The first meeting of the Los Angeles Section of the Society of American Military Engineers was held on June 15, 1920, Maj. Frederick B. Downing acting as temporary chairman. At that meeting the following officers were elected:

President—Capt. Chas. T. Leeds.
First Vice-President—Carl B. Wirsching.
Second Vice-President—John A. Griffin.
Secretary—Burt Harmon.
Treasurer—Gerald Fitzgerald.

In addition to this meeting at which the local organization was perfected, meetings have been held on July 13, 1920, October 25, 1920, February 1, 1921, April 5, 1921 and May 3, 1921. The annual meeting will be held on June 7th, when new officers for the coming year will be elected.

At all the meetings of the section it has been the practice to gather around the banquet board at the dinner hour, after which the business of the meeting is transacted and the speaker of the evening is enjoyed. Of the six meetings, two have been in the banquet room of the Jonathan Club, one has been at the Philip Levy Cafe, and three have been at the Roma Cafe.

The section has been most fortunate in its ability to obtain competent and interesting speakers. Among these are James W. Foley, Colonel Deakyne, Corps of Engineers; Colonel Keller, Corps of Engineers; General Taylor, Corps of Engineers; Capt. Hans Kramer, C. of E., Professor of Military Science and Tactics at the California Institute of Technology; Mr. McCollom and Mr. Frank Mittenzwei.

Starting at the first meeting with a membership of 46, the local membership committee has built the local membership up to a present roster of 68 names, and the efforts of this committee will be felt for some time in a growing roster and a growing interest in the society and the affairs of the local section.

Washington Post

E. P. Ellis, 2007 O Street, N. W., Washington, D. C.

At an enthusiastic meeting held at the Army and Navy Club on May 26 of officers and former officers of the Engineers, U. S. Army, who are stationed or living in the vicinity of the national capital, the Washington Post of the Society of American Military Engineers was organized and the following officers elected: C. H. Birdseye, President; J. H. Wheat, Vice-President; E. P. Ellis, Secretary-Treasurer; H. S. Graves and Maj. J. J. Kingman, Directors.

With an initial membership of more than 50, the new post has an excellent prospect of success. As its principal objects will be the diffusion of knowledge of military engineering, fostering public interest in preparedness and the development of the Citizens' Military Training Camps, the new post will materially aid the Society of American Military Engineers in its efforts along these lines.

A smoker of the Washington Post of the Society of American Military Engineers was held at the residence of Maj. George Oakley Totten, Jr., on June 21, with President C. H. Birdseye in the chair.

The enthusiastic group of officers and ex-officers of the Engineers, U. S. Army, who were present augurs well for the future of the new post, which, though less than a month old, has a membership of more than 50.

The program of the evening included speeches by officers who took prominent parts in the rapid expansion of the Corps of Engineers to meet the war emergency.

Maj. Gen. W. M. Black, retired, formerly Chief of Engineers, deplored the reduction in the size of the army that is contemplated in pending legislation. As instructors for the training camps are drawn from the commissioned and non-commissioned personnel of the army, the proposed reductions will make it difficult to obtain instructors of the experience necessary to make the training camps fully effective in view of the short period of training that is given.

The general lack of public interest in military preparedness is not surprising in the opinion of Maj. Gen. Lansing H. Beach, Chief of Engineers, who stated that opposition to military expenditures is always strong following every great war. The War Department is making strenuous efforts to offset the reduction in size of the army and the failure to adopt universal military service by developing the summer camps. Maj. D. I. Sultan, of the General Staff, stated that while it may not be possible for the country to be fully prepared for war, the Citizens' Military Training Camps, which will be held this summer in all sections, will aid materially in creating a force having sufficient training to form a valuable military asset. In his opinion the veterans of the World War should not be expected to bear the burdens of another conflict, which must be borne by the young men now reaching maturity.

The plans for the camps this year, as outlined by Major Sultan, provide for basic training only, to be followed next year by more advanced work which will qualify for commissions in the Officers' Reserve Corps. The program outlined is one that will appeal to all red-blooded young men.

Digitized by Google

With not more than five hours' work each day and ample opportunity for athletics and other amusements, those who go through the camps will be benefited physically and mentally and the associations can not fail to be uplifting.

Only 10,800 men can be accommodated this year at the camps. As the indications point to a far greater number of applications, candidates should not delay seeking admission. The camp for this locality will be at Camp Meade, August 1 to September 1.

At the conclusion of the speeches, Miss Floravianti, Jack Carter and Harlan Randall, of the Washington Opera Company, rendered operatic selections in the adjoining garden, and little Miss Jerry Williams danced, the attractive sylvan surroundings adding to the effect.

New Orleans Post

E. H. COLEMAN, 822 Perdido Street.

Arrangements have been made with the Louisiana Engineering Society to hold their next regular monthly meeting in conjunction with the local section of the Society of American Military Engineers. The usual technical paper will be replaced by an informal talk by Lieut.-Col. E. J. Dent, C. of E. The purpose of this meeting will be to familiarize the local engineers with the work and objects of our society and to establish closer relations with other engineering organizations here, preparatory to extending our membership.

Seattle Post

J. M. CLAPP, 602 Burke Building.

The first real effort to establish a post of the Society of American Military Engineers at Seattle was made by Brig. Gen. H. F. Hodges, then in command of the North Pacific Artillery District, and Lieut. Col. J. A. Woodruff, Corps of Engineers, then district engineer for Puget Sound. Invitations were sent to all interested engineers to meet at the U. S. Engineer Office, 602 Burke Building, on June 15, 1920. On this evening some eleven engineers, all but two of whom had seen service overseas, met and discussed the matter of organizing a local post. General Hodges presided at this meeting. A committee on organization was appointed, and Colonel Woodruff, who at the time was on an inspection trip in Alaska, was elected as temporary president.

A second meeting was held at the Seattle Chamber of Commerce rooms on August 15th, at which nine engineers were present. General Hodges again presided and gave many valuable and helpful suggestions. Colonel Woodruff having been transferred to another district, his successor, Col. E. H. Schulz, C. of E., was elected temporary president, and a temporary organization was completed by the election of Capt. Bertram Dean, Reserve Corps, as temporary vice-president, and J. M. Clapp, consulting engineer, as temporary secretary and treasurer. Committees were appointed, and the dues fixed at 50 cents per member for the balance of the year 1920 and $1.50 annually thereafter.

On October 8, seventeen members assembled at the Chamber of Commerce rooms, adopted a constitution and by-laws and fixed on December 3 as the date of the annual meeting and dinner. The program committee was instructed to arrange with General Hodges for a talk on the defenses of Puget Sound. However, the general was transferred from Seattle before this date, and other arrangements were made.

On December 3rd the society held its annual meeting and dinner at the Arctic Club, at which fifty-four members and guests were present. Addresses were made by Mayor Hugh M. Caldwell; Mr. T. S. Lippy, president of the Port Commission of Seattle; Claude C. Ramsay, chairman, County Commissioners of King County, and Lieut. Col. A. O. Powell, Engineer Reserve Corps. The principal speaker of the evening was Col. J. B. Cavanaugh, C. of E., who in his usual happy vein gave a very interesting talk on the Corps of Engineers and the relation of the reserve officers to the regular establishment. He also told of the great work that had been done in the World War, and showed the necessity of having a partly trained corps of civilian engineers, many of whom were better informed on special lines of engineering than were the regular officers. He pointed out the necessity for co-operation between the civil and military bodies, and how necessary it was to have some training before war actually did occur. He pointed out that the Society of American Military Engineers offered this medium of co-operation, and told of the organization of the Portland Post and of its contemplated activities, which was of much interest to those present.

Following the dinner, a business meeting took place and a permanent organization was effected. The present officers, elected at that meeting, are: Col. E. H. Schulz, president; J. M. Clapp, secretary; Maj. Oscar A. Piper, Reserve Corps, vice-president, and H. J. M. Baker, treasurer.

Two meetings have taken place since that date. At the first of these meetings, on March 11th, C. F. Uhden, chief engineer of the Skagit River development work, read a paper illustrated by slides showing the problems that had been met in that great work, and the manner in which they were solved. Much interesting information was given, illustrative of the power generated.

The second meeting took place on May 16, 1921, at which about forty members and guests had the pleasure of listening to two very interesting papers. One of these was by Sergt. E. H. Sirman, late of the 56th Engineers (Searchlight), and dealt with the activities of that regiment on the battlefields and with the operation of searchlights. The second paper was by Col. C. A. Seoane, of the Signal Corps, U. S. A., on the subject of the cables of the Pacific, including those of Alaska. His statements on this important subject were followed with keen interest.

The membership of the local post is now twenty-three and bids fair to be soon increased.

Cleveland Post

JAMES H. REDING, 1727 Bryn Mawr Road, East Cleveland.

This post has been holding meetings at intervals of about one month from the date of actual organization on January 21st up to the present. During July and August no meetings will be held. Our programs have consisted of talks, usually illustrated by slides and films, followed by discussion. Our membership is now about 52 and the attendance at meetings has varied between 34 and 39.

The speakers and subjects have been:

On February 28th—Speaker, Lieut. Col. Elliott H. Whitlock. Subject, Reminiscences of an Engineer Officer in the Late War. Colonel Whitlock, among other things, had charge of the engineer depot at Is-sur-Tille. He gave many interesting comparative statistics regarding engineer material and showed slides of military construction and destruction, all of which were made to live by the interspersed anecdote and description.

On April 4th—Speaker, Lieut. Col. Byron C. Goss. Subject, Gas Warfare in France. Colonel Goss was in charge of gas warfare in the Second Army and in the First Army prior to the formation of the Second. This talk was illustrated with both slides and films, showing

Digitized by Google

types of gas shells and gas being used in action. The tactical use of gas was particularly emphasized.

On May 2nd—Col. H. J. Twelvetree. Subject, The Functioning of a Division; the Staff and the Engineers. Colonel Twelvetree was G-1 of the 37th Division and spoke interestingly and instructively from experience.

On June 6th, the last meeting before the summer recess, will be a smoker, to further good acquaintance and afford a better opportunity for discussing matters of post policy than there has been time for at previous meetings.

We are finding difficulty in laying out a program which is both feasible and will appreciably further the purposes for which the society and posts are organized.

Our post president, John R. McQuigg, has recently been promoted from colonel, commanding 112th Engineers, to brigadier general, 37th Division.

Philadelphia Post

Lt. Col. W. G. LADUE, 815 Witherspoon Building.

On March 24th, Major General Somerall spoke before the post on the work of the engineer troops at the front. His talk was most helpful and inspiring. Many interesting and instructive points were brought out regarding the engineer regiments as combat troops.

On April 28th Maj. Gen. W. C. Langfitt spoke to the post on the subject of the railways and railway service during the war. His talk was very complete in regard to railways with the British and also with the French troops. He supplied much valuable data, especially with regard to various types and characteristics of locomotives tried, discarded and used.

Lt. Col. G. A. Youngberg spoke at the May meeting on the work of the General Staff in France and laid stress on the engineer work.

New Posts

The following Posts are now in course of organization:

Akron Post—Lieut. Sears S. Day, Lock Box 254, East Akron, Ohio.

Baltimore Post—Capt. John S. Doyle (E. O. R. C.), 309 Custom House, Baltimore, Md.

Boston Post—Lieut. Louis A. Armistead, Room 701, 108 Massachusetts Avenue, Boston, Mass.

Buffalo Post—Mr. Albert F. Krause, Builders Exchange, Court and Pearl St., Buffalo, N. Y.

Cincinnati Post—Capt. Hugh J. Krampe (E. O. R. C.), 1608 First National Bank Building, Cincinnati, Ohio.

Denver Post—Mr. Charles H. Rankin, 700 Tramway Building, Denver, Colo.

Indianapolis Post—Capt. C. L. Harrod (E. O. R. C.), Public Service Commission of Indiana, Indianapolis, Ind.

San Antonio Post—Mr. Ray S. Quick, Box 262, San Antonio, Texas.

Twin Cities Post—Capt. John F. Druar (E. O. R. C.), 512 Globe Building, St. Paul, Minn.

Our List of "Who's Where"

In this issue will be found a list of over one hundred members and subscribers to THE MILITARY ENGINEER whose mail has been returned unclaimed from the latest address furnished us. Won't you please look this list over and inform us of the present addresses of any of your friends whose names are listed? Many of them have paid their dues for the current year and are entitled to their copies of the magazine.

Personals

Leave of absence for two months and twenty-five days has been granted to Col. SHERWOOD A. CHENEY, Corps of Engineers, at the expiration of which he has been ordered to Fort Leavenworth, Kansas, for duty as instructor at the General Service Schools.

Col. CLEMENT A. F. FLAGLER, Corps of Engineers, has been relieved from his present assignment and duties in the Hawaiian Islands.

Col. CHARLES KELLER, Corps of Engineers, in addition to his other duties, is designated, during the absence of Lieut. Col. WM. KELLY, Corps of Engineers, to represent the War Department on the Advisory Board of the Superpower Survey which is being conducted under the Department of the Interior.

Col. GEORGE P. HOWELL, Engineers, and Lieut. Col. CHARLES Y. BROWNLEE, Medical Corps, have been detailed as members of the Army Retiring Board appointed to meet at Headquarters, Fourth Corps Area, Fort McPherson, Georgia.

Leave of absence granted to Col. CHARLES L. POTTER, Corps of Engineers, has been extended one month and fifteen days.

Lieut. Col. ALBERT E. WALDRON, Corps of Engineers, has been detailed for duty as Instructor, Engineers, Pennsylvania National Guard.

Maj. ROBERT W. CRAWFORD, Corps of Engineers, has been relieved from his duties at Cornell University, Ithaca, N. Y., and ordered to Washington for assignment to duty in the office of the Chief of Engineers.

Maj. BEVERLY C. DUNN, Corps of Engineers, has been relieved from his duties at Camp A. A. Humphreys, Virginia, and ordered to New York City.

Maj. GLEN E. EDGERTON, Corps of Engineers, in addition to his other duties, has been designated as official representative of the Corps of Engineers on the Government Division of the National Research Council and also on the Technical Committee for the War Department.

Maj. PHILIP B. FLEMING, Corps of Engineers, has been transferred from New York City to Camp A. A. Humphreys, Virginia, for duty as instructor at the Engineer School.

Maj. ALFRED L. GANAHL, Corps of Engineers, has been transferred from the Canal Zone to Camp A. A. Humphreys, Virvinia.

Maj. CRESWELL GARLINGTON, Corps of Engineers, has been detailed as a member of the Board of Officers appointed to consider a system of National Highways in connection with the rural post roads.

Maj. WM. A. JOHNSON, Corps of Engineers, in addition to his other duties, has been assigned to the Third Engineers and has been ordered to report to the Commanding General, Hawaiian Department, for assignment to duty as Department Engineer, relieving Col. CLEMENT A. F. FLAGLER, Corps of Engineers.

Maj. THOMAS B. LARKIN, Corps of Engineers, has been designated as alternate representative of the Corps of Engineers on the Technical Committee for the War Department.

Maj. DAVID MCCOACH, Jr., General Staff (Corps of Engineers) has been ordered relieved from further detail in the General Staff Corps effective August 21, 1921.

Maj. GEORGE MAYO, Corps of Engineers, has been transferred from Camp A. A. Humphreys, Virginia, to Portland, Oreg.

Majs. RICHARD C. MOORE, MARK BROOKE, WARREN T. HANNUM, all of the Corps of Engineers, have been detailed as instructors at the General Service Schools for a period of two years.

Maj. ROGER G. POWELL, Corps of Engineers, has been transferred from Washington, D. C., to the First Engineers, Camp Dix, New Jersey.

Maj. XENOPHEN H. PRICE, Corps of Engineers, has been relieved from further detail as a student at the Massachusetts Institute of Technology, Cambridge, Mass., and ordered to San Francisco, Calif.

Maj. DANIEL D. PULLEN, Corps of Engineers, has been ordered to report to the Commanding General, Panama Canal Department, for assignment to duty as Department Engineer, vice Col. CHARLES S. RICHE, U. S. A., Retired.

Maj. RUFUS W. PUTNAM, Corps of Engineers, has been ordered from Camp A. A. Humphreys, Virginia, to Chicago, Ill.

Maj. CLARENCE S. RIDLEY, Corps of Engineers, has been ordered to report to the Governor, Panama Canal, for assignment to duty.

Maj. WM. F. TOMPKINS, Corps of Engineers, has been transferred from Washington, D. C., to Camp A. A. Humphreys, Virginia.

Capt. PIERRE A. AGNEW, Corps of Engineers, has been relieved from duty at Camp A. A. Humphreys, Virginia, and ordered to report to the Chief of Engineers for assignment to duty.

Capt. LEONARD B. GALLAGHER, Corps of Engineers, has been transferred from the Panama Canal to the First Engineers, Camp Dix, New Jersey.

Capt. LLEWELLYN B. GRIFFITH, Corps of Engineers, has been relieved from further detail as a student at the Massachusetts Institute of Technology, Cambridge, Mass., and ordered to report to the Chief of Engineers for duty in his office.

Capt. HARTLEY M. HARLOE, Corps of Engineers, has been ordered to New York City and report for assignment to duty.

Digitized by Google

Capt. HENRY HUTCHINS, Jr., Corps of Engineers, has been granted leave of absence for one month and twenty days.

The following named officers have been transferred from Camp Benning, Georgia, and assigned to the organization indicated: Capt. WARNER A. LYON, Fourth Engineers, Camp Lewis, Washington; Capt. JOHN A. STRANG, Second Engineers, Camp Travis, Texas; Capt. F. RUSSELL LYONS, Twelfth Engineers, Camp Grant, Illinois.

Capts, JAMES C. MARSHALL, ANDERSON T. W. MOORE, EUGENE M. CAFFEY, and First Lieut. DAVID W. GRIFFITHS have been ordered assigned to duty as instructors at the Engineer School.

Capt. THOMAS H. MESSER, Corps of Engineers, has been granted leave of absence for three months on account of sickness.

Capt. RAYMOND G. MOSES, Corps of Engineers, has been granted leave of absence for one month and fifteen days.

Capt. ALEXANDER N. NEILSON, Corps of Engineers, has been ordered from Camp A. A. Humphreys, Virginia, to Washington, D. C., for assignment to duty.

Capt. DAVID L. NEUMAN, Corps of Engineers, has been relieved from his duties in the office of the District Engineer, New York City, and ordered to report to the Commanding General, New York General Intermediate Depot for duty.

Capt. ROBERT R. NEYLAND, Jr., Corps of Engineers, has been granted leave of absence for one month and twenty-three days.

Capt. DANIEL NOCE, Corps of Engineers, has been granted leave of absence for twenty-one days.

Leave of absence granted to Capt. GEORGE J. NOLD, Corps of Engineers, has been extended one month.

The resignation of Capt. ALBERT W. PIODA, Corps of Engineers, has been accepted by the President.

Capt. STANLEY L. SCOTT, Corps of Engineers, has been granted leave of absence for one month and twenty-four days.

Capt. AMOS B. SHATTUCK, Jr., Corps of Engineers, has been transferred from Camp A. A. Humphreys, Virginia, to the Fourteenth Engineers, Manila.

Capt. WM. A. SNOW, Corps of Engineers, has been relieved from further detail as a student at the Massachusetts Institute of Technology, Cambridge, Mass., and upon the expiration of leave of absence for one month and fifteen days, has been ordered to report to the Chief of Engineers for duty in his office.

Capt. CHARLES H. SWICK, Corps of Engineers, has been relieved from his present duties at Wilson Dam, Florence, Ala., and assigned to the Third Engineers, Honolulu, T. H.

Capt. LUDSON D. WORSHAM, Corps of Enggineers, has been granted leave of absence for one month.

First Lieut. VERE A. BEERS, Corps of Engineers, has been granted leave of absence for thirteen days.

First Lieut. FRANK O. BOWMAN, Corps of Engineers, has been transferred from Camp A. A. Humphreys, Virginia, to the Third Engineers, Honolulu, T. H.

The following named officers of the Corps of Engineers are relieved from their present duties at Camp A. A. Humphreys, Virginia, and assigned to the organization indicated after their names: First Lieut. BENJAMIN F. CHADWICK, Second Engineers, Camp Travis, Texas; First Lieut. JOHN S. NILES, Second Engineers, Camp Travis Texas; First Lieut. KARL B. SCHILLING, Second Engineers, Camp Travis, Texas; First Lieut. LESLIE R. GROVES, Jr., Fourth Engineers, Camp Lewis, Washington; First Lieut. WILLIAM V. HESP, Eighth Engineers, Fort Bliss, Texas; First Lieut. JOSEPH J. TWITTY, Eighth Engineers, Fort Bliss, Texas; First Lieut. WILLIAM C. BENNETT, Jr., Ninth Engineers, Fort Sam Houston, Texas; First Lieut. ROBERT E. YORK, Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. ORVILLE E. WALSH, Ninth Engineers, Fort Sam Houston, Texas; First Lieut. HOWARD V. CANAN, Twelfth Engineers, Camp Grant, Illinois; First Lieut. CHARLES D. JEWELL, Twelfth Engineers, Camp Grant, Illinois; First Lieut. WENDELL P. TROWER, Twelfth Engineers, Camp Grant, Illinois; First Lieut. JOHN H. ELLEMAN, Twelfth Engineers, Camp Grant, Illinois; First Lieut. FREDERICK B. BUTLER, Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. MARK M. BOATNER, Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. DAVID T. JOHNSON, Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. EDWIN G. SHRADER, Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. OTTO PRAEGER, Jr., Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. JAMES P. JERVEY, Jr., Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. EUGENE L. VIDAL, Thirteenth Engineers, Camp A. A. Humphreys, Virginia; First Lieut. ARTHUR J. SHERIDAN, Ninth Engineers, Fort Sam Houston, Texas.

First Lieuts. CLAUDE H. CHORPENING and JOHN P. DIETRICH, of the Corps of Engineers, have been transferred from Camp A. A. Humphreys, Virginia, to the Third Engineers, Honolulu, T. H.

First Lieut. HARRY HAIGH, Corps of Engineers, has been granted leave of absence for two months on account of sickness.

First Lieutes. NEWELL L. HEMENWAY and BEVERLY C. SNOW, of the Corps of Engineers, have been transferred from Camp A. A. Humphreys, Virginia, to the Fourteenth Engineers, Manila, P. I.

First Lieut. JOHN B. HUGHES, Corps of Engineers, has been transferred from Camp A. A. Humphreys, Virginia, to the Eleventh Engineers, Canal Zone.

First Lieut. HOMER B. PETTIT, Corps of Engineers, has been transferred from Camp Pike, Arkansas, to the Eleventh Engineers, Canal Zone.

First Lieut. VOLNEY A. POULSON, Coast Artillery Corps, has been transferred to the Corps of Engineers and assigned to duty with the Second Engineers at Camp Travis, Texas.

The orders affecting First Lieut. THOMAS H. STANLEY, Corps of Engineers, have been amended to read "Eighth Engineers, Fort Bliss, Texas," instead of "Second Engineers, Camp Travis, Texas."

The resignation by First Lieut. HAROLD A. TAYLOR, Corps of Engineers, of his commission as an officer of the Army, has been accepted by the President.

Cols. WILLIAM W. HARTS, and WILLIAM P. WOOTEN, both of the Corps of Engineers, have been assigned to duty as student officers at the General Staff College.

Cols. GEORGE M. HOFFMAN and FRANK C. BOGGS and Lieut. Col. GEORGE B. PILLSBURY, all of the Corps of Engineers, upon completion of their duties at the General Staff College, Washington Barracks, D. C., have been ordered to report to the Chief of Engineers for duty in this office.

Col. WILLIAM B. LADUE, Corps of Engineers, has been transferred from the First Engineers to the Eleventh Engineers, Panama Canal Zone.

Maj. PAUL T. BOCK, Corps of Engineers, has been transferred from New York City to Washington, D. C., for duty in the office of the Chief of Engineers.

Maj. ROBERT C. WILLIAMS, Corps of Engineers, has been transferred from the Infantry School, Camp Benning, Georgia, to Vicksburg, Miss.

Capt. WILLIAM M. HOGE, Jr., Corps of Engineers, has been assigned to duty as a student at the Massachusetts Institute of Technology.

Capt. HAROLD R. RICHARDS, Corps of Engineers, has been assigned to duty as a student at the Carnegie Institute of Technology.

Eah of the following name dofficers of the Corps of Engineers is relieved from further duty at the place specified after his name and assigned to duty as a student at the Massachusetts Institute of Technology; Capt. WILHELM D. STYER, Cambridge, Mass.; Capt. CHARLES H. CUNNINGHAM, U. S. Military Academy, West Point, N. Y.; Capt. DWIGHT F. JOHNS, U. S. Military Academy, West Point, N. Y.; Capt. ELROY S. J. IRVINE, Office Chief of Engineers, Washington, D. C.; Capt. ROBERT G. GUYER, U. S. Military Academy, West Point, N. Y.; Capt. ROBERT A. SHARRER, U. S. Military Academy, West Point, N. Y.; Capt. FREDERICK W. BONFILS, U. S. Military Academy, West Point, N. Y.; Capt. WILLAM F. HEAVEY, U. S. Military Academy, West Point, N. Y.

Leaves of absence varying from 23 days to 1 month and 15 days have been granted to First Lieuts. HOWARD V. CANAN, JOHN H. ELLEMAN, LESLIE R. GROVES, Jr., NEWELL L. HEMENWAY, JOHN B. HUGHES, KARL B. SCHILLING, BEVERLY C. SNOW, WENDALL P. TROWER, all of the Corps of Engineers.

First Lieut. BERNARD S. STEARNS, Corps of Engineers, has been transferred from Camp A. A. Humphreys, Virginia, to the First Engineers, Camp Dix, New Jersey.

Each of the following named officers of the Corps of Engineers has been relieved from further duty as a student officer at the Engineer School, Camp A. A. Humphreys, Virginia, and assigned to the duty indicated: First Lieut. WILLIAM W. WANAMAKER, Professor of Military Science and Tactics, Missouri School of Mines, Rolla, Mo.; First Lieut. CORNMAN L. HAHN, Assistant Professor of Military Science and Tactics, Virginia Polytechnic Institute, Blacksburg, Va.; First Lieut. MORRIS W. GILLAND, Assistant Professor of Military Science and Tactics, Virginia Military Institute, Lexington, Va.; First Lieut. CHESTER K. HARDING, Assistant Professor of Military Science and Tactics, University of Cincinnati, Cincinnati, Ohio; First Lieut. VERE A. BEERS, Assistant Professor of Military Science and Tactics, Alabama Polytechnic Institute, Auburn, Ala.

Addresses Wanted

The Secretary of the Society would be pleased to receive any information concerning the present addresses of the following named members, whose mail has been returned unclaimed:

Lieut. Col. Frederick W. Albert, The Tuxedo, Apt. 304, Washington, D. C.
Capt. J. D. Arnott, 134 York St. Vallejo, Calif
Lieut. Ben Badgley, 708 B St., San Diego, Calif.
Capt. H. L. Baker, Woolwich, Me.

Lieut. E. C. Ball, 814 Carroll St., Saginaw, Mich.
Lieut. John T. Bancroft, 40 Morgan, Philadelphia, Pa.
Capt. William A. Bassett, Mill Basin Inn, Mill Basin, Brooklyn, N. Y.
Capt. W. G. Baxter, 53 Eddy St., Providence, R. I.
Lieut L. H. Belk, Glen Ullin, N. Dak.
Mr. C. M. Binford, Riley, W. Va.
Mr. Ridgely Brewerton, care of Fortification Dept., Panama Canal, C. Z.
Lieut. A. H. Brown, Brunswick, Ga.
Capt. Edward W. Bullard, care of Johnson Bronze Works, New Castle, Pa.
Capt. B. R. Butt, Clarksburg, W. Va.
Capt. G. B. Byam, 1600 Q St., Washington, D. C.
Lieut. Col. Ralph E. Comeron, 435 Woodward Ave., Detroit, Mich.
C. L. Catlin, 728 S. Denver St., Tulsa, Okla.
Capt. J. L. Church, Montana Club, Helena, Mont.
Capt. Wm. A. Clark, Third Engineers, Manila, P. I.
Lieut. E. S. Cloud, 1751 19th St., Cleveland, Ohio
Harry R. Cooper, 2154 Esplanade Ave., New Orleans, La.
Capt. John T. Costello, Room 408 Majestic Building, Atlanta, Ga.
Capt. Harry M. Crawford, 500 Pearl St., So. Brownsville, Pa.
Capt. Marvin L. Davis, 100 College Ave., Princeton, W. Va.
Mr. John K. Deloach, 52 Sterling St., Atlanta, Ga.
Capt. John H. Devine, First U. S. Engineers, Camp Knox, Kentucky.
F. P. Dickson, Jr., Amarillo, Texas.
Lieut. R. G. Dillaway, 123 N. 9th St., Miles, Mont.
Mr. J. D. Dixon, Chico, Calif.
D. J. Donovan, 316 19th St., Milwaukee, Wis.
J. L. Doyle, Box 732, Johnstown, Pa.
Mr. H. K. Dyer, care of Aberthaw Construction Co., West End Trust Building, Philadelphia, Pa.
C. S. Elliot, 613 Mills Building, El Paso, Texas.
Mr. N. E. Emmons, 27 Lewis St., Hartford, Conn.
Mr. J. H. Feehan, 207 S. 45th St., Philadelphia, Pa.
Mr. Calvert Burke Filbert, Maison Blanche Annex Building, New Orleans, La.
Maj. Thomas D. Finley, C. of E., 7th Engineers, Camp Gordon, Georgia.
Mr. J. H. Flood, San Francisco, Calif.
J. J. Flynn, Lakehurst Proving Ground, Lakehurst, N. J.
Mr. Everett L. Fornyou, B. & O. Building, Baltimore, Md.
N. C. Frith, care of A. W. Shaw Co., 299 Madison Ave., N. Y. City.
Second Lieut. Wm. G. Gardner, 417 Union St., Schenectady, N. Y.
Mr. E. C. Garvin, Court House Building, Brunswick, Ga.
Lieut. N. Gerten, 41 Elmhurst Ave., Long Island, N. Y.
Capt. F. M. Gibson, 2273 83d St., New York City.
Capt. D. E. Godfrey, 312 Union League Building, Los Angeles, Calif.
E. L. Gonyou, 907 Delaware Ave., Wilmington, Del.
H. K. Graf, 708 A. O. U. W. Building, Little Rock, Ark.
Mr. G. T. Granger, 1609 Cadiz, Dallas, Texas.
Col. Ernest Graves, Commanding 2d Engineers, Camp Travis, Texas.
Mr. Wallis Green, Thornton, W. Va.
Mr. B. C. Grey, Columbus, Ohio.

Col. J. M. Wright, 1051 Spruce St., Philadelphia, Pa.

Silver Button Winners

One hundred and seventy-five new members within sixty days! This is indeed an excellent showing and is proof that members take an enthusiastic interest in building up the Society. So many requests have been received from members securing one or two new members that additional time be allowed for them to bring their total up to three, that it has been decided to extend *for thirty days the time limit of members who already have one or two applicatios to their credit.* A complete list of silver button winners follows:

L. R. Lohr, Camp Humphreys, Virginia	8
Philip B. Fleming, Whitehall Building, New York City	6
S. M. Felton, 1121 Peoples Gas Building, Chicago, Ill.	5
L. E. Atkins, Military Department, U. of I., Urbana, Ill	4
Wm. P. Cowles, 3227 Portland Avenue, Minneapolis, Minn.	4
C. B. Falley, Fort Sam Houston, Texas	4
W. A. Hill, 135 Seventh Ayenue, La Grange, Ill.	4
J. D. Schmidt, Custom House, New Orleans, La.	4
R. C. White, 1022 Railway Exchange Building, St. Louis, Mo.	4
E. G. Bliss, Munitions Building, Washington, D. C.	3
P. S. Bond, 22d Regiment Armory, New York City	3
B. B. Browne, 12th Engineers, Camp Grant, Illinois	3
L. J. Canfield, Missoula, Mont.	3
Frank J. Clark, 42 Cedar Street, Dobbs Ferry, N. Y.	3
E. K. Coe, City Engineer, Duluth, Minn.	3
F. W. Greene, 6203 Washington Avenue, St. Louis, Mo.	3
F. W. Henrici, 962 Kennebec Street, Pittsburgh, Pa.	3
Richard B. Hewitt, Birmingham, Mich.	3
F. G. Jonah, Frisco R. R. Co., St. Louis, Mo.	3
Wm. R. Lee, Minneapolis, Minn.	3
B. A. Miller, Chief Engineer, A. F. G., Coblenz, Germany	3
E. B. Murray, Camp Travis, Texas	3
H. L. Peckham, Box 629, Rolla, Mo.	3
W. H. Peters, Fort Jay, N. Y.	3
Clarence E. Raynor, 917 Bell Building, Montgomery, Ala.	3
Willis R. Tenney, 50 Court Street, Brooklyn, N. Y.	3
Dwight Trevarthen, Box 763, Montgomery, Ala.	3
W. B. Tuttle, San Antonio Pub. Service Co., San Antonio, Texas	3
F. B. Wieners, Air Service Pilot School, March Field, California	3

Dues for 1921

Are you one of the 4 per cent?

Ninety-six per cent of our members have paid their dues for 1921. This is an excellent showing, but the Engineers have always had a 100 per cent record!

If you are one of the "hold-outs," won't you reduce the 4 per cent list by one?

Dues for 1922

In order to simplify our accounts we have arranged to have all memberships expire at the end of the year. All members whose dues are payable after the receipt of No. 70 of THE MILITARY ENGINEER (the present issue) will be billed for $6.00—$1.50 for the balance of 1921 and $4.50 for 1922, and all members whose dues are payable after the receipt of No. 71, will be billed for $5.25—75 cents for the balance of 1921 and $4.50 for 1922.

It is earnestly hoped that members will co-operate by paying their dues promptly, thus reducing clerical work and postage incident to sending duplicate bills.

The Civilian Engineer

How can he best be trained for military emergencies, and how used to best advantage?

A paper read before the San Francisco Post, Society of American Military Engineers

By

J. W. Williams

Lieutenant Colonel, E. O. R. C.; Chief Engineer, Northwestern Pacific Railroad; formerly Lieutenant Colonel, 18th Engineers

This article has reference only to the training and use of civilian engineers in the technical service of the army and is not intended to apply to other arms of the service. It has particular reference to the engineer reserve officer, but some comment will be made in regard to the use, during war, of engineers who may not be reserve officers.

During the war I had a good opportunity to observe the problems, efficacy and shortcomings of the engineer reserve officer in the supply service, and feel that I can speak with some authority on that phase of the subject. A somewhat different training may be desirable for the combatant engineer, but as a technical officer the fundamentals of the training should be the same.

The principal value of an engineer reserve officer to the army is his experience as an engineer and his ability to direct men engaged on engineering projects. If he has not acquired this in his civil training, the limited amount of military training which can be given him in a training camp, or elsewhere, can not make of him a satisfactory officer of engineers.

Proper assignment of engineer reserve officers is more important than their military training. So far as practical the assignments should be made in advance of an emergency, when there is time available for an orderly and thorough study of the officer's qualifications. The reserve officer's personal statement of his qualifications should not be accepted as the sole guide in assigning him. The engineer officers of the regular army should by careful verbal inquiry among members of technical societies and leading engineers, determine the civil rating of the reserve officer, the work he has done and is doing, and the success with which he has handled his work. Such inquiry if tactfully conducted would not embarass the reserve officer. It is realized that this would be a task of great magnitude if applied to all engineer reserve officers, but if we are to have an efficient engineer reserve corps, some means must be found of assembling and keeping currently corrected an accurate record of reserve officers' qualifications. This is the base on which the entire structure must be built and if it is not reasonably sound, months will elapse after war is declared before the engineer reserve officers can be fitted into the armies in positions which they are best qualified to fill.

In order to make the suggested plan more workable, the inquiries of the regular officers as to the qualifications of reserve officers could be limited to the reserve officers of field officer grade and the reserve field officers could be required to gather and correct the data relative to officers of lower grade, subject to review by officers of the regular establishment charged with such duties. If reserve officers are assigned to skeleton organizations in time of peace, they can readily be made responsible for keeping correct records of the reserve officers who will come under their command when called to active duty.

No system of examinations can as satisfactorily determine the qualifications of engineer reserve officers as personal observation and inquiry.

The War Department's roster of engineers should not be confined to reserve officers only, but should include all engineers of special qualifications whose services might be used to the public good in time of war. This would apply especially to those incapacitated for active military duty by age or physical disability. In compiling and currently correcting such a roster, the engineer reserve officer could be of great assistance.

What are the qualifications of a satisfactory engineer reserve officer?

Good character, good physical condition, experience in planning and executing engineering projects, ability to lead, cheerful submission to discipline and a desire to acquire a knowledge of military matters. The term engineering is used in a general sense. A good superintendent or foreman of construction or operation is better fitted for some duties assigned to engineer officers than a technically educated engineer.

As the engineer reserve officer is to be used in time of war only, some qualifications which may be necessary for a regular officer can be dispensed with in the case of the reserve; for example, the social graces. During both peace and war, the regular officer is frequently assigned duties of a diplomatic nature or as an agent of the government where polish and education are necessary to the credit of the United States. A reserve officer lacking in those attainments can be assigned to duties where they are not particularly necessary. The rough diamond type of hard-hitting leaders of men and builders of works, should not be overlooked in building up the Engineer Officers' Reserve Corps.

The training camp offers the only satisfactory method of training the enlisted personnel of the engineer reserve corps and the most satisfactory method of educating the officers in military matters, but the training of officers should not be limited to the training camp nor should the retention of a commission in the engineer reserve corps be dependent on attendance at a training camp. If training camp attendance is made obligatory, a large number of the ablest engineer reserve officers will be compelled to resign, and many who should and would be in the corps but who have not applied for commissions, due to uncertainty as to the obligations involved, will remain out per-

Digitized by Google

manently. This class constitutes a large number of both the older and younger public spirited men who are in actual direction of engineering projects analogous to those required with the armies in time of war. It is inevitable that a large number of this class will be offered and will accept commissions in case of war and it is better that they be commissioned in the reserve and given such training as is possible outside of the training camp, than to be accepted in time of emergency without any previous military training.

Those officers assigned to skeleton organizations whose service when called to active duty will be with troops, should unquestionably be required to attend the training camps. Those selected for staff, administrative and other duties not involving the command of troops, can receive military training otherwise.

Military administration and law, army regulations, court-martial procedure, customs of the service, military reports, orders and correspondence, army financing and requisitions and similar subjects, can be taught by a carefully prepared correspondence course which all reserve officers should be required to take.

Reserve officers residing in the vicinity of corps headquarters, army posts or other military centers, could be required to attend lectures and classes conducted by regular officers and following a carefully prepared program.

If the law permits, or can be amended to permit, reserve officers on inactive status could sit as members of courts-martial and army boards and the few having the advantage of this special training could, when called to active service, materially assist those officers who had received a more meager training in such matters, which are of unusual intricacy to the civilian.

Reserve officers residing in the vicinity of army posts could be formed into voluntary classes for military drill and an officer or non-commissioned officer of the regular army detailed to instruct them.

These measures are not submitted as preferable to the training camp, but only as a suggestion for supplementing it and for giving the best possible military training to such experienced engineers as desire to serve in case of war, but are unable to attend a training camp two weeks or more annually on account of the exacting nature of their civil duties. Many busy engineers can spare an evening, a half day or day quite frequently for military training obtainable in close proximity to the scene of their work or homes, who could not absent themselves from their work for two weeks or more continuously, at a time designated by the military authorities. Many men of family who take only two weeks vacation each year would be reluctant to spend their entire vacation at a training camp, where their families could not participate in the vacation. This applies particularly to the older engineers in the active practice of their profession who can not spare the time, and the younger men who, due to limited means and inability to secure consent of their employers, can not be absent from their business longer than two or three weeks in any one year. Each of these classes is needed in the engineer reserve. An engineer officers' reserve corps composed largely of dilettanti and well-to-do idlers will not make an efficient organization for war purposes.

The training of reserve officers, either at the training camp or elsewhere, should not be left entirely to the younger officers of the regular army. Although most of them are fine fellows, enthusiastic, efficient and with a fine sense of public duty, only the experience that comes with age and through long contact with men of all classes, qualifies a man to teach mature men with that tact, firmness and consideration which secures the most efficient results and develops respect, loyalty and love of the service.

The reserve officer should feel that he is a part of the Army. It is to be hoped that the engineer reserve officer will have the same pride in and affection for the Corps of Engineers that the active engineer officer has. This society should, and I believe will, contribute to a marked degree in developing this spirit. So far as his own personality justifies, the reserve officer should be admitted to the army fellowship which is so attractive to any one familiar with the regular army. This will be mutually advantageous to the active and reserve officer. It will help to develop an *esprit de corps* in the reserve and the reserve officer can materially assist in obtaining legislation beneficial to the army and the national defense and in creating a better understanding and appreciation of the army by the public.

Specially qualified engineer reserve officers and engineers not in the reserve, can be profitably consulted in regard to army equipment and plans.

Reserve officers assigned to skeleton organizations can assist in selecting and recruiting for the enlisted engineer reserve corps, competent non-commissioned officers for the organizations to which they are assigned.

Engineer reserve officers can assist in preparing plans of defense with special reference to areas with which they are intimately familiar. Possibilities of military transportation by railroad, highway and waterway, water supply, topography and natural resources in every district of the United States, could be reported periodically by well-qualified engineer reserve officers whose daily work is in connection with facilities which would be utilized in time of war for these purposes. Such reports could be made to conform to plans prepared by the general staff. Such work will stimulate the interest of the reserve officer, will make him feel that he is an important part of the army, will acquaint the military authorities with his ability and be of benefit to the national defense.

Promotions in the reserve should be made with the greatest care and should never be permitted to become perfunctory. Merit and ability being equal, seniority should govern.

It would be advantageous to have reserve officers sit with regular officers on boards making recommendations as to promotions of or issuance of original commissions to reserve officers.

In conclusion, permit me to say that it is my opinion that the civil and professional duties of a civilian engineer are more important to his country, family and self than his military training, and that the latter should be conducted, so far as possible, so as not to interfere with his civilian occupation, but the preparation for national defense is of great public importance and the patriotic engineer should place the greatest possible amount of his time, consistent with the proper discharge of his civic, professional and family duties, at the disposal of the military authorities to be utilized in military training.

Membership Cards

Have you received your membership card for 1921? We mailed our new cards last month to every member who had paid his dues for 1921, *and submitted a formal application for membership.*

The latter step is essential before membership card or Society emblem can be furnished. An *informal* application submitted last year will insure your being classed as a charter member, but the formal application is necessary to complete your installation. Blanks may be had upon application.

Combat Operations of 110th Engineers

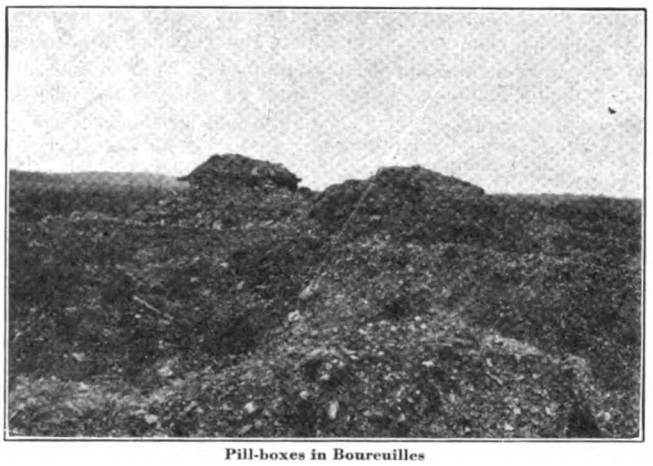
In the Meuse-Argonne Offensive

By

E. P. Rankin, Jr.
Formerly Captain, 110th Engineers

[NOTE.—The 110th Engineers were recruited in Kansas City, Mo., with the exception of Company A, which was recruited in Topeka, Kans. Among its officers and non-coms were many engineering graduates of the University of Kansas. The staff was largely composed of Reserve Corps officers.

The regiment went overseas in May, 1918, and served with the 35th Division. Captain Rankin, who was regimental adjutant at the time, gives a vivid picture of the work of the regiment in late September, when it was thrown into the line in an emergency to help the infantry, and acquitted itself with great credit, in spite of heavy losses. Two officers and seven enlisted men received the Distinguished Service Cross for their work during this period. On page 329 of this issue, Major Mitchell refers to another exploit of the 110th Engineers in connection with the crossing of the Meuse.



Col. T. C. Clarke, who commanded the regiment, died on May 25, 1921, from pneumonia, following an operation.—ED.]

In an advance the division commander, on the recommendation of the division engineer, makes assignment of the small groups necessary for accompanying each assaulting battalion, and after other special details have been made, the bulk of the engineers and all unemployed labor troops available are used for making passable the roads within the divisional area.*—*Col. C. O. Sherrill.*

SECRET FIELD ORDERS No. 44, 35th Division, dated September 24, 1918, at 5:00 P. M., contained these paragraphs:

* * * "The First Corps attacks on the front VAUQUOIS (inclusive) -LA HARAZEE (inclusive) with the 35th, 28th and 77th Divisions in line from right to left in the order named.* * *

* * * "The 35th Division attacks with the 91st Division of the Fifth Corps on the right, and the 28th Division on the left." * * *

Pill-boxes in Boureuilles

The same orders directed the 110th Engineers to concentrate efforts on the roads crossing No Man's Land, putting them in shape for animal-drawn transport, but leaving them at once thereafter to corps troops. Additional instructions were to examine and post drinking-water supply points, to install advanced material dumps, to utilize captured engineer materials and to consolidate captured enemy positions. All these duties were performed. Assignments of details to operate with the attacking brigade were as follows:

"One company of engineers will be reported to the Commanding General, 69th Brigade, for use in wire-cutting and overcoming obstacles.

"Two platoons of engineers will be reported to the Commanding General, 69th Brigade, to accompany the moppers-up in order to look for traps and concealed mines.

"One company, less one platoon, will be reported to the Corps Tank Officer, to be used in assisting the advance of the tanks."

The 110th Engineers was then in bivouac in the southerly reaches of the Argonne, opposite Rarecourt. Shacks and shelter tents mitigated discomfort. Total strength approached fifteen hundred. The staff was filled, the battalions were commanded by captains, and there were about three officers per company. A divisional dump, established at Neuvilly, had been hastily stocked with bridge timbers, road and bridge tools, sign-boards, wire-cutters, bangalore torpedoes and a miscellany of other materiel.

Col. T. C. Clarke, in command, selected for the work with combatants, Company A as wire-cutters, three platoons of Company B to assist the tanks, and the fourth platoon of B, together with the second platoon of Company C, to accompany infantry as mine searchers. Special instruction from the latest obtainable information concerning "booby-traps" was given the two platoons last named on the 24th and 25th. Company F left camp at night, on September 24, to make some forward road repairs, reporting back to the second battalion after midnight, twenty-four hours later, under our barrage. Company B, less one platoon, had marched out the previous night (corps orders received on the 22d had stipulated these details) to report to the 344th Tank Battalion. To us were attached, for road work on the 26th only, the opening day of the attack, a battalion of the 53d Pioneer Infantry.

The regiment, thus both depleted and augmented, left camp at 6:30 P. M. on the 25th, marching 16 kilometers up to Neuvilly by way of Auzeville and Aubreville. Combat wagons were with the battalions. Ration wagons, water-carts and rolling kitchens had been ordered left behind. The march to position was halted more than once, not only because roads were crowded, but to await the subsidence of periodic German shelling. We entered and cleared three husks of towns without a hit in our column, although the night fire switched back and forth over us. During the later hours of the march the horizon was scintillant far east and west, from the barrages beyond Verdun and behind the Argonne, distracting the bosches from attending to nine divisions being compressed into the intervening 18 miles. On the outskirts of Neuvilly, at midnight, the first battalion, with two companies of pioneer infantry attached, turned to the right into the Forest de Hesse, while headquarters and the second battalion, with the remaining

*PROFESSIONAL MEMOIRS, Sept.-Oct., 1919.

Digitized by Google

pioneer infantry, continued on the road toward Boureuilles, thence into the woods topping Cote 215. The regimental commander was with the Division P. C. on the reverse slopes of Les Cotes de Forimont. Maj. E. M. Stayton, second in command, personally supervised the road work. We halted for three hours in old reserve trenches under our barrage, while in reply the whine and sickly burst of gas shells sounded at lengthening intervals from the lower woods. At 5 A. M. on the 26th both battalions went furiously to work on their respective assignments. "Zero hour" was 5:30. Before 6:30 the second battalion cleared the woods and ran into machine-gun fire (Vauquois was avoided by the leading infantry and mopped up in dense, rolling fog and smoke by a battalion detailed for that purpose). The first battalion on the extreme right of the sector was delayed by the deploying of 91st Division Infantry on its road. Capt. Orlin Hudson, first battalion commander, reconnoitered two lanes leading toward Vauquois, refused to lend his men as riflemen to the 364th Infantry, and turned his attention to a road leading to the left of Mt. des Allieux, working it across No Man's Land to a junction with the paved highway running behind the German front toward Varennes, this proving the most practicable of the possible routes on his side. The second battalion head reached Boureuilles, in the German front position, by 9 o'clock. Capt. W. W. Taylor, in command, reported that his road into it would be ready for light traffic by noon. In fact he sent word at 9:40 that machine-gun carts were using it to the edge of town. Inside the area of broken walls, however, the road was badly blown about, slowing up his progress. The preliminary road work by Company F on the 25th had consisted in part of rough repairs to culverts, draining ditches and filling in holes, with rock where available, but otherwise with tamped dry earth.

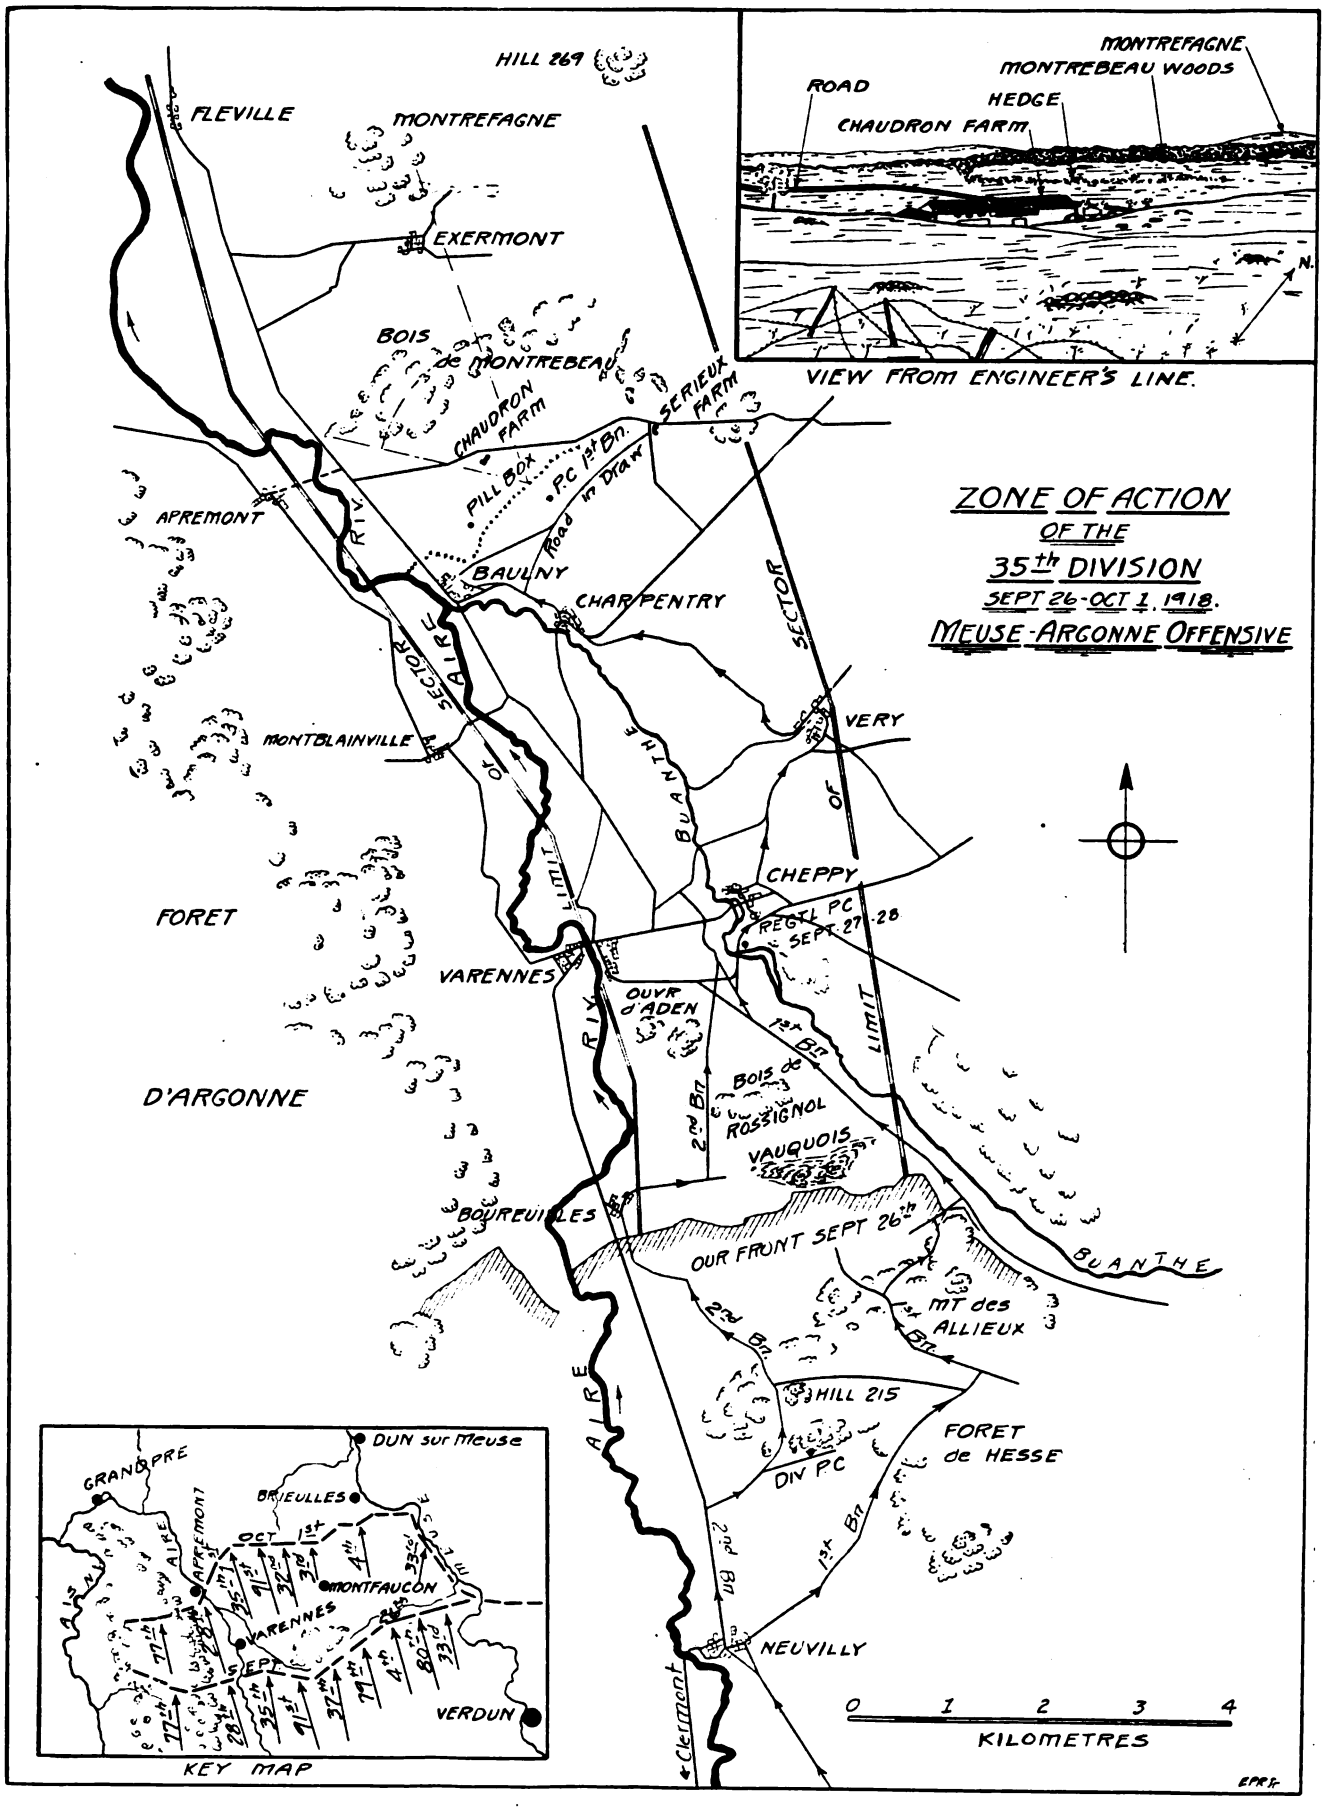
On the road to Boureuilles this company made 300 meters of corduroy over swampy ground by cutting poles in the nearby woods, three inch diameter being the largest used, cleaning off old material and tamping the subgrade; laying three stringers in longitudinal trenches, tying mats of 3 to 5 inches in thickness across the stringers; and finally covering the corduroy thus formed with several inches of shale. One platoon of fifty men was left on this stretch, to keep it in shape and boost field-pieces across it.

New crossings were found necessary, to pass French and German trenches. No spans were used. All work was done with pick and shovel. Trenches were filled with logs and rock, with a transverse corduroy of poles near the top, surfaced with earth. Where new road was required it was first marked by peeling off the vegetation, and then leveled and tamped. Wire was cut and laid to one side, and shell holes filled with whatever solid materials were available.

These roads encircled the blasted hell that had been Vauquois. We had no use that day of the wide, paved highway to Varennes, bordering the Aire in its northward flow, but had to make over for the entire up-movement these boggy lanes which for years had received no attention except that directed towards their obliteration. In front of us, from the right, Buanthe Creek entered the sector, meandered diagonally ten kilometers across our paths and emptied into the Aire at Baulny.

Headquarters detachment passed into Boureuilles shortly after noon. There was then a jam of traffic on the second battalion road, shelled at frequent intervals. Corps engineers were already in Boureuilles. Across the Aire machine guns rattled without ceasing at the forest's edge, where the 28th Division was sweeping their side of the river "trough." The second battalion was on an earth lane, running first east, then north, from Boureuilles, across higher ground skirting the silenced nests clustered in the Bois de Rossignol and the Ouvrage d'Aden. Advancing on this route there appeared in view ahead the trench-furrowed orchard and other heights before Cheppy. From steel-plate nests at its rim the Boches had spat across Buanthe Creek, at the road forks south of the bridge, which ground had been opened at noon by the little tanks after earlier assaults under lifting fog had failed.

The first battalion pushed into Cheppy over the right-hand road between two and three o'clock, followed by its train. The train had used its road repaired across No Man's Land, as had also a number of tanks, and an ammunition train of the 91st Division. Headquarters detachment, the message center, was put at 4:00 p. m. into a German strongpoint just beyond Buanthe Creek, at the edge of the road, and were shelled into dugouts that evening and irregularly during the following days. Runner service back to the regimental commander had been well maintained despite the increasing distance (from two kilometers at daybreak to seven by mid-afternoon). The mounted section expedited messages and was further detailed to boost traffic on the new up-road. The second battalion reached Cheppy during the evening and night, improving there the connection with the road over which the first had come. The first was then at the forward edge of town on the road leading to Very. During the night a combat train was turned over to the 70th Brigade, which, after having partly leap-frogged the leading brigade before Varennes early on the 26th, was to attack on the 27th. On the right of the sector Germans were in Very until midnight. Four hours later, at dawn of the 27th, engineer reconnaissance patrols gained entrance to Very but were told by the infantry to stay out.



Little traffic had passed the strongpoint. A battery had used the second battalion road to get into the Bois de Rossignol in time to fire after 5 p. m. on the 26th, but in respect of other use the night and following morning were distressingly quiet. At noon on the 27th artillery passed up, and went into action on the right and left of Cheppy, supporting the brilliant afternoon attack which ended the second day, giving us Charpentry and Baulny as further prizes.

On the 27th Col. Clarke relinquished his easy connection with the Corps Chief Engineer and made the Buanthe bridge message-center his post. Master engineers inventoried and arranged for distribution a German engineer dump in Cheppy. The first battalion was in Very by mid-morning, and scouting towards Charpentry. It regained during the day most of the details released by commanders of the infantry and tanks, and the regiment fed at its work on their exploits.

Half of Company A had reported to the 138th Infantry. It was ordered back to the engineer battalion. Captain Hudson wrote Colonel Clarke at 6 a. m. on the 26th, "C.O. 138th Inf. has returned to me one-half of A Company, saying that he has absolutely no use for them and that the detail was a piece of damn foolishness." The other platoons of Company A went to the 137th Infantry and attacked with them, in four-man wire-cutting groups. The commander's report does not specify how much wire was found to cut, but the third platoon took nine prisoners and three guns, and the fourth platoon captured an equal number of men and one gun. After release by the infantry these platoons rejoined Company A on the 27th.

The three platoons of Company B spent the 24th and 25th with the tanks, officers getting instructions and making reconnaissance for favorable routes. Two platoons

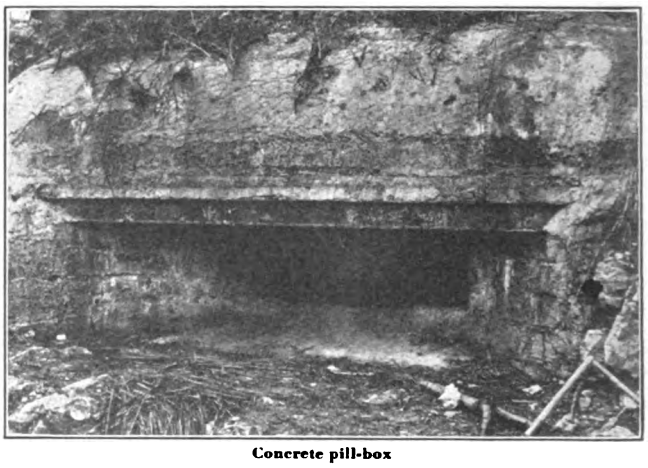
went over on the 26th with American tanks, and the third with a French section. They helped the tanks over some very difficult trenches and country on that day, digging many out of mud. Their work was perhaps hottest before Cheppy, where Lieutenant Dinglestedt, a platoon commander, received wounds from which he never recovered. The fourth platoon of Company B, assigned as mine-searchers, went to Vauquois with moppers-up, located several mined dugouts and assisted in the capture of several officers and fifty men. The second platoon of Company C on the same duty, was held without instructions by the

German pill-box covering Buanthe Creek

infantry until 8 a. m. on the 26th. They went A.W.O.L., reporting to Major Stayton, and worked ahead of the second battalion into Cheppy. Thus Captain Hudson got back his men, replacing the pioneer infantry which had withdrawn on the afternoon of the 26th under corps orders.



During the second and third day both battalions were on the Cheppy-Very-Charpentry road, held up by the slowing down of infantry advance. They crossed high clear country, shelled from north of Exermont and out of the Argonne. The first battalion moved forward from Very at 2:30 a. m. on the 28th, mending the road to Charpentry en route, at daylight burrowing into foxholes bordering the road running northeast from Charpentry. The day was spent there under irritating fire. The head of the second battalion touched them late on the 28th. Their task had been, in addition to removing mud from the rock road-base, that of filling shell holes as fast as they blew in, using rock and old surfacing. Though corps engineers worked rapidly to Cheppy, none had advanced beyond that point. At 6 a. m. on the 28th the supply officer was called up to the Buanthe bridge headquarters, and the engineer train directed to bring eight trucks of bridge materials and nails, with oil and gas for itself, to Cheppy via Varennes (not over our brush-corduroyed lanes). On the same day several batteries of divisional artillery used our road to take positions in Very and Charpentry.

At noon Colonel Clarke advised both battalion commanders to be ready to jump to the infantry's aid with tools and help. Montrebeau Woods was then being held with difficulty by mixed infantry units. At 2 p. m. he sent word to the battalion commanders, Captains Hudson and Taylor, "Infantry are to dig in. Send forward your part of their combat transport with an officer, to get in touch with the right-left (respectively) infantry flanks. Better see the regimental C. O.'s and offer technical help. Noonan starting with balance of train. Lots of wire here at dump." In compliance with these instructions an officer of Company C delivered in Montrebeau Woods 300 picks and 200 shovels at ten o'clock that night. On similar duty, transport of the second battalion drove into a Boche machine gun post on the Baulny-Fleville road, the detail was scattered in the dark and three men were captured by the Germans.

Some of the divisions in the Argonne got cut down to three or four hundred men to the regiment. Under such conditions, if the division must still stay in—and it must at times—the Division Commander must put in the engineers as infantry. * * * When a reaction starts from the enemy, the engineers are going to be used not only to dig, but to actually defend a second line.*—*Col. George R. Spalding.*

The division commander informed Colonel Clarke and Major Stayton at 8 p. m. on the 28th that the regiment would be placed immediately in divisional reserve. The train proceeded to carry rations and ammunition to Charpentry, while Major Stayton conferred, in a dugout on the edge of Charpentry, with the battalion commanders, staff and company commanders. The battalions were reported to the brigade commanders. Rations, tools and ammunition were distributed. Both battalions marched through Charpentry, a mud pit poisoned with the bodies of dead animals. The first turned to the right on a road up the draw heading near Serieux farm. It dug in on the reverse slope back of that draw, in front of Charpentry. The second battalion kept to the road, deploying before reaching Baulny. Companies E and F went to the ridge northeast of Baulny. Company D extended the line from the left of E to the Aire. At daybreak Company E was withdrawn from the center to support D down by the river, the two front companies extending towards one another to close the gap thus formed.

The regiment thus awaited developments while the division commander in person, in Baulny, with what officers were left and located with their commands, arranged for the storming of Exermont, the corps having ordered, "No

Concrete pill-box

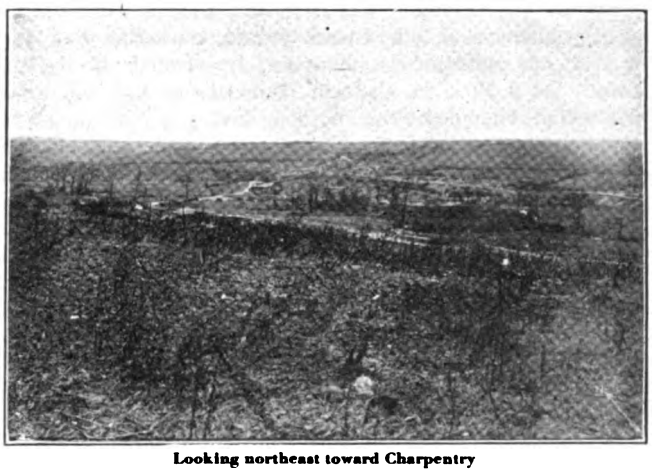
definite objective. Division will push forward at 5:30 a. m. without regard to divisions on right or left."

The second battalion advanced with the attack. At 10 a. m. it reached the south edge of Montrebeau Woods, outside the zone of carnage ahead. The first battalion remained in its early morning lines until 9:30 a. m., at which time, under brigade orders, it crossed the draw up which it had marched the previous night. A position of resistance was located under general instructions of a brigade commander, on the front slope of the next ridge ahead, which slope extended gently down to the Chaudron farm buildings and the road running east therefrom. En-

*Professional Memoirs, Sept.-Oct., 1919.

Digitized by Google

gineer officers selected and taped the ground under direction of Major Stayton. The battalion cleared the crest at 11 a. m. in excellent thin lines, Company A to the right, Company C on their left, B in support at 150 meters. The two leading companies passed through a belt of Boche wire. All started underground, B behind the wire but also fully exposed to view. The panorama of heights beyond Exermont was partly screened by the smoke of large fires in and near Fleville. To the extreme left sharp machine gun chatter rose from Apremont and the wooded slope of the Taille l'Abbe. Observation became blurred



Looking north into Baulny

and quickly restricted to the work at hand, by the wicked arpeggio of high explosive and gas which immediately fell upon the sweating engineers. They were in full view from Hill 269, taken and held brilliantly a week later by the First Engineers. From there a large number of 155s rained in slow screeches, throwing up black earth and rolling clouds of acrid, yellow smoke. From the left rear, out of the Argonne, came high-bursting shrapnel hail. At noon Colonel Clarke reached, from Cheppy, a concrete "pill-box," even with the front line but to the left, half way between Baulny and the Chaudron farm buildings, on the exposed slope. In the wire over that way was a crashed French plane, spread out like a giant butterfly.

At noon both the battalion commander and the C.O. Company B were wounded. At 12:25 word went to the colonel that Major Stayton was reconnoitering to the right because numbers of men were retiring on that side beyond the battalion, that Lieutenant Hanly was killed, that two other lieutenants were gassed and evacuated. At 12:50 word was sent back that the artillery fire against us was largely transferred to our left, that the first contact aeroplane of the day was then at work for our artillery, and that we had received additional ammunition. Shells were then breaking viciously around the pill-box. Our first battalion runners found out that Colonel Clarke was there at the time, though we did not for an hour later. At 2:10 p. m. the long-range mixture of high explosive and gas was again turned on us in force. Infantry was doggedly backing out of the woods, across the road to us. At 3 I wrote him, "As infantry filters through us we are under incessant machine gun fire from the north. We have no machine guns, grenades, etc." At 3:30 he replied from the concrete P. C., "We, the regiment, are to hold the ridge and dig in. Machine guns are on right and left flanks. We let the infantry through tonight and then give boche hell if he follows, which he won't." That message was our first ray of sunshine of the day.

By mid-afternoon the first battalion was well under horizontal cover, at a cost of thirty per cent of its strength. The first holes were individually dug, in frantic haste. The evening and night were spent in connecting them into short runs of trench, deepening them to below a fire-step, and in laying out necessarily irregular traverses. Infantry, with their officers, had quickly and willingly stopped to garrison our line, and to start three additional lines on the reverse slope along the road to Serieux farm. They would not, however, exert themselves with pick and shovel. Meanwhile the second battalion was holding its position ahead and to our left, on lower ground. At 2 p. m. it was ordered to retire and extend our line, resting its left on the river uncomfortably close to Apremont. Company F was directly in front of Colonel Clarke's P. C. and outposts from that company organized and patrolled, two hundred meters ahead of the wire encircling Baulny, the left half of the sector, from the Baulny-Fleville road to Chaudron farm, while infantry straggled through during the afternoon and during the lively day following.

That night, the 29th-30th, was fairly quiet but a ticklish situation existed down at the Chaudron farm buildings, from which wounded in large numbers were being evacuated, protected by an infantry detail spread fan-like towards Montrebeau Woods. At midnight Colonel Clarke was worried. He sent word to Charpentry, to brigade headquarters which had moved back through us, "Rockets have gone up on my direct front, three all different, sent up in woods. Warn artillery to be sure rockets are from my lines. Have no report yet that wounded are evacuated. No officer to explain French rocket, so I am unable to call barrage." Confusion is further indicated by a message of his at 1:20 a. m., "Please telephone for me asking status of command here. Colonels Walker and Delaplane have taken over east end of sector without a word. My first battalion now in reserve. This place much too thickly populated. If no attack develops recommend immediate withdrawal of troops to below hill. I don't know how many men Colonel

Looking northeast toward Charpentry

Walker has put in but in places they are two and three deep. I learn Colonel Walker did not speak to my adjutant or battalion commander saying he now commanded. Think command should revert to infantry and my command again go into reserve." The statement that we were in reserve was partly correct. Most of the engineers had been withdrawn behind the wire, but Company A still held the trenches they had dug. Nothing was heard further about a change in command and Colonel Clarke was held in charge of the sector. Meanwhile a medical officer of our regiment was operating the most advanced dressing station, on the Serieux farm road. Working in mud and

Digitized by Google

filth and gaseous air he requisitioned boche dugouts for blankets and protection for his cases.

At dawn on the 30th Colonel Clarke called for a trial barrage, having learned that Chaudron farm was cleared of wounded and guards. At 6:50 he reported, "Barrage produced no signs except a few machine gun bursts on our left in edge of woods." At nine o'clock Fritz came out of Montrebeau Woods and his artillery weight fell with great force on our entire line, punctuated with bullets. To exercise observation and to direct our fire officers and non-coms found it necessary to stay on top, out of any

Looking north across Buanthe Creek toward Cheppy

protection. The Germans used their favorite tactics, "filtering" singly and in pairs by way of the hedge and other protected spots to where they could assemble a machine gun and put it into action within a few seconds. They did not appreciate the solidarity and depth of our position, nor the grim obstinacy with which nerve resources were holding out against wounds, exhaustion and dysentery. They fell under our splendid barrage, breaking in the open and on the south edge of the woods, fell under the crack of twelve hundred rifles—and fell under machine guns which the 138th Infantry had pushed across the road at our right, in the clumps of trees north of Serieux farm. At 9:30 a. m. Captain Hudson sent word suggesting certain changes in our artillery fire. At 9:50 he wrote Colonel Clarke saying the situation was well in hand and that the machine gun fire from our right had been handled with good effect. At 10:25 he wrote, "The co-ordination between artillery, infantry and machine guns has been splendidly maintained and if kept up we can hold this hill until the cows come home." On the left the second battalion reported at 1 p. m., "Everything O. K. on left flank. Machine guns and personnel intact. I have now twenty-five men guarding three guns on my left flank. Will make every effort to increase this. Will notify you in writing at once if conditions change." This message went to Colonel Clarke at Baulny, to which he had wisely moved the P. C. after several men had been killed near the pill-box and after it had suffered a direct hit on the north (open) side during the counter attack of the morning.

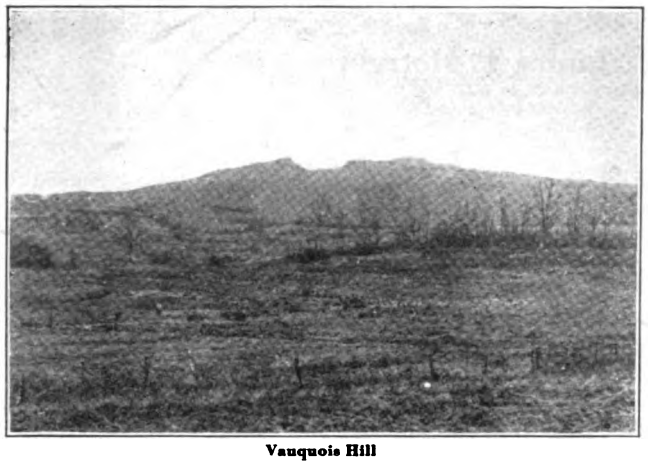
German litter-bearers were active in front of and in the edge of Montrebeau Woods. During the afternoon the fire on our line was intermittent. Units of the 82d Division, skirmishing from Charpentry, were shelled to retirement, with the exception of two companies of machine gunners and infantry, which entered our lines. The 82d later assisted the 28th in scaling the heights west of the Aire, from Apremont north towards Fleville. Towards sunset a group of tanks waddled up the draw to the 91st Division sector, attracting the attention of a boche battery in the Argonne in front of the 77th Division. This battery also bothered the second battalion, whose officers believed it to be located on stated co-ordinates two kilometers southwest of Apremont and asked for its reduction.

At 6:25 the Train Commander reported from Charpentry, "I am informed we are to be relieved tonight. We are prepared to send rations up. Will the relief change this arrangement? Shall we hold some rations back? If I don't hear from you will forward all rations after dark." This inquiry concerned a repetition of good work which had been carried out on previous nights. Cans of beef and tomatoes, and bread, had been distributed in the lines. Rolling kitchens which had somehow found their way up once reached our draw, except B Company's, which was blown up by shell-fire on the Very-Charpentry road.

Towards midnight much more gas was put down on us, not less than fifteen hundred shells in three hours. The night was chilly and very damp, without moving air. At 3 a. m. on October 1st the 1st Division took over our lines. The third battalion, 18th Infantry, skirmished over the hill to our rear, and came up, precisely as our first battalion had done two days before. Captain Hudson showed their C. O. our lines and Chaudron farm, as well as could be in the inky darkness. By previous arrangement Companies A, B and C filtered back and assembled near Charpentry. The second battalion was likewise relieved by a battalion of the 16th Infantry and was assembled on the Baulny road. The regiment marched to Cheppy, where a hot breakfast was served, and on the following morning the 110th Engineers took their place in the division column southward bound, Company F assisting the divisional trains. On the evening of the 5th rest billets were reached at Conde-en-Barrois, where six days prepared the regiment for three weeks of road work in the line east of the Meuse, from Fort Vaux to Fresnes-en-Woevre.

I believe the most important points bearing on the successful use of the engineers with a division * * * are: First, The *spirit of service* * * * This * * * is the most important single factor affecting the success of any divisional engineer regiment, for no matter how well disciplined, trained or perfected it may be * * * unless it is constantly helping the other troops * * * in battle, on the march or in camp, * * * it has failed as a divisional engineer regiment.*—*Col. Francis B. Wilby.*

Concrete pill-box used as regimental P. C. on September 29 and 30



This week of action stimulated the lively working morale of the regiment, heightened its spirit of loyal service to its division, and enriched the National Guard traditions of Missouri and Kansas, whence it came. Major Stayton and both battalion commanders received prompt promotion. The cost of the work was high. Total casualties

*Professional Memoirs, Sept.-Oct., 1919.

Digitized by Google

were more than three hundred. Eighteen men were killed on the field, eight officers were killed or wounded. Over one hundred cases were caused by gas, because it was difficult to make the men wear their masks while digging. Fifty animals of the regimental train were killed or captured during the week. It was necessary to use the divisional engineers as combatants because with their exception the division lost, by September 28, the power of manœuvre in large, intact units.

Well-deserved recognition was accorded while the regiment worked, four months later, at Camp Pontenezen (famous adornment of Brest) in this form:

Vauquois Hill

AMERICAN EXPEDITIONARY FORCES
Headquarters Services of Supply
Office of the Chief Engineer, A. E. F.
24 February, 1919.

From: The Chief Engineer, A. E. F.
To: Commanding Officer, 110th Engineers.
Subject: Letter of Commendation.

1. Before issuance of definite orders for your regiment to return to the States it is my desire that the command be advised that they have met the conditions imposed by the conflict just concluded in a most satisfactory manner.

2. The construction of field fortifications and bridges across the Somme, the front line construction, tunneling and road work in the Vosges were notably well done. The excellent record made in front-line service is a matter of pride to the Chief Engineer as it should be to each soldier in your regiment.

3. I desire that you and your command know that the services rendered were highly satisfactory and deserve commendation.

W. C. LANGFITT,
Major General, U. S. A.

Comments on "The Metric System"

By Harvey A. Hall

I have certainly enjoyed reading the excellent May-June number of THE MILITARY ENGINEER, although time has not permitted me to get all of the material that it contains as yet.

I have a decided objection to the article in the editorial section, "The Metric System," as I believe that the metric units are so much more satisfactory than the British system that they will soon be in general use and the British system gradually and thankfully forgotten.

The advantages of the metric system are acknowledged in the second paragraph of the editorial article. But in regard to the necessity of the British system in industry there is opportunity for difference of opinion. I fail to agree as to the necessity of continuing the old system indefinitely.

In any industry there is constant development. New ideas call for new equipment, and it is doubtful that much of the equipment used now will remain in use any great length of time, especially that part which may be based directly on the units of the system in use. Therefore since in any event there must be change, if such change will bring into use such distinct advantages as the metric units possess, then the change will be of far more advantage.

The argument for a possible *decimal* system seems faulty. Should any one unit of the British system be adopted, then as far as I know *every other unit* of the system would be affected by the change to a decimal system, and I fail to see why the almighty (little) *inch* must control all other units, when with almost the same amount of change to the metric system a thoroughly developed system of units in constantly increasing use at the present time will give the advantages that are admitted to be offered by the decimal system.

By Norman M. Macleod

Our contact with the French showed us that they can calculate more rapidly than we can; therefore the French system is a *time-saver* compared with the British system.

The time saved in the next ten or twenty years will pay the manufacturer many times over the cost of making the change. A saving will be effected by the reduction of errors.

The chief difficulty in the way is the fact that almost all of the measuring instruments are owned by the workman, while the advantage resulting from a change of instruments would be chiefly in favor of the employer. The workman must buy new tools at least once in ten years; therefore, if the change is made gradually over a period of ten years, the cost will not be great and the manufacturer should stand it.

The makers of measuring tools are arranging for double scale rules, and for the changing of barrels and screws on micrometers, so that the workman can change from British to metric and vice versa without difficulty, and with almost the same tools.

A great misunderstanding exists among the manufacturers, as they believe that this change means a change in the *product,* whereas a change in the *system of measuring* is the only change contemplated, and the only material affected is the measuring instrument. "A rose by any name will smell as sweet." A piece of pipe is the same size whether we measure it in British or French units.

Using decimals of feet and inches will not help, as they are irregular.

Change in Harbor Nomenclature

Owing to a diverse usage of the terms "inside" and "outside of harbor lines," certain ambiguities are often introduced into literature concerning harbor and harbor improvements. The same term is often used with opposite meanings, being applied in some cases to the land side and in others to the channel side of the lines. To avoid misunderstanding both by the public and in the Engineer Department the Chief of Engineers has directed that hereafter the designations "inside" and "outside" shall not be used in official correspondence to describe position relative to the harbor lines. Such positions will hereafter be described by the terms "Shoreward (or landward) of harbor lines"; "Channelward (or riverward) of harbor lines."

"New Organization of the Engineer Service"

Discussion

By

John A. Miller, Jr., and James T. Metzger
Formerly First Lieutenants, 104th Engineers

THE article on "New Organization of the Engineer Service," appearing in the January-February number of THE MILITARY ENGINEER, discusses a subject that is unquestionably of absorbing interest to all who served as engineer officers during the war. Probably the most striking feature of the table of organization there described is the difference between the new one and that of 1918, and in some cases between the new and the actual organization as it functioned in the A. E. F.

The best method of deciding the questions of reorganization would seem to be by interpreting in the light of probable future military needs the varied arrangements actually adopted during the war. It may be pertinent, therefore, to make a comparison between the new table and the way that one unit, the Headquarters Detachment 104th Engineers, really functioned in the field. Apparently few combat engineer regiments in France were equipped with sufficient horses to supply mounts to the mounted section of the headquarters detachment, and there is perhaps something to be learned from the experience of the 104th Engineers that would not be so noticeable in the histories of other regiments.

For the purpose of making such a comparison, a roster of Headquarters Detachment 104th Engineers was taken and divided according to the duties which the various soldiers performed during the year the regiment was in France. This roster contains one hundred and ten names, slightly fewer than demanded by the old table of organization, and while there was considerable change in the personnel of the company during that time, the assignment of duties remained essentially the same. From this it was possible to draw a very definite conclusion concerning the number of men required for each kind of work. Examination was next made of the new table of organization to see whether sufficient men were allotted to each section of headquarters company to perform the work that would be required again under similar circumstances. It was seen at once that there would be a shortage in some cases, and it is for the purpose of drawing attention to such a condition that this is being written.

The table of organization of the Act of June, 1920, provides one less clerk for the adjutant's office than was always needed at regimental headquarters 104th Engineers; six less men for the topographical office; and six less for the regimental supply office, as well as three less for the company headquarters and one less for the kitchen. While none of these deficiencies is of serious moment, yet it appears that the shortages would actually exist with the new regiment in the field, and the method of meeting the situation involves a principle of rather wide application.

Such a deficiency may be filled by the assignment to special duty of men belonging in another section, or even in another company, or it may be filled by regularly organizing each unit with sufficient men to do the expected work. It is thought that nearly all former company officers of the A. E. F. will agree that a great deal of confusion resulted from the use of soldiers for other duty than that to which they were nominally assigned.

This was particularly true of Headquarters Detachment 104th Engineers. In order that the various departments already mentioned should function properly, men were temporarily assigned from the mounted section to those duties. The proper care of their horses then became a troublesome problem for the Detachment C. O. The men themselves were too busy to attend to the animals, other soldiers had quite enough to do without caring for extra mounts, and the condition remained unsatisfactory until casualties among the horses reduced the excess. It appears that this situation would be exactly reproduced by the new organization of the engineer headquarters company. Would it not be better to provide more dismounted men?

Such an arrangement could be made by reducing the mounted section or by increasing the headquarters section. The latter plan would leave a good-sized mobile detachment for rapid movement, although it would increase somewhat the total strength of the company. It seems, however, that a mounted cook to travel therewith is an oddity. One could nearly always judge the discipline of a command by the condition of the cooks' rifles, these soldiers being habitually disinclined to care for their military equipment properly. A cook would hardly be more apt to take good care of a horse. In the emergencies when the mounted section is called upon for quick work at a distant spot, they might very well get along for a time without a regular cook. Similarly it seems that the sergeants major scarcely need mounts, and will have little time to devote to them.

A suggested organization has therefore been outlined providing in the headquarters section sufficient men to do the work found necessary in France, leaving in the mounted section the topographical N. C. O. and privates but not counting upon them for the work of the topographical office proper, and omitting the cook from the mounted section The transport platoon had no parallel in the Headquarters Detachment 104th Engineers, and no change is suggested in it save that the company supply sergeant and the clerk be placed in the headquarters section rather than with the transportation. The band section was not organized in the regiment until the spring of 1919, and no comparison is possible on that account.

The new organization will, without doubt, receive the

Digitized by Google

most enthusiastic support of former officers of combat engineer regiments. Particularly to be praised is the combination of the engineer train and the old headquarters detachment. This suggestion is offered, therefore, merely to draw attention to a condition that was a cause of minor difficulties in the past and that might, if continued, cause the same difficulties to again arise.

The following table shows the organization used in the Headquarters Detachment 104th Engineers, that effected under the Act of 1920 and that recommended by the writers:

TABLE OF ORGANIZATION HEADQUARTERS COMPANY COMBAT ENGINEERS.

Comments by F. B. Wilby

Major, Corps of Engineers

The above comment on the new organization for the headquarters and service company of the combat engineer regiment is very interesting and shows careful thought on the part of its authors. The general comparison presented by them, with the experience in the headquarters company of the 104th Engineers during the war, seems to confirm in general the adequacy of the personnel in the new organization.

No increase in the personnel allotted to the headquarters and service company can be provided without taking away an equal number of men from the companies in the regiment, already now so small as to be barely effective (106 men per company). It was recognized that the strength of the headquarters and service company should be kept to the absolute minimum in order to maintain the six companies at as large an effective strength as possible without exceeding the permissible total of 800. For this reason there are practically no extra privates in the headquarters and service company to provide for sick and other absentees, except the 16 miscellaneous privates in the mounted platoon.

The internal organization of the headquarters and service company is not restricted to the distribution shown by Lieutenants Miller and Metzger above, or even to that shown on the approved tables of organization. The organization commander is only limited by the number of men shown in each grade in the "Total" column and the number of specialists' ratings allotted to the organization in the column of "Remarks" on the approved table. Within these limits he is at liberty to organize his unit as he desires. It is believed that no two organization commanders will allot their available personnel in exactly the same manner, as they will be influenced by personal preferences, and the different situations to be met. The distribution shown on the approved table is believed to be a good working basis for average conditions in this country.

With reference to the suggestion that the mounted platoon should be reduced, I am afraid I cannot agree with this suggestion. Prior to the war each engineer company had a mounted platoon of 36 men for companies of 164 enlisted strength, and a mounted platoon of 25 men for companies of 109 enlisted strength. These platoons were found very effective for service in this country. They were not authorized, and rightly so, for service in France as the different theater of operations did not require their use. The new table of organization provides only 35 mounted men for the entire regiment, or less than 25 per cent of the number provided prior to the war for a regiment of about the same size.

It is believed that this is the minimum necessary for service in this country, and it was regretted that the limit placed on the size of the regiment prevented retaining a mounted platoon of six squads (one available for each company if desired) instead of the smaller platoon of four squads as shown.

Military Sketching as a Hobby

By

George W. Rappleyea
Member S. A. M. E.

Bearing in mind that the *raison d'etre* of The Society of American Military Engineers is "Preparedness" and that nearly every man has a hobby, some hunting, some fishing and some golf, I have chosen for myself a hobby that has three desirable attributes: first, it is healthful and interesting, as it involves exercise and brings one into close touch with nature; second, it develops skill that can be turned to military uses in time of emergency; and third, it is a source of profit rather than an expense, as I shall show later. This hobby is military sketching.

The art of military sketching is something that cannot be acquired merely by reading a book of instructions. Handling a sketching case is like handling a billiard cue; considerable practice is essential to proficiency in the use of either.

The average civil engineer who has for years been trained to tack-point, hair-splitting accuracy, finds it hard to break away from his old habits and cultivate the apparently loose and inaccurate methods that are used by the skilled military sketcher. In pursuing my hobby I often use my holidays, Saturday afternoons and vacations and with my sketching outfit I hike for the country. I generally go over one road a distance of five miles or so and return by another. With a counter I get the distances by pacing and sketch the topography on both sides of the road as I go. On returning home I take off the sketch, put on a new roll of paper and file the finished sketch. After several such trips I piece the several sketches together and make a tracing of the completed map, which generally covers an entire township and sometimes a county. The publication and sale of such maps proves profitable and well repays one for the extra trouble.

The average civil engineer spends at least six months in one locality, just about long enough to secure all the data necessary to construct such a map during his spare time.

I always try to bring along with me on my trips a fellow engineer and when he sees how interesting, instructive and profitable the work is and that it means doing something for preparedness, he generally becomes an enthusiastic devotee of the sport of military sketching.

On most of my trips I walk and thus get the distances by pacing. Sometimes I use a horse and buggy, tying a piece of rag to one of the wheel spokes and counting the revolutions with a hand counter. Sometimes, in hilly country, I use photo-surveying, utilizing a plain box camera equipped with two small spirit levels and a small compass. I have read many works on photo-surveying but I consider that General Reed's book on the subject gives the clearest and simplest explanation.

Recently I have been experimenting with a liquid marine compass, set in gimbals, attached to the instrument board of an automobile and with a properly constructed deviation table and revolution counter arranged like a speedometer, I have secured some surprising results at high speeds. Two men are required; one drives the car and calls out at the turns; the other keeps his eyes on the instruments and as the compass card swings back and forth notes and records the average course and when the driver calls "turn" the recorder notes and records the figures on the revolution counter.

Of course there still remains considerable work to be done after the trip in the way of reducing and platting the notes. This system has a further disadvantage because only a plane survey has been made and no topography has been taken, making the resulting map almost worthless for military purposes; however, two men in the rear seat equipped with clinometers and barometers might secure a limited amount of topography.

With the development of the gyroscopic compass I see no reason why an automatic automobile surveying instrument could not be perfected, that would record on a paper tape the course of the machine say at intervals of every one hundred feet. I have such an arrangement in mind and see no reason why it should not work. For want of a better name we might call it the "Auto-map-o-graph." The principle made use of involves the so-called step by step method of producing synchronous motions between the compass card of a gyroscopic aeroplane compass and a recording device provided with a wheel having around its periphery three hundred and sixty divisions to correspond to the three hundred and sixty degrees of the compass card. Also another circuit connected with the speedometer of the machine to force a strip of paper at intervals of every fifty or one hundred feet, up against the wheel, which would have rubber type set on it thus producing a printed record of the true courses and distances traveled by the machine. Now, then, if some bright young army officer would only invent some method of getting topography on both sides of the road automatically the problem would be solved.

The use of automatic moving picture cameras, placed in gimbals on each side of the car and so connected with the speedometer that the resulting photos will overlap, naturally suggests itself, but the large amount of office work required to plat the data thus obtained makes this method out of the question for military use, although topography could be secured in such a manner.

The profile of the road itself could be easily obtained by the use of a self-recording barometer. Perhaps the day is not far distant when topographic and military sketches will be made automatically from an automobile travelling at a high rate of speed.

Comment on "The Army Uniform." By F.W. Harris

Major Embury's design for a field service uniform is practical from the top of the fedora hat to the soles of the russet shoes. The constructive criticisms were fine. (1) Place company and regimental letters and numbers on reverse side of collar. (2) Lengthen the coat. (3) Make the eyelets in shoes large. Major Embury's idea of avoiding form-fitting clothes, especially breeches and leggings, should control the design of a service or work uniform. Keep to the trousers big enough to put on over the shoes. A 10-inch top-boot cannot be beaten for all-round use. It weighs but little more than the ordinary shoe, and the additional leather required would not be any real objection in quantity production in war.

The suggested design is practically the style of clothing adopted by the loggers and engineers of the Pacific Northwest. Difference of opinion in the utility of such a uniform is the difference between practical experience and theoretical ideas. These opposites generally deadlock all constructive ideas and plans.

Every soldier needs two uniforms, one for work and the other for dress. Veterans of the war would be glad to see the miscellaneous fit of breeches and the vest-like coat disappear into the limbo of things that have had their day.

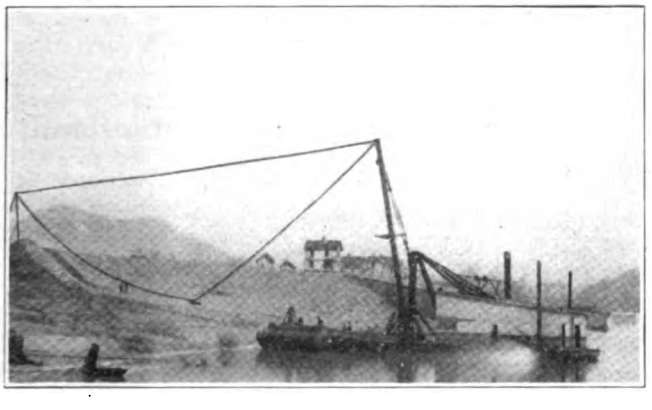
A Plea for Articles about "Little Jobs"

By

Lucien S. Johnson
Assistant Engineer, Second Cincinnati District



The tendency of technical magazines is to give accounts of construction works of large size and to ignore the "little jobs" as of no interest. It is true that these large works interest the entire profession and are entitled to plenty of space; yet there are frequently details in the comparatively trifling works that would be of interest and profit to many.

The little fellow has to accomplish his ends frequently with improvised plant, and his ingenious applications of old means are nearly always of direct benefit to someone else, and I would like to see a column or two devoted to any unusual use of an old or new idea, after the style of "Workshop Wrinkles" in the trade papers.

Now that the engineering districts having river and harbor works, especially in maintenance, are making repairs by hired labor to a greater extent than ever before, these little things have values they never before had. These repairs cover the whole range of construction work in wood, stone, concrete, and steel, and nearly always have to be made at a distance from a supply base and with inadequate or improvised plant; and it is for short accounts of such works that I plead.

Many little jobs are done by main strength and awkwardness where a little imagination might adapt some old piece of plant to use and save time and labor. Even if the method tried should not have been a howling success, it might still be of interest and keep someone else from making a similar mistake.

Just as a starter, and to give a concrete idea of what I mean, I give below an adaptation of an old idea as used on the Kentucky River to place rip-rap on the banks, which costs practically nothing and does away with the old method of wheeling in barrows or the more usual carrying of stone in the arms, if beyond the farthest reach of the boom.

Most improved rivers have derrick-boats and barges, but few of them have cable-ways or drag-line outfits; and if they did, the jobs are nearly always too small to warrant mounting elaborate plant.

Handling one-man stone down hill is an altogether different proposition to working them up hill when done by hand. With the rig shown the skip loads of stone are placed anywhere desired between the water and the top of the hill, so we have all down-hill movement to final position.

The rig has just finished carrying from the barge to the top of bank at another set about 50 yards of stone for a small repair to a road. It easily paid to mount the rig for just that little work.

The accompanying illustration is all the description really needed, but a few words may help. Nothing is needed aside from the derrick boat and barges except pieces of timber or poles about 30 feet long for the legs of an A-frame and a sill piece to move it on. This A-frame is stood up on top of the bank and back-guyed with an old wire rope and manila fall for easy adjustment. The barge of stone is placed next the shore and parallel with it, the derrick-boat is outside and head-on to it. The derrick boom is hoisted nearly vertical in order to place the skips on the barge. One of the wire ropes is led from the engine over the tip of the boom, through a sheave at the head of the A-frame, and back to the skip; the other line is led from the tip of the boom to the skip, back-haul and return.

When the skip is loaded, the back-haul is pulled and enough brake applied to the other drum to keep the skip barely clear of the ground until the desired dump point, or the A-frame, is reached. In returning, the empty skip is held rather high in the air when nearing the boom and is dropped with speed enough to overhaul the long rope until the skip hangs properly to lower on the barge.

No claims for novelty are advanced, and it is thought more than likely that many readers have used the same thing many times; it's the sort of thing that is too simple to talk about, yet its simplicity and adaptability make it worth keeping in mind. It doesn't cost much, and really saves a world of back-breaking labor.

In particular, the clear span as shown by the illustration was 240 feet; the lift from barge to top of bank, 42 feet; the load, 1¼ cubic yards of limestone.

The times of movement as taken the first day the crew operated the rig were:

	Min.	Sec.
Loading the skip (only one used that day)	3	48
Hoisting to the full limit	1	18
Dumping	0	23
Returning to barge	0	52
Round Trip	6	21

The cost on a raw winter day was:

5 laborers loading skips, 8-hour day	$15.00
4 laborers placing stones, 8-hour day	12.00
1 foreman	5.00
1 engineman	4.30
1 fireman	3 30
1 timekeeper, part	1.60
Cost for 81 cu. yds. placed	$41.20
Cost per cu. yd., barge to place	0.51

As a matter of interest in this connection, a single skip load of rock was dumped as far back as possible with the derrick-boat and placed in the upper slope in the old manner. The mere placing of this single load, aside from the unloading and dumping charge, required 3 hours' labor of one man, or $0.90 per yard.

"Our success in the war was not due to forethought in preparedness, but to exceptional circumstances which made it possible to prepare after war had been declared. It is my belief that if America had been adequately prepared, our rights would never have been violated, nor our safety threatened.—*General Pershing.*

Report of Chief of Air Service, A. E. F.

The first chapter of the final report of Maj. Gen. Mason M. Patrick, Chief of Air Service, A.E.F. (now Colonel. Corps of Engineers), rendered in March, 1919, and recently published by the Chief of Air Service, Washington, D. C., contains the following summary of the achievements of the Air Service during the war:

When hostilities ceased on November 11, 1918, there were actually assigned to armies 45 American squadrons and 767 pilots, 481 observers, 23 aerial gunners, and the complement of soldiers. These squadrons were equipped with 740 airplanes, with armament of the latest type, and the flying personnel, trained in Air Service schools, was second to none in the world for aggressiveness and skill. Twelve of these squadrons were equipped with American built airplanes and Liberty engines. This engine in actual service fulfilled the highest hopes of it which had been entertained in the United States.

On the Marne, at St. Mihiel, and in the Argonne our air forces were pitted against the best which Germany could produce, and the results show that the enemy more than met his match. Our pilots shot down 781 enemy airplanes which were officially confirmed, and many others, too far behind the lines to be confirmed by our own witnesses, but which were nevertheless undoubtedly destroyed. They also destroyed 73 (confirmed) enemy balloons. Our total losses in air battles were 289 airplanes and 48 balloons brought down by the enemy.

Our squadrons, in round numbers, took part in 150 bombing raids, during which they dropped over 275,000 pounds of explosives on the enemy. They flew 35,000 hours over the lines and took 18,000 photographs of enemy positions, from which 585,000 prints were made by the Photographic Sections attached to observation groups. On innumerable occasions they regulated the fire of our artillery, flew in contact with infantry during attacks, and from a height of only a few yards machine-gunned and bombed enemy batteries, convoys and troops on the march.

Of the 35 balloon companies then in France, with 446 officers and 6,365 men, there were 23 companies serving with the armies at the front. This balloon personnel had also been trained in American Expeditionary Forces schools and in every test proved its worth. Our balloons at the front made 1,642 ascensions and were in the air a total of 3,111 hours. They made 316 artillery adjustments, each comprising all the shots fired at one target; they reported 12,018 shell bursts, sighted 11,856 enemy airplanes, reported enemy balloon ascensions 2,649 times, enemy batteries 400 times, enemy traffic and roads and railroads 1,113 times, explosions and destructions 597 times.

Air Service depots to supply the squadrons and balloon companies at the front were in full operation and others were being prepared to maintain this force, which was to be increased rapidly. Needed steps had been taken to provide for the equipment of this force as it was placed at the front, and it was certain that it could be fully maintained. A production plant had been built and was in full operation, where some 10,000 men were employed in assembling airplanes and in repairing airplanes, engines, and balloons which had seen service at the front.

Our balloons were attacked by enemy airplanes on 89 occasions; 35 of them were burned during such attacks, 12 others were destroyed by shell fire, and 1 blown over enemy lines. Our observers jumped from the baskets 116 times; in no case did the parachute fail to open properly. One observer lost his life because pieces of the burning balloon fell on his descending parachute.

Making Highway Bridges Safe for Modern Traffic

An interesting article which appeared in a recent issue of the *Engineering News-Record* emphasizes the importance of the problem of making our highway bridges safe for modern traffic, under the conditions created by the increase of motor vehicles. Such loads give heavy concentration on individual trucks, but, owing to the dimensions of the trucks and to traffic conditions, these concentrations are not as a rule unduly close together.

It is pointed out that the design loading should comprise a heavy concentration or concentrations for the flooring, stringers, and floor beams and a uniform load say of 100 or 125 pounds per square foot for the trusses, *using also* a single excess load for the trusses which may be placed anywhere and which is equal to the difference between the end shear on the floor beam produced by the concentrated live loading and that produced by the uniform live loading. The use of this excess load insures that all the details of the truss will support the maximum load which the floor can carry, while at the same time it avoids the needlessly heavy truss which would result from maximum floor beam reactions at all panel points at once. The importance of not underestimating military loads is mentioned.

The possibility of the extension of the use of the trailer for more economical transportation leads to tractive force. which can only be gained by weight on the driving wheels of the tractor, and this fact exerts its influence towards increasing wheel loads. Highway surfaces will continue to improve and loads will continue to increase. Restrictive legislation will be repealed as transportation demands increase, and bridges designed for too light loads today will be rebuilt tomorrow because of their inadequacy.

It is stated that the weak part of the floor under modern truck loads is generally the floor beam and that wooden plank floors of ordinary construction are proving to be inadequate to sustain the heavy concentrated loads now encountered. In fact, it is very doubtful if plank floors are now economical, at any rate east of the Rocky Mountains. The wooden stringer is in turn giving way to the steel I-beam, while failures of steel I-beams are generally due to crippling of the web.

Under preferable types, there is mentioned for truss bridges a 6-inch concrete slab floor with heavy steel stringers and floor beams and a moderate truss. In masonry arches, including reinforced concrete, the distributed live load capacity of an arch ring with sound abutments is practically unlimited and it therefore seems undesirable, where avoidable, to place a superstructure of beams, whose capacity is decidedly limited, on top of an arch ring of practically unlimited strength. When financially practicable, an earth filled concrete arch is recommended because of its unlimited live load capacity and because it needs no maintenance other than that given to the highway surface.

The matter of repairing and strengthening weak structures is touched upon, since in many cases proper study and the exercise of a little ingenuity may economically prolong the life of the old structure very considerably at far less cost than the cost of a new bridge.

The Corps of Engineers had sold up to March 25 surplus supplies that cost $124,918,472. The sum of $108,550,237, or 86.89 per cent of the original cost, was realized from the sale.—*Statistics Branch, General Staff.*

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bi-monthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

Address—

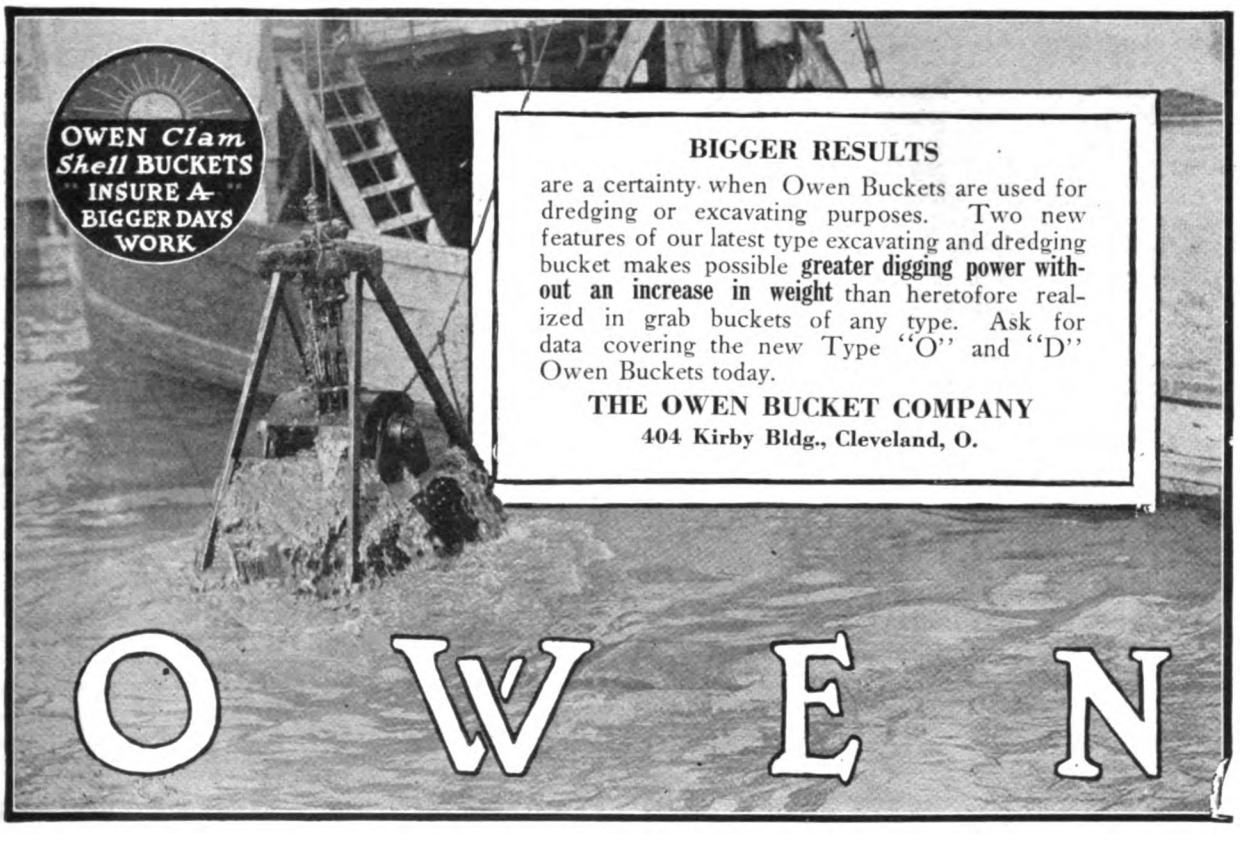
Sub-Drainage Design and Foundation Difficulties of Eel River Dam

The gravity section concrete dam for power purposes, now under construction on the Eel River, 150 miles north of San Francisco, is noteworthy as to design for provisions against underflow. The dam has a crest length of 765 feet of which 485 feet is spillway, and a height of 135 feet.



On examination of foundation conditions at the site of the dam a shale formation with talcose intrusions was disclosed. The shale was pronounced firm enough to carry the weight of the dam, provided water was kept out of the foundation. Accordingly, the axis of the dam was shifted until the structure could rest entirely on the shale, and provision was made for grouting below the cut-off wall to make the seal at the upstream face as effective as possible. Furthermore, a network of underground drains was specified to carry off seepage water which might find its way under the structure.

The excavation made before the first concrete was poured extended 15 to 25 feet below the ground surface for the full width of the dam and a cut-off trench on the upstream face, 5 feet wide, was carried 10 feet deeper than the adjacent excavation. Before pouring concrete, 3-inch pipes were left in the cut-off wall forms, spaced 5 feet apart and placed so that their tops would protrude on the upstream face of the concrete just above ground level. Through these pipes 1¾-inch drill-holes were driven to a depth of 30 feet below the bottom of the cut-off wall and when the concrete had hardened, these holes were grouted under a 200-pound pressure.

The drains under the dam consist of porous concrete tile in 18-inch sections, 3, 6, and 8 inches in diameter. Lines of drains were laid parallel with the axis of the dam and on 15-foot centers under the entire structure. These longitudinal drains are all 3 inches in diameter, except the line nearest the upstream face, which is of 6-inch tile. By means of risers each of these lines is connected every 80 feet to cross lines of 8-inch tile imbedded in the concrete 5 feet above the bottom of the excavation. The 8-inch lines are in turn connected to a gutter at one side of a 3 by 5-foot inspection gallery which runs entirely through the dam beginning at levels near the top at both ends of the structure and extending thence down to a central level 85 feet below the crest of the dam. From its lowest point this gutter discharges through a 12-inch pipe leading to the downstream toe.—*Engrg. News-Record.*

Galileo

How helpful and suggestive to an engineer is a story of Galileo's accomplishments and difficulties. As Prof. John F. Woodhall relates in a recent number of the *General Science Quarterly,* Galileo was a professor at twenty-five, on the faculty of the University of Pisa, at about the same time that a young man named William Shakespeare was seeking his fortune around the London theaters. Because of his inquiring and controversial spirit, Galileo found his dogmatic colleagues impossible to live with, and he left Pisa in disgust; in fact, he was practically driven away by their dislike and calumnies. Later, at the University of Padua, where he remained for 18 years, he lectured to audiences of a thousand and two thousand persons at a time, including distinguished foreigners who came from all over Europe to hear him. At 70 years of age, in 1633, 90 years after Copernicus had published his heliocentric theory of the world, Galileo, a frail old man, was haled before 10 red-robed Cardinals, or "Inquisitors-General," and made to recant his teaching of the Copernican system, because the "Theological Qualifiers" ruled that the propositions that the sun is the center of the world and that the earth moves are "absurd, philosophically false, and formally heretical!" —*Engineering and Contracting.*

Aerial Stereograms

The stereogram (stereoscopic photograph) has constantly grown in favor in army photography, because it far surpasses the ordinary photograph in clearness. It bears a similar relation to the latter that a relief model of a region bears to its map, since it enables the immediate recognition of all differences of elevation and the perception of houses, road-banks, battery emplacements and other details, just as bodily as the objects in one's immediate vicinity.

Like every stereogram, the aerial stereogram always consists of two pictures which, on superficial inspection, *look alike, but really differ* from each other in their reproduction of details. In like manner, the bodily shape of objects is recognized directly by means of our two eyes, the left eye seeing more of the left side and the right eye more of the right side, thereby giving the impression of depth. In a similar way, the two parts of a stereogram must be taken from different view points.

The further apart these view points are (within certain limits which depend upon other considerations), just so much more distant and smaller objects can be brought into relief on the stereogram. The same laws hold good for it, as for the folding field glasses, which give a greater relief, the farther apart the arms containing the lenses are spread. By direct observation, the eyes, on account of their small distance apart, can only see perfectly within a short radius. For example, an aviator does not see the hills and valleys in relief at the usual flying altitude, but only when he is within a few hundred meters of the ground in landing, often with painful surprise at the true character of his chosen landing place. These limits of natural perspective vision are immensely increased by the aerial stereogram, since its components may be taken from points 100 to 1,000 meters apart, or from 1,500 to 15,000 times the distance between a person's eyes. The result is, for example, the reproduction in relief of such small differences in depth as protection trenches, taken from an altitude of several thousand meters, or of wire entanglements in balloon stereograms from a distance of 6 kilometers.

Discussion of "The Army Uniform." By C. E. Carson, formerly Major, Transportation Corps

I have read with much interest the article on "The Army Uniform," by Major Aymar Embury, II, supplemented by various other officers of the Army to whom it was referred for comment, and who, I presume, are connoisseurs on the subject of military dress.

Everything from hat to boots is discussed in a masterly fashion, but practically nothing about a "Sam Brown belt." If there was any part of the uniform worn by our overseas officers during the late war in which they took an especial pride, it was the Sam Brown belt. Sometimes they might be seen with shoes unshined, but it was seldom that the belt was not glistening. This belt not only served to give the uniform a military appearance, but was useful to the officer in carrying, on the march, his military accouterments. After wearing it a few times an officer felt "undressed" without it.

When these overseas officers were returning home, they were instructed to remove the Sam Brown belt, which caused more bitterness among them than any other regulation to which they were subjected. They had sent home photographs which showed the S. B. B. in all its military splendor, and when they reached home with belt in hand, they felt like a "houn' dawg" without a collar.

As one evidence of the popularity of the belt, General Pershing, the only officer of the Army who may prescribe his own uniform, still wears it.

Map Reading

(Continued from page 335)

Discussion

George H. Cameron
Colonel, Cavalry; Commandant The Cavalry School

Major Adams' interesting and valuable personal observations should not have been introduced by a half apology, viz: "To point out, at this late date, mistakes that were made in training officers for the World War, may seem a useless expenditure of paper and ink," etc. We must all endeavor to record worth-while experience, and, in my opinion, mistakes are best pointed out "at a late date," *i. e.*, when we have had time for sober reflection.

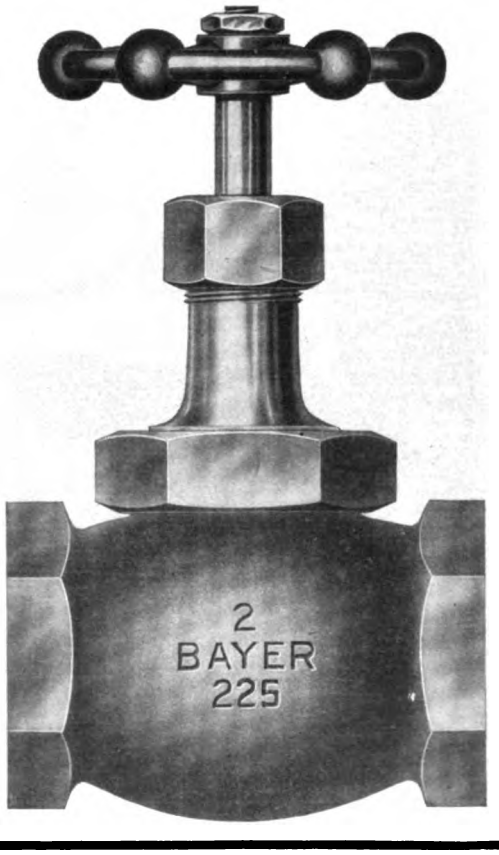
An excellent example of what I mean can be seen in the gradual changes in opinion on doctrine, armament, etc., since the armistice. Early in 1919, many officers, both in our own army and in those of Europe, presented views based on their only war service—that in France—and while its incidents were still vivid in their minds. They adhered absolutely to the methods of close trench warfare that prevailed on the western front in the World War. Step by step, but quite noticeably, there has been a return to old sound principles under the realization that conditions in France were abnormal.

A parallel to the lamentable ignorance that Major Adams portrays was shown in the lack of knowledge in the A. E. F. concerning animals and their care. But our Remount Service profited by the bitter experience, and is now firmly founded and working along excellent lines. Further, a manual on the "Care of Animals" has just been completed by the Cavalry Board; in our next training camps the emergency officer will learn the hygiene of both man and beast.

In the same way we must take steps to remedy the evils pointed out by Major Adams. There is no lack of textbooks. Major Spalding's very recent manual, a public document, shows a clear insight into the difficulties of beginners; his chapters on day and night guiding are especially useful. But when we are again called upon to develop officers in thousand lots, we need for proper training in map reading: 1st, qualified instructors, and plenty of them; 2d, active support and sympathy of higher commanders.

Here, at the Cavalry School, we have an extended course in map reading, as have, of course, all service schools, and I am not willing to admit that there is anywhere a better instructor than is in charge of this section. But our classes are very large, and we constantly observe where the student has gone astray through lack of individual attention. Hence, as I have said, we must have *plenty* of instructors.

It seems hardly necessary to say that the colonel and the brigade commander whom Major Adams cites as unable to point out on the map the routes of elements of their own commands, would not be very keen in pushing and supervising instruction in a subject concerning which they had been content to remain in a state of total ignorance. The truth of the matter is that map making was regarded by the last generation as a specialty, and even proficiency in topographical map reading was not realized to be just as essential to an officer as his ability to read the English in an order. But there are better times ahead, and we may look to higher commanders not only for intelligent support, but for



BAYER
Valves

BAYER Valves are made in heavy-pattern regrinding globe, angle and check types, screw and flanged ends—all good for working pressures up to 225 lbs. Each one is guaranteed to meet the metal composition requirements of U. S. Navy Department specifications 46-B-8, June 20th, 1913, covering valve bronzes or composition "M."

Body walls are of liberal thickness, with a uniform distribution of metal. Valve seats are radial, and can be ground continually, thus prolonging the life of the valve indefinitely. Discs are made of a hard bronze composition; stems are unusually heavy with a greater number of accurately cut threads than usually found in valves of this type.

Naturally, continued satisfaction is the only logical result that can follow adherence to the BAYER standard. Send for our book "The BAYER Valve."

vigorous measures to insure Major Adams' "fair degree of ability to read maps on the part of all ranks and branches."

To the incidents mentioned by Major Adams may be added the following much more serious case. In the Argonne offensive, a division reported that it had captured a certain hill in the sector of an adjoining division, and requested that its troops be relieved by elements from its neighbor. When an order to this effect had been passed up by telephone, a company of infantry marched straight up the hill to take possession. It was received with withering volleys and was driven back after heavy loss. The facts were reported, but previous instructions were repeated On this occasion a field officer with a suitable force was sent in rear of the lines to the P. C. of the officer who had reported the capture of the hill and thence to the position actually held.

It proved to be not the designated hill, but a knoll on a spur of the hill, and distant many hundred yards from the point indicated, which was still held by the Germans.

G. C. Marshall, Jr.

Major, General Staff; Aide-de-camp to General Pershing

Ability to read a map is one of the necessary qualifications of an army officer to-day, yet a reading of Major Adams' article on this subject would indicate that few officers in France were sufficiently trained in map reading. From the viewpoint of divisional, corps and army general staff officers, one of their most difficult daily problems was to secure accurate information regarding the location of the most advanced line in time to serve as a basis for the preparation of battle orders. One reason for this was, undoubtedly, the inability of many infantry officers to locate correctly their ground positions on the map. Air observers' reports were frequently misleading for the same reason.

No discussion seems necessary to demonstrate the importance of map reading, but, I believe, considerable discussion or argument is required to demonstrate that:

(1) A large number of officers who think they can read a map correctly and with the necessary facility, can not do so, and,

(2) Ability to read a map rapidly and correctly is seldom acquired except by practice in making maps.

There is nothing abstruse or difficult about the subject, but an efficient working knowledge can only be acquired by much practice. Merely to understand the principles involved and the conventional signs used is wholly insufficient.

R. G. Alexander

Lt. Col., U. S. Army, Professor of Drawing, U. S. Military Academy

Unfortunately, the incidents given by Major Adams, as showing the inability of American officers to read and use maps were all too common and too typical. They were not limited to junior officers either. In one case a general officer came to the map room at G. H. Q. and asked for a map covering *all France, on a large scale,* and *about two feet square, one that he could put in his pocket.*

This ignorance was all the more striking when compared with the excellent and very practical knowledge of maps common to all grades in the German army. German soldiers taken prisoners by our troops, when examined by our

intelligence officers, could almost always point out clearly and without hesitation all the important points in their sectors as well as the main and subsidiary routes of communication; this, too, on our maps, to which they were not accustomed.

The allowance of maps to the American troops was far more liberal than that in any other army in the war, and yet, as Major Adams has shown, very little use was made of them. The trench maps placed in the hands of all officers and platoon leaders were the latest intelligence information from all sources, and in great detail. They left little to be desired, and yet requests were constantly being received for relief maps, photographs, and picture maps, because the information on the regular maps could not be appreciated and correctly interpreted.

The trouble lay in the lack of elementary and detailed instruction in map reading. There were so many things to be learned by our new troops and so little time in which to learn them, that it is not surprising that some were neglected. There was probably too great an assumption that anyone could read a map and too little appreciation of the amount, character, and value for practical purposes of the information on the map. Many people consider themselves proficient in map reading when they can laboriously scale off a distance on the map or work out the direction of one point from another. They never really study the information presented or acquire the ability to visualize ground from the map.

The difficulty can, in my opinion, be overcome by starting at the very beginning and taking nothing for granted. Last summer, for the first time, the fourth classmen at West Point were given a course of twenty lessons in map reading during their first month at the Academy. The course was very elementary, including exercises in scaling distances by road and by direct line, learning the principle conventional signs, the meaning of contours, and the representation of typical ground forms, plotting simple profiles, courses by bearing and distance, the location of points by co-ordinates, and practical exercises in the field illustrative of the above.

The results were at once apparent in the ability of these cadets to use their maps in field problems under the tactical department, and later in their better preparation to take up the work of surveying under the Department of Practical Military Engineering. They will this year have a course in topographical drawing and field sketching, and will later on have advanced map problems, both indoors and in the field. The repeated drill in theory, combined with practical application to actual problems, should produce the desired results.

C. L. Hall
Major, Corps of Engineers; M. Am. Soc. C. E.

The "horrible examples" enumerated by Major Adams of the ignorance of map reading displayed by the American Army are but too typical. The writer's official position made him conversant with the map situation over the entire American front, and there is no manner of doubt that lives were lost as a result of lack of proper training among emergency officers. However, the blame for this condition does not lie upon them. Ignorance of maps and mapping was a common failure in our army prior to the war. This ignorance took two forms, first in issuing instructions for the preparation of maps which were technically impossible of fulfillment; second, in inability to use the maps in question, or, indeed, any maps, after they were prepared and furnished.

While it would undoubtedly be valuable, as Major Adams suggests, to prescribe a course in map reading during the instructional period of our next war, this measure will be totally insufficient unless the officers of the regular army receive complete and accurate instruction in map reading themselves, and unless, also, they have sufficient knowledge of map preparation and map reproduction to enable them to issue intelligent instructions to the technical staff. Colonel Alexander is to be congratulated on the course which he is giving at West Point.

The writer ventures to suggest the following additional remedial measures:

I. Instruction in map reading, as such, to be made compulsory in the basic courses of infantry, cavalry, field artillery and coast artillery schools.

II. Lectures are to be given at all these schools in the technique of surveying and the technique of map reproduction to make it certain that an officer calling for maps will know what time and labor are required to comply with his requests.

III. Instruction in map reading in all R. O. T. C. instructions to be standardized.

IV. Instruction in map reading to form a part of the course at the Blue and White Citizens' Training Camp.

The office of the Chief of Engineers is preparing a manual of topography, the first chapter of which—Map Reading—will shortly be issued to the service. It is to be hoped that this chapter will be digested by all combatant officers, and that the inspectors of tactical organizations will assure themselves that the officers of those organizations are able to comply, on the ground, with orders laid on a map.

The method which was at one time fashionable in the military service of securing acquaintance with map reading by requiring every officer to become a sketcher is somewhat outworn. It is true that every first-class sketcher is a competent map reader, but many men, perfectly capable of learning map reading, lack the manual dexterity requisite to finished sketching. Therefore, when time is limited, any hours spent on the technique of sketching can be had only by the sacrifice of time otherwise available for valuable practice in map reading. Under such conditions, to insist on facility in sketching as a part of every combatant officer's store of learning is undesirable. Men *can* be taught map reading by reading maps on the ground. This is the simplest method of instruction, and it is unwise to insist on any more complicated one.

R. A. Wheeler

Major, Corps of Engineers; Senior Instructor, Second Section, Department of Military Art, The Infantry School

In modern war, maps are the basis of all tactical plans. A mere superficial knowledge of map reading will lead to disaster. Every officer must possess a critical eye for the ground and the ability to interpret, visualize and vividly remember the conformation and character of the ground shown on the map.

For obvious reasons map reading is the first subject taught to classes entering The Infantry School. Briefly, the course embraces the usual fundamentals with practice in orientation through terrain and "map-comparison" walks, visibility problems and study of domestic and foreign maps.

This course is but an introduction to the other school work required of the student. Throughout the course he constantly improves his ability to read maps, and by association and repetition develops that "eye for terrain" essential to his success as a military commander.

Infantry reserve officers will be trained along the same lines so far as time permits.

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

Reorganization of the Engineer Service in the French Army
(Continued from page 339)

devices should certainly be used where possible, but very frequently the tactical situation will make their use impossible.

The infantry division is a fighting unit. It operates in the battle zone, where man power is the chief reliance. Engineers with an infantry division must not be burdened with a lot of mechanical devices, which will never be used, or used only in exceptional circumstances, and whose transportation is always troublesome. They, too, must rely on man power. In the emergencies where such mechanical devices may be needed, aid will be given by corps or army troops.

Discussion

by

F. B. Wilby
Major, Corps of Engineers

In commenting on this brief outline of the reorganization of the engineer service in the French army, it is rather difficult to draw accurate comparisons to our own new organization, as some details of the French scheme are missing, and some of the terms used, such as "transportation," are more or less indefinite and not quite clear as to just what they cover. In general, however, the *"Duties of engineers in the field,"* the allotment of engineer personnel, and duties of the chief engineer, as given under *"Engineer troops of a large unit,"* and the general principles enumerated under the heading *"Remarks,"* are almost identical with the accepted principles for the use of engineers in our service. This similarity is especially noticeable in the creation of a general reserve of engineers; the realization that a large proportion of common labor will be needed, and its segregation into special labor units, and the elimination of many of the mechanical devices developed during the war, with the consequent reliance upon man power, especially for units in the forward areas, such as the engineers with the infantry and cavalry divisions.

The fundamental difference between the French organization as outlined in the above article and the new organization for the engineers in our service, lies in the *"classes of engineer troops"* adopted. It is interesting to note that the French have adopted the company unit as standard for all engineer troops assigned to units above the division, with the exception of railroad regiments and transport battalions. This conclusion is in agreement with the recommendation of many of our engineer officers during the recent war, especially the engineers from civil life, whose military engineering experience was confined to that obtained during the war. It was not adopted for our service for the following reasons:

(a) The company unit, although most efficient from a technical standpoint for engineering work in rear areas where the jobs are widely scattered and often capable of being handled by one company of skilled engineers supplemented by the necessary amount of labor, is not an efficient unit for administration, movement, supply or training from a military standpoint, especially when the number of separate companies permanently required by any unit becomes great.

(b) It is difficult to create and maintain "esprit de corps" in a unit as small as a company, whereas, this much-to-be-desired esprit is more easily created and maintained for units the size of a regiment.

(c) The opportunity for advancement, both for the en-

listed man and the officer, is very much restricted with an organization consisting of a large number of separate companies, whereas there is a normal flow of promotion provided if these companies are organized into regiments.

In the French organization there seem to be a large number of special engineer units, such as mining companies, bridging companies, standard and narrow gauge railroad regiments, electrical companies, water-supply companies, forestry and hut construction companies, road companies, and several engineer trains and transportation units. In the new engineer organization for our service, constant effort has been made to eliminate special units wherever possible, substituting general engineer troops capable of performing all kinds of engineer construction work. This difference, it is believed, is most important for our engineer service, which may be called upon for duty in widely varied theaters of operation, and under various conditions of service, whereas in the French army the general prospective theater of operations is restricted and the conditions of service are very well known beforehand. It would be interesting to know the proportion of special units provided in the new French organization as compared with the number of general engineer units. In our service the proportion will be 15 per cent special units to 85 per cent general.

The number of different kinds of railroad troops provided in the French organization is not quite clear from the data given. It would seem that there are to be at least two kinds, one for standard gauge railroads and another for narrow gauge railroads, but whether each of these is subdivided again into construction, operation, and shop units is not made clear. In our service it is proposed to handle all railroad construction by general engineer troops, and all railway operation (no matter what gauge) by one type of railway operating battalion. This method, I believe, will differ from that proposed for the French army.

The "Cyclist Engineer Unit" with cavalry divisions in the French organization is most interesting, and in this connection it is pertinent to state that the supply of Ford automobiles for at least 50 per cent of the engineer personnel with cavalry divisions has seriously been advanced for the British army, although when mentioned to our own cavalry authorities this suggestion created only amusement.

Examinations for Regular Army

After the selection of the successful candidates who took the examination on April 25, 1921, for appointment in the Regular Army, there will remain more than 3,000 vacancies in the grades of 1st and 2d lieutenants. Some of these will be filled by examination for appointment as second lieutenants to be held on August 22, 1921, Appointments will be made in the infantry, cavalry, field artillery, coast artillery, engineers, air service, signal corps, quartermaster corps, ordnance department, chemical warfare service and Philippine scouts The number of appointments in each will be announced later. The general provisions covering preliminary examinations prior to the final examination on August 22 are similar in general to those governing the examination of April 25, which are given in full on pages 135 and 165 of THE MILITARY ENGINEER, No. 68, for March-April, 1921. Readers are urged to bring this matter to the attention of such of their younger engineer friends as they consider will be interested. Detailed information may be secured from any military post or station, or from the corps area headquarters.

Why Work for Uncle Sam?

By

Brehon Somervell

Major, Corps of Engineers

IN an effort to increase its efficiency the Administration has announced its intention to reorganize the Government departments. Undue duplication of effort should undoubtedly be eliminated, and if certain work now being done by a number of the departments can be handled more advantageously by being transferred to a single one of them, or by the creation of a new one, surely no one will oppose such a move.

The only danger in rearranging the work of the various departments is that the matter may be overdone. It must be reasonably certain in advance that with the proposed rearrangement the work will be handled with better technique, greater expedition, and more advantage to the departments for which the work is being done and therefore to the nation at large. Until these conditions are assured changes should be made with caution. For example, the proposal to create a Department of Public Works does not show on its face that these requirements will be satisfied by its establishment. The proposal to combine in a Department of National Defense the activities of the army and navy should also be carefully examined. A statement was made in the last Congress that 93 per cent of the money appropriated by the government to date has been spent in connection with past and future wars. This figure, of course, included pensions and other items of like nature which are not under the War and Navy Departments. Whether or not it is too large, it is certain that the bulk of government expenditures have been brought about by the national defense. In other words, the greater part of our taxes are expended directly or indirectly to maintain the policy, or lack of policy, in respect to the army and navy. Are we to combine in a department of National Defense 93 per cent of the government's activities and have 1 per cent assigned to each of seven or eight others. Such a proposal does not seem logical.

Before proceeding with the reorganization which is undoubtedly necessary along certain lines, there are certain fundamental faults existing in the present departments which must be eliminated before a change in organization will produce any real improvement.

Inasmuch as we are particularly interested in the War Department, the rest of this paper will be devoted to an exposition of those faults which prevent it from attaining its greatest degree of usefulness with the funds appropriated for its support.

Mr. Crasson, editor of a London magazine, asks for the reason why all government departments the world over are operating with a reduced output: "Speaking quietly, without rage and prejudice, can any one tell why it is that all government departments in all countries are slow, wasteful and incompetent? There must be some basic reason for this, as the individuals in these departments cannot all be inferior to individuals in private firms * * *. The fact seems to be that a man simply cannot be competent in a government job for these ten reasons:

(1) There is no payment by results.
(2) There is no fear of discharge.
(3) There are no profits to be made.
(4) There is no danger of losing customers.
(5) The main thing is accuracy, not success.
(6) Time is of no consequence.
(7) The work is impersonal.
(8) There is no competition.
(9) Routine is put ahead of service.
(10) There is no enthusiasm."

This is certainly a formidable indictment if applicable to the War Department, and a condition which, if true, should be eliminated before or during reorganization.

(1) *There is no payment by results.* This charge is true of our department as regards both military and civilian personnel. One receives as much for doing badly as one does for doing well, except in a few instances, and their number is so small as to be wholly negligible. This is really the worst evil of our system. Two officers may sit at adjoining desks in the same room. They may be of equal rank and draw equal pay, both may be promoted on exactly the same day. One is capable of much accurate work, the other manages to escape Class B by a narrow margin, and yet there is no reward for the man of superior ability in the way of advanced rank or pay. The high grade man knows this and wonders why he works hard when his neighbor accomplishes little and receives the same reward.

An officer's efficiency report has been indorsed to the effect that he is inclined to be careless when no incentive is offered. Can any one blame him for that? Persons who work merely to be at work are few and far between. Even preachers work for reward in heaven. Most are seeking more tangible results and an earlier reward for their labor.

As long as promotion by senility and not by ability continues in force, incentive is lacking and so are results. Until some scheme for promotion by ability is devised progress and output will be retarded.

What has been said about officers applies with equal or greater force to the civilian employees. Some superannuated, doddering clerk will hold a position merely by reason of length of service and, indeed, in many cases, when he has nothing else to recommend him.

(2) *There is no fear of discharge.* This is not entirely applicable to our War Department, but the legislation and regulations governing discharge are so clumsy and bound up with red tape that it requires a great effort to rid oneself of any undesirable subordinate. Ordinarily he is transferred, not discharged, and some other executive finds himself burdened with a piece of dead wood.

Digitized by Google

(3) *There are no profits to be made.* The War Department is not a business concern as are some of the other government departments, such as the Post Office, which show a yearly deficit. However, it does handle immense sums yearly, and every taxpayer should demand their economical expenditure in time of peace. War is not inexpensive and cannot be made so, but expenses will be reduced by adequate preparation in time of peace and the provision of competent officials to regulate expenditures in peace and war. The idea that "there is no possibility of bankruptcy and that the Treasury has plenty" should be scrapped for good and all.

(4) *There is no danger of losing customers.* The War Department has no customers but it can estrange its supporters by wasteful and inefficient methods.

(5) *The main thing is accuracy and not success.* With the present system of efficiency reports the timid or overcautious individual is afraid to try something new for fear that he will fail and receive a black mark on his record. The result is obvious. His idea is to avoid mistakes. The less he does the fewer mistakes he makes. No one knows what per cent of the Department is affected by this form of disease, but indications are that it is rather high.

(6) *Time is of no consequence.* One has so many years to do before one retires. What is the use of hurrying a job along when another is bound to show up? Nothing results from getting this one finished. It is somewhat like eating in that one has to eat a certain amount to live; any more causes discomfort of some sort.

(7) *The work is impersonal.* An improvement along this line is noticeable but "the buck is still passed" many times a day. The clerks generally arrange a system whereby no one of them is to be blamed no matter what happens.

(8) *There is no competition.* This is not exactly true of our War Department, as we have the Navy and Marines to line up with on certain occasions. Competition is generally severe at the service schools and there are always applicants for soft jobs. What is the reason for taking a hard one when the individual gets just as much compensation and advancement for taking the easy one? The result is competition for easy instead of for responsible jobs, or for pleasant stations instead of those affording better opportunities for real work.

(9) *Routine is put ahead of service.* The file clerk thinks the office is run to provide him with papers to be put away. Months are often consumed in getting a complete set of visas on requisitions instead of shipping promptly the articles called for. The auditor is just closing accounts of disbursing officers who ceased to function in 1918.

(10) *There is no enthusiasm.* This is one of the charges which can be denied in part. If some officers did not have a conviction that the service is the best as well as the oldest profession the army would go to pot in a short time. These are the enthusiasts who have prevented a collapse when incentive or reward were lacking and who confidently hope that some day the War Department will function on a sound basis. This hope, which has never been closely realized except in the A. E. F., where conditions more nearly approximated those demanded by correct principles, is all that has kept the army going.

With the present system there is practically no hope for enthusiasm among the civilian personnel. No real career is offered them and they are reduced to being bread winners and nothing more.

From the above analysis it seems that Mr. Crasson's arraignment of the faults of all government departments is applicable in almost every specification to our War Department—the most expensive of all our government agencies.

Before proceeding with the reorganization of the government let us eliminate the faults which he has pointed out. An improvement can be secured only by providing (1) proper incentive by means of reward for good service in a reasonably short time; (2) instant elimination of the incompetent and unfit; (3) suitable competition, which will result from providing a proper incentive; (4) definite chains of authority and responsibility. Until this is done, little if any increase in efficiency will follow a mere reallotment of government functions. A change in form, though helpful, does not go deep enough and will not make the departments efficient machines.

ADAPTABILITY FOR ANY KIND OF WORK
WILLIAMS BUCKETS

Whether it be in loading or unloading and handling all kinds of bulk materials, for dredging and excavating work, or for any of the many heavy capacities in which buckets are commonly employed, WILLIAMS BUCKETS may be relied upon thoroughly.

Williams Buckets

"Built to Dig and Last While Digging"

They live up to their name. They are built to give constant service. Built with large bearings and with well-guarded cables. They hold their alignment and stand the gaff in all kinds of digging and handling.

Principles Governing the Use of Combat Engineers

With Illustrative Examples

By

W. A. Mitchell
Major, Corps of Engineers

(Continued from Page 331)

Principle: *The problem of the engineers to-day is different in almost every operation, and the assignment of engineers must be varied according to circumstances.* The following is quoted from the report of St. Mihiel operation, showing how the 2d Engineers were divided up for this battle.

"It was evident that the Engineers must make preparation to cross the river at Thiaucourt and must assist every one in getting over 'No Man's Land;' the artillery needed help, the tanks needed help, and we had plenty of work of our own to prepare the bridges for crossing the Rupt de Mad at Thiaucourt. Studies of the map were made, aerial photographs were thoroughly gone over, and all possible information was obtained from the French records. The regiment was finally divided as follows for the operations:

"(a) Two companies, less a few detachments, as wire cutters (almost a whole company of these two later diverted to take care of the large tanks).

"(b) Four platoons at Noviant Dump to load and unload material and for emergency work which would later arise.

"(c) Nine squads to go with the small tanks.

"(d) Six squads to go with the artillery.

"(e) Two trap-hunting platoons, one to follow each attacking infantry regiment and look for traps and do other effective work.

"(f) Balance of the regiment (about two and one-half companies) to follow in rear of the advancing troops and repair roads.

"(g) Map section to follow the 3d brigade and report concerning the character of the roads, and what work would be advisable on them.

"As it was believed that the Thiaucourt bridges would be destroyed, 24 standard trestles, 10 feet high, were made and placed ready on trucks so that they could be run forward for repair of these bridges. Three special squads from the platoons at Noviant Dump were detailed for this work.

"Two officers were specially detailed to study up beforehand and look out for the water supply. They were instructed to label such water as could be found and to be prepared to furnish all possible information, with their recommendations, as to development of water points. In this instance a water monograph was obtained from the army engineer, and this information proved to be of great value to the divisional engineer troops in the advance of water reconnaissance. It was seen that it would constantly be of much benefit if the divisional engineers were, prior to each operation, furnished a copy of the water monograph of the sector to be covered in advance. This was not always done; in fact, it was the exception and not the rule. For this reason it was impossible in many cases to obtain very valuable information contained in these monographs relative to water-supply systems, bridges and river bottoms.

"For road work, small bridges of the 'Cheney' model, in half sections, were prepared and loaded on artillery caissons and engineer wagons and transported, so that they would be thrown over the old and new trenches in 'No Man's Land.'

"Also, fascines were built for the tanks, so that ditches and trenches could be filled. They were not considered as of much value, but the tanks wanted them, and we built them.

"Two wagon loads of tools had been delivered at convenient points for each of the two regiments (9th and 23d Infantry) which formed the attacking brigade, and four extra loaded wagons were held in reserve for the two regiments of the 4th brigade, as they stated that they did not want any tools for the present.

"The army and corps engineers had stocked up engineer dumps at St. Jean, Noviant, Dieulouard, etc. Consequently, there was no lack whatever of engineer material."

The following is quoted from a message from a battalion commander concerning the work of the platoons hunting booby traps and pit-falls, showing the varied character of their work:

"Lieut. Slade reports our tanks going up to line; occupation of Jaulny completed yesterday p. m. One squad of Lieut. Slade's detachment under Sergt. Poteet captured 7 Germans and a machine gun in Bouillonville 12th Sept., and with 8 infantry from the 89th cleared the town and captured several prisoners, including 10 officers; prisoners turned over to 89th Am. Div. He further reports the main 3-way road to Jaulny clear. Two-way steel bridge (girder), 50 meters long, was in shape for heavy traffic last night; mine chambers emptied. One trestle pile bent, wooden bridge alongside needs repair of one bent on enemy side before possible for traffic. He reports narrow gauge line, Thiaucourt-Ese to 5th Div. front, was ready for operation last night. His steel gang, with work trains, is laying rail to meet Company 'B.' He (Lieut. Slade) has taken steam engineer and work train to Thiaucourt and works north of Jaulny. One detail is going on to Jaulny, presumably to reconnoiter, and rest of platoon is ready to go forward. Complete itemized inventory at dump at 364.9-240.2 has been made and filed there. A copy will be sent here later. I ordered Lieut. Slade to remain on the job. Herewith copy of list of materials at Thiaucourt received last night from Lieut. Slade. An itemized list of narrow gauge railroad material and supplies at Thiaucourt received last night from Lieut. Slade. An itemized list of narrow gauge railroad material and supplies at Thiaucourt turned over to Lieut. Wyman by me this morning."

The following is quoted from the official report showing the varied character and amount of work done by the engineers in the Blanc Mont Campaign:

"Summary of Results. It is believed that in this operation the engineers did about all classes of work that could have been expected of engineer troops, and some classes of work which need not have been expected of engineer troops. The following is a summary of the results accomplished between October 2 and October 10, inclusive:

"(a) Thirty kilometers of wagon roads were repaired and put in shape.

"(b) Twelve kilometers of two-way paved road were repaired, including actual paving of 200 yards of two-way road by means of rock hauled principally by the engineers with its engineer train transportation, and the temporary construction of 600 yards of side roads at the point, to carry traffic in the meanwhile.

"(c) Regulation of traffic during two nights along seven kilometers of two-way road and fifteen kilometers of wagon roads, and during two more nights along seven kilometers of two-road way.

"(d) Two bridges about 20 feet long were built to carry light traffic, one of the bridges requiring about 100 linear feet of fill in its approach.

"(e) A pile bridge, 22 feet long, was constructed, capable of carrying the heaviest traffic.

"(f) All necessary tools were furnished to the infantry at places selected.

"(g) Maps showing engineering information were prepared and distributed daily, when necessary.

"(h) Two or three pumps were repaired and the water supply materially improved thereby.

"(i) Considerable material was hauled, about 500 loads of stone being hauled by the 2d Engineer Train.

"(j) Probably 1,000 German prisoners were fed while awaiting evacuation.

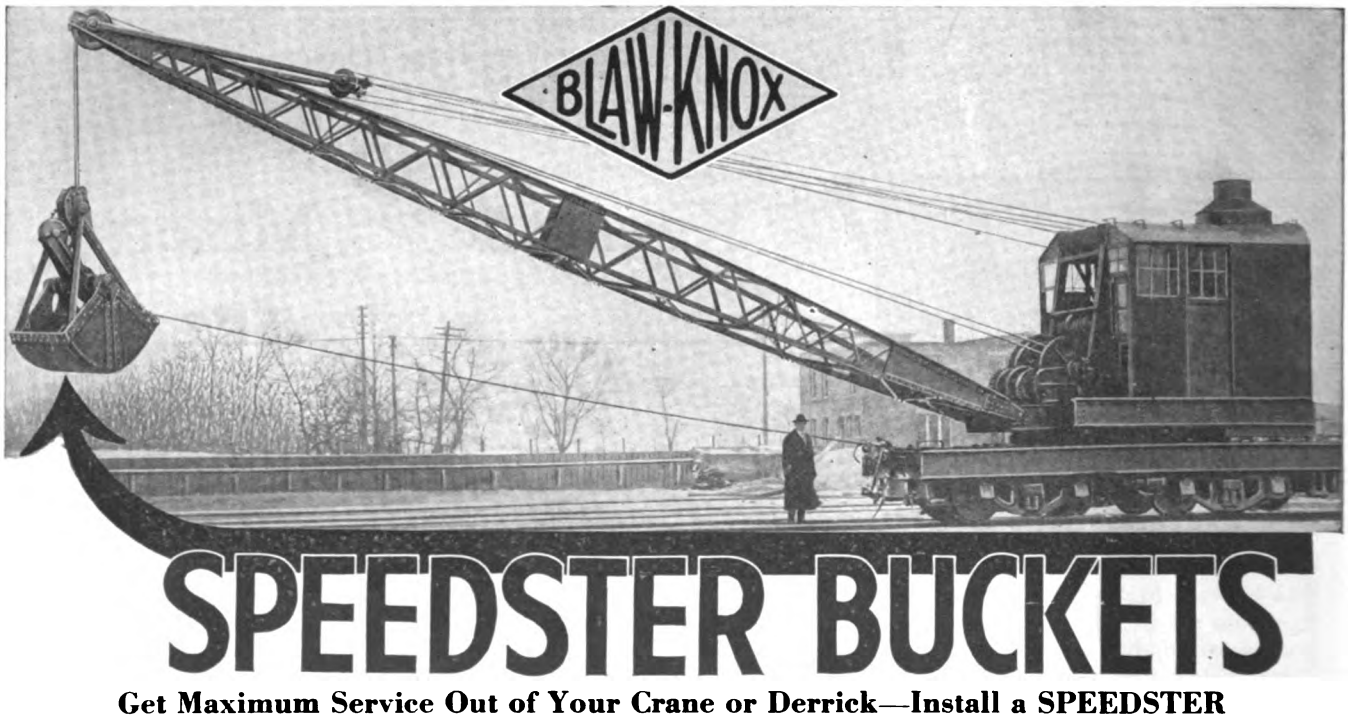
"(k) About 200 yards of roads were built for various field hospitals.

"(l) Electric light equipment of one field hospital was repaired and put in shape.

"(m) Two dumps of engineer material, captured from the Germans, were taken over and lists made of their contents and furnished to the Chief Engineer, American Expeditionary Forces, so that the United States would get credit for the material. Later, we obtained receipts from the French for these dumps and forwarded them.

"(n) A gap was filled in the right of the fighting lines; supports and reserve were placed back of this gap and other portions of the line. Four machine guns and thousands of rounds of ammunition were taken by us from the Germans in front of us. These machine guns were then manned by engineers and used effectively against the Germans.

"(o) Two companies were placed in the left of the fighting line, and one company in support, thereby closing a very large gap. A few prisoners were captured.



"(p) Four American machine guns were partly manned by engineers specially detailed for this purpose.

"(q) A platoon built roads for the rapid movement of the artillery, and at one time, believing that a counter-attack was imminent, this platoon gathered together some Browning and Hotchkiss machine guns and manned them preparatory to repulsing any dangerous break-through by the Germans."

Principle: *In general, communications are the main work of a division engineer regiment. The main duty is to get the division forward. When not otherwise occupied, the engineers will work on roads or railways or bridges to be used by the division.* At the St. Mihiel campaign the 2d Engineers (2d Division) repaired the light railway from "No Man's Land" to Thiaucourt without orders. In the Blanc Mont sector they repaired 12 miles of light railway in order to connect up with the French. In the Meuse-Argonne they repaired several miles of railway at Landres-et-St. Georges in order to help out the light railway troops. Reconnaissances were made into adjacent sectors in order to determine just what railways should be repaired. In the Meuse-Argonne these reconnaissances showed that the railways were very badly broken in both adjacent sectors.

Principle: *Combat engineers are equipped for superficial road work only; systematic road work should be done by engineers having the necessary trucks and road equipment.* It takes over 2,000 3-ton truck loads of broken stone to build a mile of 2-track road. As a combat engineer regiment can at most use for such work some 8 or 10 trucks, it is evident that its work will not be very effective.

At St. Mihiel and the Argonne, especially at Avocourt, the combat engineers carried rock in their hands to repair the roads. This was necessary because no road troops were available and the roads were blocked by vehicles which should have not been forwarded at this time; but if road

Get Maximum Service Out of Your Crane or Derrick—Install a SPEEDSTER

The Blaw Knox Speedster Bucket is the highest possible development of grab bucket for rehandling loose bulk materials—it is especially suitable for loading and unloading cars, and for the speedy transferring of coal, gravel, sand, ashes, cinders, granulated slag, etc., to and from stock piles. Also suitable for light excavating.

This standard line of varied dimensions and capacities is carried in stock in convenient shipping centers throughout the country. Prompt delivery of exactly the bucket you need is assured.

Blaw-Knox Company manufactures clamshell buckets for every digging, dredging or rehandling need—a type suited to your equipment.

troops had been available and the combat engineers could have been used on the more effective work of getting forward the division units, it is very probable that the advance would have been more successful.

In the last phase of the Argonne almost every combat engineer regiment had to drop behind in order to work on roads. This work was very inefficient, but had to be done because there were no road troops available and food and ammunition was needed at the front; moreover, the crossing of the Meuse was delayed thereby because the engineers could not be with the leading elements of the division to help them in their crossing.

The 1st Engineers scraped the mud off of part of the Bugancy-Stenay road with shovels. Probably a thousand engineers spent one day on work that could have been done in half the time by three men, a truck and a road scraper.

Principle: *Engineers should move with the infantry lines if necessary in order to take care of the technical engineer work.*

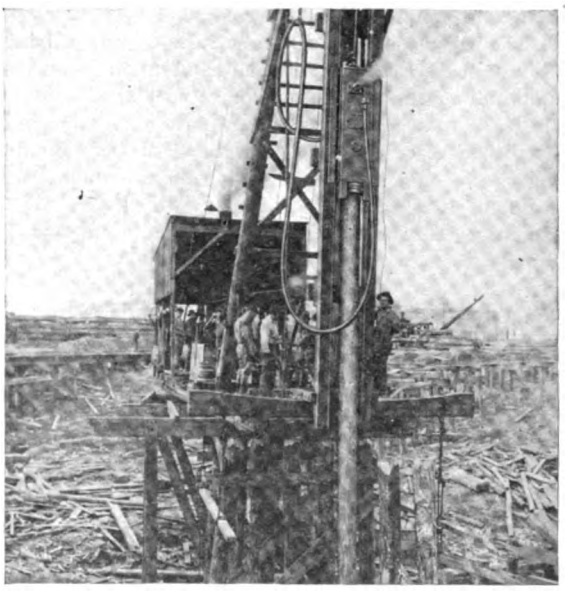
The principal work before the engineers in the Meuse-Argonne was seen to be the maintenance of roads. A study of the map showed that the whole 2d Division trains would have to go through Landres-et-St. George; consequently this was the critical point, and the 2d Engineers decided that they must clear the streets and get across the creek at that point with the utmost possible speed. One whole engineer company was ordered to follow the infantry support into the town of Landres-et-St. Georges, fix the bridge and clear the streets of the town. They did this as ordered and lost twenty-four men. However, it is thought that the advantage gained was worth the losses, because this road through Landres-et-St. Georges was, for a time, the most popular line along the whole corps front. It was used by all of the three divisions, by portions of two other divisions, and by corps and army troops.

Principle: *Engineers should be used as infantry when necessary. When used as infantry, they should be used on special duty assigned by a division commander; they should not be split up and farmed out to infantry brigades or regiments.* The 2d Engineers, in the battle of Chateau-Thierry, were used in many ways as infantry. In some cases the companies were separated and sent to do engineer work with different infantry regiments. In such cases, the infantry commander immediately figured that he had just that many more riflemen and generally proceeded to use them solely as riflemen. In the Chateau-Thierry campaign it is possible that this could not be helped in several of the cases in view of the fact that this battle was at first in the nature of a meeting engagement; but when possible this practice should be avoided.

Before using engineers as infantry, a division commander should consider certain things, viz:

1st. Has he any infantry left that can properly do the work? There was at least one case where engineers were used as infantry when there was plenty of infantry available and suitable for the purpose.

2d. Is the emergency sufficient to justify using his engineers?



3d. If he wins, will he not find that he made a mistake in using his engineers, in view of the immediate need of them for road and bridge work?

4th. If he loses, will he not find that he made a mistake in using his engineers in view of the immediate need of them for demolitions and for rear guard?

After considering all these things, he should use them as infantry when necessary and count them "expended" as infantry for that particular day's work. As stated in the discussion regarding training, he is responsible for the results.

and he should train and use his troops properly; otherwise he is not fully acquainted with the duties and capabilities of the troops of his division.

There were many cases of improper use of engineers as infantry; but more often the combat engineers were used on road work when they could have been better employed in helping the artillery, machine guns, etc., or even as infantry. One case was reported where an engineer platoon was ordered to stand up and dig holes for a certain number of infantry who were lying down and shooting; the engineers did not dig long, as some of them lay down unintentionally and some of them lay down intentionally and began shooting.

The following is quoted from an official report of a combat engineer regiment:

"To the division staff, engineers are specially trained men, who can fight as infantry, but to an infantry brigade or regimental commander, engineers reporting to him represent only an additional force of infantry and generally are used immediately as such. This battle showed, and it was promptly adopted as a future policy in this division, that the engineers must be kept under the direct control of the division commander; that they should be kept generally on engineering work under his control; that they should never be attached to infantry brigades or regiments except for a specific task as engineers or even as infantry; and that they must be returned to the direct control of the division commander immediately upon completion of the specific task in which they have been assigned."

The following are examples of excellent use of engineers as infantry:

(a) The 1st Engineers in the Argonne captured and held Hill 269, an important hill on the right of the division line.

(b) The 2d Engineers at Soissons and Blanc Mont were ordered by battalions into certain parts of the line to assist a much exhausted infantry.

(c) The 6th Engineers (3d Division) in the Argonne materially assisted the infantry in a desperate and successful attack against part of the German line.

(d) The 316th Engineers (91st Division) sent a battalion into the fight at Eclisfontaine in the Argonne which made the final and successful effort to drive back the Germans.

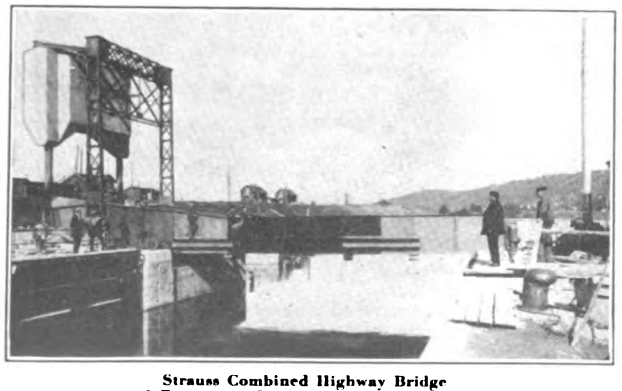
(e) The 110th Engineers (35th Division) were thrown across the front of the sector of the 35th Division during the emergency and intrenched and held the whole front of the sector of that division for nearly two days.

Principle: *Combat engineers who have been used as infantry understand conditions and work more effectively as engineers.* It is admitted by all that corps and army engineers did not work as rapidly or effectively as combat engineers. It is even claimed by some that the 1st, 2d and 6th Engineers were the best workers in the army because they had experienced more fighting.

The men of the battalion of the 316th Engineers (91st Division) that fought at Eclisfontaine always had the edge on those of the other battalion and called them "supply troops."

One combat engineer regiment sent forward to build a bridge, sent back wild reports to the effect that the bridge could not be constructed and that the engineers had been forced to retire by the heavy firing; investigation showed that not a man had been killed or wounded. This combat engineer regiment had previously had no fighting experience.

Principle: *It is an error to have the engineers do nothing while waiting in reserve; they should be ordered to work on communications, being prepared however to assemble at a certain selected point for use as infantry.*



In the Meuse Argonne the 1st, 6th and 316th Engineers were used as infantry. In all of these cases they were being used on road work before being used as infantry. There is no criticism of the use of engineers as infantry, and it was proper to make them work on roads until needed as infantry, having in mind their physical condition after toiling on the roads.

At Soissons the 2d Engineers, while waiting as division reserve, without orders cleared the Paris-Soissons road. This work was very useful, as troops from many directions used this road within the next twenty-four hours.

Principle: *Combat engineer troops need rest just like other division troops.* If they work as they should work when work is to be done, they get tired physically and mentally, just like other troops, and a division commander should take care of his engineers just as he takes care of his other troops.

When the last phase started in the Argonne, many of the artillery and engineer units had been about thirty days with the front-line divisions. During this time the infantry had been withdrawn, rested, and were ready for a new tilt with the enemy. The artillery and engineers were tired, and they showed it. During the next ten days one combat engineer regiment lost over 7 per cent from sickness alone, and the artillery reported that they had left only about one-half of the able horses that they needed. In one case it was necessary to build them a narrow gauge railroad to carry ammunition, because they did not have horses to haul it the usual distance from an ammunition dump. One engineer company wore itself out on this work and another company had to be substituted.

Principle: *It is not practicable to throw a large bridge across a river when the enemy holds the opposite bank.* A bridge is a defile, with the added difference that the defend-

Digitized by Google

ers of the defile may scatter in a line perpendicular to the defile and shoot the bridge builders at their leisure. Such bridge building has been impossible in wars before the World War, and the greatly increased power of modern weapons makes an attempt at such bridge building even more inadvisable.

At Fredericksburg the Union engineers attempted to construct a ponton bridge across the river while the opposite bank was held by the Confederates. Many men were killed and no progress was made. Finally, infantry was ferried across, seized the opposite bank, and the engineers built the bridge.

In the work of the Union cavalry to protect the flank of the Union army marching to cross the James and advance on Petersburg, the cavalry complained very greatly because the engineers did not build a bridge across a small stream so that cavalry could cross and drive the Confederates from the opposite bank. Finally, the cavalry crossed and drove the Confederates from the bank, and the bridge was then built.

Principle: *It is possible by surprise to construct a foot-bridge across a small river held by the enemy on the other side; such a bridge can be made of rafts and the whole bridge lifted and shoved across the stream. A raft bridge can ordinarily be made of material taken from any lumber yard or of pieces taken from old wooden houses.*

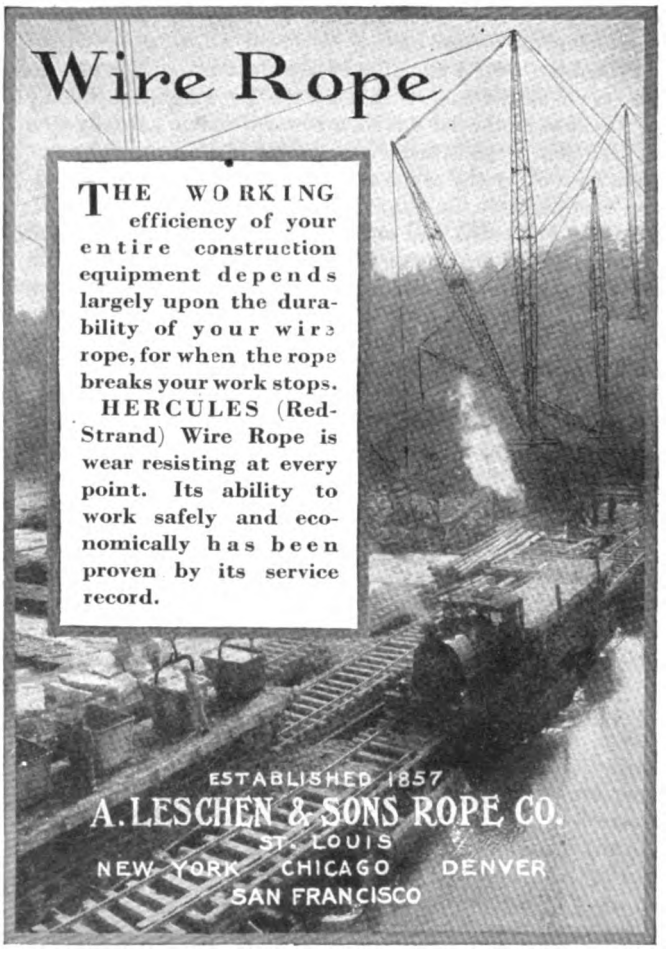
At the point selected by the 2d Division for crossing the Meuse River, it is 168 feet wide and 5 to 20 feet deep. The stream is not swift, consequently it is possible to push a series of rafts across the river without fear that the current will carry them downstream too fast.

A series of rafts 12 feet long and 6 feet wide were built at Beaumont, 3 miles away, carried in wagons to the site and lashed end to end. Two complete bridges were lashed perpendicular to the stream. At the word of the commander the 2d Engineers, assisted by details from the 9th Infantry, shouldered the bridges and pushed them across the river. The time consumed from the beginning of the lashing of the rafts together on shore to the time when the bridges hit the far side of the Meuse was seven minutes for one bridge and eleven minutes for the other. During all this time, and before and after, the enemy was firing in that direction with artillery and numerous machine guns. Actually, however, very few were killed on the bridge, although some 250 infantrymen, marines and engineers were killed in that vicinity during the night.

Principle: *For ordinary bridges, regular bridge equipment is not needed by combat engineers. It is possible to build small bridges in almost every case with material found on the site.* In the World War, so many bridges were built by the combat engineers with material on the site that no mention need be made of the special cases. In one combat engineer regiment four ordinary bridges were built in one day, two for horse-drawn vehicles and two for heavy trucks.

Principle: *A ponton bridge can be constructed by a combat engineer regiment without previous training in ponton work, but naturally it will take longer to build the bridge.*

After the infantry of the 2d Division had crossed the Meuse on foot-bridges, it became necessary to build ponton and trestle bridges. For the ponton bridge the engineers used pontons of various patterns—German and French. The bridge was a good one and was used; but it took the division engineers one and one-half hours to build the 200 feet of bridge, this long time being necessary because they had never had the training in building ponton bridges.



Principle: *In any movement the engineer map section should issue at suitable times a map showing engineer information, such as condition of roads, watering points, condition of railroads and future prospects on these points.*

"As soon as we began to advance it was found that the trucks, and even the troops, were very much in the dark as to the roads which they could profitably use; consequently the engineer map section issued maps showing conditions of roads, location of water points, strength of bridges, etc."

Principle: *The engineers in any advance can materially assist the artillery in many ways in advancing over fields and poor roads and in maintaining themselves in position* The following is quoted from a letter from one of the officers detailed with engineers to accompany and assist the artillery:

"The road for the 15th Artillery on left was opened through to advance. The artillery took position behind ridge. Two trench mortars, German, continued to shell

road after infantry had passed. We located them to left of division sector about 200 yards from road. I sent Sergt. Farce and six or seven men to get them; they did, turning four prisoners over to an artillery lieutenant. Fifteenth Artillery finally moved to within about 500 yards of front line. They then received machine-gun fire from the right. I went after this gun, but failed to find it. However, it ceased firing and evidently moved out, since we were not bothered any more."

After telling how the artillery was under fire during its movement forward, he continues his narrative.

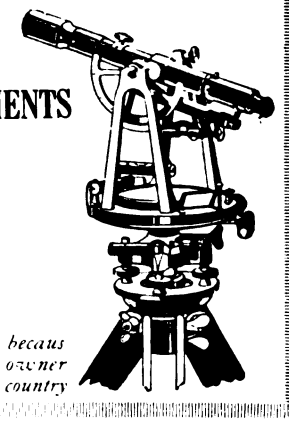
"Sergt. Stimel dug the artillery in under fire the entire time. He sent for me. I took three or four men from my detail, went over to the left of the sector; some marines came back from the front with two machine guns, the artillery sent over one machine gun and some twenty men. With this bunch we mopped up after the machine guns had shot up what ammunition they had, killed three or four Germans, but the rest got away.

"It was not my men who helped man the artillery guns. It was Benjamin's men who did that. They were distributed throughout the regiment, so that the engineers did not actually man any gun entire."

Principle: *In an advance by the division the combat engineers should accompany the division and assist its units in advancing; they should not be kept in the rear to repair roads which should be repaired by corps and army engineer troops.* This principle was not followed by the 2d Engineers in the Meuse-Argonne for the simple reason that the corps and army engineers could not do their own work and the 2d Engineers had to keep up the roads in the back area in order that the 2d Division could get its supplies. This inability of the 2d Engineers to work in two places at once operated to a certain extent to delay the 2d Division in crossing the Meuse.

Probably the best example of a proper use of combat engineers in an advance is that of the 1st Engineers during the advance of the 1st Division toward Sedan. Briefly, the 1st Division decided that if the roads in its rear were not taken care of by the corps and army engineers the 1st Division would starve, and the 1st Division decided to risk it. Naturally the corps and army engineers would have found it necessary to take care of the 1st Division, or the 1st Division would have been ordered to stop. As the operation was a short one, and as the 1st Division returned in a very short time, the division managed to pull through this brilliant operation without running entirely out of food and ammunition.

The following is quoted from the 1st Division records, showing the kind of work that is done by a division engineer regiment that properly accompanies its division in a pursuit:



"A and D companies moved forward with the 1st and 2d Infantry Brigade when they attacked from the Beaumont-Stonne road and opened up their communications. Roads and mine craters were repaired and bridges built to facilitate the advance. The remainder of the regiment worked all day on the roads around Commauthe, and then, at night, made a forced march toward Sedan, a distance of 38 kilometers, over roads congested by the movement of a whole division and obstructed by the enemy, who had destroyed every bridge and blown mine craters at every road crossing. A march of 70 kilometers was made in 48 hours. That was a heart-breaking march, because the regiment had been working all day and marching all night for three days and nights. During the march we constructed bridges where the enemy had blown them up.

"At one point near Stonne the division was held by a destroyed bridge, and detachments from F and B companies performed a remarkable feat of rapid military engineering when they constructed a bridge in a single night without any tools. Our wagon transportation and pack mules were far behind us, because we were going so fast, so it was a case of constructing a bridge from a growing forest with the aid of a few axes that were found somewhere. The men were almost exhausted from the long and trying march and loss of sleep, but with unbreakable spirit and determination they went to the task and labored cheerfully all night long, completing the task in a remarkably short time.

"Company A advanced with the 16th Infantry and alone attacked and captured the village of Pont Mangis without artillery assistance and under direct fire of the enemy artillery. The company attacked in face of heavy machine-gun fire and under the fire of an enemy 77 gun, firing point-blank at them as they advanced. They silenced the enemy by rifle fire alone and entered the village, making a house-to-house search and cleaning out the entire village."

• • • "From a purely military standpoint our policy should provide, first, a permanent military establishment large enough to guard against sudden attack; second, a force sufficient to meet our international obligations, particularly on the American continent; third, such force as may be necessary to meet our internal requirements; fourth, a trained citizen reserve organized to meet the emergency of war.—*General Pershing.*

Military Engineering, Note 1

Foreword

THE problems in military engineering, which it is proposed to publish in these columns, are similar to those given in the subject of field engineering at The Engineer School. This subject, in the curriculum of the school, is covered in two courses of instruction—namely, the basic course and the company officers' course.

Roughly speaking, the problems in field engineering of the basic course are those which normally would confront the lieutenant or captain of engineers serving with a divisional engineer regiment. The company officers' course continues this instruction to include problems which the field officer, serving with divisional or corps engineer troops, would encounter. In the first course the engineer company is the largest unit which is dealt with; in the second course it is the regiment.

The order in which the problems will be published will conform to this division of the subject, the problems in the basic course being given first, to be followed later by the more advanced problems of the company officers' course.

The aim of the basic course of instruction is to teach the junior officer of engineers the technique of his profession and to train him to make a definite plan of operation for carrying on the job assigned to him. He should know the details of the various types of construction with which field engineering is concerned; the number of men, the quantity and kind of tools and materials required in the construction, and where and how they are obtained; the rate of progress that may reasonably be expected on the work and how he can best organize his working force so as to accomplish his mission. The scope of the course is, therefore, limited generally to questions of technique and organization. It is thus limited, because it is believed that theoretically at least the problem confronting the lieutenant or captain is usually a quite definite one. To be sure, he has decisions to make based upon the military situation, but the problem as presented to him is so narrowed down that the unknown quantities usually can be quite definitely determined by the application of the technique of his profession.

In the company officers' course, field engineering problems are taken up in their broader aspects. That is, those questions are presented which should be decided before a more specific task can be allotted to the captain or lieutenant. The military situation has a greater bearing on these questions than in similar problems of the basic course. For example, in the company officers' course the student is confronted with the problem of planning stream crossings for a division on the offensive. Given the military situation and the mission of his division, he is required to decide what method shall be used in crossing the stream and where and when the crossing or crossings shall be made. This having been decided, a problem based upon this decision may be a proper one for the captain or lieutenant. Such a problem, for example, would require the junior officer to construct a bridge at a certain point to take a certain load and to be completed at a certain time. In this problem the student might be given information affecting the supply of tools, materials or personnel. He would then be required to make more or less detailed plans as to what he actually proposes to do. Such plans should be as much in detail as it is possible to make them, the amount of detail depending upon the accuracy of the information which is given him. The military situation is, however, not entirely eliminated from consideration in his problem.

The form of the problems in field engineering, which will be printed in these columns, will follow that in general use in the applicatory method of military instruction. A general situation will be outlined in order to give the student a general picture of the theater of operation and the particular place which he occupies in the general scheme. This will be followed by a special situation in which the part which he is to play is laid down. In this special situation the solutions to larger questions are given him; he is assigned a task and is given information as to the means available for accomplishment of the same. This is followed by the requirements of the problem, in which questions are propounded, the answers to which will indicate the student's ability to estimate the situation and to utilize the knowledge of his profession in making his decision. The questions thus propounded will pertain to one or more of the following factors which enter into the problem:

Types of construction,
Supply of tools and materials,
Personnel and proper organization of the same,
Time.

References to text-books and government publications will be given to be studied with each problem. Map references will usually be to the Camp Humphreys 1:5000 Map and the Mt. Vernon quadrangle, U. S. G. S., which will be furnished upon application to THE MILITARY ENGINEER.

The organizations with which the student will be concerned at present are the platoon and the company of divisional engineer troops and the infantry rifle company. For the benefit of those to whom the new tables of organization are not available, there are presented below organization charts in the forms which are in use at The Engineer School. A thorough understanding of these charts is essential before attempting the solution of any problems.

Engineer Company (Combat)

War Strength—4 Officers, 106 Enlisted Men

Distribution of Personnel

Road space, 145 yards

Captain (h)

Headquarters
2d Lieut. (h)

Office
First Sergeant
1 Staff Sergeant
1 Supply Sergeant
2 Sergeants
2 Corporals
(1 Clerk)
1 Mail Orderly (pvt.)
2 Motorcyclists (pvts.)

Mess
1 Mess Sergeant
2 Cooks

Stables
1 Stable Sergeant (h)
1 Horseshoer (a)
3 Wagoners (pvts.)
1 Blacksmith (a)
3 Privates (d)

First Platoon
1st Lieut. (h)
1 Staff Sergeant
2 Sergeants
5 Corporals (b)
34 Privates (c)
Including 1 Bugler (Bicylist)
1 Wagoner (a)

Second Platoon
Same as First Platoon

(a) Privates with specialist ratings
(b) One in charge of platoon tool wagon
(c) One assistant to wagoner
(d) One acting saddler
(h) Mounted

Note:—The following specialist ratings are authorized for a company:

3d Class	4th Class	5th Class	6th Class
1 Blacksmith	2 Carpenters, bridge	1 Cook, assistant	1 Carpenter, mine
1 Carpenter, general	1 Cook, first	1 Demolition man	1 Demolition man
		1 Horseshoer	1 Draftsman
			2 Motorcyclists
			2 Wagoners

EQUIPMENT
With Office Detachment
2 Motorcycles, with side car
With Stable Detachment
1 Wagon—ration and baggage
1 Rolling kitchen
1 Water cart
With each Platoon
1 Tool Wagon
1 Bicycle
Arms for Company
21 Pistols
89 Rifles
4 Autorifles

Organization of Infantry Rifle Co. (War strength)

and

Notes on Organization of Machine Gun Co. of Infantry Battalion

Infantry Rifle Company
1 Captain
2 First Lieutenants
2 Second Lieutenants
200 Enlisted—including 8 privates, replacements

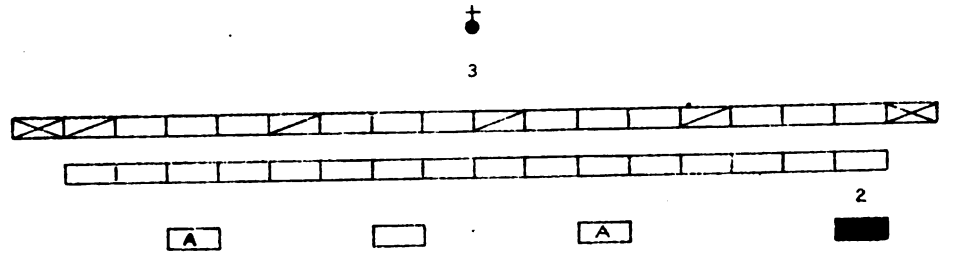
Captain in Command

Company Hdqrs. (1-21)
First Lieutenant
First Sergeant
Gas Sergeant
Mess Sergeant
Supply Sergeant
2 Corporals (1 clerk)
(1 agent)
2 Buglers (s)
4 Cooks (s)
2 Mechanics (s)
3 Shopmen (s)
4 Privates (r)

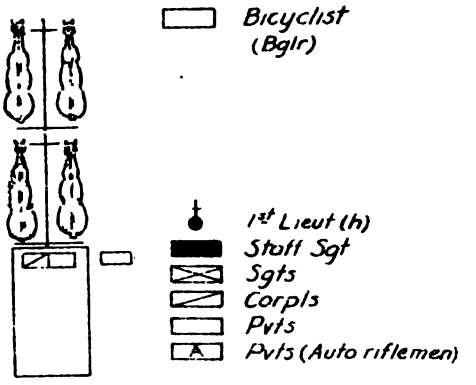
First Platoon (1-57)
Platoon Headquarters
First Lieutenant
1 Sergeant (p)
4 Privates (r)

First Section
1 Sergeant (l)
4 Corporals (g)
21 Privates (q)

Second Section
(same)



Second Platoon
Same as first, except second lieutenant



Third Platoon
Same as second

Notes:
(s) Privates and Privates First Class, several with specialists' ratings.
(r) Runners and agents.
(p) Platoon sergeant.
(l) Section leader.
(g) Includes 1 section guide and 3 squad leaders.
(q) Grouped, with 3 corporals, into 3 squads; one private in each squad armed with automatic rifle and one with grenade discharger.

For diagrams of formations of the platoon, see p. 48, Infantry Drill Regulations, 1919.
For formation of the squad, see p. 34, I. D. R.
The M. G. company (5-141) consists of 2 platoons, each of 2 sections. Each section has 2 machine guns, operating as a unit. Each gun is accompanied by a M. G. cart and an ammunition cart.

EQUIPMENT IN TOOL WAGON

1 Set Carpenter Equipment, Field
1 Set Demolition Equipment, Field
1 Set Pioneer Equipment, Field
1 Sketching Outfit
(See Cir. 445, 1919 Notes 3, 5, 22 and 26)

The following table of engineer equipment is compiled from War Department Circular No. 445, and shows the distribution of the important items of engineer equipment with which the student is concerned in the solution of problems:

Engineer Equipment for Divisional Engineer Regiment

(Extracts from Circular 445 W. D., 1919.)

INDIVIDUAL EQUIPMENT

Compasses, Prismatic, illuminated	1 per Master Sgt., Technical Sgt. and Staff Sgt.
Knives, Clasp	1 per enlisted man.
Pliers, side cutting	1 per Corporal.
Rules, 4 foot, folding	1 per Sgt. and higher enlisted grade.
Tapes, 50 ft. metallic	1 per Master Sgt. and Technical Sgt.

PLATOON EQUIPMENT

(Carried in Platoon Tool Wagon)

CARPENTER

3 Augers, ship, 7-16 inch, 11-16 inch and 1¾ inch
1 Brace and bits
3 Chisels, cold and framing
9 Hammers, claw
6 Hatchets, broad
4 Rules, 2 ft.
6 Saws, hand
3 Squares, steel
3 Tapes, 50 ft.
Miscellaneous small tools and supplies.

DEMOLITION

2 Crimpers, cap
2 Drills, cordeau
1 Pliers
2 Slitters, cordeau
100 Caps, electric
50 Caps, non-electric
40 yds. Cord, detonating
100 lbs. explosive, T.N.T.
100 Fuse lighters
100 ft. fuse, Bickford
100 ft. fuse, instantaneous
6 boxes matches
Insulating tape and twine.

PIONEER

2 Adzes
1 Auger, earth
13 Axes
3 Bars, pinch
3 Blocks, 8 inch
14 ft. chain, ⅜ inch
3 Cutters, wire, ⅜ inch
3 Drills, stone
6 Machetes
3 Mattocks, pick
2 Mauls
17 Picks
9 Pliers
2 Saws, 2-man
31 Shovels
2 Sledges
7 Wrenches
40 Bolts, drift
14 Handles, pick, saw and sledge
5 lbs. Marline
110 lbs. Nails, wire, 60, 30, 10 and 8d
250 ft. rope, 1 inch
6 50-ft. lashings, ¾ inch
25 18-ft. lashings, ½ inch
1500 ft. Tracing tape
Miscellaneous small tools and supplies.
1 SKETCHING OUTFIT

COMPANY RESERVE EQUIPMENT

(Carried in 1½ ton truck with Headquarters and Service Co.)

CARPENTER

4 Augers, ship, 11-16 inch
5 Chisels, framing
16 Files
2 Planes
1 Draw knife
3 Saws, compass, keyhole and nail cutting
9 Handles, hatchet, chisel and hammer
4 Gross screws
Miscellaneous small tools and supplies.

DEMOLITION

2 Detectors, circuit
2 Exploders, magneto
2 Reels, wire, firing
200 Caps, non-electric
200 Caps, electric
160 yards cord, detonating
300 feet Bickford Fuse
2000 feet wire firing

PIONEER

4 Bars, pinch
2 Blocks, double 8 inch
15 Drills, stone
6 Hammers
4 Jacks, screw, 10 ton
4 Peavies
4 Sledges, 8 lb.
2 Wedges, 5 lb.
10 yards canvas
20 Handles, adze, axe, sledge and hammer
2 kegs nails, 60d and 10d
500 ft. rope, 1 inch
MACHINE BLACKSMITH'S TOOLS
DRAFTING
ILLUMINATING
OFFICE
PHOTOGRAPHIC
PIPEFITTING TOOLS
TINSMITH'S TOOLS
SIGN PAINTING

REGIMENTAL EQUIPMENT

(Carried in 1½ ton trucks with Headquarters and Service Co.)

DRAFTING
ELECTRIC LIGHTING SET
FOOT BRIDGE LAMPERT
MAP REPRODUCTION
Blue Print
Cyclostyle
Duplicator
Lithographic
PHOTOGRAPHIC
RECONNAISSANCE
SURVEYING
WATER SUPPLY
ILLUMINATING EQUIPMENT
OFFICE EQUIPMENT
SIGN PAINTING EQUIPMENT
TINSMITH'S EQUIPMENT

INFANTRY INTRENCHING EQUIPMENT

(One set for each infantry battalion in the division; carried in escort wagon with Headquarters and Service Company of Engineer Regiment)

26 Axes
4 Bars, pinch
9 Files
125 Mattocks, pick
1 Maul
26 Saws
250 Shovels
1 Tape, 50 feet
13 Handles, axe and pick
2 kegs nails, 10d and 40d
500 Sandbags
3000 ft. Tape, tracing

Problem No. 1

Military Bridges

Map Reference:

Mount Vernon Quadrangle, U.S.G.S.,
Northwest Section, Camp A. A. Humphreys, 1:5000.

General situation:

Occoquan Creek (Mt. Vernon Quadrangle) is the boundary between hostile states—Blue (south) and Red (north). A Blue army has crossed the boundary, encountering little opposition. The main body of this army has halted on the line of Accotink Creek; its advance guards hold the line, Mt. Vernon-Franconia-Springfield; its advance cavalry is in contact with the Red cavalry along Four Mile Run. The time is early summer; heavy spring rains have passed and the main roads are in good condition.

Special situation:

You command a company of the 1st Engineers, 1st Blue Division. This division has marched on the Occoquan-Pohick road. Your company reached Pohick at 6 P. M.

Digitized by Google

At this place your colonel (the Division Engineer) gives you the following oral instructions:

"Tomorrow this division is going to advance along the Telegraph Road.

"The bridge over Accotink Creek on the Telegraph Road has been destroyed. I want you to take your company and build a one-way bridge over Accotink Creek, at the site of the old bridge, to carry 1½ ton trucks. This bridge must be ready for use by 6 P. M. tomorrow.

"Yellow pine timbers of the following sizes are available at Woodbridge: 8×8 inch, 6×8 inch, 6×6 inch, 4×8 inch. 2×8 inch and 2×4 inch, all in lengths up to 24 feet. There are also drift-bolts, spikes and nails in various sizes. If you let me have a requisition by 8 o'clock this evening I can have the material delivered on the Standard Gauge Railroad where it crosses the Telegraph Road at 9 o'clock tomorrow morning."

You direct your senior lieutenant to march the company to the site of the bridge. You go ahead in a side car and make a reconnaissance of the bridge site and the stream in the immediate vicinity. This reconnaissance discloses the following: The stream at this point has a velocity of about 3 feet per second; the stream bed is about 6 inches of sand and clay over-lying gravel; the maximum depth of stream (midstream) is 3 feet, freshets may raise this to 6 feet; the width from shore line to shore line at the bridge site is 35 feet; the abutments of the former bridge are of stone masonry and in good condition; the clear span from abutment to abutment is 45 feet, the height of the abutments is 10 feet above the surface of the water; from the bottom of the abutments the ground slopes uniformly down to the bed of the stream; there is a good ford for animal transportation just east of the bridge site; the wreckage of the former bridge is lying in the stream between abutments; this bridge was a steel truss (Pratt type), it was destroyed by cutting the lower chords with explosives; there is very little timber suitable for bridging in the vicinity.

Required:

(1) Your decision as to the type of bridge you will build.

(2) Dimensioned sketches showing side elevation and cross-section of bridge.

(3) The organization of your company into working parties.

(4) A working schedule showing the estimated time of completion.

(5) A list of tools and materials required, showing where you propose to obtain the same.

(6) Measures adopted for security.

Note.—In the preparation of this problem the following texts are given for study and reference:

Engineer Field Notes, A.E.F., Nos. 4, 7, 8, 10, 48 and 52.
Engineer Field Manual, Part II.

Map Reading

As the ability to properly read a map is essential to the solution of many problems in military art and military engineering, there is given below a map reading exercise. This subject is a highly important one in the training of an officer, so that a study of the questions presented below cannot be too strongly urged. The questions given refer to the Taneytown sheet of the Gettysburg map which is one of the sheets which the reader will require for the problem in Minor Tactics which appears in this issue. The answers to these questions will appear in the next issue of THE MILITARY ENGINEER.

1. (a) What is the scale of the Taneytown sheet expressed in inches to the mile?

(b) What do the various divisions mean on the scale underneath the letters "M. D." at the bottom of that sheet?

2. (a) What is the true azimuth and distance of Centennial School House from cross-roads 533 at Koon?

(b) What is the magnetic azimuth of this line?

(c) What is the magnetic bearing of this line?

3. (a) In marching along the main road from Taneytown through Bridgeport to the extreme western boundary of the sheet, what is the highest elevation encountered.

(b) What is the lowest elevation?

(c) What is the steepest ascending grade encountered expressed in degrees? Where does this occur?

(d) What and where is the steepest descending grade?

4. A sketcher is sent out to map the country to the east of Bridgeport on a scale of 1:10,000. In making his sketch he uses a scale of strides based upon the assumption that the length of one of his strides is 70 inches. On the map which he makes the distance from cross roads 472 at Alexander to crossroads 476, about 650 yards east of Boyd, measures 10 inches. What length of stride did he actually use? What is the true R. F. of his map?

5. A mounted sketcher made a road sketch of the country in the vicinity of Bridgeport on a scale of 1:20,000. The rate of his horse was supposed to be six miles per hour and on this supposition his working scale was constructed to show minutes and half-minutes of travel. On the map which he makes, the distance from cross roads 472 at Alexander to cross-roads 476 about 650 yards east of Boyd measures 6 inches. What was the rate of his horse? What is the true R. F. of his map?

6. An observer is lying down on hill 547 about 850 yards west of Koon. An enemy patrol has reached the point where Allaway Creek crosses the road running eastward from Koon and is continuing its advance westward along this road. At what point will the head of this patrol be visible to the observer? Disregard obstructions to the line of sight by trees and houses.

7. Will an observer lying down on hill 452 about one-half mile south of Clear Ridge Farm be able to observe the ford over the Monocacy at Pinehill Mill. Disregard obstructions as in question 6.

8. (a) A machine gun occupies a position at the farm house of Mountain View Farm. Will it be able to employ direct fire on the bridge over the Monocacy at Bridgeport?

(b) Can it cover the cross-roads at 472 at Alexander by direct fire?

(c) If this gun is ordered to cover the bridge over the Monocacy northwest of Mountain View Farm, by direct fire, will it be necessary to move the gun? If so, at what point east of the Monocacy would you locate it? Assume maximum effective range of gun to be 1500 yards.

General Subjects, Note 2

An Approved Solution of Test on Military Administration

(See Page 4, Military Instruction, Vol. XIII, No. 69)

By Maj. C. C. Gee, C. E.

(References are to U. S. Army Regulations 1913)

Question number	Reference paragraph	Answer
1	271 (C.A.R.72)	(a) By regimental commander upon the recommendation of the company commander.

Digitized by Google

Question number	Reference paragraph	Answer
		(b) By the unit commander with the approval of the next higher tactical commander.
2	276	(1) By sentence of a court-martial.
		(2) On recommendation of company commander, by the order of the commander having final authority to appoint such non-commissioned officer.
3	317	(a) All officers present for duty with company.
	316	(b) To audit the company fund; to ascertain and examine the sources from which and methods by which the fund has accrued; and to recommend expenditures from the fund.
4	355	A roster is a list of officers or men for duty, with a record of the duty performed by each.
5	387	(a) Return his salute.
		(b) Call company to attention and salute.
		(c) Call company to attention and return the lieutenant's salute.
6	922	(a) An officer is placed in arrest by his commanding officer in person or through another officer, by a verbal or written order or communication, advising him that he is placed in arrest, or will consider himself in arrest, or words to that effect.
	923	(b) He should repair at once to his tent or quarters, and there remain until more extended limits have been granted by his commanding officer.
	933	(c) The gravity of the offense charged, and the known character of the accused, indicating the probability of an attempt to escape.
7	1493	The duties of the Corps of Engineers comprise reconnoitering and surveying for military purposes, including the laying out of camps; the preparation of military maps of the United States and its possessions, including co-operation with other Government and private mapping agencies, and in field operations, of maps of the theater of operations; selection of sites and formation of plans and estimates for military defenses; construction and repair of fortifications and their accessories; the supervision of the location of all buildings in or within one mile of any fortification; the installation of electric power plants and electric power cable connected with seacoast batteries, and furnishing the necessary electrical supplies connected therewith; planning and superintending of defensive or offensive works of troops in the field; examination of routes of communications for supplies and for military movements; construction and repair of military roads, railroads and bridges; military demolitions; execution of river and harbor improvements; construction and repair of military roads, railroads and bridges; military demolitions; execution of river and harbor improvements assigned to it; and such other duties as the President or Congress may order. It collects, arranges and preserves all correspondence, reports, memoirs, estimates, plans, drawings, such deeds and titles as relate to the Washington Aqueduct and public buildings and grounds in the District of Columbia, and models which concern or relate in any wise to the several duties above enumerated. In time of actual or threatened hostilities, within the theater of operations, it has charge of the location, design, and construction of wharves, piers, landings, storehouses, hospitals, and other structures of general interest; and of the construction, maintenance and repair of roads, ferries, bridges and incidental structures; and of the construction, maintenance and operation of railroads under military control, including the construction and operation of armored trains.

An Approved Solution of Test on Military Law

(See Page 4, Military Instruction, Vol. XIII, No. 69)

By Maj. P. C. Bullard, C. E.

Question number	Reference paragraph	Answer
		ders (limitations as to punishments and persons triable not being affected).
7	89, 89a	Challenges for cause, Findings, Sentence: By the closed court only Admissibility of evidence: By the law member only. All other questions: By the law member subject to objection by member of the court. In case of objection by the closed court.
8	90a	(a) Two-thirds (b) All (c) Two-thirds (Note: conviction, not sentence) (d) Two-thirds (e) Three-fourths
9	120, 120a	A peremptory challenge is one which causes the removal of a member of the court without cause stated.
10	145	1. Plea to the jurisdiction 2. Plea in abatement 3. Plea in bar of trial 4. Plea to the general issue.
11	159	Trial judge advocate.
12	168 and App. 20	A warrant of attachment is an order to a proper official to bring to court a witness who has refused to obey a subpœna.
13	158c	When the prosecution rests.

Questions on Infantry Drill Regulations

(Reference—Infantry Drill Regulations, 1919, pars. 101-296)

No.	Wt.	Question.
1	12	How are the members of a squad armed? How are they arranged?
2	10	Show by diagram how the squad is arranged when deployed alone. When deployed as part of a larger unit?
3	4	What is the normal interval between skirmishers?
4	12	The squad being in line, by what commands does it turn on a fixed pivot? Describe in detail the execution of the movement.
5	12	The platoon being in column of squads, by what commands does it form line of sections to the front? Describe the movement.
6	15	The platoon being in column of squads, by what commands does it deploy as skirmishers? Describe in detail the movement.
7	5	Where are the platoon runners when the platoon is deployed when acting alone?
8	12	The platoon being in line of sections, by what commands does it change direction? Describe the movement.
9	10	What is a section column? What is its interior arrangement?
10	8	The company being in column of platoons, by what commands does it form line of platoons to the right?

Questions on Military Law

(Chapters XI-XVI, Manual for Courts-Martial, 1921)

No.	Wt.	Question.
1	6	Where are the rules found which are binding on Courts-Martial as to admissibility of evidence?
2	8	In each of the following cases, state whether the witness should be disqualified from testifying, on the grounds given: a. Witness owes money to accused. b. Witness has been convicted of embezzlement by a civil court. c. Witness is father of accused. d. Witness called by defense in case of desertion is wife of accused.
3	8	In the trial of Private A for desertion, testimony was given as follows. State in each case whether the testimony should be admitted: a. Capt. B testifies that Pvt. A has been previously convicted of disrespect to a non-commissioned officer. b. Sgt. C testified, "Capt. B told me he saw Pvt. A in Washington." c. Pvt. D testifies that Pvt. A told him, just before he (Pvt. A) left the company, that he was going to see his sick mother and would come back when she was well. d. Sgt. E testifies that Cpl. F (now deceased) told him that he (Cpl. F) saw Pvt. A in Baltimore in civilian clothes during the alleged desertion.
4	6	What two facts must the prosecution prove as to the identity of accused?
5	8	Name three cases in which leading questions can be asked when questioning a witness.
6	4	During a trial, the Trial Judge Advocate states to the court: "I wish to offer in evidence an affidavit executed by the accused in my presence after I had warned him that anything he might say might be used against him." Should this affidavit be admitted in evidence?
7	9	When is a copy admissible in evidence instead of the original document?
8	8	Name the ways in which the accused can get before the court his personal account of the actions for which he is being tried.
9	5	What is meant by judicial notice?
10	6	It is proven in a trial for murder that the accused was drunk at the time he committed the crime. How may this affect the findings of the court?
11	7	A soldier having five previous convictions is to be tried for violation of A.W. 63 (maximum punishment under Executive order, 6 months' confinement at hard labor and forfeiture of two-thirds pay for 6 months). By what court should he be tried, and what is the maximum punishment that can be adjudged on conviction?
12	5	How does the Trial Judge Advocate dispose of the original record of a trial by a general court?
13	8	Describe the method of voting by members of the court on the findings.
14	6	What action may the reviewing authority take on a sentence which is in excess of the legal limit, there being no other errors in the trial?
15	6	On what date does a sentence of confinement begin?

Military Art, Note 2

MAP PROBLEM NO. 1. A Solution.

The following is a solution of Map Problem No. 1, which was published in the May-June issue of THE MILITARY ENGINEER, page 303.

First Requirement:

Mission.

Captain A's mission is to march his company to Taneytown on the 4th instant, arriving at the school house not later than 11 A. M.

Enemy.

The Red infantry battalion at Gettysburg is too far from Captain A's line of march to affect his mission. The same is true of the troop at Emmitsburg, so long as it remains there. The reports of the Red patrols at Bridgeport and Harney would seem to indicate that this troop is sending small detachments to reconnoiter; there are probably other patrols on the road, which have not been reported to the Blues. It is possible that Captain A may encounter one of them to-morrow, but he believes that it can hardly be of sufficient strength to interfere seriously with his march.

Our Own Forces.

The Blue forces at Littlestown and Taneytown are, roughly speaking, between Captain A and the enemy. In the improbable event that the Red troop at Emmitsburg, or what is left of it after deducting the patrols, should advance on Taneytown, Major M's command will be between Captain A and the enemy. Otherwise his supporting troops do not affect Captain A's mission.

Plans of Action.

In view of the definite orders which he has received, Captain A's plans of action are reduced to selecting his route of march, the time of leaving camp and his march formation.

Captain A has no choice of routes until he reaches the road-fork one-half mile west of the Green Valley school house (elevation 496). From there he may go by a northern route, starting northwest and approaching Taneytown by the Taneytown-Kingsdale road; or he may go by a southern route, starting southwest and approaching Taneytown by the Taneytown-Stumptown road. Both routes must at some time cross the range of hills running northeast from Stumptown. A closer examination of the map, however, shows that the southern route, which follows Silver Run and Big Pipe Creek to Stumptown and crosses those streams or other tributaries five times, has appreciably more up and down grades than the northern route. In view of the state of the weather, considerably more mud is likewise liable to be encountered. The northern route (496-625-626-546-545-509-469-Taneytown) is only eight miles long, against 9 miles for the southern route (496-Big Pipe Creek Mill-466-467-488-Zimmerman Mill-Stumptown-Taneytown). From the standpoint of ease of marching the northern route is to be preferred.

On the other hand, for the last mile and a half, the northern route lies close to the possible theater of operations of the Red patrols. Captain A, however, does not believe these patrols can interfere with his march seriously and, since he feels sure of defeating them with ease, he would not much object to meeting one, because a successful brush with the enemy at the outset would tend to raise the morale of his troops. He therefore selects the northern route.

Captain A has 8 miles to march—

2½ miles	50 minutes
(Halt)	15
2½ miles	50
(Halt)	10
2½ miles	50
(Halt)	10
½ mile	10
8 miles	195 or 3 hours, 15 minutes

If he starts the march at 7:00 A. M. he should reach Taneytown at 10:15 A. M., thus allowing a margin of safety of 45 minutes, or more than 25 per cent of his actual marching time, which he considers ample. Since reveille is now set for 5:30 A. M., a start at 7:00 A. M. will give an hour and a half in which to get ready for the march, without changing the hour of reveille. Captain A therefore decides to begin the march at 7:00 A. M.

Captain A considers that a section would probably be sufficient for his advance guard, but in order to avoid splitting tactical units and to provide flank march outposts at points on the road where the line of march makes sharp changes of direction, he decides to use a platoon.

Decision.

To march by the Green Valley SH-496-626-626-546-545-509-469-Taneytown road; to place one platoon in the advance guard and to take up the march at 7:00 A. M.

Second Requirement: Captain A's orders.

(NOTE.—Since Captain A's company has been in its present location for three days it is reasonable to assume that he has previously considered the possible routes to Taneytown.)

(a) At 10:40 P. M., to the orderly who brought in the motorcycle messenger: "Tell Lt. B. (the Officer of the Day) that I should like to see him here at once."

(b) At 10:45 P. M., to Lt. B., "The Reds declared war late this afternoon. This company will march to Taneytown to-morrow, starting about an hour after reveille. I want all the company officers to assemble in my tent with their maps at breakfast call tomorrow morning. Please inform the other lieutenants."

(c) See 3rd Requirement.

(d) At 5:45 A. M. on the 4th, the officers having assembled in his tent, Captain A spreads out his map on his folding table and dictates the following verbal order:

"The Reds declared war late yesterday afternoon. According to our secret service, they have one battalion of infantry at Gettysburg and about one hundred cavalry at Emmitsburg (points out these towns). Civilians say that Red mounted patrols, of ten to fifteen men, were at Bridgeport and Harney yesterday afternoon. (Points out these towns.)

"Our troops at Littlestown and Taneytown are ordered to remain in their present localities.

"This company will march to Taneytown this morning; it will form at 6:45 A. M., in the normal formation and at the usual place.

"Lt. C., your platoon (the 3rd) will form the advance guard and will precede the main body by 200 yards. Follow this route. (Indicates on map the route stated in Decision, above.)

"The main body will march in the order: First Sergeant and Company Runners, 2nd platoon, 1st platoon.

"The Company wagons, escorted by the Company Head-

Digitized by Google

quarters Section (less First Sergeant and Runners), will follow the main body without distance.

"I shall ride at the head of the main body."

(e) The Company having formed as ordered; at 6:50 A. M. Captain A says to Lt. C:

"Take up your advance guard formation on the road and signal me when you are ready to start."

To Lt. E (commanding Co. Hdqrs.): "Make your dispositions for escorting the train and take up your formation as we move out."

Upon receiving Lt. C's signal, Captain A signals to the Company, "Forward, *March.*"

He waits for the entire company to march past him and then rides forward to his place at the head of the main body.

Third Requirement: Captain A's message.

SILVER RUN, 3rd June, ——, 10:50 P. M.
C. O. 1st Bn. 1st Inf.,
TANEYTOWN.

Reference your message of 9:45 P. M. this date; I expect to reach TANEYTOWN about 10:30 A. M., tomorrow the 4th, arriving by the KINGSDALE-TANEYTOWN road.

A,
Capt. 1st Inf."

The above message is sent by the motorcyclist who brought Major M's message.

MAP PROBLEM No. 2. Patrolling.

Maps—
Gettysburg General Map
Gettysburg 3-inch Map, Gettysburg, Taneytown and Emmitsburg sheets.

General Situation:

This problem is a continuation of Map Problem No. 1, which was published in THE MILITARY ENGINEER, Vol. XIII, No. 69, May-June, 1921, pages 302, 303.

Special Situation:

Same as Special Situation for Map Problem No. 1, with following additions:

At 10:00 P. M., June 3rd, Major M, commanding 1st Bn. 1st Blue Infantry at Taneytown, receives the following telephone message from his regimental commander at Littlestown:

"The Reds appear to be prompt with their reconnaissance. It is rumored here that an infantry detachment, about a platoon in strength, left Gettysburg this afternoon, marching by the Baltimore Pike. My outpost, at the southwestern exit of Littlestown, drove off a Red mounted patrol at 8:00 P. M. today.

"I am sending patrols to my front tomorrow. The most southern one, containing six mounted men, is ordered to go to Koon's place, about two miles northeast of Harney.

"Tomorrow, the 4th, I want you to send out the necessary forces to keep the general area Koon's-Harney-Bridgeport-Stull house (on the Monocacy, about two miles southwest of Bridgeport)-Taneytown-Longville-Koon's under observation. Withdraw all your detachments to Taneytown by dark.

"Inform me promptly of the definite presence of the enemy in this area."

Major M has secured eight saddle horses, with the necessary riding equipment and has improvised a mounted detachment under command of 1st Lieut. L. Major M has also obtained three motorcycles, with sidecars.

The battalion is camped in the square northwest of the school house. (The exact location of the outpost line is not needed for the solution of this problem.)

Required:

(1) What forces does Major M send out to comply with his Colonel's orders? Give brief reasons for decision.

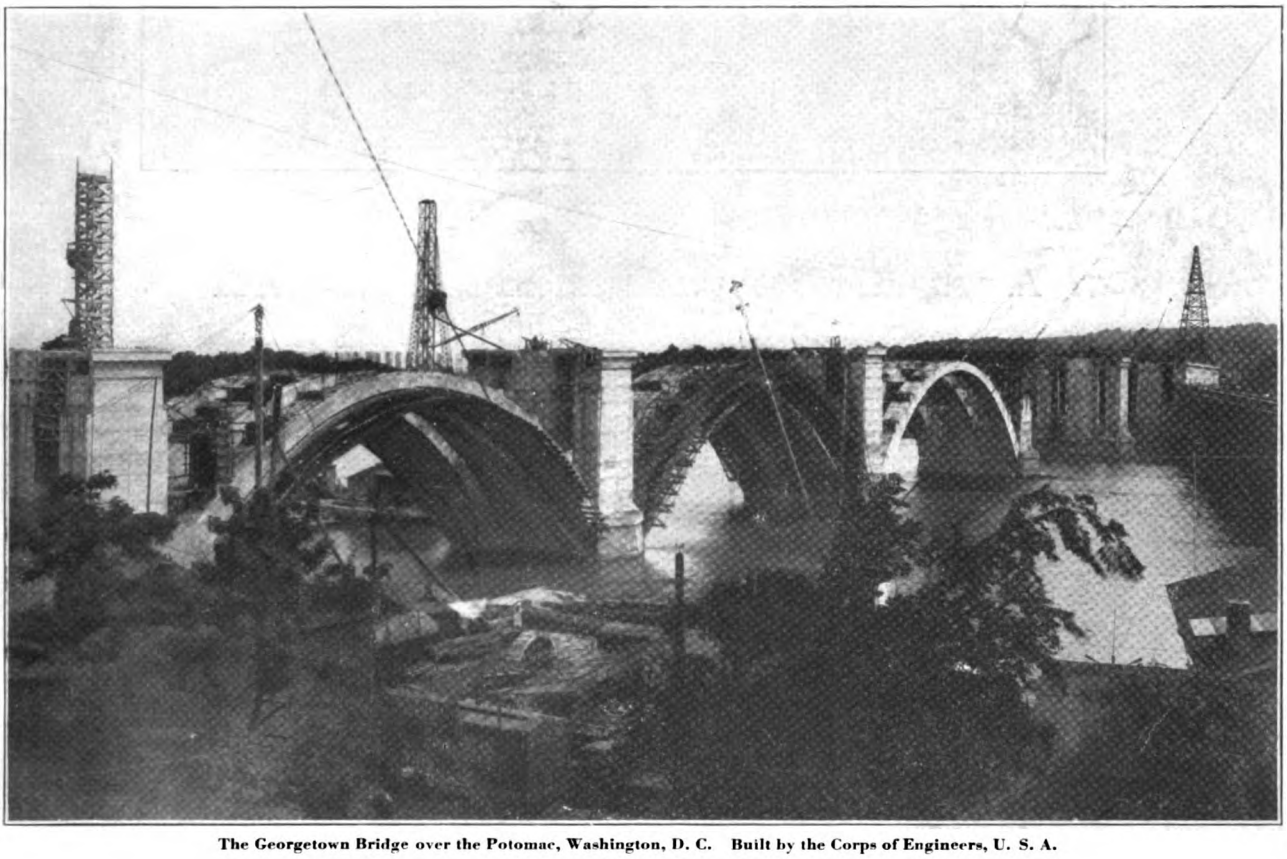
(2) Give Major M's orders for the commanders of his patrols and detachments, if any. Indicate the time and method of issue, and use Major M's exact words.

References:

The following references, in addition to those listed at the end of Map Problem No. 1 (see MILITARY ENGINEER for May-June, 1921, page 303) should be studied in connection with the above problem:

Technique of Modern Tactics, Chapter III.
Field Service Regulations, Pars. 9-36, inc.

"God grants liberty only to those who love it, and are always ready to guard and defend it."—*Daniel Webster*



"We may well pause for a few minutes over the history of our own country. Its lessons, unfortunately, are little understood. Every generation has been called upon to fight, every generation has neglected preliminary training, and the fact that all our wars have been ultimately won often obscures the real lessons of our past conflicts and renders it imperative that they be taught and understood."—*Sidney Ballou.*

The Battle of Cantigny

As seen by one who was there

By

Boleslaw Suchocki

Formerly Sergeant, 1st Engineers, First Division, A. E. F.

[*Note.* Intimate accounts of their personal experiences by those who participated in the World War are not only of great interest at the present time, but unless they are recorded now they will be lost to future generations. It is for this reason that the editor has made repeated appeals for such experiences.

The following account was furnished by a former officer of the First Engineers. It was written by Sergeant Suchocki within a few days after the capture of Cantigny, which was the first offensive operation of any importance in which American troops participated. Coming at a time when the great German offensives of 1918 were at their height, Cantigny on May 28, 1918, was the one bright spot on three hundred miles of Allied front. It gave promise of the great power of the new army which was so soon to turn the tide of battle. The little town was captured by the 28th Infantry; Company D, 1st Engineers, of which Sergeant Suchocki was a member, took part in the attack as infantry. May 28, 1918, was a red-letter day in American history.

The author of this article, a Pole, and a cabinet-maker by trade, was neither an experienced soldier nor an experienced writer. Yet as a soldier he fought for his adopted country with a courage and skill that stamp him as a natural leader of men, and as a writer he has given us a graphic account, a "close-up," of battle that no war correspondent could hope to equal unless he had himself gone over the top with the first wave of the assault.

The account is reproduced as Sergeant Suchocki wrote it. Efforts to improve it would be futile.—Ed.]

Cantigny, May 28th, 1918.

The First Part

The Night Before the Battle of Cantigny.

THAT afternoon Lieutenant Jones assemble all non-commissioned officers of his command for the necessary instructions, which were a very useful for the operations of Cantigny for the next morning.

First he announced to the boys, after they all gather together at the woods were we camp, southeast of Tartigny. "Company D, 1st Regiment Engineers is elected to go 'Over the Top' to-morrow morning," he said, "and I want you boys to understand fully the part of our work which got to be done in Cantigny. Here is a map and I will explain to you the location of our position. We will go with Doughboys in the front line. There won't be a very far for us to go, only about 350 yards beyond the cemetarium, where a single house of some kind is standing, and from the leading road to the cemetarium the First Section will dig a trench to the house for the infantry, with connecting some shell holes for strong points, than when we complet the trench the infantry will drop back, take the position in, and we will probable be send to the back to the rear. but remamber these few points men, if I get bumpt off or any of us, so the rest will know where they are and what they ought to do."

The afternoon passed by very busy, the boys have been telling stories, singing and joking, also prapaire themselves for the unknown future.

The country around Cantigny we practicly knew very well, first our work was barb wire entanglements for two weeks, for four weeks trenches and dugouts and for last two weeks it was night work in the vicinity of Cantigny, though we work there at night but it was a plane view of the village and the death Vally (as generally was called) the leading Valley to the village, was also well knowen to us.

The evening was slowly approaching, the bright golden sun was sinking beyond the far dimmy hills, the men have been anxiously waiting for the wonderful night.

Supper time came, right after the supper evrybody was ready to go, but still it was to light for the expedition, the Company Commander, Captain Smith, ordered to wait until complet dark.

The Company was formed at the edge of the woods waiting for the convinient time and signal to go.

The evening was remarkable, the silvery moon rose up in horizon with a full smiling face, the night was very quite, could hear a fly buzing in the air, only now and then a heavy roar of a cannon bruke out the silence.

During the waiting time the boys start to bit good bye to each another, and jokes of all kinds broke out, they-ve been joking and laughing until the order came out to go.

Here we are! A single file strachet out about mile long across the field, there was a grave silence amongs the men, just in full step going ahead through well known trail to us, the camp was left far behind, there was no whisper of any kind, just now and then some of the men turned their heads towards the camp, look just like they left it for ever.

We slowly approach to the death Vally and enter it, without of any disturbans came to the quarry that was the place where we intend to wait until the next morning.

The quarry was large enough for about two companies, the southern wall gave us a good protection from enemy artillery shells, it was about 30 feet high and steep bank of solid rock containing a temporery first aid station, also two dugouts, it was quite save shalter for the men to take rest before the time to go over the top.

Nobody there expected any ceriouse danger that night in the quarry, but Ales! appear different shortly after.

The boys took their packs off and equipment, lay it besides them where they seat or lay, some lite cigaretts and smoke, some went to sleep. I capt my pack on and rifle in my hand seating down about in the center of the quarry, the time seemes to me was very long, I felt tired from seating down, get up and cemmencet to walk in the empty spays of the quarry, thought what will come next?

While I was walking, 1st Sgt. Hastings stoped me and said, "Suchocki, why don't you take your pack off, and make yourself easy while you have the time for, there is a big job for us to do to-morrow so take rest all you can to-night."

Sgt. Haistings was quite right so I di'nt wait for repeat. I stop right at the entrance on the leading road to the quarry.

The right side of the road as you go in to the quarry was a high bank about three or four feet high, where three officers been sitting, and on the left side of the road there was of some kind dugout and big chunks of rocks been piled about six or seven feet high, so I thought that will be the best for me to lay my pack and equipment on the lower of

Digitized by Google

the right side of the road, just simply to keep it seperat from the rest in case of mixed up.

I took my pack off, lay it on the bank, rifle and carteladge belt lay on top of it, stood there for a while leasten to the officers which were right in front of me carry on very interesting conversation. There was Lieut. Jones, Crawfford and several other officers, about four feet away from where I've had my pack layd.

Then I look a round there was very quite. German shells never fell near the quarry from the time we've came there, only airoplane turned my attention which was sailing around the quarry over our heads for about half an hour, then I saw some the boys seating near the high wall smoking cigarettes, well I've said to myself, I di'nt smoke tonight yet, so about the time for me to have it, I took a cigarettes out of my pocket, walk to the first man and light it from his cigarette, sead down besides him and start to talk about the time that is so long.

At that time we've hear a shell was coming from the German side, we were of course accostumed to such and sound and di'nt pay much attention to it, but there was worst than we expected, the shell of a heavy caliber land a bout fifteen feet from quarry on the road, and burst with a thunderous roar, the fragments of the bursting projectile been carry away up in the air, with bozzing sound as a sworm of beas.

The boys that seat jumpet up to their feet and those that slept been a waiked. I've raised from my seating position, also there become a slight tumult, I walk to my pack and put it on, before some one else will take it, I told the boys that it is no use to run a round because we don't know where the next shell will fall, will be much better to remain where we are, so they quite down for a moment.

I've stood at the same place fixing my pack, my rifle was still laing on the bank where I've had my pack laid. Some the officers walk away from their previous locations, but Lieut. Jones, Crawford and enother Lieut. remain at their former places. I've also had mind to go look for safer position but it was to late.

At that time enother shell (or three of them together) have been coming down, there was no time to thing very long about, but I laid down flat on the road right where I been standing, every body else have doen the same thing.

At once! a tremendeuse explosion shooked the air, the quarry was filled with thick dust, blood and terrible sight. some the men been toren in to pieces.

The shells fell direct in the quarry struke solid rock di'nt buried themselves in the soft ground as usely was. but exploded on top the rock, and cause awfell damedge to the men that were in the quarry.

I get up and look around all the stars I saw while laing down disappeared, but my neck and right side of my face was numb. What was happened? I've asked myself, I've placed hand on the neck and felt it, it was hot as fire and little bliding. Oh! that i'st so bad I wisper to myself.

First I've cast my sight where the officers been sitting. Ales; what I saw; there was a small howle in the rock and a round it nothing but a mass of human bodies. I've ran to the first aid station but there was crowded impossible to come near to the place where the streachers been piled at that time several voices holled for the streachers finely one of them was passed to us, the boys ran with haist, first was picked Lieut. Crawford, they brought him near to the first aid station and laid on the rocks. Lieut. Jones was brought afterwards, and the third Lieut. I don't know his name had one of his legs cut and face.

I've come to Lieut. Crawford again to put him back on the streachers I call for help but in the excitement nobody hear me, so a fellow was standing right behind me, I hollerd at him (without of recognize who he was) why do'nt you help me to put Lieut. Crawford on the streacher. "I ca'nt." he answered, "I'm wounded myself, am waiting for the first aid." I raised my head and saw Corporal Gordon. His neck was covered with blood, I tolled him to wait a moment I will give you the first aid, as soon as I lay Lieut. Crawford on the streachers.

I try to put him on the streachers alone, but as soon I put my arms under his shoulder there was no bowns at all, it was soft as a pillow, so in the meantime LaMagdelaine came, and we both laide him on the streacher again, when I was bend low over his body, I jest hear a deep sigh, that was the last signe of his life. LaMagdelaine and another man carry him to the first aid station, but Lieut. Crawford di'nt need a doctor any more, his quiet soul was between the body and the future.

I turned to Copl. Gordon perceived that he still was waiting for the first aid, I've asked him if he's got first aid package he answer me that he hasn't, "I don't know where any parts of my equipment are, use your own package." I thought to myself, I might need it for my owne use soon, so I took off of some another field-belt first aid package, wrapped his neck and the head as well as I could.

I was also slightly wounded too, but it was nothing to compare with the others, there were about 23 men when to the Hospital besides thoes that died right at the quarry, two Lieuts and a few inlisted men. McDougall, Patterson and also some Frenchmen was torn in to pieces and several others.

What ever we've doen there, it was doen in a hurry, one of them Officers hollerd to the men "Get out from this place before a nother sheel will burst here." We started to look for better and safer place, every one of us suite himself, and all the boys mooved out from quarry no time, the safest place was on the steep hill side of the death Val'y, we located ourselves right there temporarily because the day brake jest started.

In the dimmy light early in the morning we could see each other moch better, and also the visinity of our station, though the German artillery fire was very heavy, G. I. Cans and shrapnels been falling insecently all a lone the vally, in spite of the grave danger that was a round us, we start to talk and jocking again.

Sgt. 1st Class Thoete, the section leader said, "why do'nt they let us go over the top instead waiting so long. I am wounded but I can stand it, for today yet, and am ready to go." So the medical man came, he asked him "Say can you paint my back with iodine," "yes," the first aid man replied. He rubbed his back well with iodine, there was several bad cuts on his back and in some parts of his back been sunked chunkes of the shell.

After then he finished operate on Thoete I asked the Doctor if he will paint my neck also, "sortainly" the Doctor said. He looked at my neck and said, your neck and the ear are very bad bruised, so Thoete said "Suchocki, you better go to Hospital," "why don't you go," I said, "you are worse woundede than I am and you refuse to go when 1st Sgt. Hastings called you to go to Hospital." "Oh! no, I am ready to go over the top today and I will stay here as long as they gone keep me."

The Second Part

The Barrage.

The American artillery of the 1st Division with some French help, open up the fire stronger and stronger, there was many different sounds penetrating the air from different sizes of guns, the echoes was almost continental and became more louder than ever, and from the enemy side also have been puring hundreds of shells on the heights of Cantigny and into the death Vally, where the

Digitized by Google

most convenient passage was only for the transportation of our troops and supplies.

Wounded soldiers have been carried one after another to the first aid station, we laid right at the steep slope of the hill, no shell fell amongst us that time, but at the base of the hill the earth was turned from its natural bed over and over.

Copl. Gordon become very ill from his wounds and another man fainted from gas faction we had to carry them to first aid station, that was also interesting.

The time was coming near, the barrage of the 1st Division was in full live, also trench mottors open its fire, with more like theatrical play, it was similar jest as a famious jugler was jugling a dozen balls with one hand, but each of thoes balls fall, cause death and distruction for the enemy.

The air was full of whistling, roaring, and exploding echoes, jest like a pitty tempest was passing through the peacefull forrest, with its open mouth devouring everything that dare to stand against it.

It's time, for Capt. Smith assemble all his men, and instructed section leaders for the necessary action, also announced with deep sorrow of his heart, "we lost and lost heavy, some our losses never can be replaced."

Sgt. Thoete was not there at that time so Sgt. Kelly took his place, he received an order to send two men with the doughboys to laid out a line for trenches, the plan was changed, we had to do all different now. Sgt. Kelly called me, "Corpl Suchocki and Nickolas you both will go with Lieut. and stay with him until you get the order to come back." "Yes sir," I said. I and Nickolas we took two spools of tape with us and some hooks to pin it to the ground, and start off with Lieut. We walk to the very top of the hill the Lieut. went in to a small dugout, I asked him if there is room enough for two more men, "No" he said, of course the small dugout was full all ready.

We've had fifteen more minuts to wait before to go over the top, we laid down in the lowest spot that we could find aroun the dugout, and wait. German shells been falling very heavy but the bushes protected us from fragments and injories.

The tanks been comming with some kind groumbling noise, one tank was hurt with shell and stop right on the spot, the others passed him around and went by. Time was ripe and everything was ready for Lieut. came out the dugout told us, "Let us go."

Part Three

"Over the Top."

The great theatrical play start on the wide planes of Cantigny, thoes men that were in the reserve trenches been already in skirmish line approaching the fearful village of Cantigny, but these men from the vally been coming by squads in a single file, as soon as they reach the plane field they deploy themselves in to a skirmish line too, and formed as one waiving onbrokable chain with heads up and smiles on their faces, approaching the first and biggest battle that the 1st Division ever pulled off.

A little ways behind there was another waive coming, and another behind the second all the men were jest like a single onbended rod of one spirit, were going forward, nothing could stop them.

We cross the field under the curtain of our barrage, reach the left side of Cantigny there was no German in sight yet, but a wild boar came in to view and turned our attention, the boys start to chase him but soon it disappear.

The happy village of Cantigny remain nothing but ruines, where the houses were standing if there was not a shell hole so pile of debris.

We passed the ruines and on the other side we find many orcherts and also there was barbwire fance with four strings of wire about ten inches a part, it was hard to cross it, so I came to the post, knock the wire down with the bot of my rifle, low enough to step over for me and the others that were behind me. I jest moved on one side the post and a bullet struck the post and penetrated through, that was a nother my good luck.

We cross the fance and start up again I notice that the boys bee falling down very often, there a shell burst about ten feet on front of me and exploded, I almost was in tance rising dirt, lump of dirt or chunk of rock stroke me square in the chest knock me down on my back, become very dusty and smoky from the bursting shells, I could not see farther than 100 feet a round me, I rose start up again, I hear somebody holled "lay down," I kneeled on one knee and was waiting what will.

The barrage moved moch farther, and the command was "forward" I perceived that there was Lieut Conel third man on my left side, leading the wave. I asked a doughboy, "who is that man?" He taled me that the man is Lieut Conel Maxey.

Colnel Maxey was a tall man smooth shave and red cheeks, with a revolver in right hand and streaching arms lead the 1st Division into victory.

At that time we approach near to a hedge of Crategus Coccinea, the hedge was thick and high it was impossible to see what was behind it, there stop us of some kind unknown power, many boys fell on both sides of me as I look about a 100 feet on my left and right side, there only six of us left, the rest killed or wounded were left behind.

Colonel Maxey gaive order for the tank to go ahead, and order us to lay down, most the time we were ahead the tanks, tanks crowled and open up machine gun fire at that direction and discharged the 75 gun several times and advance closer to the hedge.

Hail of bullets that was puring upon us from behind the hedge stopped, while I was laing I noticed low stumps of the hedge that there behind an apple tree some one was standing it was about forty yards away, I took good aim right through bushes, fired, and saw that something fell to the ground.

The command was given forward again, but we di'nt walk that time we ran as fast as we could to the hedge. There was only three of us in a grupe, myself and two doughboys, one of the doughboys had Automatic rifle what I never saw before, I shoot as fest I could but he shoot much faster, I asked him what kind rifle it was he toled me that it is an Automatic rifle, my partner Nickolas went closer to the tanks and I ve lost him for ever.

Three of us crossed the hedge, there was full of small dugouts all alone the hedge and a regular firing trench a bout two hundred yards long in the orchert.

First the doughboy with Automatic rifle was hurt in right arm I and the other fellow we ran to the trench, I saw that a Dutchman stick his head out over the parapet I shot at him and he rolled in, into the trench.

The doughboy was chasing a nother Dutchman but he di'nt shoot at him only was trying to staob him, the Dutchman grasp the doughboys bayonet with one hand and pust it a side, bend the bayonet pretty bad right at the handle I look at the struggle it was about ten feet away from me, so I holled "shoot him" but the Dutchman throw his hands up and holled in German "do'nt shoot me I will tell you something," I said to the doughboy "halt on," but it was to late, the shot fired and the Dutchman tumble down.

Digitized by Google

Now he start one way and I start other alone the trench, the traverses of the trench have been covered with plates and about two or three inches of dirt over it, and caumflage with grass on both sides the entrance was covered with buarlap like a cortaine.

I saw that the cortain was moving I holled few times "Come rouse" but no one was coming out, so I open fire right at the hole, fired five rounds, then I hear of some kind squiling in the hole. I steped closer to the trench and pull the top off, there was four men convolsively twisting in the trench.

I turned a round and saw the doughboy was fighting with two men so I fired at one and he stabbed the other, but the Dutchman that were in the small holes saw it and start to come out by bunches three bullets penetrate my close, two below the waist and one in the right hand sleeve.

We laid down and start to shoot but that was only our good luck that the second wave reach the place and become boutchering.

We were about 150 yards to far ahead so the Lieut came to me asked if got the tape, of course I had the spool on my arm with me all the time, "Where is the other fellow?" he asked me, "I don't know Sir," I answered, last I saw him that he was on the other side of the hedge, he was behind the tanks, after that I didn't see him at all. Shall I look for him, I've asked the Lieut. "No," he said its no use, "but how we will start the trench line?" he asked me again, "I don't know Sir; Lieut Jones instruct us that the trench duged about 300 yards beyond the cemetarium from this road to the house that was standing on our right, (but instead of house there was pile of debris only) "wait a minut" he said "I'll soon find out" he stepped just across the hedge where the narrow road was and Colnel Maxey was there, he talk with him a while and came right out, I was gaizing at the bunch German prisoners which been waiting for transportation.

"We are to far" the Lieut said me, he moution his hand to the doughboys which all ready start to dig themselves in, and walk about 100 yards to the rear I fastened the end of the tape to the ground and follow the Lieut he was directing the way.

I streached the tape as far as it reached, it was on the spool about 300 meters, but one spool wasn't enough so the rest of the part we lined up by the green grain that was growing there. "Now you are throew with me, you can go to your company," the Lieut said to me. "Yes Sir;" I said, "Lieut do you know where the Engineers are working?" I asked the officer. "No, I don't know very well but I think that some Engineers are working in the woods on the right side of Cantigny," and he poited out with his hand in that direction. All right Lieut I said Goodbye. Goodbye he repeat and we parted.

I walked a cross the ploughed by shells field to the woods I found that bunch fellows been digging a trench I've asked them where the Engineers are working, some of them working right here a fellow told me and showed me the direction, I came into a large shell hole there was Copl Bragg, Ruh and Lieut Cox, I've asked Copl Bragg where the first section is working, on the other side of the woods, but you better stay here and help us to dig this trench, because is danger to travele through this woods today.

I accepted the invitation. I seat down in the shell hole took little rest I toled them all the stories what I saw and doen, then took shovel and start to dig. We finished the trench and some strong poins by one o'clock afternoon and start up back to the Death Vally agin.

We passed the woods and came on sloping field down the Vally, when Infantry open up maching gun barrage fire on moving Germans across the Vally, the bullets of our guns were high up over our heads but the Germans observed us and they open up their machine gun barrage too, the bullets been falling down like hail amongs us, but by good luck nobody got hurt.

Lieut Cox said that we are in both barrages the enemy and our own too, we all laid down for a moment then start up double time again down the hill, at the end we ran as fast as we could to reach the bushes, then when the trees cover us up Lieut Cox asked of any body was lost no, there was every body present.

The machine gun barrage stopt right after but the Germans send few shells after us and they exploded about two hundred yards away from the path that we been on.

We returned to the same place that we left in the morning, all the boys take the same places under the steep slope of the hill.

Later the report come out that we will wait here till dark, and after dark will go back to the camp, but six o'clock that afternoon the Company was formed and march up to the first line trenches to reinforce Infantry.

On our way to the position we went through Cantigny. A house was standing right at the edge of the steep hill looking in to the death Vally, that was the Germans observation point, from where they could observe every single movement of the American troops in the death Vally.

The house was caved in, and several dead Germans bodies laid out side the house and few in side, hanging over the beames pined down by the falling roof.

The German artillery was in action all the time, we came again to the first line trenches by ducking, the trench was not duged a cross the road so we had to clime over the bank to get in to the trench when I clime it over there was big shell hole, the shell hole was full of men I stood for while, but a fellow toled me "you better get down," soon I laid down, I saw that Sgt. Thoete was right behind me on the ground, dead. Pvt Loftis, Miller and Riordan was shot in the legg, he was laing on top the ground Lieut Cox was in the same shell hole too, so he toled him "why don't you run farther up here is no room for all the men," "I can't Sir; I am shot in the legg." "Roll in, into the shell hole, don't lay on top," I said, but here is no room to do it.

I start to holled, we got to get out from this hole, and give chance for the fellows behind to get into this shell hole, so Lieut Cox told me all right show the way.

I get up and ran, Le Magdelaine and Laube follow me, I ran to the very top. I stop at a strong point and ask the boys occupying the trench if there is enough room in the trench for me to get in, "don't ask for room but get in before you get your wing cut off," the doughboy said.

The trench was very narrow and shellow also full of men, but I got in and start to dig the trench wider and deeper and they all been digging too.

We stay here for all night, and all next day, been relieved next morning two o'clock we came back and took position in the first line reserve trenches, we eat cooked meal at eleven o'clock that day that was the first meal we've had in three days.

The evening we been complitly relieved and for the camp, the boys in the camp received us a very warmly and with open heart.

Many happening is left out in the last part, just an account that probably the story would be too long and dissedisfied the readers.

The battle of Cantigny was for a long time transfered from leaps to leaps. I thank God for my safety and sank the passed in the dept of my heart for ever.

Chicago's Harbor Problem

The need of present planning for future growth

By

W. V. Judson

Colonel, Corps of Engineers
District Engineer, Chicago District
Division Engineer of the Northwestern Division

[The Esch-Cummins law places upon the War Department the duty of studying local harbor conditions and advising with localities as to wharf developments suited to meet the demands of commerce. An expert branch of the shipping Board, devoted to the study and planning of wharf facilities, has been transferred to the Board of Engineers for Rivers and Harbors, which is under the War Department.

The District Engineer of the War Department stationed in Chicago has been studying the wharf requirements of this region for many years, and he believes that the Lake Michigan shore near Wolf Lake, including Wolf Lake itself, offers the greatest opportunity in all this region for the creation of wharf facilities of a character, magnitude and location suited to meet the demands of the future. He has drawn general plans for these harbor facilities, and they have been approved by the War Department agencies in Washington.

The port facilities which the Board of Engineers is advising the City of Chicago and the States of Illinois and Indiana to contemplate at this time are especially for transfer purposes, and in such transfers there would probably be involved ocean vessels, lake vessels, barges, lighters, railway cars, trucks and warehouses. By no means is there any thought that all of the harbor facilities of the Chicago industrial and commercial district will be concentrated in the proposed location, but only the major transfer port facilities.

Since this article was written, the States of Indiana and Illinois have passed legislation for the creation of an inter-state harbor commission along the lines recommended by Colonel Judson, and it is hoped that this vast project, which means much to the entire Mississippi Valley, will soon find itself on the way toward realization.—ED.]

Chicago's Future

CHICAGO is the greatest railway center in the world. In less than 10 years Chicago will be the northern terminus of an 8-foot barge channel connecting the Great Lakes and the railways centering at Chicago with the coal mines of Illinois, the cotton belt of the southern States and the ocean port of New Orleans.

It seems reasonable to assert that within less than 15 years Chicago will be connected with the great ports and sea routes of the world by a channel from 22 to 25 feet deep, following the Great Lakes and the St. Lawrence River.

Never before did it seem as fair to point out in prophecy a region where there must inevitably, and soon, be established the world's greatest port facilities to take care of the vast warehousing and transfer operations which will be required when and where there will be a common meeting place of so many agencies of transportation.

The locus of this great prospective center of commerce is the Chicago district.

Possibilities and Limitations of Harbor Development

Where in a great stream of commodities undergoing transportation there is a breaking of bulk, it is customary to find an industrial and commercial city, where many of the commodities passing through are changed in character by manufacture, or warehoused and resold by local merchants.

Within the Chicago industrial and commercial district, extending say from the Evanston line to Gary along the lake shore and far landward thereof, we find nature's most marvelous preparation of land and water to serve the ends of man in the requirements of the future.

The lands are low-lying and flat, without bluffs where land and water meet, such as occur to the north, and without sand-dunes such as lie to the east. Bluffs and sand-dunes are picturesque, but they add vastly to the cost of adapting shore lands to purposes of commerce and industry.

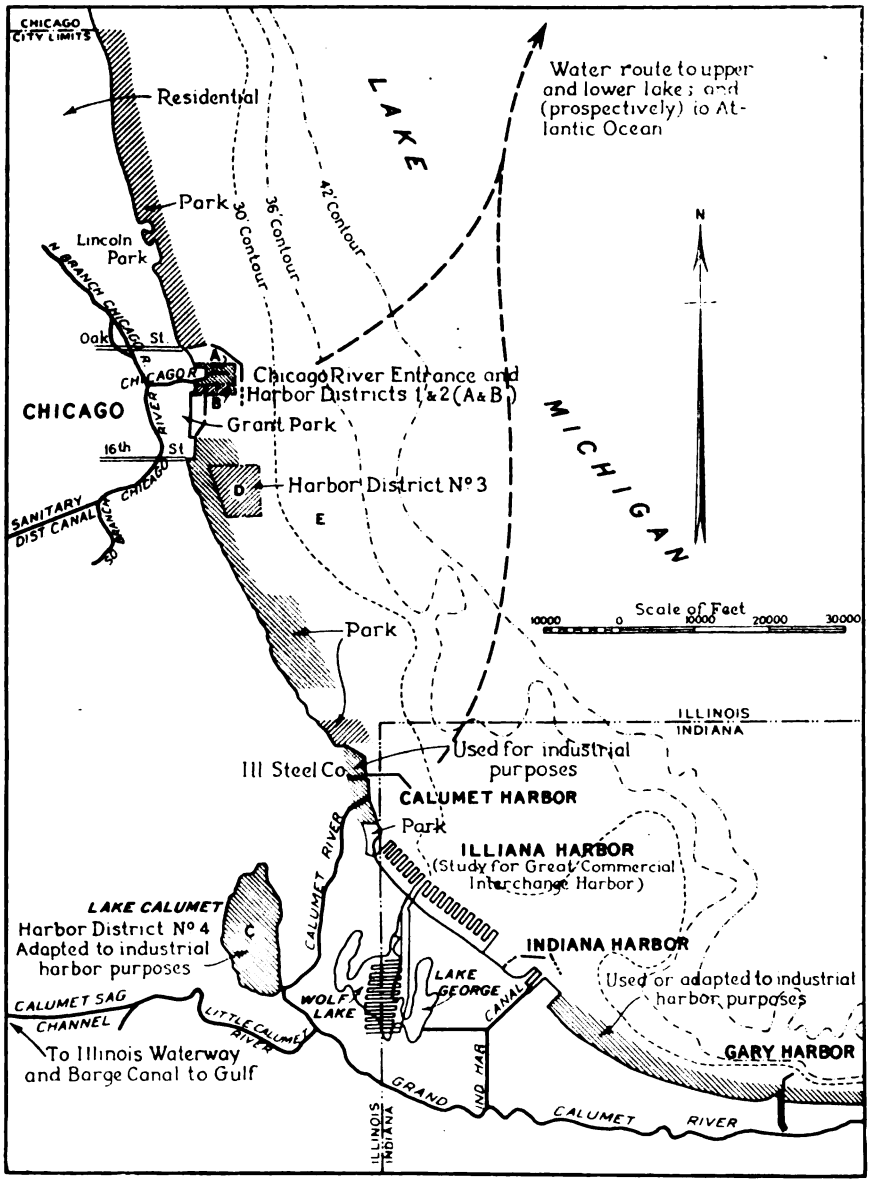
Digitized by Google

The foreshore of Lake Michigan fronting the Chicago district slopes very gently lakeward, so that the 7-fathom contour is 4 miles off-shore, instead of ¾ of a mile, as is the case east of Gary. This means that in submerged lands, or foreshore, all publicly owned, the Chicago district possesses nearly a hundred square miles, any part of which it is within the power of man to raise into land to serve one great purpose or another. This is an asset of almost incalculable value.

Back of the lake shore there is, in the Chicago River and its branches, the main and Sag Drainage Canals, the Calumet River and its branches, and the Indiana Harbor Canal, some 92 miles of channel available within the urban area for barges and lighters, and in some parts still promising long continued useful navigation for lake vessels.

Possessed of these marvelous assets, and confronted with vast expansions of commerce in the immediate future, Chicago is indeed no less in the presence of opportunity than of demand upon every resource to plan and exercise foresight.

Where, for example, shall be planned and built the wharves with the warehouses, the railway yards for car storage convenient to the wharves, the breakwaters and the channels of approach?



The lake shore from Oak Street to Evanston is devoted to high-class residential purposes and to parks.

In Lake Michigan, north and south of the mouth of Chicago River, lie two small harbor districts. Their limited extent and other circumstances, especially relating to convenient and general accessibility by rail, preclude all thought that they go far to solve the wharfage problem.

The Chicago River, in response to inexorable urban requirements, has become unfit for navigation by large vessels. Its commerce now is but little more than one-fifth what it was many years ago, and what lake commerce now utilizes the river places indirect costs upon this community for bridge operation and interruptions to land traffic, which would not longer be endured if they were fairly envisaged.

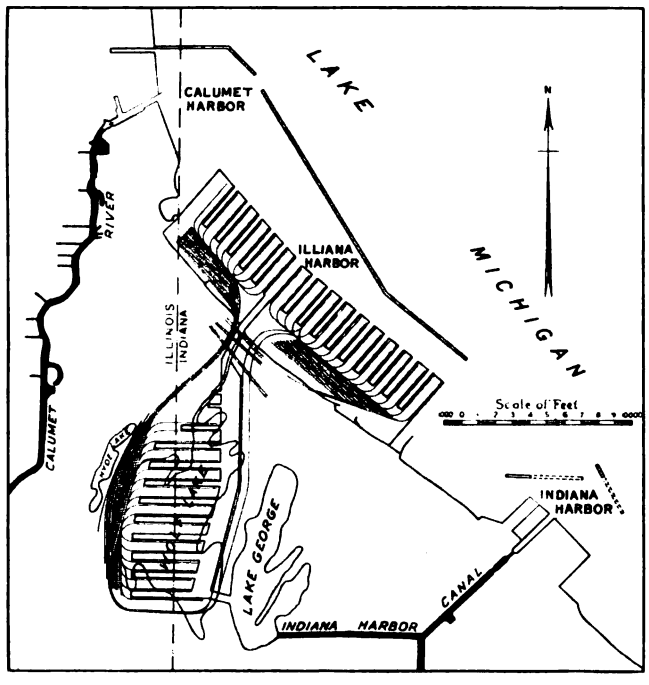
Grant Park, the Field Museum, Jackson Park and other park projects occupy the lake shore from Randolph Street southward to the Illinois Steel Company's great industrial plant at South Chicago, although lakeward of some of these park lands, south of Sixteenth Street, and embracing a part of them if necessary, wharves may be built.

The banks of Calumet River and of the Indiana Harbor Canal serve excellently as sites for great industrial plants requiring water transportation of coal and other raw materials. Lake Calumet may be developed into similar industrial sites, but will not serve as a locus for a great transfer harbor by reason of the number of bends and bridges interposing between it and Lake Michigan.

From the Illinois Steel Company to Gary, both inclusive, the Lake Michigan shore is largely taken up by industrial plants, including the Iroquois Iron Works, Whiting, the Marks plant, Inland Steel and Universal Portland.

Fortunately, the shallow lakes known as Wolf and George, with their marshy margins, lying close to Lake Michigan upon the Illinois-Indiana state line, have preserved from industrial or urban development about 3½ miles of Lake Michigan frontage and some 6 square miles of submerged and marshy lands lying immediately shoreward thereof, and it is to this locality that Chicago must look for her future transfer port.

Ample Room Available



No man can now predict what portion of the development shown on the general plan will be required within the next ten, fifty or one hundred years. The vast amount of wharf frontage shown, when compared with the corresponding available frontage of the great ocean ports of the world, indicates that here there will be room for any business, however large, that the future may bring. The general plan shows 16 piers on the Lake Michigan shore, each 3,000 feet long and 750 feet wide, affording simultaneous accommodation for 232 vessels of an average length of 500 feet. In rear of the wharves, upon the lake front, there is shown, for railway yards, 15.-

Digitized by Google

840,000 square feet, sufficient for the storage and movement of 16,000 freight cars. Inside the shore line, in Wolf Lake, are indicated 9 piers, each 750 feet wide and averaging 4,100 feet long, together with 14,200 additional linear feet of quay or wharf front, affording accommodation for 212 vessels, averaging 500 feet in length. In rear of the Wolf Lake piers are indicated yards occupying 7,240,000 square feet, sufficient for the movement and storage of 8,400 freight cars. Thus the total wharf frontage indicated both within and outside the shore line aggregates 222,840 linear feet, sufficient for 444 vessels averaging 500 feet long. More than 24,400 cars may be moved and stored within the yards. The warehouses on the piers, if but one story high, aggregate in floorage 164,900 feet in length and 225 feet in width, or 37,102,500 square feet. Allowing 15 square feet of warehouse for the storage of each ton, the warehouses shown on the piers alone would accommodate 2,473,500 tons of freight.

Cost of the Project

Inasmuch as no man can now say how much of this development should occur in any stated period of time, an estimate of cost of the entire development would be of little practical importance. Approximate unit costs may be stated, however, and with these before him anyone may easily compute the cost of such portion of the system as he may see fit. Thus the cost of wharf front or revetment, per linear foot, would average about $120. The cost of excavation of basin and slips in Wolf Lake, including disposition of material in piers, wharves and yards would average about $0.18 per cubic yard; railway yards, for trackage, would cost on an average about $40,000 per mile; warehouses on piers would cost on an average say $6.00 per square foot; necessary excavation in Wolf Lake, 25,000,000 cubic yards, would supply all fill required in the Wolf Lake portion of the development and furnish in addition 9,000,000 cubic yards toward the Lake Michigan frontage development, and such additional fill as may be required for the latter would cost say $0.40 per cubic yard.

Types of Piers

The piers shown on the general drawing are of the quay system. That is to say, they are of such width as permit of the storing of incoming and outgoing cargoes in warehouses on the piers themselves. Piers of this type may be of far greater length than those of the narrow bridge type, such as we see in New York for example, and each pier bears several railway tracks, and would be equipped with cranes of various types, conveyors, etc., so as to be adapted to the handling of different kinds of freight. Doubtless, it would be found economical and convenient to provide some of the warehouses with more than one floor and some piers with no warehouses at all. Upon the general drawing are indicated, immediately inside the shore line, on the one side, a certain length of wharf front adapted to the fueling of vessels, whether with oil or coal; and on the opposite side repair facilities, including dry docks, machine shops, foundry and the like. Certain portions of the wharf front are indicated as devoted to grain elevators, coal storage and transfer, and the handling of ore, in the latter case for furnaces in the nearby industrial district, which have no wharf facilities of their own. Needless to remark, the arrangement of the wharves shown on the general plan and above described is only in the broadest sense suggestive. When the development is begun, and constantly as it progresses, there should be study of the details of lay-out and equipment.

Breakwaters and Bridges

It is fair to assume that Congress would give consideration to building with Federal funds the breakwater and the entrance to Wolf Lake. The breakwater is shown on the plans as extending some 20,000 feet in a southeasterly direction from a point opposite the end of the existing Calumet breakwater and sufficiently distant (say 600 feet) therefrom to provide an entrance. This breakwater would protect the lake shore development and the entrance to Wolf Lake from wave action. Barges from the Illinois and Mississippi Rivers would reach the wharves via the Sag Channel and the Little Calumet and Calumet Rivers, either passing out of the mouth of the latter into the breakwatered area or being admitted to Wolf Lake by a canal connecting the south end of the latter with the Calumet. Lake and ocean vessels might, with but slight deviation from their courses, stop at wharves near the mouth of Chicago River to put on and off passengers and certain express and local freight. Stops of this character are common at Hamburg, for example, and might prove both economical and convenient. As Wolf Lake and the entrance to it are legally navigable waters of the United States, the building of proper draw-bridges could be exacted of those now crossing the channel of exit near the Lake Michigan shore line. It is probable that a detour could be arranged for the many fast passenger trains which now cross here, and the same detour might save these trains delays at present experienced at Indiana Harbor and Calumet River bridges.

Administration of the Port

In Great Britain it is common practice to develop and administer ports and port facilities through the agency of so-called "Harbor Trusts." Such a trust is composed of unpaid gentlemen of the highest character and ability, willing to devote themselves to the public service for the satisfaction that such service brings. To create the port facilities herein advocated, it would seem advisable that the states of Indiana and Illinois should by concurrent legislation establish an inter-state harbor commission, half the personnel to be appointed by the governor of each state. To this

Digitized by Google

commission should be granted title to the lands under water in Wolf Lake and along the margin of Lake Michigan where the piers are to be built, which lands are now the property of one state or the other. The commission should be empowered and directed to issue bonds, to acquire certain marginal lands, to settle riparian controversies, to build wharves and related port facilities *pari passu* with the increase of need for them, and to exact dues for their use. The submerged lands conveyed to the commission would possess a value of many millions of dollars. The power to collect port dues would eventually produce a revenue ample to meet all interest, sinking fund and other current charges Whether or not the commission would require any direct appropriations by the two states at the beginning of its work, or whether it would be better if the bonds were simply guaranteed by the states, is a question, of course, for study and determination. There are understood to be no constitutional objections to the course herein outlined, and such management and control would probably be on a higher plane in some respects than if a single state or municipality were to exercise them.

Forethought and Co-operation Necessary

It will require much careful study and effort on the part of many public-spirited men in this country before the two states may be expected to enact the necessary legislation. In the meantime there is always danger that private individuals or corporations may seek to take action which would destroy or mar the opportunity that now exists, perhaps through industrial developments unfortunately located, or perhaps through purchases of land to be held at high prices until the public requires it. It is hoped that the publicity necessarily given to this subject at this time will operate as a warning against rather than as a suggestion of activities contrary to the public interest.

Principles Governing the Use of Combat Engineers

A Correction, By

D. D. Guilfoil

Major, E. O. R. C.; formerly Major, 108th Engineers

[*Note.*—The author and the editors regret that through inadvertence the crossing at Consenvoye was credited to the 110th Engineers of the 35th Division, instead of the 108th Engineers of the 33rd Division, and are glad of this opportunity to make the correction.—Ed.]

I WANT to call your attention to an error in the July-August issue of THE MILITARY ENGINEER. In Major Mitchell's article on "Principles Governing the Use of Combat Engineers," it is stated, in the last column on page 329, that the 110th Engineers of the 35th Division constructed the foot bridge and heavy wagon bridge across the Meuse at Consenvoye. In the editor's note preceding the article on page 353 this is again referred to.

The bridge work in question was accomplished by the 108th Engineers of the 33rd Division. On October 8, 1918, the writer, then a captain in the 108th Engineers, was in charge of Companies B and C of that regiment and acting on orders which had been received the previous day, constructed an infantry foot-bridge across the Meuse River at a point about 600 yards up stream from the ruins of the wagon bridge crossing into the town of Consenvoye. On the following day, this ruined wagon bridge was reconstructed by Company B of the 108th Engineers under the command of Captain L. J. Hughes.

As our division held this front from the early part of September until the latter part of October and as the front was considerably north of Consenvoye at the time they left this sector, it is hard to figure out how this work was credited to the 110th Engineers.

Major Mitchell might also be interested in knowing that while this river crossing was anticipated as he states, the engineers had been unsuccessful in securing any of the necessary materials through the regular source of supply.

Companies A and E of the 108th Engineers also constructed an infantry foot bridge across the Meuse at the town Brabant earlier on the same day. The materials for both of these foot bridges were obtained by tearing up an old German plank road which ran through a portion of the swamp lying west of the town Forges.

The orders for this bridge work were received about noon October 7 and carpenter details were immediately sent to the plank road and constructed bents from the bridge balks and tore up the chess for use as planking on the bridges. That night the bents, planking and what rope could be secured, together with the carpenters' tools spikes, etc., were taken into the town of Forges by horse transfer. On October 8 this material was carried to the bridge sites by the companies mentioned above. This entailed carrying a distance of nearly two miles.

The depth of the river was an uncertain matter and as a consequence the heights of the bents were more or less guess work. Very few of the bents could be used at the bridge sites without a certain amount of splicing as the river was found to be deeper than anticipated.

The bridge at Consenvoye was 156 feet long, and the deepest water encountered was 16 feet.

The work was started with the enemy entrenched on the opposite bank of the river, but due to the effective work of the infantry covering party consisting of one platoon, the rifle and machine gun fire of the enemy did not in any way hinder our operations. When the bridge was constructed to about the half way point, the advance of our troops on the opposite side of the river caused a complete let-up in the rifle and machine gun fire on us. Of course the enemy's artillery was on us constantly from start to finish.

Another principle brought out by Major Mitchell and emphasized in this bridge operation is the ability of engineer troops to produce the necessary material for the work in hand. The bents, planking, etc., mentioned above were not sufficient to construct over two-thirds of the bridge required but the carrying parties produced the balance of the needed material and in no instance were they asked for anything needed by the bridge builders but what it was supplied or a very satisfactory substitute was furnished.

Engineer Supply in War

By

T. H. Jackson

Colonel, Corps of Engineers; and Engineer Purchasing Officer
Formerly Engineer, Advance Section, Service of Supply, A. E. F.

[*Note.*—The fundamental economic principles which should find application in the conduct of war are of such importance and so vitally necessary to success that we have given freely of space in this journal to the statements of successful practical men as to the manner in which they have applied these principles. We believe that there is no other item in the preparation of the engineer for service in war which is comparable in importance with the inculcation of these sound ideas on the application of a just sense of proportion or common sense in the conduct of the engineer's part in warfare.

The many engineer officers and former officers who came in contact with the energetic, resourceful and clear-thinking officer who contributes this article, during his very active service in the A. E. F., will be interested to learn the basic understanding of economic principles which enabled him to steer a straight course through the difficulties which he, in common with us all, had to encounter. They will also be interested to note that Colonel Jackson's ideas of the importance of simplicity, the value of time, etc., are in general accord with the ideas of other successful practical men, heretofore presented.—ED.]

ENGINEERS have in war two great problems to solve—personnel and supply. Much has been written since the war regarding the former and covering both its combat and non-combat aspects. Little, however, has been written bearing on the supply, and that little has been as a side issue to the personnel problem.

Why is this? Is it because the supply problem is not known, or because its importance is not appreciated? There is a tendency to exaggerate the use of personnel, particularly the combat, and to overlook the supply service. There are several reasons for this, of which the following are the most important. Officers, both temporary and regular, have, in general, a lack of field experience, without which one cannot know how to use supplies economically either in peace or war. The greater portion of our regular officers enter war with little experience except with troops. Add to the above the fact that all officers realize that the greatest opportunities for distinction and reward come with troop duty, and it is easy to see why officers, irrespective of their qualifications for troop duty, seek it, and particularly that with combat troops.

My experience from August, 1917, to February, 1920, was with supply and construction. It involved contact with the supply problem from all sides—purchase, storage, issue, and use in field. I had the good fortune to come into close contact with the engineers who did the most for engineer supplies in France, and I believe that most of the opinions advanced in this discussion coincide closely with those of these men. I have always held that we learn through mistakes more than through successes, and when I try to point out the mistakes that were made I am not doing so with a view of drawing attention to individuals or their shortcoming. Yet, one cannot write a useful article on a subject like this without stepping on someone's toes, however much one may wish not to do so.

The Supply Section of the engineers was, I believe, more efficient than that of any other service. But it should have been. It was not as efficient as our construction or combat sections, though it should have been and could have been had we realized its importance. As a body we know something about combat and construction, and realize fully their importance in war. As a body we had little knowledge of supply. This is why our supply was so far behind the combat and construction. A good service, however, should not have such a weak link in its chain as we had.

As illustrating the lack of appreciation of the supply problem within a service, I desire to invite attention to two very interesting discussions on the use and merits of the narrow-gauge railroads in the war, which have appeared in recent engineering literature. In neither has any mention been made of the relation of the supply of this facility to the general supply of the service. Now, a discussion of a war utility is not complete unless this relation is thoroughly discussed. Furthermore, before you can prove the desirability of the utility in war you must prove beyond a doubt that its usefulness more than compensates for its complication of the supply problem. Personally, I am convinced that in the case of narrow-gauge railways this complication completely eliminates it as a means of war supply for our army.

In this article the term field and construction engineer will be used repeatedly to distinguish men trained in the handling of labor and materials on construction from those who have had little or no such training. The former are the desirable type in war.

The war operations of engineers are more like the first stages of the work on a construction job than any other engineering work in peace. War has little of no place for the inside man, men who design, inspect, administer, instruct, etc. I never knew a field man to fail, while I have known dozens of the inside type to do so. Their failure may be attributed in most cases to timidity, which was the result of their lack of training. When called upon to do field work they had only theory to draw on, and theory does not go far in war. The oft repeated statement that in war there is a place for every man, is almost too foolish to discuss. It certainly does not apply to engineers for engineer work. The organization in war is entirely different from that in peace, and it calls for very few inside men. For example, a section engineer working 15,000 men on various construction jobs will have at the most two or three officers whose duties are inside. Their duties will be such that field men are preferable, too. In time of peace, with an equal field force, he would probably have in his office from 30 to 50 men of the inside type, and they would be giving full return.

Probably no one thing caused so much trouble in our supply section as the foolish statement constantly appearing in print at the beginning of the war that it was a war of experts and specialists. In consequence, every possible effort was made to get special troops, and the expert proceeded to try, at least, to load our supply section with supplies that were not necessary in war. I suppose the same condition existed in other services to an extent even greater than in ours. Now, in war the engineers have no use for experts, and very little for specialists. They want the field type construction man, for war work is throughout the simplest kind of engineering.

Digitized by Google

During the first stages of the war, and frequently throughout its duration, the supply problem is more important than personnel. By important I mean it is the one that must be developed the more rapidly and efficiently in order that the progress of the operations as a whole may be promoted. There is no use in supplying men for combat or construction when there are supplies available to employ efficiently only 60 to 80 per cent of them. My experience in France showed that so far as engineers were concerned, the critical element were always in the following order: transportation, supplies, men.

Transportation has always been, and probably always will be, in war, the critical element of the general supply problem. The Transportation Service should therefore be the most efficient in the army. It is probable that it has always been the least efficient. This may seem peculiar, but it is the logical result of our organization. For a service to be efficient in war it must have had a free existence in peace, and have had the best possible facilities to build up its personnel, esprit, and organization. Our transportation has always been a side issue in a big supply service that has had little recruitment of men trained in transportation or the handling of men.

In the past war a step was made in the right direction and an effort was made to place transportation—motor and railroad—in the hands of men trained in its use. However, a war-created service always labors under a heavy handicap as compared with one that has functioned in peace. The efficiency of a service in the first year or so of war varies directly with the number of regular officers of ability with the service. After that, the high-grade temporary officers will have learned enough of the war to take up and carry the load they should bear. But you cannot create a new service in war and have in it any considerable number of regular officers of ability, for good men hold to their own service at that time.

Though the engineers are vitally concerned with transportation itself, our control over it will be limited to that obtained by the use of our personnel in the operation of motor and animal-drawn vehicles. The operation of the railroads in the theater of operations by the engineers is dependent on the decision of the Commanding General, hence cannot be depended upon to have any important bearing on the supply problem. It is probable that it will be the unusual rather than the usual thing when we operate for any considerable time railroads back of the most advanced depots. Supply within the Transportation Service is the important transportation problem and over it we have little or no control.

Such being the case, we must always expect a shortage of transportation—animal-drawn, motor, and rail—and must do all in our power to function with that available for use. This requires that we reduce our needs to absolute essentials. It is here that the great distinction between regular and emergency officers (the trained and untrained officer) is noticeable. The regular officer may not know how to exercise economy in supply, but he is usually willing to cooperate to gain that end, even if his functioning is impaired. Emergency officers for a long time, however, are generally prone to insist on their pound of flesh. We expect this from men not trained as engineers, but it is inexcusable for engineer officers to fail to see or to meet the supply situation with an open mind. I have heard high ranking emergency officers state repeatedly the inability of their service to meet demands on it for supplies, yet insist that every other service should give to their particular service its full demands. They could not see that all services were in the same condition as to supplies—short.

It is very difficult to exercise control over engineer supplies used by troops in combat operations other than in the number of items. Furthermore, this is not very necessary, since nothing but the absolute essentials are usually available. Control in the S. O. S., including rest areas back of the lines, is possible to almost any extent. It is therefore with the use of supplies in the S. O. S. area that we are principally concerned. Moreover, the great bulk of the engineer work is behind the line. In France, probably 90 per cent of our effort was there. What applies there, however, so far as the providing of unnecessary items, applies equally to the armies. There should never be furnished to the armies items that they cannot or should not use.

In considering the problem from a general standpoint, it must be remembered:

That the engineer service furnishes engineer supplies to all other services;

That the engineer service performs all construction in the theater of operations;

That the engineer service, being a combat service as well as a supply service, must supply its own troops whether combat or construction.

In the solution of the problem, therefore, the needs of the various services, including our own, must be considered and co-ordinated. This co-ordination is a function of the General Staff. The General Staff, in acting, settles definitely certain previously determined factors. With these known, the engineer service can consider the factors affecting its own service, and having settled them can proceed to a solution, which, if correctly made, will give efficient results. I will try to consider in turn the factors referred to above.

The General Staff determines such factors as the number of troops for which quarters will be provided and for which supplies will be furnished and stored; the sites at which the depots for these stores will be constructed; the floor space that must be provided in barracks for personnel, commissioned, enlisted, and sick; certain details regarding the construction of buildings, such as no floors in barracks, storehouses, etc. These and similar questions will be settled by the issue of general orders, G. O. No. 46, A. E. F., specifying no floors in barracks, and the floor space for all personnel, meant more to the engineers than any other order issued in France.

The General Staff also approves the projects for all installations. The procedure should be as follows: A service desiring an installation, camp, hospital, depot, etc., at a certain point, presents its needs in the form of a project, which, in general, is not detailed. This project is considered by the engineers, and an effort made to secure an agreement satisfactory to the service concerned and the engineers. If an agreement cannot be reached, the project is sent up with such comments as both sides may desire. The General Staff officer concerned then makes a decision and directs what is to be done. It was not until about September, 1918, that the above procedure became the policy in France. Previously, the engineers were rarely consulted, and many poorly designed installations were approved. That they were not always constructed as approved was due to the refusal of the engineers to use supplies on non-essential work which were needed on necessary authorized work. It is not fair to a service, however, to make it carry a load of this kind; furthermore, it creates an antagonism between services that should be avoided.

Digitized by Google

The General Staff did not appreciate the fact that a stroke of the pen cannot provide men or supplies except at some time in the future. In war, we cannot deal beyond the immediate future.

Within the service the demands of the combat troops and those of the construction section must be met. As indicated before, those of the latter are the greater, and such that they can be better controlled to increase efficiency.

The supply problem within the service is simplified in two principal ways:

By reducing the total tonnage required;
By reducing the number of items to be furnished.

Reduction of items increases the efficiency of the supply section faster than reduction of tonnage. I would rather provide in depot, 1,000,000 tons on a basis of 10,000 items than 500,000 on a basis of 30,000 items. (The inventory made following the armistice showed that we had in depots in France a total of approximately 500,000 tons of engineer supplies and about 30,000 items.) That this is not appreciated even after our war experience is obvious from a knowledge of what was being done by the General Staff and the various services in 1919-20. A great effort was being made then (it may be in progress still, since a scheme like that is apt to run on indefinitely) to improve the purchase side of the supply services. The services were all being worked on detailed specifications for the various items in their category. In peace this may be all right for services that have officers with no technical training, but for war it is wrong. It simply handicaps the buyer when he goes into the market for items in large quantities. For example, there was never a time in the A. E. F. when we were not short of the commonly used supplies—tools, pipe fittings, etc.—and they may say the shortage extended to the United States. Why complicate a shortage like this by an action that will obviously increase the shortage? Any commercial type of material, tool, fitting, etc., will answer in war, and any action that will handicap the purchasing officers in buying such articles should be avoided. Instead, we see a definite plan to perpetuate this handicap. It is different when items of plant are under consideration, since the fewest possible types should be permitted to avoid multiplicity of spare parts.

What should have been done by the General Staff at that time was to determine the supplies each service should furnish in war on a basis of predominant use. This was the A. E. F. policy, and it proved a success. Instead, we have a system untried in war which places in the category of the Quartermaster Corps all supplies common to two services. If the engineers and artillery use shovels, then the Quartermaster supplies them. Such a system does not even sound right. It may be all right in peace, but in war it will last just long enough to cause a general tie up of all supplies. It is the result of the failure of the General Staff to perform its co-ordinating function during the war. In France, where the Staff co-ordinated the supply services, we had no trouble.

Having determined the categories of each service, the Staff should have called for detailed lists of war items, insisting that these lists should carry not over one-half as many items as they did during the war. If the services wanted more, they should have been made to show the need. If specifications were desired for peace purposes, no harm could have followed the preparation of same. So, in short, what we wanted was categories on a basis of predominant use, and lists of war supplies cut to the bone. Instead, we get a lot of paper useful only in peace, and because technical supplies are to be purchased by a service that lacks officers with the technical knowledge that is necessary to purchase such supplies.

In the general problem, however, reduction in tonnage is the more important, since transportation (rail and motor) always controls supplies, and transportation takes little account of anything except tonnage. This is effected by:

Having a few simple standard designs. This applies not only to buildings, but to installations.
Eliminating all construction on a building, and installation, to that necessary to permit its functioning.

In France we had three standard types of buildings, one for troops, one for sick, one for stores. These have been described in other articles, and are familiar to all. The barrack building was of about the same class as is found on a construction work for housing labor. The important feature was that it had no floor. Similarly the storehouses, except in the Advance Depot at Is-Sur-Tille, had no floors except for perishables like salt, sugar, and flour, or where the construction officers failed to exercise proper economy. The design in each case had a very low factor of safety. Many of the hospital buildings furnished under contract had to be strengthened. This was not objectionable for it proved our design was on the right side of the allowable factor of safety, *i. e.*, the low side. I wish to quote here a remark of one of our best construction officers. He had reduced the strength of the storehouse design repeatedly. One day one of them blew down before it was finished. He said, "Now we have a good factor of safety, we know what will just stand and that is all we want." Such officers are invaluable in war. I have repeatedly remarked, "Anyone can construct anything if you give him all the men, materials and time he wants. Do not cite, as qualifying yourself for war, the simple fact that you have done such and such work of magnitude." In war I would rather have a man who can build an outhouse economically than one who can build a skyscraper slowly or uneconomically.

To be able to eliminate all construction not needed for functioning should be the highest aim of the engineer in charge of the construction of an installation in war. To illustrate, a building must have roof and sides to house men but it does not need a floor. The same applies to storehouses. The man who puts floors in storehouses except for certain perishables like flour, salt and sugar, or who puts in raised floors, except under positive orders overruling his protests, is failing in his duty, yet there was a constant fight to prevent this from being done; a fight with the service for whom we were building, and a fight with many of our assistants who had not learned war construction. This fight ended very abruptly, however, in the case of floors, when General Pershing gave orders in person that there should be no floors except for perishables. It was wonderful how quickly many people saw light after that. What applies to individual buildings applies also to installations. Designs came to me with forty-foot roadways and the same facilities duplicated from one to ten times.

The greatest difficulty in installation design came when we had to deal with the specialist, the man whose aim in peace is to provide what will give the greatest efficiency in operation or who was accustomed to such facilities. Such a man has no place in war if he cannot accommodate his designs or his needs to war conditions. The Railroad Transportation Service was a particularly great offender in this respect. We had heard so much of railroad efficiency in time of peace that much was expected of its individual engineers. That service showed the least ap-

Digitized by Google

preciation of the need of simplicity and economy in war. It was fully a year before it seemed to realize that we were at war and that we were constructing with time, simplicity, and just sufficiency of construction to permit operation as the essential elements in the railroad problem as well as all problems. As was to be expected, the worst offenders were the inside men. The Water Supply Section of our service was equally noted for its failure to see the real object of our efforts. Some of us succeeded locally in getting good results from that section, which had excellent personnel in general, by eliminating the men who lacked field training.

Our efforts resulted eventually in pretty complete standardization of installations and on a basis of minimum needs to function. It was really simply a case of education. As stated before it was a constant struggle, not only with other services, but with one's own assistants. It is remarkable how trained men will insist on doing in war what they would not do in peace. Those who were leading in simplifying our work finally took steps to train all of their construction officers before giving them independent charge. They were detached from their organizations and tried out on jobs where we had tried and proven men. If they showed, under such supervision, that they had possibilities as economists of men and materials, they were given independent jobs; if not, they remained always as assistants or were "canned," depending on their ability to conform. Many officers failed to make good in this struggle simply because they had lost or had never had ability to fight—to resist the demands made upon them by others. This is why I have always insisted that for war construction we want no majors over forty. I would give thirty to thirty-five as the desirable age for that grade, adding about five years for each grade above. The older men cannot go back to the lessons they learned or should have learned in the construction camps when they were young.

It will be seen from the above that in the settlement of the factors that the service can settle, the engineers in the combat and construction sections must strive in every way possible to reduce their needs in tonnage and number of items to a minimum. To secure this, every engineer officer must be educated to realize that the exercise of economy in the expenditure of supplies is his most important duty.

We finally come to the supply section of the engineers. This section must bear the blame if supplies are not forthcoming. It would seem that not much is left for it to do but buy, store and issue. Well, that in itself is a big problem and it may be all it may be able to do. But it should not be. It should never be content to accept requisitions blindly and try to fill them. In the early stages of the war, and before the construction and combat sections have learned the game, it must keep its blue pencil sharp and apply it vigorously. Many object to this blue-penciling of requisitions, but when one stops to think that in the early days of the war, hundreds of incompetent and inexperienced officers are requisitioning and that these requisitions get little or no examination prior to receipt by the supply office, it will be realized that much elimination is necessary. An examination of the first thousand requisitions for supplies, either in France or the United States, would be most interesting. I am satisfied that, outside of the company equipment, which was definite, at least 50 per cent of the items and the tonnage were not war supplies. When road troops requisition asphalt concrete plants to take into the field, almost anything may be expected.

As the other sections learn their war duties, and what supplies are war supplies, then the bluepenciling will decrease and the effort of the supply section to keep requisitions limited to essentials will be directed at the heads controlling requisitions on it. But the time should never come when it should furnish supplies simply because they are requisitioned. It must fight to prevent the recurrence of unnecessary requests, carrying its protests to the highest authority. There is nothing that will breed unnecessary demands like acquiescence to similar ones. The supply service must be a fighting service if not a combat one. The fact that we had 30,000 items in stock at the armistice showed that something was wrong with our supply service, that it had not fought for simplicity. It is my estimate that 25 to 40 per cent of the items were not war supplies. In no individual case was this more true than in the water supply. The number of items for its stock was abnormal. In war this service is one adapted to the greatest simplicity.

The efficiency of a supply service increases more rapidly with decrease in number of items than with decrease in tonnage. This, even the most ignorant must admit; yet it is a queer fact that the people who preached this principle and did the most to secure it, were not supply, but construction officers. They were not many in numbers either, probably half a dozen. The curse of the supply office was its acquiescence to the demands made upon it. There were a number of section engineers in France who were first, last and always for simplicity of construction. They showed the supply section what was possible, yet it went on merrily trying to meet the demands of the most inefficient. To illustrate the lack of fight in the supply service in France, I need but cite the fact that the lumbering operations were taken from the supply section and put under the construction section, though the production of timber products was a phase of supply and not of construction. It was a most direct indication of the lack of confidence in the supply section, and fully justified by later results.

Any discussion of simplicity of design to gain reduction in items and tonnage must sound like kindergarten work to the field engineer. It should be part and parcel of such engineer in peace time, and of every officer in time of war, yet in my peace and war experience I have heard less than five people preach it and I know of but two or three who do so naturally and constantly.

The trouble with our supply service in the United States during the war was due to:

Poor organization in the office of the Chief of Engineers;

Lack of sufficient experienced personnel in the supply section.

The supply problem was the most important problem in the office of the Chief of Engineers in the beginning, and was the one that required the most attention. There had been no preparatory work worth mentioning, which made the problem very difficult. The organization of the supply section of the office of the Chief of Engineers indicates that the supply problem was considered to be of less importance than either enlisted or commissioned personnel, while as a matter of fact it was more important. The regular officers assigned to the supply section were excellent, but they were too few in number. There were just sufficient to handle the administration. There should have been at least three times as many. The answer that there were not officers available is not sound. An experienced officer on such duty was worth five times as much

Digitized by Google

as with a combat or any other regiment in the United States. It was the placing of troop duty above supply, combined with the foolish idea that men of less than fifteen years commissioned service were not qualified to command combat engineer regiments, that caused this apparent shortage of officers in the early stages. Now ten to fifteen years is the ideal length of service for commanding officers of combat troops. It is much better than twenty to twenty-five and infinitely superior to thirty to thirty-five. You may at first not admit this, but you will realize it is true if you stop to think or if you know what combat duty demands physically. The officer of our service who went farthest with combat troops, puts thirty-five years as the limiting age of a commanding officer of a combat regiment in war. I would not increase it to over forty years.

In France there was the shortage of personnel, but the great trouble was the changes. There were about eight changes in the Chief of the Supply Section in a period of about fourteen months. You can get nowhere with a big job under such conditions. No one wanted the supply job, but the trouble lay in the lack of appreciation by the higher authorities of its importance. What was needed was to place supply, both in the United States and in France, on a par with personnel, combat and construction. The combat and construction sections succeeded because they were recognized as important, and given a reasonable number of qualified officers. The supply failed to make an equal record because this was not done. There was no *fight* in the supply section, and, as I have stated before, that is an essential quality for success in war. War is no place for the timid; they should stay at home or be sent home. I do not mean that courage necessarily gains one rewards in war, but it prevents failure. It also makes a man able to look his fellow man in the face and say that he did not shirk his duty because it was disagreeable, or because he could not see a reward. Courage, energy, physical vigor and common sense are the essentials in war. If a man has these he cannot fail.

To illustrate how necessary it is to have construction men in the supply section, I could give a hundred illustrations. The cement sub-section in France produced 5,000 tons of hydraulic lime, none of which was used, or would ever have been used, since it was not a war material. This was done because the man in charge of the sub-section was not a construction engineer and did not know field construction. Bath tubs were accumulated by the hundreds though the construction section announced the policy in 1917, that no tubs would be installed, even in hospitals. The same reason applies. Some eight asphalt concrete mixing plants were sent to France though there never was any intention on the part of the construction section to use such plants. The amount of work done on the roads was large and it showed conclusively that road work in war is of the simplest nature. Our best officers knew this and preached it.

Our mistakes in war are the direct result of our lack of training in peace. You cannot expect officers to strive for simplicity and economy in war, if they do not hear of those things in peace. There is no excuse for the regular officer not knowing such things. Every war has been the same old story so far as construction and supply are concerned, and our older officers should know it and teach it. But they do not. I had but one regular officer teach me any of the principles of simplicity of construction and economy of materials in either peace or war. It is somewhat different with temporary officers. Unless they are field men they think of economy and efficiency in terms of dollars saved in the first cost or in operation. Now in war there is no thought of money, it becomes zero in the equation. In war, *time* is the element that counts. It counts in peace construction, too, though most engineers do not realize it fully.

To facilitate operations at the beginning of a war it is necessary that we have schedules showing the items and the quantities of these items that should be furnished without further information than that giving the number of divisions that are to be supplied. Also lists that show the standard equipment for all engineer troops. These lists, no matter how crude, will be of the greatest assistance. The most essential thing is that the number of items be low. The lower the better, for no matter how low it will contain unnecessary items and many more will soon be added. Remember that it is easy to add, but almost impossible to subtract. No officer not qualified as a construction man should be allowed to meddle with this preparatory work. As an example of what the other type may do remember our limber and caisson wagon experience. Another shining example is our present army water cart. It would be a task to conceive of more unserviceable pieces of war equipment than these two devices.

The importance of the supply section should be clearly understood. Provision should be made for adequate and competent personnel, particularly in the depot sub-section. By competent personnel, I mean men with construction experience. No others should be considered, for a man who does not know construction work cannot succeed in this sub-section. The purchasing sub-section should do nothing but purchase under orders from the depot section, hence what it wants principally is active, intelligent, experienced buyers. However, if the depot sub-section is inefficient then the purchasing unit must handle many of its duties and should be controlled by experienced construction men. When competent officers are secured they should not be changed until the policy as to items is definitely settled and the service functioning smoothly.

In conclusion it is believed that in training and preparing for war the following points should be emphasized to all officers, and dwelt upon constantly in instruction:

Construction in war is seldom equal in quality to that on a contractor's camp, and on the installation of his construction plant.

Efficiency in war rests in the standardization of buildings and installations; these to be of the simplest and fewest possible types.

No construction should be done beyond the point that will just permit of functioning.

Efficiency in the supply section increases with the decrease in the number of items it must supply.

What is most needed, therefore, for the successful solution of the engineer supply problem in war is:

Realization by the General Staff that its power to bring about co-ordination of the ideas of each service, with those of the engineers, must be promptly, vigorously, and wisely exercised.

Realization by the office of the Chief of Engineers that its most important problem is that of supply.

Realization by all engineer officers of the importance of the principle that bare necessities only govern all phases of construction and supply.

The Rise and Fall of Traffic on the Willamette River

Above Portland, Oregon

By

E. Burslem Thomson

U. S. Assistant Engineer

THE Willamette River rises in the Cascade Range in southwestern Oregon, flows northerly and empties into the Columbia River about a hundred miles from the ocean. The city of Portland, incorporated January, 1851, is 13 miles above the mouth of the Willamette River. For the purposes of this article the river may be conveniently divided into two parts, viz, from Portland to Oregon City (13 miles), and from Oregon City up to Eugene (159 miles). At Oregon City there is a horseshoe-shaped rocky reef, causing a drop in the river known as Willamette Falls. The difference between the upper and lower pools averages 41 feet, which, since 1873, has been taken care of by a series of four locks on the west side of the river. The City of Eugene (172 miles by river from Portland) is the highest point that has been reached by steamboat service.

In the year 1850 transportation on the Willamette River above Willamette Falls was in the hands of two pioneers, Capt. George Pease and Capt. Jas. D. Miller. Captain Miller owned a flatboat 65 feet in length, motive power for which was furnished by four Indians, each of whom received $16.00 a trip for their services. Captain Pease had a larger flatboat of 6-Indian power. The two boats did a lively and prosperous business between Canemah (just above Willamette Falls) and the towns of Dayton and Lafayette. Dayton is 5 miles and Lafayette 8 miles above the mouth of the Yamhill River, which enters the Willamette River about 42 miles above Portland. They carried from three to four hundred bushels of wheat to a downstream load at a rate of 50 cents a bushel. Upstream charges were $35 per ton.

The first commercial steamboat operated on the Willamette River between Portland and Oregon City was the *Columbia,* a side-wheel vessel 90 feet long with a carrying capacity of about 20 passengers and 75 tons of freight. The *Columbia* made her first trip at noon on July 3, 1850, starting from Astoria near the mouth of the Columbia River, where she was built. The boat arrived safely in Portland the following afternoon. The trip is now made in from six to seven hours, the distance being 100 miles. The *Columbia* reached the foot of the rapids below Oregon City at 8 p. m. the same day.

The following is copied from the "Portland Weekly Oregonian," dated December 4, 1850, Volume I, Number 1:

Regular Steam Packet
Twice a Week
Between Astoria and Willamette
At the Foot of Clackamas Rapids
THE STEAMER COLUMBIA
Captain J. Frost

Will run regular twice each week, leaving Willamette on Wednesday and Saturday, returning will leave Astoria on Monday and Friday, touching at Milwaukie, Portland, Vancouver and St. Helens.

For freight or passage apply to A. P. Dennison, Agent, Portland, or to the Captain on board.

The passenger rate between Astoria and Portland was $25 each person, and the charge for freight between the same points was $25 per ton. The trip regularly occupied 24 hours.

The enterprise of the citizens of Astoria stirred the ambition of the town of Milwaukie, about 6 miles above Portland, and they responded by building the side-wheel steamer *Lot Whitcomb,* which was launched December 26, 1850, and started on a run between Oregon City and Pacific City, the latter then a small town near Ilwaco, Wash. The rates on this, the second steamboat to navigate the river above Portland, were:

For passengers, Astoria to Oregon City, without board	$22
For freight, per ton	25

A lower scale of rates was adopted March 10, 1851, the passenger fare being reduced to $15, with board, and the freight to $15 per ton, or 40 cents per cubic foot.

In May, 1851, the *Lot Whitcomb* made the first trip up the rapids at the mouth of the Clackamas River, one mile below Oregon City, to Oregon City, where a company was organized to purchase and operate the boat. About this time a small steamboat, the *Hoosier,* was purchased by some enterprising citizens of Oregon City and operated on the run between Portland and Oregon City. This boat was a side-wheeler made out of a ship's longboat, and a pile-driver engine. The *Hoosier* was shortly after taken above the falls at Oregon City, achieving the distinction of being the first steamer to run on the upper river.

The first boat to run between Canemah (just above the Willamette Falls) and Corvallis (105 miles above) was the *Multnomah,* a side-wheel steamer about 100 feet long. Corvallis was at that time, October, 1851, known as Marysville, the name being changed by the legislature to Corvallis January 1, 1854. Following this, various boats—*Canemah, Washington,* and others—took part in the upper river transportation, the southern limit at this time being Corvallis. In 1854 the competition on the run between Oregon City and Portland increased to an extent which makes it questionable whether there was enough business to go around. At this time the steamers *Gazelle,* running between Oregon City and Corvallis, and the *Oregon,* running between Oregon City and Lafayette, on the Yamhill River, were monopolizing the transportation business on the river above Willamette Falls. Passenger rates from Portland were $3.00 to Lafayette and $5.00 to Corvallis, and freight charges $15.00 per ton to Lafayette, and $20.00 per ton to Corvallis. The steamer *Belle* carried all upper-river freight from Portland to Oregon City, whence it was transferred by portage at Oregon City to the steamers above the falls.

Digitized by Google

In March, 1856, the steamer *Canemah,* running between Oregon City and Corvallis, announced the following freight rates per ton from Oregon City: Salem, $16.00; Albany, $22.00, and Corvallis, $24.00. Tonnage rates from Portland on the upper river were reduced in May, 1867, as follows: $8.00 to Salem, $10.00 to Albany, and $11.00 to Corvallis. The Peoples Transportation Company were then running a boat as far south as Eugene, to which place the rate was $16.00 per ton. Special rates were made for flour, oats, apples, separators, and reapers. Hampered by the cost and delay of portage over the falls at Oregon City, the Peoples Transportation Company, in July, 1869, began the work of constructing a canal and locks on the east side of the river. By September of the same year they had excavated three sections and the work was then discontinued.

In 1870 the Willamette Falls Canal and Locks Company secured, by an act of the State Legislature, October 21, 1870, assistance to the extent of $200,000 in 10-year 7 per cent State bonds for the construction of a canal and locks on the west side of the river. An agreement was made that the company should limit their charges for toll to 50 cents per ton of freight and 10 cents per passenger. An unsuccessful effort was made about the same time by the Peoples Transportation Company to interest the Legislature in the completion of the canal and locks upon which they had already commenced work on the east side of the river. In accordance with an agreement made with the State to complete the work of constructing the locks on the west side of the river by the end of 1872, the Willamette Falls Canal and Lock Company formally opened the locks to traffic January 1, 1873. From that time to date the locks have been in continuous operation. The locks were operated with toll by various companies until April, 1915, when they were purchased by the United States. Since then they have been operated by the Government without toll.

Until the locks were opened, the bulk of the traffic was handled by the Peoples Transportation Company, who at one time operated seven steamboats above the falls at Oregon City and two below. Transfer was made on a mule-track railroad from Oregon City to Canemah, a distance of about one mile.

Prior to 1872 there was no organized plan for maintaining the channel of the river, but the steamboat *Success,* owned by the Canemah Transportation Company, was engaged by the Peoples Transportation Company from time to time to remove obstructions in the upper river.

Improvement of the river by the general Government was first undertaken in 1871, with an appropriation of $16,000, under the river and harbor act of March 3, 1871. The work consisted of removing snags and scraping bars.

About this time the Peoples Transportation Company, who for ten years had practically controlled the upper river traffic, sold their interests to Ben Holladay, who organized the Oregon Steamship Company to carry on the business.

At the formal opening of the newly constructed locks at Oregon City, January 1, 1873, the first vessel to pass through the locks was a small stern-wheel steamboat, the *Maria Wilkins.* From this date there was keen rivalry for the business on the upper river, various local companies vieing with each other, and with independent steamboats, for the privilege of carrying the rich crops of the valley to the markets.

In 1874 Capt. U. B. Scott designed and built the *Ohio,* a light-draft stern-wheel steamboat. The *Ohio* made her first trip December 12, 1874, proceeding up the river to Eugene on a draft of 8 inches light. The return trip was made to Portland with a load of 70 tons of wheat. As no other boat then on the river could come within 40 miles of the upper Willamette River points the *Ohio* could reach, the venture was a financial success. Strenuous rivalry existed for several years, until in 1881 the Oregon Railway and Navigation Company secured and held the bulk of the upper river traffic.

In 1894 the Oregon City Transportation Company started a boat on the run from Portland to Independence, 83 miles, making the ninth steamer plying on the upper river. Competition became still more acute, until in 1904 an agreement was reached to turn the business over to the Oregon City Transportation Company, the railway company agreeing to withdraw their boats from the upper river. The Oregon City Transportation Company held a practical monopoly of the upper river traffic until May, 1918, when their boats were withdrawn, owing to lack of business. Since then two attempts have been made to renew regular traffic, but in each case the effort resulted in financial disaster.

Investigation as to the reason of the failure of the Oregon City Transportation Company to successfully maintain their boats on the river developed the following contributary causes.

(1) An aggressive and successful campaign by the Southern Pacific and Oregon Electric Railroad Companies in 1913 to secure the bulk of the local traffic for their respective lines.
(2) Failure of the boat company to maintain a business front in opposition to the railroad competition.
(3) Lack of determined effort on the part of the boat company to afford satisfactory accommodation to the public.
(4) Irregular and unsatisfactory boat schedules.
(5) Increase in cost of materials and labor.
(6) Insufficient differential in rates which was found to be but 4 per cent in favor of water traffic. (See note below.)

Note.—The 1912 final report of the National Waterways Commission (Senate Document No. 469, 62d Congress, 2d Session) states on page 556, under the head of "Comparative rail and water rates," as follows: "The amount of difference between rail and water rates necessary to give the waterways a fair share of the traffic varies in each case according to the circumstances. Ordinarily a difference of at least 20 per cent is necessary. In some cases on the Mississippi, hull and cargo insurance alone would require a difference of 33-1/3 per cent. There are instances, however, both in the United States and abroad, where the waterways secure a large traffic at rates as high or even higher than those charged by the competing railway."

From 1871, when, as above stated, the United States first appropriated funds for the improvement of the Willamette River above Portland, to 1920, there had been expended by the Government for this purpose a total of $1,013,880, of which $498,078 was for new work and $515,802 for maintenance. As a result of this expenditure, the river is in good navigable condition, has a depth of 6 feet at low water between Portland and Oregon City and 2½ feet between Oregon City and Corvallis. Above Corvallis there is but little traffic, and that only at the higher stages of the river. The distance by water from Portland to Corvallis is 119 miles.

There is at present no public service transportation on the river above Oregon City, and it is worth while to consider why this river traffic has within a decade dropped from a remunerative business to practical extinction.

The decline began in 1913, when the Southern Pacific and Oregon Electric Railway Companies succeeded in persuading the valley merchants and farmers that they could supply more satisfactory transportation than the boat service. It is probable that if the water traffic interests had met this inroad into their business with increased facilities and more regular and reliable schedules the boats might yet be running. However, no such effort was made, and since October 17, 1920, when the steamer *Northwestern* was taken off the upper river by her owners, the Portland Transportation Company, there have been no regular boats running above the falls at Oregon City. The company stated that their venture was not a financial success.

Digitized by Google

It is possible that to the causes contributing to the failure of the water traffic companies may be added the competition of the auto trucks operating on the highways. At the present time there is no doubt that this highway auto traffic is a real menace to the water-borne commerce of Oregon, and perhaps to the water-borne traffic of the United States. It is not within the scope of this article to discuss the larger aspects of the subject, but the local situation as affecting the present trafficless condition of a formerly busy section of the Willamette River is worth investigation.

Prior to 1918, when comparatively few auto trucks were operating, truck competition was not materially felt on the river. Since then there has been a rapid growth of this business, until even the railroads are considering whether it may not be necessary to absorb this traffic to co-operate with their own systems of transportation.

In March, 1918, a line of trucks was started between Portland and Eugene, 127 miles. The service is controlled by the Willamette Valley Transportation Company. Following are their present freight rates per hundred-weight compared with the railroads:

	Portland to Salem		Portland to Eugene
Class	Auto	Railroad	Auto and rail rates are equal
1st	30 cents	37½ cents	72 cents
2nd	26½ cents	33 cents	61½ cents
3rd	22½ cents	28 cents	50 cents
4th	20 cents	25 cents	44 cents

It is to be noted that Salem is easily accessible by river and Eugene is not.

The business of the Willamette Valley Transportation Company has developed since 1918, until to-day they are operating a 24-hour service with 16 auto trucks. The average day's load is 50 tons, with a maximum capacity of 100 tons. The concern is run on a co-operative plan, each man owning his truck and working on a commission basis. The average operating cost per day per truck is $16.00.

The auto truck is here to stay, and it is not unlikely that its advent will put some of the smaller rivers of the country out of business so far as the transportation of freight is concerned. With rates by auto truck closely similar, and with the added advantages for the truck of more rapid delivery, combined with a warehouse to warehouse service, it seems hardly possible that the small river traffic can survive.

Discussion

By

Charles Keller
Colonel, Corps of Engineers

The preceding article by Assistant Engineer Thomson might, with minor modifications, be adopted as a fair discussion of the state of navigation upon many of our small inland rivers, on which the general rule is that traffic at the present time amounts to little or nothing.

The question arises, Whether the day of the minor waterway has definitely gone or whether, on the other hand, it may be restored to its former position of usefulness as part of a properly planned transportation system? To this question it is impossible to give a reply applicable to all. Probably some of them are in a state of permanent decline and will never again really be useful. Others appear merely to require that they be made to give service in accordance with modern developments to be once more the scene of a remunerative traffic.

It is axiomatic that what the customer desires is the best service obtainable for the least money. Speaking in terms of transportation, what he expects of the Willamette River or any other waterway is that he shall be able to move his commodities upon it at least as conveniently and satisfactorily as he can have them moved by rail, by electric trolley car or by motor truck. To fulfill this demand on the part of the public, vessel interests must therefore furnish, at reasonable rates, a dependable, regularly scheduled service, equivalent to the most convenient service that can be given by any other agency. To do this, they should have capital sufficient to enable them to procure plant of the most economical and efficient kind. They must accept responsibility for the safe and proper handling of goods committed to their care, and probably, in the majority of cases, they must be prepared to make store-door delivery. The Willamette Valley is apparently a prosperous, well-settled farming community. The freight to be handled is high grade, and if there was enough of it to keep quite a number of river boats busily occupied prior to 1913, it seems quite clear that the loss of the business to the river since that time must have been due to the fact that the Southern Pacific and the Oregon Electric Railway Companies were able to prove that they could be relied upon for better service.

Taking the average of the motor-truck rates between Portland and Salem, listed herein, it will be seen that the charge for a haul of approximately 60 miles is $5.00 a ton, or say 8 cents a ton mile. A properly organized vessel line, capably managed, ought to be able to build up a profitable business on rates much less than this and to absorb the cost of store-door delivery at both ends of the haul. Everything, however, depends upon the quantity of traffic available in the territory under consideration and the daily rate at which it moves. If the business to and from Salem is as much as 50 tons a day, apparently it ought to be possible to organize a motorboat service or an economical steamboat service to handle this business on regular schedules. In the final analysis, however, what is needed is to find out just what the business is and then to ascertain what must be the equipment and service to handle it to the customer's best satisfaction. Undoubtedly there seems, on the evidence, opportunity for modern equipment and progressive management to establish on the Willamette River a common carrier service which should also exchange business on through-bills of lading with rail lines and other common carriers.

Mechanical-Chemical Protection of Piles

In THE MILITARY ENGINEER for May-June, 1920, we published a short article on methods of providing mechanical protection for piles. The article discussed several schemes of completely armoring the piles by jackets made of concrete, vitrified pipe or sheet metal. It also mentioned the fact that the Romans had made use of nails—studding the exposed surfaces as a protection against the ravages of the Teredo—and stated that this method was still used in European waters. Apparently the nails used had large square heads and were so driven that the edges of the nailheads touched, thus forming a complete metal casing for the surface of the pile.

A variation of this method has been tried in the harbor at Charleston, S. C., using nails about one inch long with round heads one-fourth inch in diameter, spaced on three-fourths inch centers. This leaves by far the greater portion of the surface exposed. The resulting protection is chemical rather than mechanical for the reason that in the salt water the nails at once begin to rust and the products of the corrosion impregnate the interior of the pile to the depth of the nails. This impregnation has proved an effective protection against the activities of both the ship worm (*Teredo Navalis*) and the gribble (*Limnoria Terebrans*). Piles so protected have been in use for three years and disclose no indications of either the Teredo or the Limnoria, while other untreated piles of the same species, driven at the same time, have long since ceased to be of any value.—*C. A. Y.*

A Science of Infantry Tactics*

By

Capt. B. H. Liddell Hart, K.O.Y.L.I.

Reprinted from *The Royal Engineers Journal.*
[Concluded.]

The Expanding Torrent System of Attack Against Defence Distributed in Depth

We have dealt so far with the principles of attack on any one body or center of resistance of the enemy.

In modern war, however, armies are distributed in great depth, and the attackers are faced with the problem of breaking through a series of positions extending back in layers to a depth of several miles.

To this problem, an effective and scientific solution has yet to be found. Moreover, every defending infantry unit also is itself distributed in depth in successive posts. We need to invent a system which will ensure—as far as is humanly possible—that our attack sweeps through and overwhelms the successive layers of the defence with an unslackening momentum combined with a minimum loss of men.

We have learnt by bitter experience, that it is sheer waste of force, when we come against an enemy position, to press our attack equally at all points.

We must feel and test the position everywhere, and endeavour to push in the weight of our reserves where a weak spot is found or made. This principle has been definitely established and the problem yet to be solved is our tactics when an initial breach has been made at any point in the first layer of the defence.

On the one hand, if we press forward at full speed beyond the gap without attempting to widen it simultaneously, it is risky. We lose the *weight* of our blow because we cannot push adequate reserves through a bottle neck. We lose *time* because the passage through a narrow gap causes delay and confusion. We *endanger our security* because we leave the enemy on our flanks untouched, and so able to cut off the head of our advance.

On the other hand, if we halt our advance while we widen the breach, we lose *time,* the advantage of *surprise* and the *opportunity* of exploiting our initial success, thus allowing the enemy time to organize strong resistance in rear, and await us. Hence we must create a scientific system of attack which will reconcile and combine *speed with security.*

The breach must be *widened in proportion as the penetration is deepened,* by automatically progressive steps beginning with the platoon and working up to the brigade.

Such a system I have endeavoured to deduce by examining and analysing Nature's method of attack.

If we watch a torrent bearing down on each successive bank or earthen dam in its path, we see that it first beats against the obstacle feeling and testing it at all points.

Eventually it finds a small crack at some point. Through this crack pour the first driblets of water and rush straight on.

The pent up water on each side is drawn towards the breach. It swirls through and around the flanks of the breach, wearing away the earth on each side and so widening the gap.

Simultaneously the water behind pours straight through the breach, between the side eddies which are wearing away the flanks.

Directly it has passed through, it expands to widen once more the onrush of the torrent. Thus as the water pours through in ever increasing volume the onrush of the torrent swells to its original proportions, leaving in turn each crumbling obstacle behind it.

Thus Nature's forces carry out the ideal attack, automatically maintaining the speed, the breadth, and the continuity of the attack. Moreover the torrent achieves economy of force by progressively exploiting the soft spots of the defence.

By applying this natural system to battle I deduce these principles for the attack against defence in depth:

i. The forward sub-unit which finds or makes a breach in any of the enemy's positions should go through and push straight ahead so long as it is backed up by the manœuvre body of the unit.

ii. The forward units on its flanks who are held up should send their manœuvre bodies towards and through the breach. These will attack the enemy in flank, destroy his resistance and so widen the gap.

iii. Meanwhile, the units in rear press through the gap and deploy (expand) to take over the frontage and lead the advance in place of the temporarily held up units.

iv. The held up units, as soon as they have accounted for the enemy opposing them, follow on as manœuvre units to support the new forward units.

(N. B. If the forward units are able to clear away the enemy opposing them before the rear units have passed through the gap they will naturally continue to lead the advance.)

Thus an automatic and interchangeable system of attack will be achieved. This system is applicable to all units and formations from the platoon upwards.

Taking for example the infantry attack: the left forward platoon of a company might find or make a gap whilst the right platoon was held up (see Plate I). It would press straight ahead, whilst the company commander moves towards the gap with his manœuvre platoons (see Plate II). The held up platoon is still engaged with the enemy resistance, when the company commander has passed through the gap. He will therefore send one of his manœuvre platoons forward and to the right to take over the frontage of the held up platoon and carry on the advance in its place (see Plate III).

If the company commander judges that the held up platoon can destroy the enemy resistance by its own resources, he will press on at once with his remaining manœuvre platoon, to back up the forward platoons.

If not, he helps the held up platoon by a flank attack before following on.

In any case, directly the enemy has been destroyed the checked platoon would follow on as a new manœuvre platoon.

The company commander would be ready to repeat this method against each successive position of the enemy, thus

*A lecture delivered at the S.M.E. on 6th Jan., 1921, by the author.

Digitized by Google

ensuring the relentless momentum of the torrent. (See Plate IV.)

Likewise the battalion commander may infiltrate his manœuvre company through the gap made by an advancing forward company to expand the front and replace another forward company whose advance is checked or delayed.

Thus any gap in the defensive system will be progressively enlarged and deepened on the initiative of each successively higher commander.

The battle tactics of infantry will become automatic and depend less and less on fresh orders from superiors in rear. Moreover artificial geographical objectives will be restored to their right position as mere stepping stones in the advance. We shall fulfil the principle of economy of force by concentrating our efforts on the only true objective—the enemy.

Thus we see that the respective phases of *Reconnaissance, Fixing* and *Decisive Manoeuvre* will be carried out against each successive resistance, whilst the "expanding torrent" will ensure that the momentum of the attack is not lost by the delay caused by the clearing of these enemy defence posts.

Maxim i. No forward unit must however press on even if it finds a gap, unless it has cleared, or made arrangements to clear, all enemy resistance within its frontage.

Maxim ii. To ensure good team work in the confusion of battle, every unit commander, separated from his own superior, who finds another similar unit in front of him engaged in fixing the enemy, must be ready to act as a manœuvre body to the unit in front. To this end he should get in touch with the unit in front and find out if the latter requires him to aid it by a decisive manœuvre.

Maxim iii. In the case of the platoon, its commander must remember that his sections are not tactical units. This means that they are not composed of interdependent fighting parts and so capable of fixing and manœuvring simultaneously. They possess no manœuvre body of their own, and therefore the platoon commander must use his own manœuvre sections to help any of his forward sections which are held up, before continuing his advance.

Maxim iv. The forward section therefore which finds or makes a gap should only make a bound as far as the nearest tactical point from which it can cover and hold open the breach. It will not move on until it sees the rest of the platoon coming on to back it up.

Maxim v. In the attack against a large force distributed in depth, the expanding torrent system will abolish the need for battalion pursuit. Hence the battalion commander may use his reserve company, also, for replacing forward companies.

Three outstanding advantages of this system are firstly that an automatic continuity of the pressure of the advance is ensured, secondly, that the expanding of the front of the advance rests with the immediately superior commander, thus ensuring that tactical unity is preserved instead of an unorganized dog fight to get forward, with each unit playing for its own hand; thirdly, that the units which lead the advance will automatically be those which have encountered the least opposition. This will mean that the leading infantry are those which are freshest and have the most ammunition. It will be far easier to supply extra ammunition to those who have fallen behind than to those who are leading the advance.

Infantry in Defence

The defence is simply the attack halted. *Any unit which halts its advance is capable on account of its open and self-contained formation of offering an immediate resistance to any hostile attack or counter-attack.*

Thus it resembles our simile of the human tank, possessing both the power of offence and defence. It only remains for it to consolidate the ground within its area so as to gain the most cover and best field of fire.

Once we have grasped this obvious truth the whole problem of tactics in general, and defence in particular, will be vastly simplified. Our previous method of creating a complex system of watertight compartments for each tactical action appears truly unscientific.

From this realization that defence is the attack halted, we deduce the truth that the five battle principles of protective formation, reconnaissance, fixing, decisive manœuvre and exploitation are equally applicable to the defence as to the attack.

A.—PREPARATION.

I.—Formation.

This will be generally similar to that of the attack. The company and platoon will be distributed into a forward body and manœuvre body. The battalion or higher formation into a forward body, manœuvre body, and reserve. The reserve will consolidate a final position of resistance for the battalion, or brigade.

Maxim i. Each unit in defence should be allotted an area to hold, and not a definite point. Thus if the enemy takes a defence post at a disadvantage, by crushing shell fire, smoke or manœuvre, the commander should use his initiative to quit the post and take up a fresh position on the flanks of the post so that he can out-manœuvre the attacking infantry.

Maxim ii. One difference in regard to the formation in defence will be that the manœuvre bodies can be previously placed in readiness on a rear flank of the forward body. They should be placed to cover with enfilade fire the flank on which it is most likely that the enemy might break through. They should take up a position from which they can best sweep the breadth of their area with fire.

Maxim iii. The actual distribution in defence will depend mainly on the frontage and the field of fire. Two sub-units forward and two for manœuvre will be normal, but if the field of fire is restricted it will be best to place three sub-units forward and one for manœuvre. The essential need is to cover the whole area with intersecting rays of fire from the posts of the sub-units. A diamond formation, modified according to the ground, is very suitable for the forward platoons in defence.

Maxim iv. It will be advisable for all forward, or stationary defence, platoons to consolidate in section posts in order to cover more ground with fire.

Maxim v. In the case of manœuvre platoons it will normally be advisable for them to consolidate in platoon posts so that they may be kept more concentrated ready for manœuvre.

The "Contracting Funnel" in Defence

Just as manœuvre is far superior to frontal attack, so manœuvre fire which enfilades the enemy from a flank is the most damaging both in material effect and to the attackers' morale. It represents the main sub-principle of economy of force, which is surprise. Thus the defence should be so disposed as to develop their greatest fire effect to the flank. To this end it should be our aim so to dispose infantry for defence, that the attacking enemy is encouraged to penetrate into channels in which he can be raked by flanking fire.

Digitized by Google

One step towards this is to site our Lewis and machine gun posts to mutually support each other with fire, rather than to fire direct to the front.

Another is the placing of manœuvre bodies so that they fire mainly to a flank.

A third way is to *echelon* backwards the posts of the manœuvre platoons and companies along the natural channels of approach to form a gradually contracting funnel raked by fire. Thus the further the attacker penetrates the more resistance he encounters and the more confined becomes the space in which he can manœuvre.

A diagram of a battalion disposed for defence may make the idea clear.

If we study such a disposition, it becomes apparent that the only effective counter to such defence is the "continually expanding torrent" system of attack.

II.—Reconnaissance.

1. Preparatory reconnaissance will be carried out on similar lines to that for attack. Each commander both before taking up a definite position and during its occupation should study all available information, personally survey the ground and the possible ways of manœuvre, and send out company scouts on special missions.

2. Battle reconnaissance will be carried out mainly by patrols.

Maxim i. If not yet in contact with the enemy they should be sent out to keep watch on all likely lines of approach.

Maxim ii. When in contact with the enemy as in position warfare, they will be sent out at night, in fog, or in dense country by day to keep his forward defences under observation, discover his dispositions, and give warning of a likely attack.

Maxim iii. They should usually be supplied by manœuvre or reserve bodies.

Maxim iv. In darkness or fog, patrolling is the best means of protection from surprise, and not the massing of more infantry in the forward positions.

Maxim v. Patrols and observation posts should be used by manœuvre and reserve bodies during an enemy attack to obtain information as to the situation in front and flank, and so enable instant and correct action to be taken.

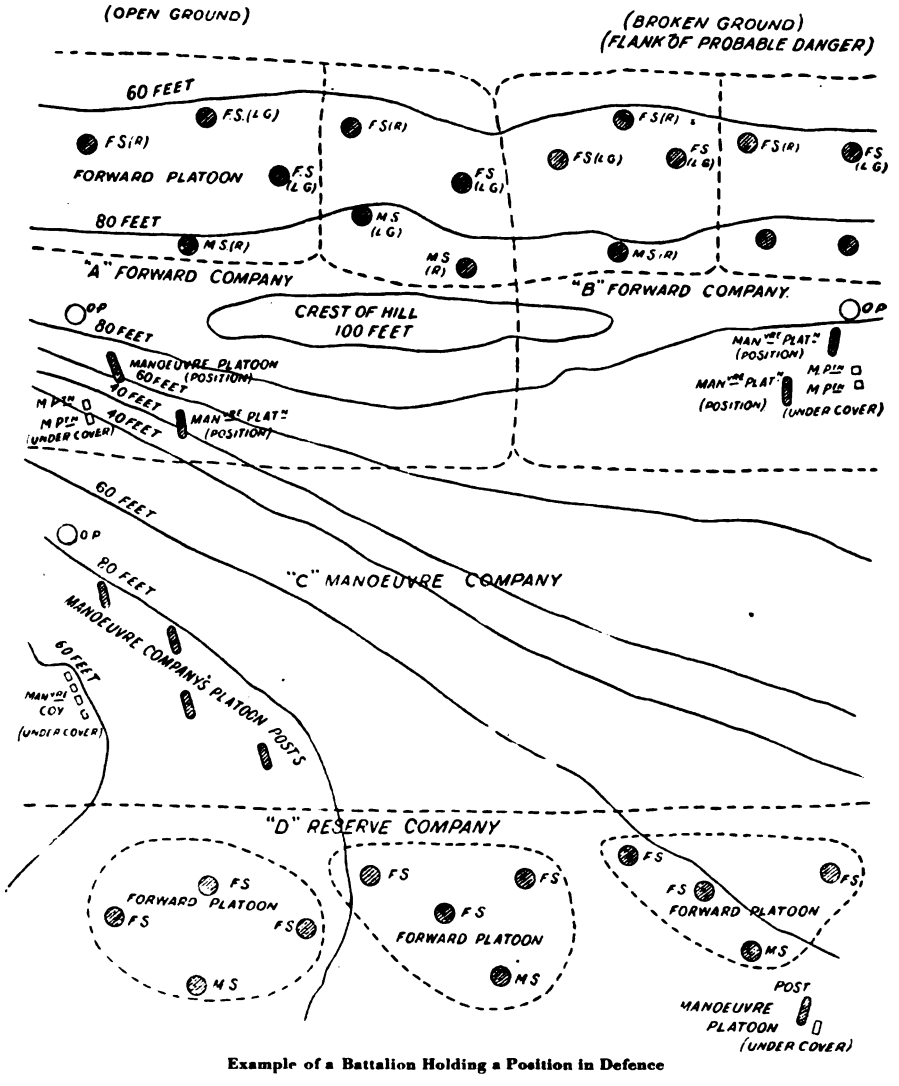
III.—Fixing.

Defence in itself is one method of fixing the enemy. It is incapable of beating him, and therefore a defensive attitude will only be assumed in order to fix and weaken the enemy so that another force may be able to attack the enemy decisively elsewhere, or that you may yourself attack later when his vigour is spent.

In the actual infantry defence the phase of fixing is carried out by the forward bodies. If the forward and manœuvre companies of a battalion fail to fix and break up the enemy's attack, it will be the duty of the reserve to fix him in order to allow higher formations to decisively manœuvre against him.

Maxim i. Forward bodies holding positions should defend to the last man and the last round the area allotted to them.

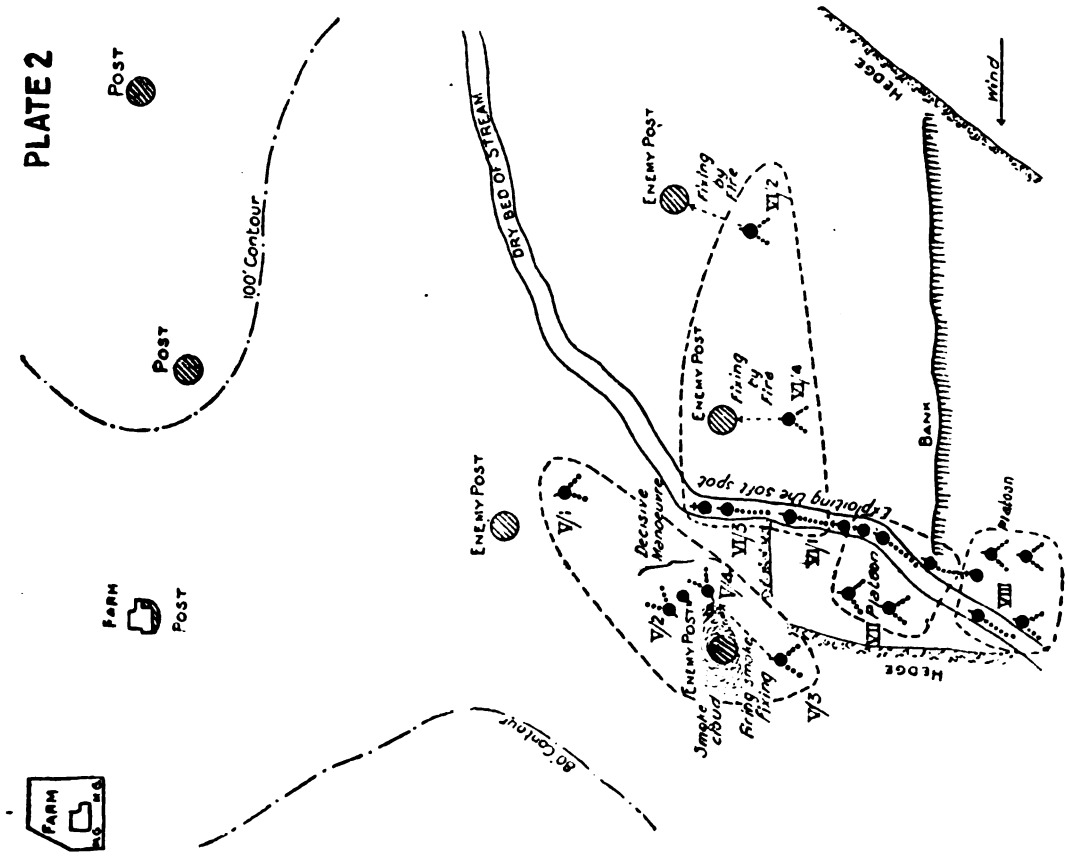
Maxim ii. To instil this idea that troops who have consolidated should not withdraw, fighting patrols should be detailed from the reserve if it is desired to harass the enemy's attack before the main positions of resistance are reached. Moreover troops who have consolidated are more likely to hold on too long, and so if allowed to withdraw would mask the fire of the posts in rear when they fall back.



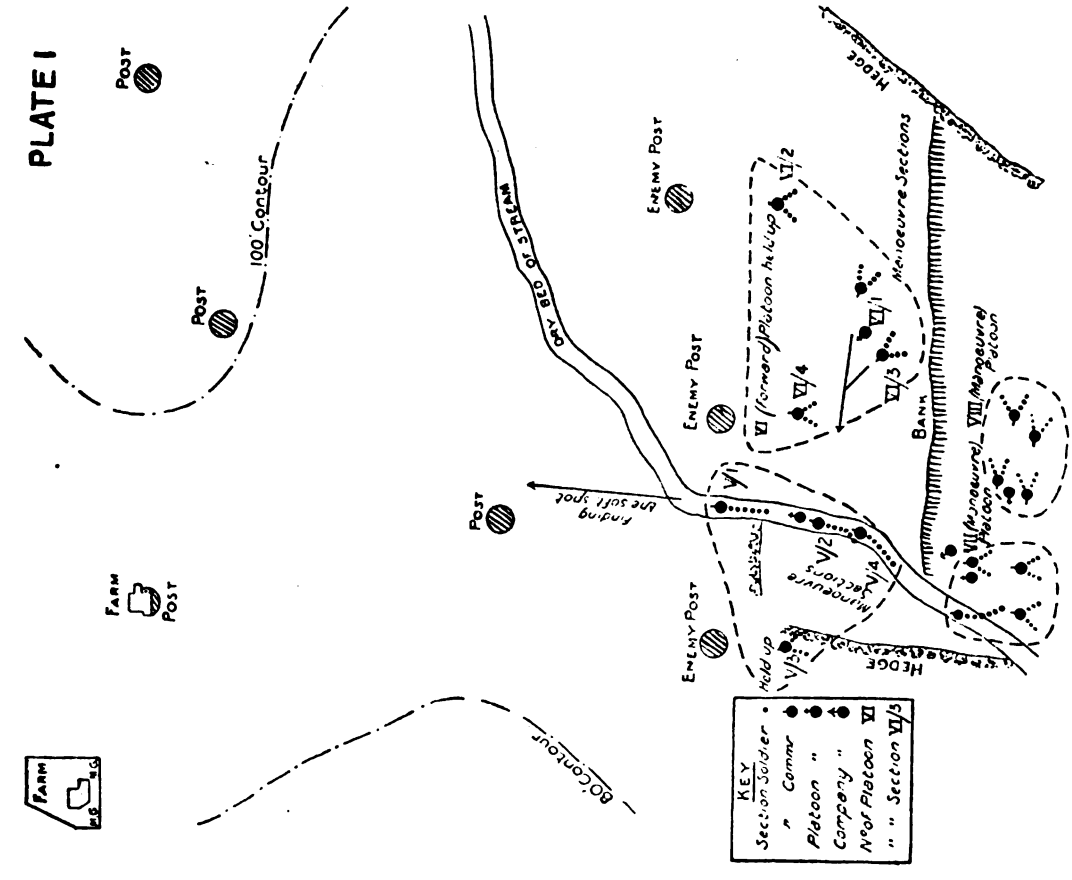
Maxim iii. The *role* of forward bodies is stationary defence by fire.

Maxim iv. The commander of any forward section must however be ready to quit the post and take up a position on its flank, if the enemy take it at a disadvantage by shells, smoke or manœuvre.

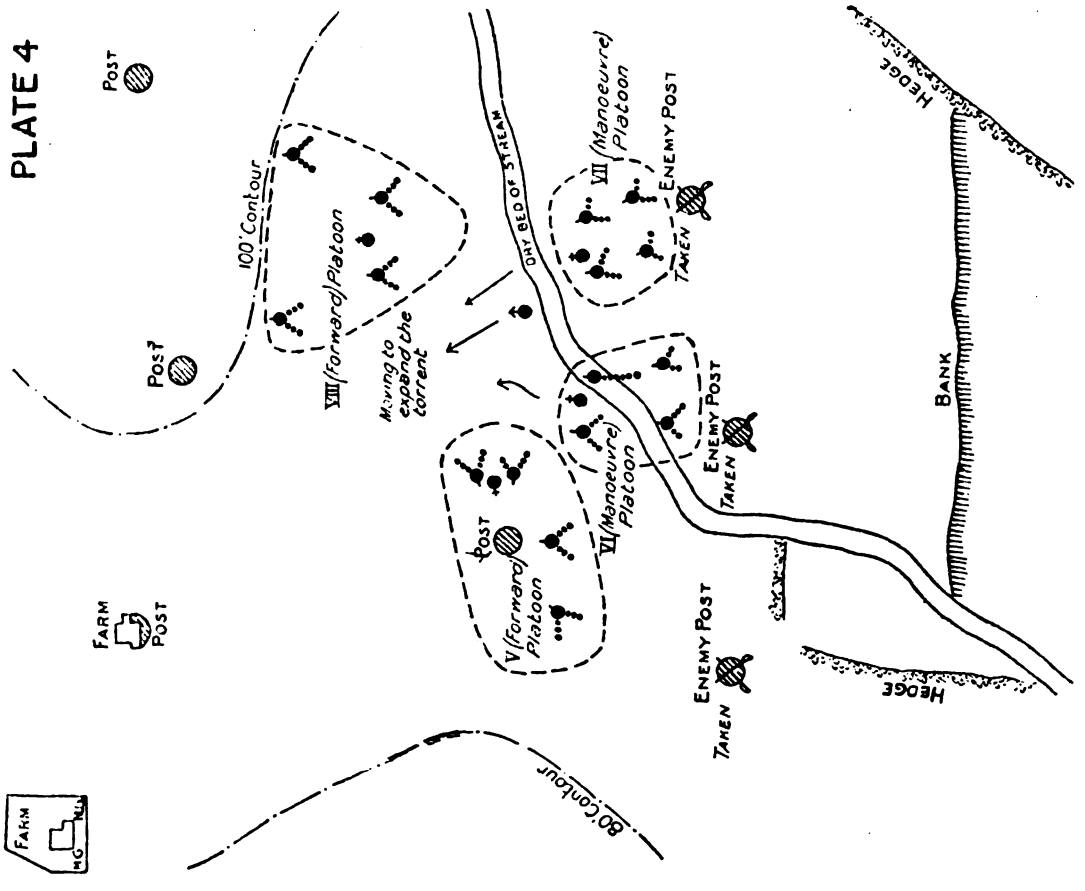
B. (IV).—DECISIVE MANOEUVRE.



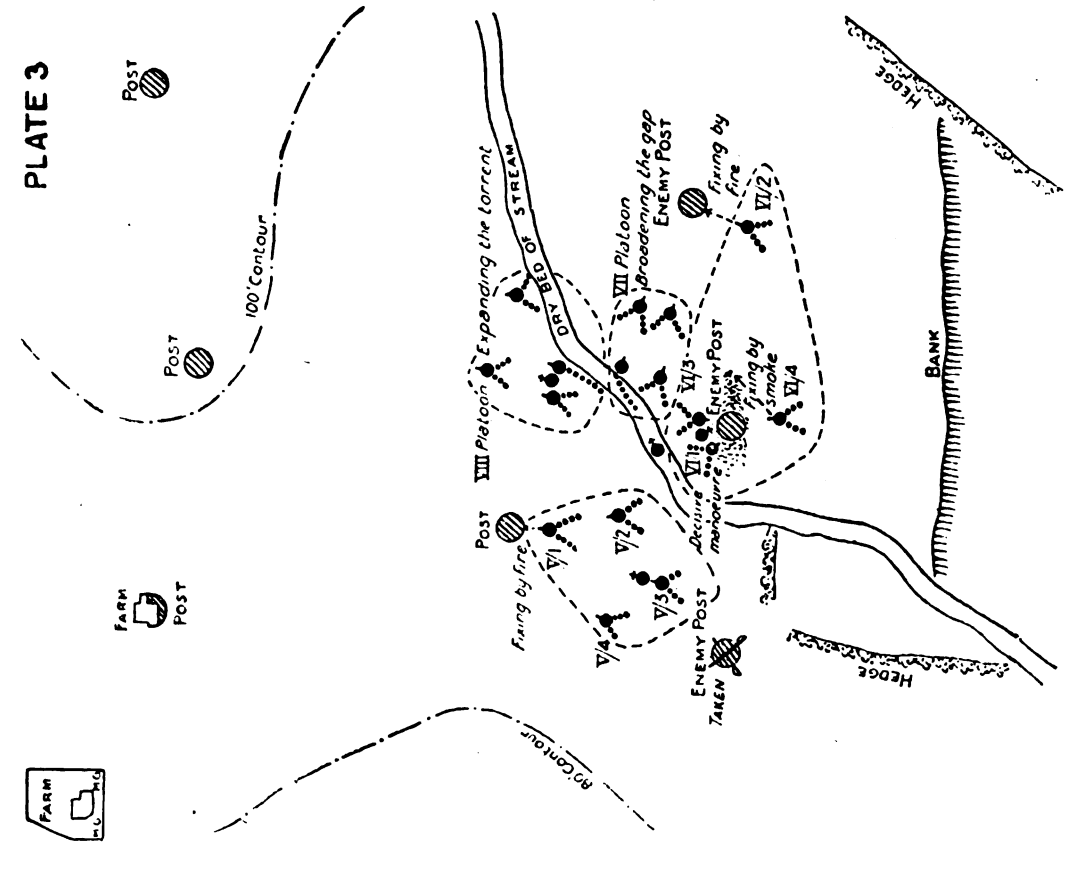
The manœuvre bodies carry out the decisive manœuvre in defence as in attack.



If the enemy makes a gap or effects a lodgement in the positions of the forward body, the manœuvre body will make an immediate counter-attack to throw him back, or manœuvre by fire to close the breach and destroy him in a contracting funnel.



Example of a Battalion Holding a Position in Defence



Digitized by Google

Digitized by Google

Digitized by Google

The function of its commander is manœuvre, which does not necessarily imply assault.

The commander of a manœuvre company or platoon has a choice of two main alternatives:

1. If the enemy break through the forward positions quickly and on a broad front, it will be best for him to man his prepared positions to take enemy in flank by fire.

2. Otherwise he should manœuvre to assault or fire.

Maxim i. A counter-assault which fails is a sheer waste of force. Hence it should not be launched unless the enemy is engaged with other defending units.

Maxim ii. Lewis gun sections of a manœuvre platoon may be used to surprise and fix the enemy with fire while the rifle sections assault.

Maxim iii. If the company commander decides to manœuvre to fire he should move to suitable positions on the flanks of the enemy's breach from which he can enfilade.

Maxim iv. Above all he must remember that whether he uses fire or assault, or both, it will be most effective if delivered against the flanks of the enemy's wedge of attack. In this way the flanks of the breach will be strengthened and his advance cut off.

Maxim v. A counter-attack will be carried out according to the same principles as for the attack, but a definite objective should be fixed for it, and it should never be pressed beyond the forward positions of the defence.

Maxim vi. The one great advantage which the defence possesses is that every move can be thought out and rehearsed beforehand. Every possible line of enemy advance should be reconnoitred and plans worked out for countering them. The possible routes of manœuvre and fire positions on them for each manœuvre company and platoon should also be reconnoitred and marked.

Maxim vii. A counter-attack by any unit smaller than a platoon is rarely effective. Hence fire and not counter assault is the best course for manœuvre sections to adopt.

C (v).—EXPLOITATION.

Exploitation is the counter-offensive when the enemy's attack has failed, and is therefore not true defence.

Outposts.

It should be clear from our analogy of the human tank that outposts *are* simply a temporary form of defence.

Maxim i. When contact with the enemy is unlikely the main consideration is to rest as many troops as possible. Hence units should usually be disposed with only *one* subunit forward and three for manœuvre.

Maxim ii. It will suffice, particularly at night, if the main channels of approach are covered by forward bodies.

Maxim iii. With this reservation the disposition and routine duties of outposts will be similar to those for defence. Only the first stage of consolidation—disposition over the ground for observation and resistance, will be needed.

Maxim iii. With this reservation the disposition and routine duties of outposts will be similar to those for defence. Only the first stage of consolidation—disposition over the ground for observation and resistance—will be needed.

Retirements.

These are simply a mobile defence.

Maxim i. Hence security is the first consideration.

Maxim ii. Retirements should be carried out therefore by a series of leapfrog bounds, the forward body retiring behind it, from which, in turn, it can cover the retirement covered by the fire of the manœuvre body to a position of the manœuvre body. Thus the strain of holding off the enemy will be evenly distributed between forward and manœuvre bodies.

Maxim iii. In flat country zig-zag bounds should be used to avoid the risk that the fire of the covering body may be masked by the retiring body.

Maxim iv. If the enemy presses the retiring body too hard, a sudden counter-attack should be made by the manœuvre body to relieve the pressure.

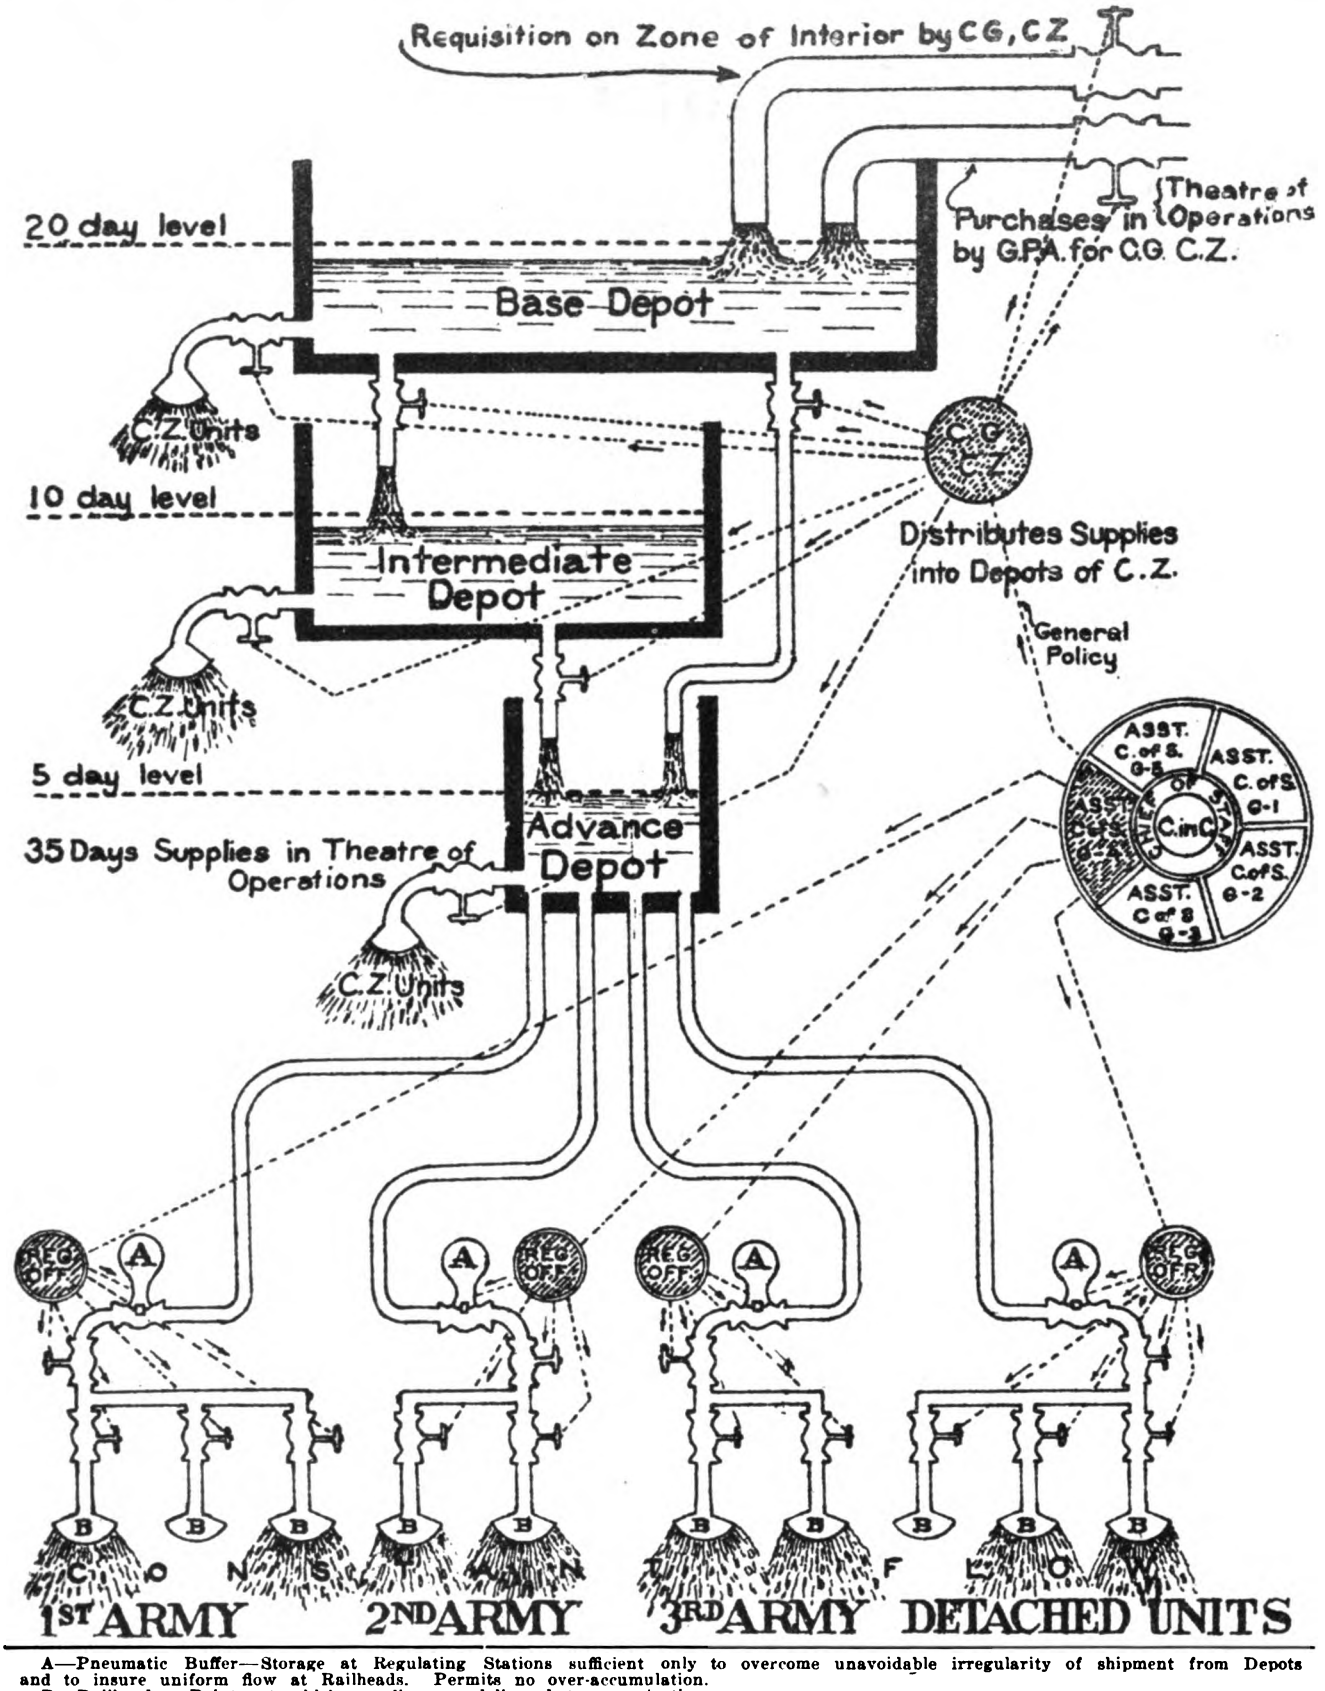
Summary

Thus we see that by working out our principles of tactics upwards from the elementary, instead of downwards from the complexities of large operations, we can simplify infantry tactics to a flexible framework of clear principles which are applicable to all forms of action. This frame work provides us with a sound base upon which to build up our practical knowledge of ground and weapons. It has been the hope and aim of the author to create the foundations of a true science of infantry tactics.

Good Roads

The growth of "The Good Roads Movement" in the United States and Canada since its organized inception in 1880, and with the great stimulus it received in the periods immediately following the advent of the automobile and the appearance of the motor truck has been so rapid, so extensive and so effective that highway construction to-day constitutes one of the greatest, if not the greatest, problems in American economic life.

There are now 1,702 organized agencies actively and directly pleading the cause of good roads. The agitation, to date, has brought about the construction of 310,000 miles of surfaced highways—raising the highway mileage of the United States to 2,478,552 and that of Canada to 255,000.



The automotive industry, fourth largest in the country, with 368 manufacturing plants capitalized at $1,204,378,642 and employing 325,000 workmen; having an annual output of 2,205,197 passenger cars and trucks valued at $3,594,814,620, and supplemented, as it is, by 1,900 firms producing auto parts valued at $300,000,000 a year, together with 1,000 firms manufacturing annually 35,000,000 tires valued at $1,000,00,000, is absolutely dependent upon highway improvement for its stability and upon increased road mileage for greater expansion. In addition, 33,000 distributors of automobiles are involved as well as 45,800 dealers in automobile accessories and 35,000 dealers in tires. So great, too, has the road-building industry become, in consequence of the demand for improved roads, that there are now 7,500 contracting firms engaged in actual construction work. The roads are now traversed by 9,211,295 licensed cars and trucks, of which 3,000 are used on the farms. These cars consumed 3,200,000,000 gallons of gasoline.

Prior to 1880, when Amos G. Batchelder, late Chairman of the Executive Board, American Automobile Association at Washington, with H. S. Earle, of Detroit, and other pioneer advocates, organized the League of American Wheelmen and began a systematic campaign, a good roads enthusiast was looked upon with undisguised curiosity or amusement as something of "a nut"—a loquacious, but, no doubt, well-meaning person who might be seen but not heard. Usually he was "sat upon" by the taxpayer.

Opposition gradually melted away, however, as the campaign became more fully organized and extended. Since 1880 more than $3,000,000,000 has been spent for highway improvement in the United States and Canada. More than $1,300,000,000 is now available, and $1,500,000,000 additional will be necessary to carry out projects under contemplation. And yet, with all this, only a beginning has been made. Billions more must be expended before the country has anything like a highway system adequate to the traffic needs.—*Highways Information Service, N. Y.*

Graphic Representation of System of Supply in the Theatre of Operations

A—Pneumatic Buffer—Storage at Regulating Stations sufficient only to overcome unavoidable irregularity of shipment from Depots and to insure uniform flow at Railheads. Permits no over-accumulation.
B—Railheads. Points at which supplies are delivered to organizations.

The accompanying chart is self-explanatory. It was originated in the 4th Division, General Army, A. E. F., a short time prior to the armistice. It was reproduced in its present form by the General Staff School, Fort Leavenworth.

The abbreviations are as follows—

C. G., C. Z.—Commanding General, Communication Zone. (Note—In future the abbreviation "Cn.Z." will be used instead of "C. Z."
G. P. A.—General Purchasing Agent.
C. in C.—Commander-in-Chief.
Asst. C. of S.—Assistant Chief of Staff. The five assistant chiefs of staff handle the following departments: G-1, Administration; G-2, Intelligence; G-3, Operations; G-4, Supply; G-5, Training.
Reg. Off.—Regulating Officer.

Morale and Leadership

By

J. A. Woodruff

Colonel, Corps of Engineers
Assistant Commandant, The Engineer School

[The following, substantially as here printed, was originally delivered as a lecture to the officers detailed to take the basic course at The Engineer School.—ED.]

Morale

THROUGHOUT the military service we hear constantly of morale—that it is the most important possession of troops and that with morale ten men can beat a hundred. Its value is universally recognized and yet many leaders assume that their men will be endowed with it by nature. They take no means to inspire it—even worse, their conduct of office is often such as positively to injure and even destroy the previously existing morale of their subordinates. It is almost criminal to allow such alleged leaders to be responsible for training men for battle. They are quite as dangerous in training for battle as in leading in the actual battle itself.

The morale of the fighting line has been defined as "that instinctive feeling of strength and superiority which at the very outset gives a feeling of confidence and an assurance of victory through our own irresistible ability." "Having the morale," means that no matter what obstacle or enemy we face, we meet it absolutely confident of our ability to overcome it. *Confidence*—a justified confidence, is, therefore, the real foundation of morale. It is seated in man's loftiest sentiments—patriotism, pride of race, faith in the cause, abhorrence of the enemy's crimes against humanity, determination to overwhelm him, devotion to duty, regards for comrades, loyalty to leader, and in the glory of individual self-respect, skill, vigorous health and general fitness as a superior human being. It is developed by personal example and through intimate talks by the leader with his men on all appropriate subjects, in which he arouses these feelings, always pointing the way to ultimate victory and instilling cheerfulness, pride and determination. But even more, it is developed by the proper training and in the daily handling of the men, in so handling the individual as to develop his self respect and confidence in the excellence of his instruction and in his personal fitness, in so training the team in precise drills and successfully conducted minor tactical exercises that each member is made confident of the skill, team-work and co-operation of his fellows; and above all in the leader's so conducting himself as to inspire the men's confidence in his ability, physical stamina, self-control, judgment and courage.

To develop morale on the drill or manœuvre field requires that the leader be sure and accurate, cheerful, self-controlled, vigorous and undismayed no matter what the discouragement. He must note good performance and commend it, and by encouragement and praise increase his men's endeavor, and confidence in their own ability.

The subject of Morale is intimately connected with that of Leadership. In the discussion of the principles of leadership we find their constant application in how they affect morale.

Leadership

Your first consideration, if you wish to succeed in the military service, is to fit yourself to be the team-captain of your group. To be a good team-captain requires first that you be a good disciplinarian, next that you acquire and use those qualities that characterize natural leaders of men. In all dealings with your men you must have their respect, unhesitating obedience, and if you are man enough to win it, their enthusiastic loyalty.

To attain the confidence and respect of your men, the first requisite is *superior knowledge.* That will give you the self-confidence to appear as a leader, and will justify your men in following you. Therefore, never appear before them unprepared to play your part in the game. You are a sorry object pretending to lead when there are men in ranks who know your part better than you do.

There are many circumstances in which a leader may advise with his subordinates, but it must be clear in the end that the judgment is his own. It is possible, too, for the best men to make mistakes. These should always be frankly acknowledged as such, and no attempt made to bluff them through. Apologies for and explanations of failure are only harmful. The men appreciate manliness; you can not fool them long, and once unmasked as a bluffer, your leadership is hopeless.

It is proper that you should aspire to genuine popularity, to be beloved by your men, to be one of those leaders of whom it is boasted that their men will follow them anywhere. But do not be deluded into thinking that this popularity is attained by easy-going methods, by favoritism, by winking at delinquencies and by overlooking failures in strict performance of duty. Such popularity is false and fades when the real test comes; it changes to disrespect, insubordination and contempt, when real men are at the fore, leading through hardships and dangers. Build your popularity on the firmer qualities of justice and fairness to all; inflexibility in demanding obedience and faithful performance of duty and constant vigilance for the welfare and interests of your men; and above all, by forethought and preparation. In a word, found your position on such qualities and on such conduct of your office as will inspire respect and even admiration for your ability as a leader. Imagine yourself in the other fellow's place and then "do as you would be done by," while not forgetting your own responsibilities as the leader.

It is psychologically true that every group of men, working together for any purpose, soon comes to have a soul of its own. It is true of a company, it is true of a squad. The good leader learns to know that soul, and deal intelligently with it—knows its aspirations, its limits of endurance, how to inspire it to increased endeavor, how to inspirit it when discouraged in fatigue or hardship, how to arouse its interest in the work at hand. There are many means of appeal to this spirit; you must learn and use them.

It is spirit that makes the soldier endure and dare. Especially among volunteers spirit will carry through when

Digitized by Google

cold-blooded training alone must fail. Watch the good troop leader; on the march, in camp, at drill, in the class room, by word and even more by thoughtful conduct of the work in hand, he is always fostering spirit. His men know that what he requires is reasonable, they feel that he is regarding their welfare in every move, making their work as interesting as possible and conducive to future success.

Every man delights in work well done, in actually doing well what he puts his hand to. Remember this when you direct the drill or work of your men. They enjoy being "snappy," being efficient, doing the right thing at the right time, avoiding wasted time or energy, and they are disgusted with the reverse of these.

The state of discipline, a mental status, is attained more by a system of rewards than of punishments, yet both are necessary and potent factors. And do not imagine that there is a class to be controlled by punishment alone.

In the system of rewards the leader finds the most powerful ally in building up that discipline which leads to esprit and morale. He must be on the lookout for opportunities to use it. A word or even a look of approbation is often sufficient. In every group will be found natural leaders, men who, when hardships bear down the spirits of the majority, are found doing more than their share, and not only by example, but often by cheerful word or joke, are unconsciously inspiring the whole to better endurance. The leader must find every opportunity to show public recognition of the merit of these men, thus strengthening their influence with their fellows. Give them the important missions; if favor must be shown, be sure it goes to such a man. Again, there are always found would-be leaders of the opposite temperament, chronic pessimists and critics, who by example, and frequently by grumblings and veiled complaint, lower the average of endurance and performance. It is equally important that the leader undermine the influence of these men, quietly giving them the disagreeable details that often must be performed, and never making the vital mistake of appearing to approve by selecting such a man for a conspicuous detail.

In such cases avoid more sedulously still any injustice, either apparent or real, and all appearance of discriminatory action, for this places you in a position of grave disadvantage.

How absolutely important then that a leader truly know the personalities of his men. Not only must he pick the man best qualified for the task at hand, but he must consider the effects of his selection on the morale of his group, and this demands constant observation of his men at their work. He must learn from the very first to know them by name and then study their individual characteristics.

Punishments can not be administered in accordance with any inflexible rule. Every offense involves the elements of the personal equation of the offender, the attending circumstances, the motive, and always the effect on the discipline of the group. Your decision must be the voice of calm impartial justice.

The authority in you to reward and punish the acts of individual men is a great force for good or for evil, not alone to the individual, but through your treatment of his case, to the whole group. Cultivate patience and justice, a knowledge of human nature and of cause and effect. It is also of the greatest value to be able to see from the soldier's viewpoint, as well as from your own.

Since both punishments and rewards are given for their effect on the discipline and morale of the whole group, they should always follow the delinquency as closely as possible, thus giving full effect.

Be calm in emergency; unruffled, even sardonic (if you have it in you) in the face of hardships; unperturbed and even casual in the face of danger. If you are a real leader your men will take their mental attitude from what yours appears to be. In time of unavoidable hardship you must avoid showing annoyance or impatience. In emergency you must show perfect self-control. Remember that your conduct will determine that of your men. If you are excited, they will be more so. With calm self-assured demeanor give your directions as becomes a real leader. Directions so given are a great comfort to the men and assure steady intelligent execution. This is one of the most characteristic failures in inexperienced troop leadership. Try to train yourself so that you will be one of the exceptions by acquiring the habit in any given situation, of being first sure of yourself, and then calmly giving directions to your men.

It is of the genius of war to seize the fleeting opportunity. Train yourself to quick decisions, carried out with calm self-confidence. It is in general not so important what you do, as that you do something and do it quickly. Do not waste time in searching for the idéal method of procedure. Make a quick decision and then calmly carry it out. Do not change to another plan that may look better an instant later. Vacillation destroys all confidence in a leader. Do not fear to assume responsibility for anything appropriate to your office. Take a simple plan, a bold one, and then unhesitatingly bend every energy to its accomplishment. You may train yourself for this in peace time.

One of the surest means of attaining company spirit is to train your unit to excel in something; it may be in shooting, in close order drill, or in having the best mess. The men begin to take pride in their organization for excellence and they are more excellent, and their personnel is easily maintained from the best men. A good company is always popular and men seek to join it by transfer or re-enlistment from other units.

A good leader is as one with his men; he speaks their language, he shares their comforts and their hardships, he is jealous of their name, he defends their sensibilities and their rights in the larger organization; in fact, he is the recognized guardian of their welfare, physical and mental, as individuals and as a group. He becomes their hero and is affectionately nicknamed. He strives at all times to promote their best interests and thus make them feel that he is concerned with their welfare rather than with his own selfish comfort. It is incidentally true that when hardships come he will be more than repaid by their devotion to him and care for his comfort.

The ability to give orders properly is most important. Disobedience is almost always the fault primarily, either of the order or of the way in which it is given. Make your orders fit the intelligence of the men. It takes time for a man of low intelligence to comprehend an order.

It is a safe rule that your men originally intend to do right. Assume that first, then be sure that your order is right and that it is something that should be done. It is demoralizing to discipline to give an order, and then have to change it. And above all, be sure that there is no suspicion of a question in your own mind but that the order will be obeyed.

Give your orders in a quiet, decorous tone. Too often those placed in authority mistreat their subordinates. By word, tone or manner, they wantonly insult their manliness and thus sacrifice loyalty and cheerful subordination. Remember that military courtesy is a reciprocal relation; it is due as much from the superior to the inferior as from

Digitized by Google

the inferior to the superior. You want to command a team of men, not of curs, and you will never get discipline from men by outraging their sensibilities.

He who can make his men jump with a low firm tone of voice has an enviable force of character. The man who has to raise his voice, scream and roar and curse in order to get action is pathetic. He will be an even sorrier figure when trying to lead in an emergency. He has probably missed the first essential, self-control, and is too likely conscious of his own inherent weakness or inability.

Avoid giving too many orders, or indefinite half-hearted orders. Your order must be so expressed as to leave no question whatever as to your intentions and above all take time and care to see that every order is carried out.

The leader is held responsible for the appearance, conduct and performance of duty of his men. He accomplishes this first by being an example in neatness of dress, care of arms and equipment, punctuality at formations, cheerfulness in performance of all duties, unvarying observance of regulations, military courtesy, etc., and then follow up the delinquents, to see that they also conform.

You expect loyalty, so show it yourself to your superiors. If you are not loyal to your superiors, your men will not be loyal to you. If you receive an order for your command to perform a disagreeable duty, go to its execution loyally; do not try to purchase cheap popularity with your men by saying "so and so has ordered this and we've got to do it."

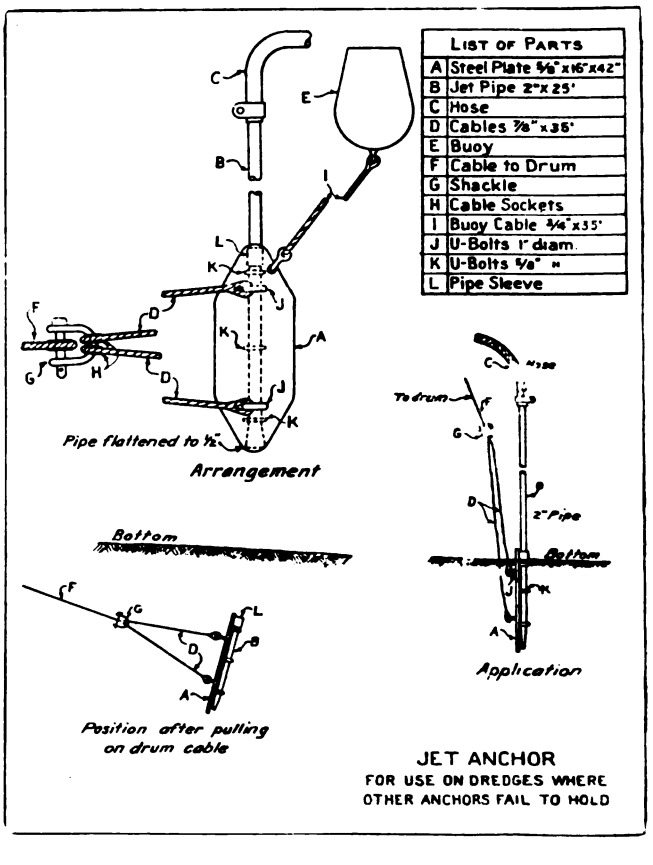
Try to arouse the men's interest in the work at hand. The men should know at least what they are about and why it is necessary and so be allowed to participate with you in the pleasure and credit of doing it well.

Most tasks require special forethought and planning on the part of the leader. You have got to sit down and study it ahead of time, foresee every detail and plan to meet it with system and the least friction and lost motion for the men. Then only will you be able to conduct the work as a real **leader.**

Any man of innate character may fit himself to lead successfully. Hundreds of thousands of civilians thus fitted themselves in the late war to lead as officers and N. C. O.'s. Many had had no experience of command to guide them, had never given a direction even to a servant. Yet by application they rapidly learned how to handle themselves as leaders and their men as loyal followers, and carried through with a success that varied with the degree of proficiency they attained in the art. No one expects perfection. It is impracticable to follow rules or to assume personal qualities that are not natural. The thing to do is to realize that leadership may be developed, to absorb its fundamentals into your system, and to study yourself as applying them to the problems of your profession.

Jet Anchor in Use by the U. S. Suction Dredge "H. S. Taber"

By



John C. Oakes

Colonel, Corps of Engineers

The U. S. dredge *H. S. Taber* was built for the Little Rock, Arkansas, district, and is a pipe-line suction dredge with no cutter head but with shovel suction, using water jets to stir the material. The dredge is moved forward by means of lines fastened to piles or anchors placed ahead of the dredge. This dredge was transferred from the Arkansas District to the Norfolk District to work in Croatan Sound on the inland waterway, and on arrival at the site of the proposed work immediately encountered very stiff material. At first it was found almost impossible to pull the dredge ahead against the kind of material found in place. Ordinary 3,000-lb. and 4,000-lb. anchors were insufficient in weight to hold, and it was impracticable to use piles. In this contingency, Mr. George O. Rogers, Master of the dredge *Taber*, suggested the use of sheet steel jet anchors, and their use has proven very successful. It is thought that the design and method of operation of these anchors may be of general interest to operators of dredges throughout the United States, and the accompanying description with drawings is, therefore, furnished.

The anchor consists of a steel plate $\frac{5}{8}''\times16''\times42''$ to which is attached a 2-inch jet pipe. This pipe is flattened at the lower edge until the opening is about $\frac{1}{2}''$ wide. At the upper edge of the steel plate a pipe sleeve is attached, so that the upper portion of the pipe can be unscrewed and removed after the anchor has been jetted down to a sufficient depth. Two anchor lines are attached to the plate by U-bolts 1 inch in diameter, and the two lines come together about 8 feet from the plate, and are connected to the cable by a shackle. At the upper edge of the plate is a shackle to which is attached a cable leading to a buoy. The anchor plate up out of the material. The accompanying illustration and after it has been jetted to sufficient depth the upper section of the pipe is unscrewed and removed. When the time arrives for the removal of the plate, the derrick picks up the buoy fastened to the cable and simply pulls the plate up out of the material. The accompanying plate shows method of fabrication, position of anchor sunk, and position of anchor after stress has been put on the cable.

The use of these anchors has been proven very advantageous, as they are much lighter than the heavy ship's anchors formerly used, can be jetted to any desirable depth in a few minutes and can be removed and handled much more easily than can be the ordinary anchors.

The Insignia of the Corps of Engineers

By

S. A. McCarthy

Chief of Division, Office Chief of Engineers

IT is a matter of common knowledge that the use of regimental badges instead of the more prosaic and less picturesque "regulation" devices does a great deal to encourage esprit de corps. Badges that can boast a definite meaning, commemorate notable achievements, by characteristics and suitable design, are regarded with reverent pride by those privileged to bear them.

The Corps of Engineers is particularly fortunate in the choice of its two time-honored distinctive devices—the embrasured bastion, and the turreted castle. They have a long and inspiring history, now the premier badges of the Army, and the story of their origin is interesting.

There is no record of the use of insignia to designate the Engineers during the Revolutionary War.

During that period the different branches of the Army were distinguished from each other only in the uniform. In the orders from Short Hills, June 18, 1780, the Corps of Engineers appears for the first time with a distinctive uniform:

> The Corps of Engineers and that of Sappers and Miners, a blue coat with buff facings, red lining, buff underclothes, and the epaulettes of their respective ranks.

General Orders from Newburg, December 5, 1782, directed a change in the uniform of the Infantry and that—

> The Corps of Artillery is to retain its present uniform, and the Sappers and Miners will have the same.

Thus it appears that the traditional "blue and buff" of the Revolution was worn generally only by the general officers, unattached aides, the Corps of Engineers, the Sappers and Miners, Washington's Body Guards, the 1st and 2nd Continental Infantry, and the 1st and 2nd New York Continental Infantry.

At the conclusion of the Revolutionary War the armies were disbanded and the military establishment reached its lowest point. In May, 1784, the army consisted of only 80 men, all artillerists.

The Act of May 9, 1794, provided for a Corps of Artillerists and Engineers to consist of four battalions. In 1798, an additional regiment of artillery was raised. This Corps had its distinctive buttons and uniform, patterns for which were deposited in the public stores in 1800. The buttons of the different branches of the service began to have definite individuality. Those of the Corps of Artillerists and Engineers, found on a uniform of Colonel Henry Burbeck who commanded the 1st regiment of Artillerists and Engineers from May 7, 1798, to April 1, 1802, were stamped "1st Regt. U. S. A. & E.," together with a field piece and a stack of cannon balls.

Insignia of the Corps of Engineers of the Spanish Army (enlarged)

It is not a castle but a "towered tower, crenellated, bracketed, and machicolated"

In Spanish heraldry towers are used frequently, sometimes singly, as above, or in groups of two or three. In turn, they may have towers superimposed on them, and thus become towered towers, double towered or triple towered towers.—S. A. M.

It was soon discovered that the Corps of Artillerists and Engineers could not combine effectively the duties assigned to its members. A law was therefore enacted by which it was abolished and the Corps of Engineers and a regiment of artillery created, and the Military Academy established under the Corps of Engineers. This Act, March 16, 1802, is the organic act of law for the existing Corps of Engineers.

Major Jonathan Williams, late of the 2nd Regiment of Artillerists and Engineers, was appointed to the command of the Corps of Engineers and superintendence of the Military Academy.

He recommended a uniform for the new Corps. In approving it, the Secretary of War commented:

> Having carefully examined the sample forwarded by you for the uniform dress of the Corps of Engineers, but one objection presents itself and that is the dress will be an expensive one and I am fearful that the officers of the lower grades may find it difficult at times to furnish themselves. If, however, in your opinion this objection may be obviated it will receive my approbation and you are hereby authorized to consider it as the adopted uniform of the Corps.

No description of this uniform can now be found. The Purveyor of Public Supplies (later styled the Commissary General of Purchases) in Philadelphia, was the custodian of all patterns for clothing, buttons, epaulettes, belts, plates, hats, shoes, harness, etc., entered into contracts for their manufacture, and issued them to the army on requisitions therefor. The records of his office are very complete and contain much information of interest.

At that period buttons were imported plain (principally from Birmingham) the adopted design being stamped on them later.

The records of the Purveyor contain considerable correspondence with Colonel Williams on the subject of changes in the uniform. Having been so recently derived from the Artillery the Engineer uniform followed to a considerable extent the style of the elder corps, the principal difference being in the coat and the hat. The hat was the subject of much correspondence, whether it should have a brim all around or not; if not all around, it was called a "yeoman," or human crown; whether black feathers were to be used or a woolen knob. But there is nothing to show the use of a distinctive button or other insignia

Digitized by Google

for the Engineers. Invariably Artillery buttons are mentioned as being supplied for the Engineer uniforms, occasionally Infantry buttons when those of the Artillery were not available.

After the separation of the Engineers from the Artillery a change was made in the button of the latter Corps so as to show—

An eagle standing on a field piece which points to the left and stands on an earthen parapet, a dull ground of parallel lines, the whole in an oval, the outer edge milled.

A variation shows a stock of cannon balls at the bottom.

In the early days of the Army, the chief of each corps fixed the uniform for his command. In 1810, the Purveyor says: "The Secretary of War authorized Colonel Williams to vary at his election the clothing of his little Corps of Engineers."

At the time of its organization, the Corps of Engineers consisted of only seven officers, and under the law it had expanded to only sixteen prior to the War of 1812. As only 28 buttons were necessary for use on the exposed parts of a uniform (non-uniform buttons were used on the unexposed parts) the total number used was hardly enough to warrant the expense of making a separate die for stamping them.

Artillery buttons, probably of the designs mentioned above, continued to be used on Engineer clothing until the "Essayons" button was adopted for the Corps of Engineers.

Essayons Button

The earliest date to which mention of the "Essayons" button has been traced is 1814. This is found in Gen. George D. Ramsay's "Recollections of Cadet Life," published in General Cullum's Biographical Register of the Military Academy, III, 627, as follows:

Captain Partridge was never known to be without uniform, and it was believed that he had none other than military clothes. His was that of the Corps of Engineers with the embroidered* collar and cuffs and the Essayons buttons.

Captain Partridge was on duty at the Military Academy as acting Superintendent from 1808 to 1817, and General Ramsay was a cadet there from 1814 to 1820.

A uniform coat worn by Capt. Alden Partridge during his stay at the Military Academy, 1808-1817 (probably the same one mentioned by General Ramsay), was found by Prof. E. S. Holden of the Military Academy, at the home of Captain Partridge and deposited in the Museum at the Military Academy. As no record of the Engineer uniform of that period has been found elsewhere the following description of it is printed:

In a general way it resembles the coat of the Engineer officer shown in plate 15 of "Uniform of the Army of the United States, 1774-1889," published by the Quartermaster Department.

The coat is of blue cloth. It has a high standing collar of black velvet; there is no collar ornament. The coat has a single row of nine flat Engineer buttons, precisely like the buttons of today. The buttons are stamped: T. Potts, Birmingham, and fasten on wire rings through eyelet holes.

The herring-bone pattern braid has no loops at either end.

The cuffs of the sleeve are of velvet cut on the outside to fit the lower one of three herring-bone braids, as in plate 15 referred to. On the inside of the cuff the velvet runs straight across. It is slashed half way up so as to leave the sleeves loose for the hand. There are three Engineer buttons on the sleeve.

*He meant black velvet.

The tail of the coat has two buttons at the waist, two buttons halfway towards the tail, two buttons at the extremity of the tail, and three buttons at the points of the herring-bone on each flap. There is one pocket in the inside of the right coat tail.

A single epaulette is worn on the right shoulder to designate a captain's rank. (The button at the top of the epaulette is a light artillery, *i. e.*, an eagle sitting on a wheeled cannon.)

Doubtless this is the style of the uniform referred to in the orders of May 1, 1813, and of 1816, prescribing the uniform for the Army, as follows:

Note. Officers of the Corps of Engineers will wear the uniform already established for the Corps.

The device of the Engineer button is unique and does not resemble that of the Engineer service of any other country.

France, Belgium, Norway and Greece use the cuirass and helmet. That of France has had an existence of nearly 200 years, except during the Revolution, when republican symbols were substituted.

Italy—helmet, shield and cloak.

Netherlands—helmet for the army; torch, arrow and anchor for the navy.

Sweden—star and rays.

Switzerland—crossed hatchets.

Spain, Portugal and Brazil—tower in various forms, which in Spain and Portugal is surmounted by a royal crown.

Mexico—a fascine with wings, and an anchor with lightning issuing from the stock.

Great Britain—Royal cypher with the words "Royal Engineers."

Russia—Imperial eagle, hatchet and spade crossed.

Confederate States—Old English E.

The device of the Engineer button shows the masonry of the bastion of a marine battery, embrasured, casemated and crenellated, surrounded by water, a rising sun with rays, all surmounted by a soaring eagle bearing in his beak a streamer displaying the motto "Essayons."

The whole is splendidly symbolical of the work of the military engineer and commemorates the first great public achievement of the youthful Corps of Engineers. The design has not undergone any change from its first appearance and it is the production of an artist of rare merit and excellence.

Prompted by the unsettled condition of our foreign relations and by the indications of the approaching war with England, steps were taken in the first decade of the last century to put the defenses of the country in safe condition. Heretofore such defensive works as had been undertaken were defective in design, small, weak, and being built for present economy, of cheap materials and workmanship, were very perishable.

While exercising the superintendence of the Military Academy, Colonel Williams devoted himself personally to the fortification of New York Harbor. In 1807 he planned the construction of Forts Richmond and Tompkins for the City of New York.

Most of the forts which constitute the inner line of defense of that harbor—Fort Columbus, Castle Williams (at first designated "the stone tower"), Castle Clinton, and Fort Gansevoort—were planned by him and built under his supervision.

They were the most important works of fortification that had been attempted by the national government, and in them Colonel Williams introduced a notable innovation into the system of military defense of this country, that of

Digitized by Google

the casemated embrasure. Casemate is combined from two Spanish words: *casa,* house, and *matar,* to kill. The term came later to mean any vaulted room under the earthwork of the rampart or glacis whether intended for the service of guns, quarters for troops or storage purposes.

Castle Williams was the first casemated battery erected in this country. Its construction was commenced in 1807. It was planned under the systems of Montalembert with which Colonel Williams had made himself acquainted while resident in France as American Agent during the Revolutionary War, and where he pursued his professional and scientific studies.

Says Colonel Williams in 1807:

> It was further considered that the modern improvements of marine batteries which give double the number of guns on the same horizontal base and by multiplying the tiers may give six times the number of the heaviest metal with a bomb-proof security above, rendered the question of combat a question of floating wooden walls against impregnable stone walls on shore with equal power as to celerity of action and number of guns within the same space and weight of metal. It is not a very bold assertion to say that no ship sails on the ocean that would engage on such terms.

Such was the enthusiasm created by the brilliant project of the Chief Engineer and the vigorous measures taken for defense that the freedom of the city of New York was granted to Colonel Williams, August 1, 1807, together with the gift of a large sum of money, but the latter he declined.

The works of defense were finished in 1810, and "the stone tower" was named after Colonel Williams:

> Orders. Fort Columbus, Nov. 24, 1810.
>
> In future, the stone tower on this island (by the approbation of the Secretary of War) will bear the name of Castle Williams, in honor of the commandant of the United States Corps of Engineers, who designed and erected it. And on Monday next, at twelve o'clock, a national salute of seventeen 42 pounders will be fired from the lower battery of Castle Williams in commemoration of the 25th of November, 1783, the date on which the British troops evacuated the City of New York.
>
> HENRY BURBECK,
> *Colonel, Commanding the Harbor of New York.*

It may be noted that the gateway of Castle Williams was ordered to be as follows:

> The gateway of plain stone work, with a plain stone arch, turned over the gate, with a table or inscription for the words Castle Williams and with the month and year in which it was completed—an eagle over the center and no other ornamental work.

Thus we find the principal elements typified in the button: a casemated, embrasured, crenellated battery of masonry defending a waterway, the national eagle over the center.

Of the remaining elements the challenging French motto would naturally be suggested by Colonel Williams' residence in France and the influence of his studies and associations there; and the sun rising in his radiance portrays the coming of the genius of the new Corps.

In July, 1821, new Army Regulations were issued. Article 64, Section 41, directed:

> The button of the Engineers will be flat, of yellow metal, with only the device and motto heretofore established.

This remains the earliest authoritative reference to a distinctive device for the button for the Corps of Engineers. The same order directed that the belt plate be yellow; that the black velvet standup collar be embroidered with a sprig of laurel encircling a star, and velvet cuffs.

No change has been made in the design of the button since it was originally adopted. Until 1840, it was made flat. In that year it was ordered to be made slightly convex with a raised, bright rim; and the device was described for the first time officially:

> An eagle holding in his beak a scroll with the word "Essayons," a bastion with embrasures in the distance, surrounded by water, and a rising sun; the figures to be of dead gold upon a bright field. (G. O. 7, A. G. O., Feb. 18, 1840.)

For a short time, 1832 to 1839, the Engineer belt plate carried the device of the button, but in the latter year that was changed to the turreted castle.

The rank and file attached to the Corps of Engineers (bombardiers, sappers and miners) used Artillery buttons until 1846. From 1846 to 1851, turreted castle buttons were used. From 1851 to 1857, the Engineer soldiers wore buttons corresponding with those for the officers of the Corps; after 1857, they returned to those of the Artillery which finally changed to "regulation."

In 1902, when "regulation" buttons were adopted for the Army, the Corps of Engineers alone was allowed to retain its distinctive button.

Star and Wreath

The star and wreath was a distinctive collar device worn by officers of Engineers from 1821 to 1851.

Originally the Engineer collar was of plain black velvet. In 1821 it was ordered to be "embroidered with a sprig of laurel encircling a star." (Army Regulations, 1821, Article 65.)

In 1832 this was changed to a "gold embroidered wreath of laurel and palm crossing each other at the bottom encircling a star of gold embroidery." (G. O. 50, A. G. O., 1832.)

The use of this device ceased with the issue of new clothing regulations in 1851.

Its passing was probably unregretted. It displayed no originality or invention. It had no story to tell, recorded no particular corporate achievement. As a device it was hackneyed. While it served as a collar ornament for the Engineers, it was displayed on other portions of the anatomy in other branches of the Army, on the skirts of the general officers and staff; and the star was used as a badge to indicate rank for the general officers.

The Turreted Castle

The turreted castle as an insignia of the Corps of Engineers was adopted by General Totten in the summer of 1839. In that year new clothing regulations were under consideration and when published (G. O. 36, A. G. O., 1839) it was ordered that the belt plate of the Engineers be "gilt, according to the pattern in the Engineer Department."

This pattern was the device of the "turreted castle." It may be described as representing a portion of a castle with a central arched entrance, grilled, and approached by steps, in a central tower, leading at either side by galleries pierced by two windows, to a corner octagonal tower, the galleries and towers crenellated.

The appropriateness of the castle as a symbol of the military engineer is at once apparent. The medieval castle is inseparably connected with the subjects of fortification and architecture.

In heraldry, the castle and the tower are frequently used in coats-of-arms of persons, cities, corporations, and guilds. They are often given as charges in the shields of persons who have reduced them, or who have been the first to mount their walls in an assault, or for a successful defense. In the arms of medieval cities they indicated that the cities in question were walled towns. Such castles occur in the Arms of Berlin, Hamburg, Budapest, Limburg, Madgeburg, Klausenberg, Linz, Oldenburg, Toulouse,

Digitized by Google

Bordeaux, Caen, Dublin, Carlisle, Exeter, Norwich, Barnstable, etc.

Heraldry's universal requirements in the designing of a badge or coat of arms are the commemoration of some noteworthy thing, simplicity of design, and practicability. All these are happily consummated in this badge.

In this country, the term "castle" was applied to the strongest of our early works of fortification, viz.: Castle Williams, Castle Clinton (which now survives in Castle Garden), and the Castle on Hendricks Reef, N. Y.; the works on Castle Island in Boston Harbor, and Castle Pinckney, S. C. These, together with the entire system of permanent defense of the country, are the particular achievement of the Corps of Engineers.

The design represents a castle in its most conventional form without decoration or embellishment, even the usual machicolations and supporting brackets being omitted, to secure simplicity of design and practicability in use.

General Totten was the military engineer par excellence. From 1808 to 1838, when he became Chief Engineer, his time was almost entirely devoted to the construction of heavy masonry fortifications. The great work of his life was the fortification of the Atlantic coast. He was an indefatigable analyst and experimenter. It would be almost impossible to enumerate the various objects of his researches. There is scarcely a subject connected with the art or science of the engineer, civil or military, which did not engage his attention and of which he has left some record, such as the thickness of sustaining walls, thrust of arches; composition of stuccoes, paints, lacquers, washes for stone and brickwork; tests of timber, and of building stone. He was the author of many publications of professional and scientific interest. His "Hydraulics and Common Mortars," published in 1838, constitutes to this day an authority relied on by the American engineer.

While designed as the badge of the Corps of Engineers, it is a matter of record that the device was first used by the cadets at West Point. In response to a request from General Totten, in September, 1839, Colonel Delafield made suggestions regarding changes in the uniform of the Corps of Cadets which, with very slight modifications had remained unchanged for about twenty-five years. For the cap-plate, in lieu of the yellow eagle and crossed cannon, he proposed "to have the eagle surmounting the wreath encircling the castle, as prescribed for the Corps of Engineers, being the distinctive characteristic of the Corps of which they form a part." The suggestion was approved by General Totten, October 10, 1839.

February 17, 1840, General Totten submitted to the Secretary of War his recommendations for the uniform of the Corps of Engineers specifying among other items:

Epaulettes—gold, according to rank, as described in G. O. 36 of 1839; within the crescent, a turreted castle of silver.

Belt plate—rectangular, dead gold field with a bright gold double rim, a wreath of laurel and palm enveloping a turreted castle, raised, in silver, according to design in the Engineer Office.

Colonel Totten's recommendation having been approved by the Secretary of War, was published in G. O. No. 7, A. G. O., Feb. 18, 1839, and constitutes the first published mention of the turreted castle device.

In 1841 it was used as the cap plate ornament, and in 1857 as the hat ornament, in 1872 it appeared on the shoulder-knot, but it disappeared from them in 1902 when these devices became "regulation." In 1896 it made its appearance on the saddle-cloth.

As a collar ornament the turreted castle made its first appearance in 1892 on the undress coat collar, embroidered. In 1894 this was changed to metal (silver).

The castle appeared on the buttons and the shako of engineer soldiers from 1846 to 1851, and on the forage cap plate from 1846 to 1902, when a "regulation" device was adopted.

A resemblance has been suggested to the insignia of the Corps of Engineers of the Spanish Army, founded 1711. This is not true, however. The insignia of the Spanish Engineers is not a castle but a tower, or rather a towered tower. In Spanish heraldry the tower is a favorite device, sometimes used singly, as in this case; other times in groups of two or three. In turn they may have towers superimposed on them, and thus become towered towers, double towered towers, and triple towered towers.

Prize Essay on "Citizens' Military Training Camps"

Recently the War Department set aside $100.00 to be offered as prizes for an essay contest among the enlisted men of the 2nd Corps Area. The subject of the contest to be "The Benefits to be Derived from One Month's Training at a Citizens' Military Training Camp."

Approximately 150 essays were submitted by enlisted men at the various posts, camps, forts and stations throughout New York, New Jersey and Delaware. A Board of Officers, which was appointed at the Headquarters, 2nd Corps Area, on Governors Island, to determine the winners, had considerable difficulty in arriving at a unanimous decision on the essays submitted.

Master Sergt. Joseph M. Woods, of Cornell University, who is working under the direction of the Professor of Military Science and Tactics at that College, was adjudged winner of the first prize, and received $50.00. Other prize winners within various stations were as follows: 2nd prize, $25.00, First Sergt. Allen G. Spitz, 2nd Co. C. A. C., Fort Dupont, Delaware; 3rd prize, $15.00, Master Sergt. Michael Tansey, Governors Island, N. Y.; 4th prize, $5.00, Staff Sergt. Richard Bennett, Station Hospital, Fort Totten, New York; 5th prize, $5.00, Sergt. Arthur Carlton, Station Hospital, Fort Totten, New York.

The camp for the 2nd Corps Area, which was the subject of the essay, will open at Plattsburg on August 7th, and will continue for 30 days. It is open to young men from 16 to 35 years of age, and the government will pay all the expenses incurred, car fare, uniform, food and all expenses that are necessary for the students. Young men who are selected for the camp will be on a cadet basis, and afternoons during the month will be devoted to sports under competent physical directors and coaches. A number of dances and excursions are being arranged by the citizens of Plattsburg.

The prize-winning essays read as follows:

Dear Jimmie:

They're goin' ter hev a camp ter train civilians in this summer an' frum all I hear 'em tellin' yer kin bet she'll be a hummer. Durn funny why a thing like thet wuz never done afore. You bet yer bottom dollar thet I'm goin' ter be thar, shore. The camp whar I'm goin' is the one they call the RED, whar yer git the first installment uv this nowlege in yer head. It ain't called thet in honor uv no Bolshiviki rag, but frum the bright red stripes yer see on our ol' starry flag. Bob sed

Digitized by Google

he wisht he had a chance ter git a better trainin' afore they took him over whar the shot an' shell wuz rainin'.

The last war I wuz most too young ter git inter a battle. Pap kep me home upon the farm a milkin' uv the cattle, but brother Bob went over thar an' fit with all his might. I like ter set around an' hear him tellin' uv the fight.

I reckin thet frum what he sez there's many a pore feller what lost his life through ignorance an' not because he's yeller. I figgered out thet I would git sech nowledge as I could, an' ef I'm ever in a pinch she'll do me lots uv good. Not only maybe save my life frum bullet or exposure, but lives uv others who hev never heard uv the disclosure uv all the different ways an' means a soldier gains his end ef he gits inter a fix where on him other lives depend.

A soldier's life in times uv war is not a bed uv roses, ez stories of the latest one to every one discloses. So ef a bunch of fellers hev some nowledge uv their job, they're right smart mor effective than a nervous, scary mob.

Hoss sense will tell most any one thet ef he don't know how, he'd never build hisself a watch or even milk a cow. An' so I'm goin' ter learn an' ef the country needs my service, I'll no jest what I hev ter do an' then I won't git nervous.

Expect I'll hev a pile o' fun frum what I hear 'em say, fer 'sides the work uv drillin' they'll be lots uv games ter play. Learn more uv human nature mixin' with my feller creatures than I ever would at college with it's eddicated teachers. They'll teach me how ter live a life what's healthy, clean an' true, besides a lot uv other things a soldier hez ter do. So ef the time should ever come the country needs my backin', I'll be a man whut no's his work when rifles get ter crackin'. I'll no jest how ter guard my health when sickness is around. The other fellers would too, ef they'd not hung back an' frowned when they wuz offered sech a chance ter pick up all this learnin'. I bet they'll be durn sorry when the fever gits ter burnin'.

Now, Jimmie, make yer mind up same ez me an' go thar too. We'll show folks how we're backin' up the ol' Red, White an' Blue.

Yer friend,

HIRAM.

Origin of the "Sam Browne" Belt

[Reprinted from *U. S. Army Recruiting News*]

The recent authorization of the Sam Browne belt as a part of an officer's equipment has doubtless raised in a great many minds the question of where and by whom the Sam Browne belt originated.

The original Sam Browne was Gen. Sir Samuel Joseph Browne, K. C. B., K. C. S. I., a most gallant English officer and gentleman, and one of the best known English officers who took part in the early Indian campaigns and the Indian Mutiny. He first saw service with the English army in India in the Punjab campaign in 1848-1849, and also served in India throughout the great Indian Mutiny and Sepoy Wars, during which he was twice severely wounded, and lost an arm at the battle of Seeporah, which nearly cost him his life.

It was the loss of his arm which caused him to devise a new sort of saber belt, which was later generally adopted by the British Army, and also by numerous other military forces. This is the belt, which, with some modifications, is to-day known as the Sam Browne belt.

Lord Roberts, English field marshal, and advocate of preparedness in England who was a close friend of the dashing cavalry officer, gives in his "Forty-one Years in India," the following account of the dead hero who during and since the late war has received so much publicity.

"This popular and gallant officer, well known to every native in Upper India as 'Sam Brun Sahib,' and to the officers of the whole of His Majesty's Army as the inventor of the swordbelt universally adopted on service, distinguished himself greatly in the autumn of 1858. With 230 sabers of his own regiment and 350 native infantry he attacked a party of rebels who had taken up a position at Nuria, a village at the edge of the Tari, about ten miles from Tilibhit. Browne managed to get to the rear of the enemy without being discovered.

"A fierce hand-to-hand fight then ensued, in which he got two severe wounds, one on the knee, from which he nearly bled to death, the other on the left shoulder, cutting right through and severing the arm. The enemy were completely routed, and fled, leaving four guns and 300 dead on the ground. Browne was deservedly rewarded with the Victoria Cross."

Sam Browne died at The Wood, Ryde, Isle of Wight, March 14, 1901. A memorial tablet has been erected for him in St. Paul's Cathedral in London.

A Visit to the A. F. in G.

By

H. A. Finch

Major, Corps of Engineers

ONE of the few pleasant though minor by-products of the World War is the opportunity now open of visiting the American army colony on the Rhine. Callers on our flourishing army posts in and around Coblenz can not fail to be impressed by the delightful surroundings in which our forces are serving in this beautiful and interesting part of the world. There are also some who upon dropping in on our garrisons in Germany are forcibly reminded of the contrast between the service on the Rhine and that rendered by a similar outpost of our army established in 1911 in the days of Yuan Shih Kai's coup d'etat in Tientsin, China, and still "sitting on the lid" in that far country. Those who have visited both stations reflect that on the one hand we saw a flat, treeless and melancholy land, inhabited by a Mongolian race with whom, for all their virtues, we can have no genuine intercourse as man to man and can therefore never fully understand. On the other hand in the Rhine Valley we are transported to a land of legends, legends with which we are familiar and many of which we have inherited. We see a beautiful country, well-ordered, highly cultivated and delightful to look upon, and diversified by hills with vineyard-covered slopes, by fields in all tones of green and brown and by entrancing stretches of forest, river and mountain scenery.

One does not need to hold a brief for the Germans to reflect to oneself that surely a people capable of maintaining such a civilization can not be altogether untrustworthy and useless as world citizens.

For the lucky army officer who secures a furlough to visit the Coblenz colony the pleasant impressions begin as the monthly transport clears from Hoboken. On board the tight little steamer he and his family will find fifty or more officers, some, like him, on leave with their families, others bound for duty as *attaches* in European capitals or detailed abroad for some months to study foreign languages or perhaps slated for service with the troops in Coblenz. The days slip by very pleasantly. There will inevitably be friends aboard whom one has not seen for years; there will also be the customary quota of army children of assorted sizes, a flapper or two, and always, *always*, a young male mandolin player. Why this last should be is a mystery unless it is so ruled that every ointment must have its fly! Since the mandolin player has broken into this discussion, and that is one of the very best things he does, it might perhaps be worth while to digress for a moment to put down, free of charge, a prescription by which travelers in the future may rid themselves of this perennial pest. This step is taken in the interest of public morals, for though charity is a virtue, bad music is an incentive to crime. A chapter out of the experiences of Captain J. will serve to point the moral even if it doesn't adorn this tale: Late one evening the Captain was retiring as the mandolin mosquito was twanging away just outside the defenceless officer's stateroom. Captain J. does not testify as to his thoughts at that moment, but perhaps he was agreeing with Joseph Conrad that there is a dreadful fascination about systematic noise. At all events as he was resignedly climbing into his upper bunk the boat gave a providential lurch and he stepped downward and backward toward the floor. His foot came down squarely on top of the little covered enamel-ware vessel doing duty in that particular room. It set up an awful clatter—and the mandolin player stopped short. He seemed to realize that Captain J.'s brand of music was of far higher class and more soothing to the ear than anything he could hope to coax out of his benighted box, so he "quit cold!"

After twelve or thirteen days of bridge, books and conversation the south tip of England is sighted and shortly afterward the boat slips along the white cliffs near Dover; then comes the anchorage at Flushing, Holland, to await the favorable tide up the Scheldt to Antwerp. At Flushing no one is allowed to go ashore, but one is treated to a near view of an immaculate Dutch city with houses of stone, roofs of tile and slate and with gleaming window panes. A hundred or so burghers gather on the pier to gaze at the U. S. boat across the narrow stretch of water separating us from the shore but no one comes out to barter either lace or liquor for our money. This fact leads one thirsty soul to remark that "if those fellows were Americans things would be a whole lot different," and he goes on to explain that if an American city were situated as the port of call for ships from a dry country the anchor would not have time to take hold before the vessel would be surrounded by boats lined with rows of men carrying bottles equipped with 15-foot straws so that the passengers could drink without descending from the deck! It is said that prohibition took the breath away from some of our best citizens; with others it seems to have made no great difference.

Upon arriving in Antwerp one has a day for exploring that interesting old city before taking the night train for Coblenz. During the month just past (June) the interest of the new arrivals seemed to be about equally divided between the Rubens pictures in the cathedral and the wonderful strawberries, each as large as a fair sized peach, and packed in baskets in which the bottom layers (unlike the familiar American practice) are found to contain berries even finer and larger than the "facers" on top! The tourist soon learns to stop every fifteen minutes to offer thanks to Providence that the rate of exchange is in his favor, but at that the cost of living is not so low. The French and Belgian francs (now about 8 cents) have fallen to about two-fifths of their prewar values, but prices in francs have been raised to 50 per cent and more above their 1914 level. A double room with bath at a hotel, not of the first rank, now costs at least 45 francs per day in Brussels. This is a prewar figure equivalent to about $9.00 but now amounting to only $3.60. In 1913 such a room could doubtless have been had for about F4.50 per day, perhaps a bit less. Dinners, without wine, for two

Digitized by Google

will amount to 40 to 50 francs, now equal to $3.20 to $4.00, including such items as 8 francs (a prewar equivalent of $1.55) for one portion of sole, 6 francs for a portion of macaroni and 3 francs for soups.

Modest travellers content to occupy a room without bath would probably have difficulty getting along on less than 12 to 15 dollars per day per person, including travel and living expenses only.

On reaching the territory occupied by the American troops the army tourists' financial spirits begin to rise, for the mark, once rated at about 24 cents, can now be bought at 65 to 75 for the dollar. Prices in marks have also been raised enormously but the heavy depreciation in German money makes the difference in favor of the American traveller much greater than in Belgium or France. A good double room without private bath can be had in Coblenz for 40 to 60 marks per day (68c to 90c) thanks to the army billeting rates in force. Very wholesome, well-cooked meals, also without wine, are served for 50 marks per person, the equivalent of about 75 cents. All transactions are conducted in marks, and the tourist handing over 20 or 25 five-mark notes for a meal is inclined to think the German money is about on a par with that of the Confederate States. O. Henry wrote, by the way, that the Confederacy maintained the only sensible and comprehensible system of coinage that had come to his notice—one in which prices were stated in terms of money measure instead of some arbitrary value assigned to the bank notes by the authorities. He points out the simplicity of such a system where a pair of hundred dollar bills bought a pair of shoes, a hat full of bank notes purchased a hat and a barrel of money was exchanged for a barrel of flour!

The American army garrison in and around Coblenz numbers some 420 officers and about 13,000 enlisted men. So far as a dozen conversations with the rank and file can develop an outstanding idea among these soldiers, the force may be said to be intensely proud of their little army and anxious to remain on the Rhine for the year or two remaining of their three-year enlistments. Soldiers, as Kipling says, don't grow into plaster saints, but the American visiting Coblenz will have no cause to feel anything but pride in the military representatives of his country stationed there. The men throughout are well set up and smart looking; they are busy with their maneuvers and school duties and their conduct appears to be excellent. The American soldier is apparently considered by the Germans as a good enough fellow if he isn't imposed upon, and the American doughboy in turn seems to feel that so long as the Germans work and behave themselves they should be entitled to a "show." Observers seem to agree that after a round two years of discontent and unrest the Germans are now hard at work and will come back strong industrially.

Map Reading: Discussion

Hugh A. Drum
Colonel, Infantry
Commandant, General Service Schools

The article of Major Adams in the July-August issue is very much to the point. Our officers are not sufficiently trained in map reading. However, we are learning rapidly, and the various army schools, from the lowest to the highest, either teach map reading or require a knowledge of map reading.

At the General Service Schools the members of the School of the Line have a course in map reading which takes up considerable time in an already crowded course of study. This map-reading course is really intended only as a review subject, but much is taught to the officers, and these are many, who have an incomplete knowledge of the subject. The course comprises a study of slopes, contours, differences in scales, magnetic declinations, topographical signs, etc. The officers are required to apply a knowledge of the above to designation of proper location for artillery, selection of roads for night marching, consideration of visibility from hill tops and from balloons. Each day a number of practical questions are asked, and selection is required of most suitable places for command posts, military crests, aid stations, etc. Beginning next year, a short time will be devoted to reading or aeroplane photographs, with a view to showing how details can be obtained from these photographs to fill in between control points and how it is even possible within certain limits to obtain an approximate idea of certain sections without any control whatever.

The course in sketching, which includes three tactical rides and three terrain exercises, is an application of map reading and requires further study of ground forms and the reading of maps. The best way to learn to read a map is to make one. This is exactly what is done in the course in sketching. The officers are required to make maps showing the essential military features of the terrain. As a result they are better able to pick out on a map the topographical features which will have especial bearing on the military situation. The results have been unusually satisfactory.

At these schools, although some officers are taught much about map reading, it is only just to say that most of the officers are fairly well taught before they come here. In the American Expeditionary Forces there were many reports of errors due to failure to properly read the map, but luckily none of these errors were of vital importance. The most remarkable case of which I have heard was the assertion of a field officer, a regular, who claimed that the Germans had changed the location of a forest in order to confuse us in reading our maps.

The reading of aerial photographs has not, however, received the attention it deserves, and special time is devoted to it. It is realized that proper control is necessary for accurate mapping, and that aerial photographs are best used for filling in the unmapped spaces or for bringing up to date the maps already available, but valuable results can be obtained from aerial photographs of unmapped areas. The field for study is very great, and it is regretted that more time cannot be devoted to it than is available here. It takes an expert to determine the hill forms even approximately; but every officer should be able to read aerial photographs sufficiently well to determine the general character of the country, the woods, cultivated fields, roads, etc., and the relative distances. It is impressed upon them that, if central points are available, it is possible for experts to produce valuable maps.

In future wars we can hardly expect to obtain the excellent maps we had in France. Therefore, we shall have to get along with much poorer maps. This means that we shall have to know ground forms, estimate the contours from the general character of the country, and make our plans from insufficient data. As in the Philippines, where the maps are poor, we shall look for and expect on the ground to find roads and trails in accordance with our knowledge of the country and of the inhabitants. Aerial photographs will help very greatly in finding these roads and trails; but in spite of every effort on our part, the fog of war will be greatly increased in these future wars, owing to poor maps or none at all, and we must learn to make every possible use of the available maps. For such work we must have a better knowledge than we now have of map reading; we must be prepared to do more work with less data.

The Development of Heavy Ponton Equipage for Increased Army Loads of the Future

By

Theodore Wyman, Jr.

Captain, Corps of Engineers

Requirements for Future Ponton Bridges

THE adoption for the mobile army of recently developed heavy mobile cannon, self-propelled or tractor drawn, heavy tanks and heavy truck transportation, has necessitated the development of heavy ponton bridge equipage, of greater capacity than the present standard equipage. Heavy ponton bridge equipage of construction along the lines of the standard equipage, of minimum weight, and adapted to being transported readily on vehicles subject to being animal drawn, truck drawn or tractor drawn, must carry safely the heaviest loads which accompany the Corps, namely, the loaded 5½-ton Mack truck, which, when loaded to capacity, has a maximum concentrated axle load of 13,500 pounds on the rear axle and 7,800 pounds on the front axle, the distance between axles, center to center, being 13 feet 4 inches. There must also be developed a reinforced type of ponton bridge, using the new equipage, supplemented by special materials deemed necessary to carry safely the loads which accompany the army, which recent developments of Ordnance materials indicate may include the new Christie Self-propelled Mount for a 6-inch Gun, weighing 19 tons, and the Christie Medium Tank, weighing 18 tons. Extensive studies of all available records showed that the allowable weights for a ponton equipage, readily transportable, would limit the capacity of the ponton boat to a supporting power of 20,000 pounds, with a 9-inch freeboard, and the length of the normal bay to 16 feet, which would require a super-structure consisting of seven or eight balk of weights readily handled by two men, rigidly connected to two side rails by transverse balk and balk collars, and a double thickness of 2-inch chess.

Ponton Boats

Three types of experimental boats, namely, wooden, steel and aluminum boats were designed, manufactured and tested.

The wooden ponton boat was of the scow type, similar to the present standard boat. Its dimensions were: length 32 feet, beam 5 feet 8 inches, depth 3 feet 1 inch, and it weighed 2,225 pounds. It was constructed entirely of wood with an oak frame and ⅞-inch white pine skin.

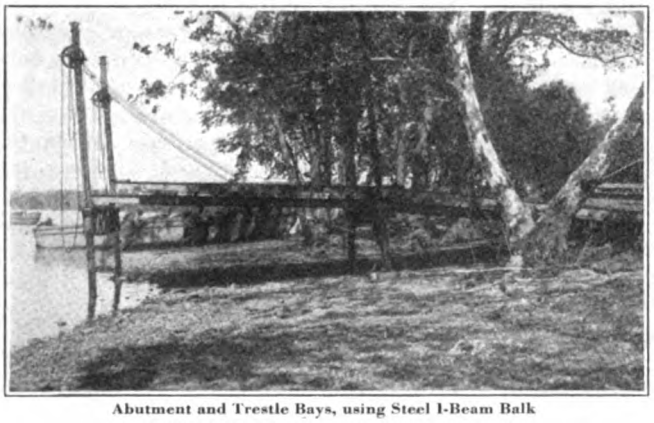
The steel ponton boat was of the boat type of galvanized steel construction throughout and its dimensions were: length 31 feet 6 inches, beam 5 feet 8 inches, depth 3 feet 1 inch, and it weighed 1,765 pounds. It was constructed of galvanized sheet steel, riveted to an angle iron frame and channel iron gunwales and was divided into four watertight compartments by transverse bulkheads, which materially strengthened the boat and increased its flotation, as it was necessary to pierce at least two compartments in order to sink the ponton when in its position in a ponton bridge.

The aluminum ponton boat was of the boat type and was constructed of aluminum skin mounted on an oak frame, of sufficient flotation to prevent the ponton from sinking when filled with water. Its length was 31 feet 6 inches, beam 5 feet 8 inches, depth 3 feet 1 inch, and it weighed 1,635 pounds. This boat was also provided with four separate watertight compartments by means of transverse bulkheads, in order to increase its strength and its carrying capacity when one or two of the compartments were punctured by gun fire or otherwise.

These boats had sufficient displacement to carry superimposed loads as follows and allow for a 9-inch freeboard:

Wooden boat	20,000 pounds
Steel boat	22,000 pounds
Aluminum boat	23,000 pounds

Tests of Boats

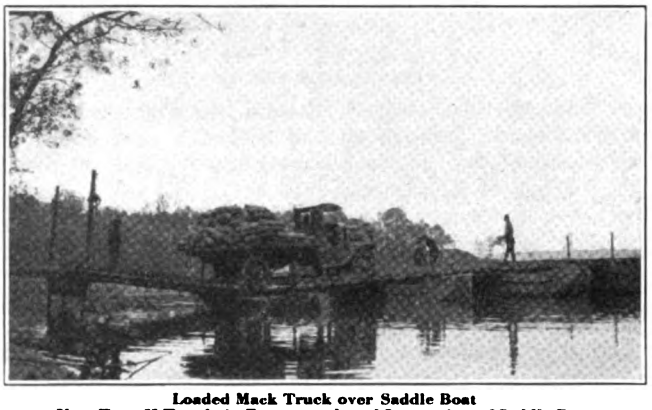


During tests conducted at Camp A. A. Humphreys, Va., those boats functioned equally satisfactorily in a ponton bridge constructed in water, and carried successfully axle loads ranging up to and including 17,900 pounds. The Mack truck and the 10-ton Holt tractor were passed over the bridge without incident, and later the Mack truck and 10-ton Holt tractor were passed over the bridge together, spaced so that the centers of the loads were located over adjacent ponton boats. A Mack truck was loaded until its gross weight was 27,280 pounds, divided approximately with 9,380 pounds on the front axle, and 17,900 pounds on the rear axle, and then passed over the bridge. Under this load the saddle boat was immersed until it had only 4 inches freeboard, while under the same load the second boat in the bridge from the shore had 9 inches freeboard. This indicated that the capacity of the saddle boat determined the maximum load which could be passed over the bridge. This was due to the fact that the span between the trestle and saddle boat was longer than the normal span and also because only a small part of the load was transmitted to the adjacent pontons.

A ponton bridge of five bays was built on land with the pontons resting on a bed of river gravel simulating the bottom of a stream. All of the experimental ponton equipage carried axle loads up to and including 17,000 pounds without incident. Under a 30,000-pound axle load both the aluminum boat and the steel boat commenced to fail by buckling of the gunwales. Under a 40,000-pound axle-load the gunwales of the metal ponton boats were so badly

Digitized by Google

crushed that they had to be removed. Both metal boats failed to the extent to make their repair difficult. An axle load of 46,000 pounds was successfully carried by the wooden boat without showing any signs of failure. These tests showed conclusively that the wooden boat was superior in a grounded bridge. In view of the wide tidal fluctuations of the coastal streams of this country, it is believed essential for ponton boats to carry successfully the increased army axle loads when the boats are grounded on the bottom of a river.



All three types of boats were readily loaded and unloaded and none presented any difficulties when handled by a detail of eighteen to twenty men. The differences in the weights of the boats made no material differences in the tractor drawn and motor drawn transportation tests. In a horse drawn test all were easily hauled. All boats were easily handled in the water, and the higher freeboard presented no real difficulties in rowing. A load of sixty soldiers with heavy marching packs were readily transported by each type of boat. Under rifle fire at a range of 125 yards five shots were sufficient to put the steel boat in danger of sinking. In each case the bullet made a clean entrance hole through the near side and from two to six ragged holes through the far side. Eleven shots were sufficient to flood the aluminum boat. In each case the

Abutment and Trestle Bays, using Steel I-Beam Balk

holes through the aluminum skin, in and out, were clean and no bullet caused more than two holes. One hundred and twenty-five rounds were fired at the wooden boat without stopping to doing any patching. Holes were generally clean and the water entered very slowly. The results of the rifle tests were decisively in favor of the wooden boat. However, it must be remembered that the range was only 125 yards and that at a greater range difficulties might be encountered in penetrating sufficient compartments below the waterline of the steel and aluminum boats to flood same with water. Furthermore a ponton bridge constructed of boats subject to being readily sunk might prove extremely advantageous during a retreat when, due to lack of time to remove same, the destruction of a ponton bridge might be highly desirable. A few hand grenades properly applied to the steel ponton boat could easily accomplish this result. The bullet holes in both metal boats were readily plugged before the boats were filled with water, by a rubber gasket patch which consisted of a rubber washer on a wide headed bolt provided with a wing nut. Several other types of patches were tested but did not prove adaptable to patching ragged holes in the skins of the boats.

All of the boats were equipped with four skids which proved a decided improvement and aided materially when moving boats on land and handling same in the water. All boats were equipped with a windlass located in both the bow and stern, similar to that used in the German pontons, but under tests this equipment did not present

Loaded Mack Truck over Saddle Boat
Note Type II Trestle in Foreground, and Immersion of Saddle Boat

any great advantages over the mooring post now in use.

The principle argument in favor of the metal boats is their resistance to time and the elements while in storage in a hot arid climate and their immediate availability for service at all times after construction. So far as availability of materials for construction and rapidity of construction is concerned, our experience in the manufacturing of boats indicated that the steel boat should rank first, the wooden boat second and the aluminum boat third. In general the performances of the aluminum boat under tests were superior to those of the steel boat, and the officers conducting the tests recommended to the Chief of Engineers that sufficient aluminum boats for an experimental ponton division be procured and subjected to field tests over a long period of time.

Balk

Due to results of tests conducted by the Bureau of Standards and the Forest Products Laboratories, of lumbers which may be secured in large quantities, Douglas fir was selected as the material most suitable for balk construction.

Tests of balk constructed of Douglas fir, reinforced by steel plates and ½-inch twisted steel rods, indicated the impracticability of reinforcing wooden balk with metal. Studies indicated the impracticability of using steel I-beams for balk due to excessive weights.

The following table shows the types of balk constructed,

10-ton Holt Tractor and Loaded Mack Truck on Bridge

dimensions and weights of same, and the loads carried by bays constructed of same. In each case seven balk plus two side rails were used per bay.

Digitized by Google

Type	*Size*	*Weight*	*Type of Bay*	*Load under which bay failed*
1 Piece wooden balk of Douglas fir, rectangular cross section.	4¼ inches by 6⅜ inches by 23 feet	166 pounds	Boat to boat span 16 ft. Transverse balk used.	This bay carried an axle load of 46,000 pounds without failure.
Do	Do	Do	Boat to boat span, no transverse balk.	Failed under an axle load of 44,500 pounds.
Do	Do	Do	Boat to trestle span 18 ft, 10 inches. Transverse balk used.	Bay failed under an axle load of 36,000 pounds.
2 Piece wooden balk. Two pieces of Douglas fir bolted together. Rectangular cross section.	4½ inches by 6⅜ inches by 23 feet	155 pounds	Boat to boat span, 16 ft., transverse balk used.	Bay failed under an axle load of 42,000 pounds.
1 Piece wooden balk of Douglas fir, I-beam cross section.	4¾ inches by 6¾ inches by 23 feet	146 pounds	Boat to boat span, 16 ft., no transverse balk.	Bay failed under an axle load of 40,000 pounds.
Do	Do	Do	Trestle to trestle span, 20 ft., transverse balk used.	Bay failed under an axle load of 19,000 pounds.
Steel I-beam balk.	5 inches, 9¾ lbs., 15½ feet long.	155 pounds	Trestle to trestle span, 13½ feet, no transverse balk.	Bay failed violently under an axle load of 40,000 pounds.

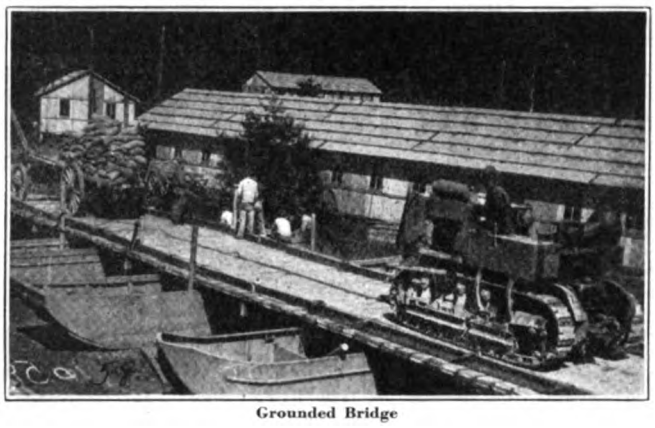
From the foregoing figures it is obvious that the one-piece balk, constructed of Douglas fir of rectangular cross section, 4¼ inches by 6⅜ inches, is the strongest type of balk. However, all bays made up of the various types of balk carried successfully a loaded 5½-ton Mack truck, a 10-ton Holt tractor, and axle loads up to and including 17,000 pounds without incident or excessive deflection. The figures also indicate clearly the advantages obtained from the use of the transverse balk for partially transmitting the load to the side rails. The transverse balk was constructed of Douglas fir 4¼ inches by 6⅜ inches by 12 feet, and was equipped with spacing cleats which engaged the longitudinal balk. It was rigidly connected to the side rails by means of balk collars constructed of steel. These collars consisted of two pairs of lazy tongs which opened to receive the transverse balk and supported it when closed, and which were flexibly connected to a saddle provided with a jack-screw that rested upon and across the side rail balk. The balk collars tested were equipped with a cam to open and close the tongs. This refinement proved unnecessary and it is believed that a simplified design will provide a strong and flexible means of lashing the side rails, chess, longitudinal and transverse balk firmly together. The balk collars may be quickly installed from the bridge floor.

All of the balk tested were equipped with steel pins which engaged in balk-pin sockets on the pontons, thereby providing a positive though flexible connection between balk and boats and also eliminating the temporary lashing now made when laying balk in place. The retention of the balk pin is favored. It did not present any difficulties when stacking the balk in piles or transporting same on wagons. In addition to the balk pin connection, the balk were lashed to the boats by means of the standard ½-inch lashing, to prevent movement in the vertical plane only. Numerous studies were made of designs for mechanical lashings which in most cases were a mechanical contrivance located on the balk, thereby precluding an adjustable length of bay. The aluminum boats were equipped with a mechanical lashing consisting of a strap constructed of brake-lining material, one end directly connected to the gunwales and the other end adjustably connected by means of a ratchet device and adaptable to lashing the balk to the boat at any point along its length. However, under test they proved cumbersome and unreliable and presented no advantages over the rope lashing now in use.

The boats were provided with lashing hooks. However, it is believed that a waling piece fastened to the inner sides of the ribs of the boat, about 6 feet below the gunwales, would provide a more suitable means for lashing balk at any location throughout the width of the roadway.

In order to make all ponton boats identical as to the layout and location of the balk pin sockets, it is necessary to lay the balk with a slight slant, or at an angle whose offset from the center line of the bridge equals the width of the balk. It would be impossible to lay the balk parallel to the center line of the bridge unless three alternate balk pin sockets are provided for each balk location. Another advantage gained by the angular method of laying the balk applies to the side rails of the bridge. When the side rails are laid in this manner, the inside roadway end of the balk pointing towards the far shore on the right-hand side, no projecting balk ends are in a position to be struck by, or to interfere with, traffic which bears to the right in the usual manner.

Chess



The chess were constructed of white pine on account of its lightness, 1 11/16 inches thick by 12 inches wide by 12 feet long. Twenty-three inches at each end was reduced to a width of 10½ inches and reinforcing rivets of ¼-inch steel were riveted through the chess 1½ inches and 21½ inches from each end to prevent the chess from splitting. Its weight was 43 pounds. A double thickness of chess was used on the bridge tested and proved to be the weakest element. The white pine was badly crushed under the wheels of the heavy loads and in many cases the loads cut through the double layer of chess when the wheels were not located directly over a balk. These tests indicated that white pine is no longer adaptable for the construction of chess intended to carry the increased loads, and studies of the possibilities of longleaf Georgia yellow pine, maple and oak, for use as chess, are being made. The width of the roadway of the bridge tested was 9 feet 6 inches, but later developments proved the necessity for a bridge with a 10-foot 6-inch clear roadway. This increase will undoubtedly require eight balk per bay in order to decrease the chess span between balk to a minimum.

Trestles

Two types of trestles were designed, manufactured and tested. Type No. 1 trestle was constructed entirely of structural steel and Shelby cold-drawn tubing. It consisted of two threaded steel columns that adjustably supported, by means of capstan nuts, housing and clamp members, a 9-inch 21-pound I-beam transom together with its rein-

Digitized by Google

forcing members. The entire transom unit could be raised, lowered and clamped in place from the roadway of the bridge by two men. The trestle consisted of seven separable units: the transom, two struts, two columns and two trestle shoes, and weighed complete 1,090 pounds. In

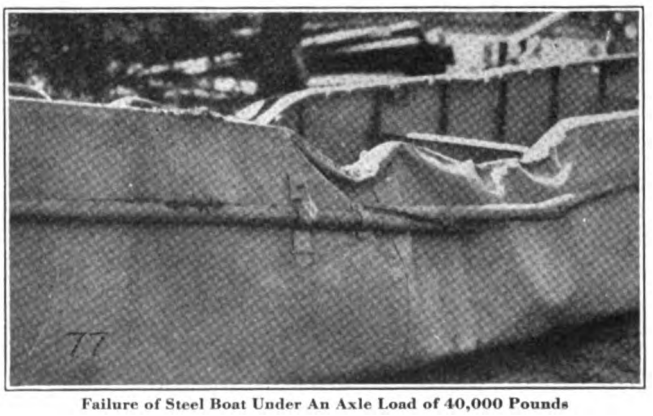
Grounded Bridge

order to strengthen the transom, its unsupported span of 12 feet was reduced to 8 feet by the use of two struts of 3-inch 5½-pound I-beams, 2 feet 8 inches long, used as diagonal braces. When the transom and its struts were placed in their respective housings and the suspension members and cross guide rods were tightened to their home positions, the entire assembly became a complete bridge panel, adapted to be supported by its two side columns and trestle shoes. The trestle shoes had approximately 4 square feet of area and were constructed of wood, reinforced with angle iron around the bottom edge and across the bottom face, and equipped with steel teeth projecting downward to prevent side slipping. The connections between the shoes and the columns allowed the shoes to accommodate their positions to inequalities of the foundations without disturbing the vertical position of the side columns.

Type No. 2 trestle consisted of a lattice angle iron transom slidingly adjustable along its two end supporting steel columns by means of chain hoist supported by the upper end of the side columns. The transom was supported in place by pins that passed through the end plates of the transom and corresponding holes in the column. The trestle consisted of seven separable parts, transom, two columns, two chain hoists, and two trestle shoes, and weighs approximaetly 1,300 pounds. The transom was of 12-foot 6-inch span, 18 inches deep and 9 inches wide. It was built up of two lattice transoms, 2 inches by 18 inches by 12 feet 6 inches, set back to back, the ends of the transoms being riveted to the transom column housing and the intermediate portions of the separate transom members connected together by splice plates. The shoes consisted of flat steel plates reinforced with angle iron around the lower edges and provided with teeth at the corners to prevent side slipping. Their construction was such that the shoes could rest firmly on their foundations, and at the same time allow the side columns to stand in vertical positions.

Both types of trestles functioned equally satisfactorily under tests and successfully carried axle loads up to and including 46,000 pounds without excessive deflection or incident. The second type described is favored because of its simplicity and relative ease of assembly. It is well to note here that a standard wooden trestle was used in the ponton bridge constructed on land until it failed under an axle load of 13,500 pounds. The wooden shoe failed by splitting, allowing the unsupported leg to enter the ground a distance of 16 inches, which in turn allowed the wooden cap to strike the ground with such force that the cap and three balk were completely fractured. This incident showed the relative weakness of the standard wooden trestle.

Saddle Boat Support



The tests indicated that the weakest bays are those adjacent to the saddle boat and the trestles. An effort was made to eliminate the standard saddle and to adapt the long balk for use in the bays adjacent to the saddle boat. The saddle boat was equipped with seven saddle transoms designed to secure a long firm bearing over the center of the supporting boat, independent of any rise or fall in the water level resulting from rain or tides. Each saddle consisted of two wooden rockers constructed of oak, lying side by side and free to move independent of one another. The rockers supported their respective balk across the entire width of the ponton boat, the balk being held in position by balk pins that engaged in balk pin sockets in their respective rockers. The rockers were housed in a steel cradle that extended across the gunwales of the ponton boat. Under tests those saddle transoms did not function as expected due to the fact that the saddle boat turned on its side in the water before the wooden rockers adjusted themselves to the gradient of the roadway. In view of the fact that the tests showed that an axle load which could not develop the full capacity of adjacent boats would immerse the saddle boat to a 4-inch freeboard, it appears advisable to construct the saddle support of two boats fastened together by lashings, with transom members lashed to the gunwales of both boats supporting a sill of the standard type now in use to carry the super-structure. It would also be advisable to reduce the length of the spans adjacent to the saddle boat.

Miscellaneous Equipment

An abutment sill similar to the standard type and equipped with balk pin sockets to engage the trestle balk, 14-foot hickory oars reinforced with a special aluminum tip to prevent splitting, rowlocks adaptable to the higher freeboard of the pontons, and pickets constructed of standard galvanized wrought iron pipe, were tested and found suitable for use with the new ponton equipage.

Transportation

Studies of the requirements of modern armies in the

Failure of Steel Boat Under An Axle Load of 40,000 Pounds

field showed the desirabilty of having ponton vehicles subject to being animal drawn, truck drawn or tractor drawn.

The following extract from the historical record of the

Digitized by Google

464th Engineer Ponton Train indicates clearly the necessity for having our ponton vehicles constructed along automobile lines and capable of being truck drawn:

"On October 29th we received an order to prepare to move overland to Bethelainville. Twenty trucks were provided to complete the movement overland of 67 vehicles, movement to be completed in one haul.

"As this was a physical impossibility we decided to comply with the order to the best of our ability. On October 30th, 19 motor trucks arrived and departed at 9:30 a. m. with 38 vehicles, each truck towing two vehicles. We were obliged to borrow one hundred horses to bring this equipment from the Island to the main road, this work being done during the night of October 29th under a bombing attack aimed at the adjacent Steel plant. At 10:00 p. m., October 31st, this convoy completed the movement to Bethelainville and at 4:00 a. m., November 1st, the equipment was hidden in the forest.

"It would be well to note that we had advised very strongly against towing the ponton equipment behind motor trucks, and this trip reduced the efficiency of the equipage about fifty per cent. All tongues were broken, braces twisted, bolts sheared and in some instances entire wagons overturned.

"On October 31st, 1918, about 4:00 p. m., fifteen French motor trucks arrived for the purpose of convoying the balance of the equipment to Bethelainville. Seventy-five horses were again borrowed from the Ammunition Train of the 92nd Division and by working all night the twenty-nine wagons were hauled up onto the main road and hooked in pairs ready for the trucks. At 5:30 a. m., November 1st, all supplies, rations and office and equipment were loaded on the trucks at Pompey. The train then proceeded to Harbach where the wagons were lashed on and convoy started off at 8 a. m. The last truck reached Pierfeitte at 9 p. m. the same date, some motor trouble was experienced but the greatest trouble was due to broken tongues and wheels on the ponton wagons as these wagons were never made for this method of transportation.

"At 4:30 a. m., November 3d, four trucks (attached from 23rd Engineers) were started out with billeting detail, kitchen detail, all supplies and office equipment. At 5 a. m. Captain Goodwin left with seventeen boat wagons drawn by four horses each, thus using all horses fit to work. It was found en route that four horses were not sufficient for handling the wagons over the rough and muddy roads encountered and in many cases it was necessary to put eight and ten horses on a wagon to get through some of the bad spots. At 6 a. m. eighteen of the promised trucks arrived and left with eighteen wagons. At 1 p. m. same day all horses fit to move were sent forward on a moving picket line."

A ponton wagon to transport the balk and boats, a chess wagon to transport the chess, and a trestle wagon to transport the trestle equipment, all capable of being drawn with equal facility by animals, tractor or truck, were designed, manufactured and tested. The wagons weighed approximately 2,400 pounds each and were equipped with 40-inch rubber tired wheels, suitable pintles, lunette rings and drawbars, and constructed in accordance with the general type of automobile design and practice. The wagons were reversible and capable of being turned or steered from either end when used as a single wagon or in trains of two wagons or more.

Tests of those wagons were conducted on the roads in and about Camp A. A. Humphreys, Va. A horse drawn test of ten miles was made. The loaded ponton trailers were drawn by six line mule teams and the loaded chess and trestle trailers by four line mule teams. On the whole the march was very satisfactory, the roller bearing wheels reduced the friction so that the team pulled the greater loads with greater ease than the standard equipage. The route included several very steep grades, both up and down, ditches and several soft spots where the wheels cut in from twelve to sixteen inches. The day was warm and the mules came in sweated but showing no lather and were apparently good for ten miles more.

Various types of trucks, including the 1½-ton Garford, 3-ton Liberty and 5-ton Mack, were used to haul from one to three trailers over various types of roads including concrete, gravel and dirt, at various speeds for distances up to and including fifteen miles. These tests indicated that the 1½-ton Garford and 3-ton Liberty trucks were on the whole more successful for this work than the 5-ton Mack and that the lighter trucks were better for the poorer roads. More than two trailers should not be drawn by trucks except under very favorable conditions when the truck may operate over a two-way road with little opposing traffic. The speed should not exceed twelve miles per hour. At higher speeds the trailers skidded away from the crown of the road towards the ditch, especially for speeds exceeding fifteen miles per hour.

The Cadillac 2½-ton tractor, the 5-ton Holt tractor and the 10-ton Holt tractor, were used to draw trains of one to five wagons. The vehicles tracked as well as could be expected. On narrow roads with a high crown, the third wagon would often slide off the road into the ditch. On turning a train made up of two ponton boat wagons and one chess wagon, drawn by a 5-ton Holt tractor on a 60-foot curve, the rear wheels of the third vehicle tracked 9 feet inside the track of the front wheel of the first wagon. Trains of two or more wagons could not be backed in any desired direction. No more than three vehicles should be hauled by a tractor on a good road and not more than one vehicle on a poor narrow road. The stability of the load was increased materially when the ponton boat was loaded on the ponton wagon bottom side up. In general the tests were severe and the wagons stood it well but many weaknesses in the design developed which indicated that the trailers tested would not stand up under service conditions for a very long period. When the vehicles were drawn by animals the brakes, which were of the automobile type, were applied over long periods of time, which caused same to overheat and wear rapidly. The rubber tires wore out too rapidly, indicating the necessity for wider treads. The requirement for reversibility introduced many intricate features in the designs, requiring a two-point suspension similar to that of the Ford automobile, which obviously is inferior to a three or four-point suspension. It also necessitated a complicated brake mechanism which quickly became unserviceable. However, a direct action brake precludes the use of rubber tires which are considered essential for a truck drawn vehicle. The springs proved to be too light. The radius rods proved to be weak and were badly bent when the ponton boat wagon was mired in a mud hole and drawn therefrom. In general, all small parts such as steering arms, brake rods, tongues, pintle hooks, chains, etc., were too lightly constructed, due to an effort made to develop a ponton wagon trailer weighing less than 2,000 pounds, and would soon become unserviceable under severe service conditions. The superstructures of the various vehicles proved satisfactory.

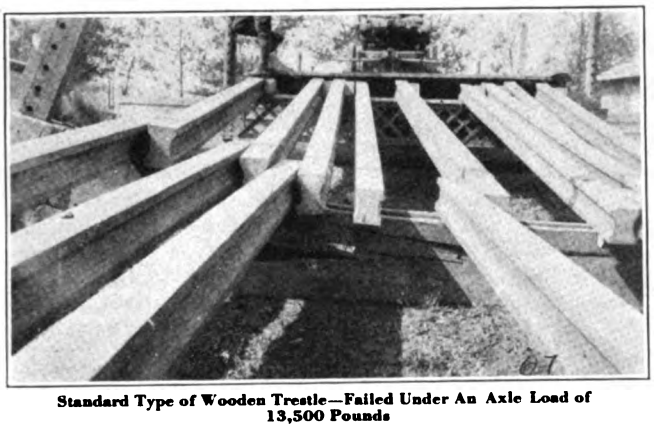
Discussion

C. P. Gross

Major, Corps of Engineers



In the main Captain Wyman has faithfully set down the results of the experimental tests of the new heavy ponton equipment recently conducted at Camp Humphreys, Va. His article does convey, however, an impression that the bridge will be based on the metal boat and that all elements of a heavy bridge train have been developed to the point where relatively simple modifications will result in standard equipment.

During the tests the chief interest naturally centered on the comparative performances of the three types of pontons. Was a metal boat to upset our traditional faith in the wooden ponton?

The wooden boat did prove its superiority. In order to emphasize its victory the following rating is submitted. Entries bracketed indicate opinion, largely; others, fact.

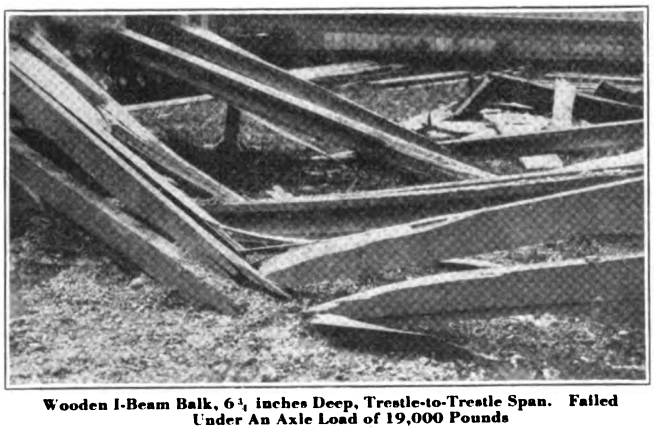
	First	*Second*	*Third*
Light Weight	Alum	Steel	Wood
Nonsinkability	Wood	Alum	Steel
Minimum attention required	(Wood)	(Alum)	(Steel)
Ease of repair	Wood	(Steel)	(Alum)
Resistance to time and elements	(Alum)	(Wood)	(Steel)
Construction approximating boat lines	Alum	Steel	Wood
Rapidity of construction	(Wood)	(Steel)	(Alum)
Availability of material for construction	(Wood)	(Steel)	(Alum)
Immediate availability for service	(Alum)	(Steel)	(Wood)
Ease of loading and unloading	Alum	Steel	Wood
Ease of transporting	Alum	Steel	Wood
Behavior under rifle fire	Wood	Alum	Steel
Ferrying capacity	Alum	Steel	Wood
Strength in bridge	Wood	Steel	Alum
Displacement capacity	Alum	Steel	Wood
Cost	Wood	Steel	Alum

As all types can be drawn by a six-line team, the differences in weights of the boats are relatively unimportant. The three pontons are so easily handled in the water that a consideration of ship lines should have no weight. All are readily loaded and unloaded. All have practically

Standard Type of Wooden Trestle—Failed Under An Axle Load of 13,500 Pounds

equal ferrying capacity. These points, therefore, are not decisive in recommending any one particular type of ponton. As far as they go they do favor the aluminum boat.

In nonsinkability, ease of repair, behavior under rifle fire, strength in the grounded bridge and in lower cost, the superiority of the wooden ponton is decisive.



A constant argument by the advocates of the metal boat is that materials for the construction of the wooden one are not readily available. A journey along the seaboard reveals such quantities of idle wooden vessels that the lumber interests prevailed on Uncle Sam to believe would win the war, that one trembles to think of the flood of pontons that would result if the idea were conceived that pontons were to win the next war. The high quality of lumber demanded in the past is not entirely essential. Necessity would satisfy itself with commoner grades. Better a few knots than leaking rivets.

The wooden boat is unsatisfactory when stored in a hot climate. The aluminum boat seems to offer relief in being at all times serviceable. Such serviceability is, however, more apparent than real. For instance, in unloading this equipment for test, two holes were stove through the bottom of the metal boat. Four hours were required for its repair by welding with results none too good. In the field such repairs are not easily made and such condition would frequently invite abandonment.

The one argument not to be disputed in favor of the aluminum boat is the fact that for the same loading it has a 2-inch higher freeboard, and as a support, therefore, has a buoyancy greater by two tons than the wooden ponton.

The wooden type is hardly an experiment. Its advantages are known through long experience. No new discoveries concerning it were made in the tests conducted. It just lived up to its traditions.

The recommendation referred to by Captain Wyman, to purchase a division of aluminum boats is not to be considered a decision in favor of the aluminum ponton. Funds available were for experimental purposes. It was thought that little more could be learned with respect to the wooden boat. It was felt that the many advocates

Wooden I-Beam Balk, 6¼ inches Deep, Trestle-to-Trestle Span. Failed Under An Axle Load of 19,000 Pounds

of metal would hardly be satisfied by tests so short in duration, and which could not, in fact, be called complete.

Digitized by Google

Additional experiments with the metal boat were, therefore, urged to give it a better chance to recommend itself as a type, or failing that to hush the clamor of its champions.

The equipment tested, with numerous minor modifications, does contain the elements of a bridge carrying the

Steel Boat—Rifle Test—Range 125 Yards. Departure of Fourth Shot Produced Four Holes

loads for which designed. All elements are not, however, properly balanced. The pontons will support greater loads. The chess, doubled, will not. No matter for what load intended, in the field the bridge will get all it can take. Chess 1 11/16 inches thick belong to the old equipment. They have no real place in the new. This thickness should be increased to 2½ or 3 inches, one wagon carrying enough for one bay (chess doubled).

The manual of bridge construction remains very much the same. Placement of the trestle requires sixteen men, however. Boat crews, balk carriers and balk lashers have no new duties. The balk, while of larger cross section, is shorter and still a two man load. The chess, even if 2½ inches thick, continues as a one man load. The side rail section has a slightly easier task. An added section of four men must be added, however, to place the transverse balk and balk collars.

While the bridge equipment proper is reaching a solution, no satisfactory transportation has yet been developed to carry it. That tested failed beyond hope of recovery by simple modification. The requirements asked were far from simple, demanding construction not even commercial. The basis of military success is utter simplicity. It would seem apparent that to require a vehicle to be horse drawn, motor drawn and reversible must necessarily produce a hybrid. Reversibility is not essential. In this country of poor highways, the railroad rather than the motor truck should be used for the longer hauls. The vehicle must be animal drawn. For controlled speeds it can be made capable of being tractor drawn. Sure mobility even though slow is far more successful in campaign than bursts of speed separated by wild scrambles for spare parts.

Reginald Whitaker

Captain, Corps of Engineers

Captain Wyman in his paper leaves little to be said by way of controversy. The actual tests made upon the experimental heavy ponton equipment were conducted by Company C, 13th Engineers, from April 3, 1921, until June 2, 1921, at the Ponton Grounds, Camp A. A. Humphreys, Va. The site was in every way favorable to the prosecution of the tests, Gunston Cove affording suitable space for the water tests and its flat open shore room for storage, parking, and the construction of land bridges. The tests in order to be as thorough as it was possible to make them within a limited space of time, included the following general points:

Transportation Tests,
Boat Tests,
Tests of the Material in the Ponton Bridge,
Tests of the Material in a Grounded Ponton Bridge.

Transportation Tests

The transportation tests lasted from April 3 until April 25. Vehicles to be tested comprised three ponton trailers, one chess trailer, and one trestle trailer, built on automobile chassis lines, all steel, and with solid rubber tires. A method for loading each type had to be worked out, a matter which caused no difficulty as the bodies of these trailers were admirably designed to carry the new equipment.

First the loaded trailers were hauled by tractor singly and in trains up a hill whose maximum slope was 13½ per cent. The Cadillac 2½-ton tractor took one loaded ponton trailer and one loaded chess trailer up the hill easily, two men riding on each vehicle to work the brakes in case of mishap. In addition to the men riding, about three squads followed the train ready with shovels and logs to prevent slipping and backing. Incidentally, in several cases when the train seemed to be about to stall, the men riding worked the brakes with such enthusiasm that the iron handles were completely broken off.

The Holt 5-ton Ordnance Tractor similarly pulled one ponton trailer, one chess trailer, and one trestle trailer up the hill. The length of this train made the rear vehicles follow but poorly in the path of the tractor.

The Holt 10-ton Ordnance Tractor hauled all five vehicles to the top of the hill quite easily, but the same difficulty was experienced of keeping the rear of the train on the road. After the hill climbing test a run of four miles was made with the tractors.

The next phase of this test consisted in repeating the hill climb with motor truck traction, the ¾-ton G.M.C., the 1½-ton Garford, the 3-ton Liberty and the 5-ton Mack trucks being used successively. One trailer, either ponton, chess, or trestle, was the most that each truck could haul up this grade.

Upon completion of the hill climb a test run of fifteen miles was made, over concrete road, gravel and dirt road, and dirt road. While on the concrete road the steel pole

10-ton Holt Tractor Going Up Ponton Hill with Five Trailers

of a ponton trailer broke and before the brakes could be applied the trailer ran off the road, smashing running gear and springs.

The next phase of the tests consisted in a ten-mile mule drawn test. Six-line teams hauled the ponton trailers and

Digitized by Google

four-line teams hauled the trestle and chess trailers without trouble.

Boat Tests

The boats were put into the water and manned with crews of five men each—four rowers and a steersman. They were loaded in accordance with the provisions of the Ponton Manual with men in heavy marching order. As we are told by that manual, the troop ferrying capacity of the boats is limited by space rather than buoyancy and by the necessity for allowing freedom of movement to the rowers. It was found that a load of sixty men could be be carried safely.

In the test of the ability of the pontons to withstand rifle fire, one of each type was moored about 125 yards off shore, and fired at with a service rifle. At this point I wish to dispute a statement made by Captain Wyman with reference to the steel ponton that each bullet made a clean entrance hole through the near side. On the contrary, bullets striking above the waterline made round holes much larger than the bullet, nearly 5/8 inch in diameter, and bullets striking at or below the waterline tore jagged, irregular holes from two to three inches across, because of the striking effect of the water itself upon the brittle steel of which the ponton is made.

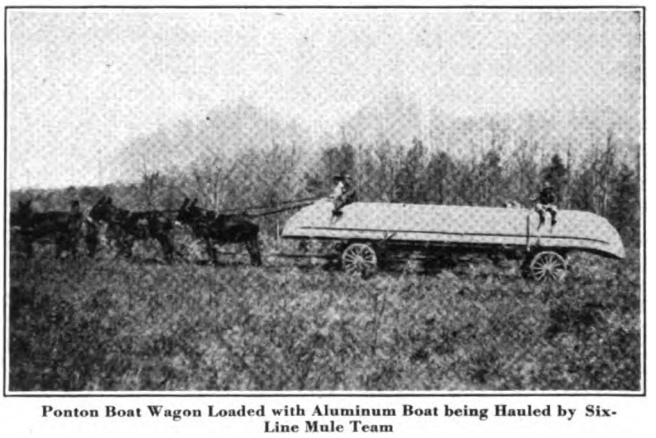
10-ton Holt Tractor Hauling Ponton Boat Wagon through Mud Hole

Tests of Material in the Ponton Bridge

A bridge of eleven bays was constructed, with the same number of men and practically the same details as are normally prescribed for the present ponton equipage. The capacity of the boats in the bridge was measured by applying both static and moving loads to it and measuring the height above water of the gunwale of every ponton. In the case of static loads sandbags of known weight were piled on a two-wheeled cart which was placed over the ponton whose immersion was to be measured, the bridge was cleared of people and gunwale heights read with tapes weighed at the ends. The same measurements were taken for moving loads, applied by auto trucks while passing over each boat.

Tests of Material in a Grounded Ponton Bridge

The purpose of this test was to determine simultaneously the supporting power of the several types of materials in the superstructure and the supporting power of the three types of boats in the bridge when grounded. A dry ponton bridge of five bays was built with no two bays similar. Each bay and therefore each type of material was tested to failure. One ponton of each type and both experimental trestles were used, every ponton resting on a prepared bed of river gravel simulating the bottom of a stream.



To determine the action of the various kinds of superstructure the actual deflection of the bridge under all loads was measured by taking six sets of level rod readings for each load and on each span. One rod was placed on the bridge floor just outside the side rail and directly over the inside gunwale of a ponton; another rod was placed on the bridge floor just outside the siderail in the exact center of the span and a third was placed to correspond with the first but at the other end of the span. After readings were taken with a level on the rods in these positions they were placed in corresponding positions over the reinforced balk, *i. e.*, at the tread line of the bridge, and level readings again taken. These readings gave the difference in elevation between the center and the ends of the span, at the edge of the flooring and at the treads of vehicles, and whether or not the ends of the span were level was immaterial.

Ponton Boat Wagon After Going Through Mud Hole
Note the Bent Radius Rod and Broken Steering Arm

To obtain the maximum effect, loads were applied on one axle and that axle placed in the center of the span when readings were taken. In addition, however, a loaded 5-ton Mack truck and a 10-ton Holt tractor were run over the bridge and the deflection of each span noted.

The single axle loads up to and including 13,500 pounds were obtained by placing bags filled with sand and gravel, each bag weighing 150 pounds, on a cart built upon the detached rear axle of an old ponton wagon. For all loads greater than 13,500 pounds a complete ponton wagon was used with the bags so arranged over the rear axle that the front wheels were balanced and imparted no weight to the bridge. The axle to be loaded was first placed at one end of the bridge and sufficient bags placed on it to bring the gross load to 2,500 pounds. It was then moved along the bridge and brought to rest at the

Ponton Boat Wagon Loaded with Aluminum Boat being Hauled by Six-Line Mule Team

Digitized by Google

center of each bay in turn and level rod readings taken as described above. Having reached the other end of the bridge more bags were added and the load moved back and deflections measured as before. Whenever a span broke it was rebuilt and reinforced and attention directed thereafter to the unbroken spans until they, too, failed.

Although the methods followed in this work lacked the refinements of the laboratory it is thought that the results obtained furnish a reliable index to the characteristics and action of this experimental equipment.

A. A. Keesler

Major, E. O. R. C.

It is quite evident from Captain Wyman's description of results in the tests of heavy ponton equipage that the vehicles tested were inadequate for the duty required. It is not necessary to use either a reversible trailer for this purpose or one equipped with rubber tires. The objection to the reversible trailer is that its construction is greatly complicated and its efficiency greatly reduced by the attempt to make it suitable to haul from both ends. The fact that it is reversible is partly the cause for its inability to track well on a crowned road. The reversible feature also increases both the difficulty of production and the cost, far beyond their worth. There is occasionally a situation in which it would be an advantage to attach the power to the rear end of the train but these situations are rare and it is thought that a one way trailer of simple design would be an advantage.

It is not necessary that the cushion be obtained by means of rubber tires. It is entirely practicable to construct a steel tired wheel which will maintain speeds up to fifteen miles per hour and the cushion for vehicle and load should properly be obtained by means of spring suspension. The difference in cost as between rubber and steel is approximately $100.00 per wheel or $400.00 per vehicle and this sum, in ordinary times, would go far toward procuring the complete trailer.

The outstanding requirement for a vehicle to be hauled by truck, tractor or animals interchangeably, is that it be mounted on a frictionless bearing such as balls or rollers, and it must be borne in mind that mounting a vehicle on ball or roller bearings does not particularly decrease the force required for traction. It will move much easier on level roads but in ascending a grade the problem is one of foot pounds. I agree entirely with Capt. Wyman as to the necessity of having these vehicles so that they may be drawn both by animals and motors. It would appear that the problem of the bridge for heavy weights has been practically solved. The matter of transportation vehicles must receive further attention.

Appointment of Nominating Committee

In accordance with Article VIII, Paragraph 4 of the By-Laws, a Nominating Committee, consisting of Messrs. E. P. Ellis and Robert Coe, representing the membership at large; Col. John Stewart and Maj. J. J. Beaman, representing the Reserve Corps; and General Harry Taylor, C. of E., representing the Regular Army, has been appointed, and has organized by electing General Harry Taylor chairman and Maj. J. J. Beaman secretary. This Committee is charged with the duty of nominating the following officers for the ensuing year: President, First Vice-President, Second Vice-President, and six Directors to serve for three years, of whom two shall represent the Regular Army, two the Reserve Corps and National Guard, and two the membership at large.

The By-Laws provide that the list of nominations made by the Committee shall be transmitted to the Secretary of the Society not later than the twenty-fifth day of October and that the list so made shall be published in THE MILITARY ENGINEER for November or in the discretion of the Executive Committee shall be otherwise published to the members not less than sixty days before the date of the annual meeting.

Paragraph 5 of Article VIII is quoted for the information of our members:

In addition to the nominations so made by the committee, nominations may be made by a "nominating letter," signed by not less than ten active members:

Provided, That such nominating letter shall be received by the Secretary not later than the first day of December. The Executive Committee shall verify the eligibility of all nominees and their acceptance of nominations, and all nominees found eligible for election shall be included in the printed election ballot, which shall be mailed to all active members between the first and fifteenth days of December. The names of candidates for each vacancy shall be arranged in alphabetical order, with such data as to place of residence, civil and military record of each candidate, as the Board may deem pertinent or desirable: *Provided*, That no person shall at any one election be a candidate for more than one office or position.

The nominating committee will be glad to receive suggestions from the membership, but such suggestions should be in the hands of the committee not later than October 15, in order to receive consideration prior to the date on which the nominating committee must transmit its report to the Secretary. Nominations made thereafter by "nominating letters" prior to December 1st, will be handled by the Executive Committee under conditions specified in the By-Laws.

"Dollar Membership" Drive

Have you sent in the blank in the front of this issue with the names of six prospective members who should be interested in our special dollar membership offer?

Under the terms of this offer, one dollar sent in any time after September 1st will pay the dues of anyone qualified for membership in the Society to January 1, 1922, and will entitle him to a recent number of THE MILITARY ENGINEER (as a sample copy) and also to a copy of the regular November-December issue.

Application blanks covering this special membership have been mailed to all local posts, and will be furnished to members upon request.

The names of individual members and the names of local posts, with the number of applications secured, will be published in the next issue of THE MILITARY ENGINEER.

How near the top is your name and your post going to be?

Personals

Col. EARL I. BROWN, Corps of Engineers, has been transferred from Cincinnati, Ohio, to Wilmington, Delaware.

Col. JOHN MILLIS, Corps of Engineers, has been transferred from Fort Sheridan, Ill., to Chicago, Ill.

Col. MERIWETHER L. WALKER, Corps of Engineers, has been relieved as Commanding Officer at Camp A. A. Humphreys, Va., and ordered to report to the Governor, Panama Canal, for assignment to duty.

Col. GEORGE M. HOFFMAN, Corps of Engineers, has been appointed as a member of the board of officers to prepare a detailed plan for marking American battlefields in Europe.

Col. GEORGE P. HOWELL, Corps of Engineers, has been appointed as a member of an Army Retiring Board to meet at Fort McPherson, Georgia, for the examination of such officers as may be ordered before it.

Maj. LAYSON E. ATKINS, Corps of Engineers, has been granted leave of absence for one month.

Cavalry-Engineer Rifle Competition

The Rifle Competition heralded in our last issue took place at Fort Bliss according to schedule and was completed on the 17th of August. The Engineer organizations, while not doing as well as they might, did put up a rather good showing considering the practice and preparation which they were afforded. The main idea of the Shoot was to select the best men for the Cavalry-Engineer team, which will compete in the national matches at Camp Perry and it is believed that this has been done. Two Engineers are qualified to go to Camp Perry—Captain Ross and Sergt. de Hart, both of the Eighth Engineers. In the team match the Eighth Engineers were the only Engineer organization to qualify in the competition open to both services. They finished second among all Cavalry and Engineer regiments represented. In the individual matches the Cavalry produced better shots, with the result that none of our men qualified in the open competition. The individual Engineer championship was won by Captain Andrews of the Engineers.

The Shoot on the whole can be considered a great success as it brought together men from all Engineer organizations for the first time and has indicated to the different regiments what is necessary for them to do in order to produce a winning team. It is now up to all organizations to apply the knowledge gained from this year's competition and turn out a high-class outfit to represent them next year. Detailed results follow:

Cavalry-Engineer Individual Championship:

Gold medal—	
Mr. Fody, 13th Cavalry	321
Silver medal—	
Sgt. Jensen, 16th Cavalry	314
Bronze medal—	
Major Martin, 2nd Cavalry	311

National Engineer Individual Championship:

Gold medal—	
Capt. Andrews, 1st Engineers	302
Silver medal—	
Sgt. Long, 2nd Engineers	301
Bronze medal—	
Sgt. Yearian, 4th Engineers	299

Fort Bliss Trophy Match:

First—Mr. Fody, 13th Cavalry	91
Second—Capt. Gerfen, 13th Cavalry	88
Third—Sgt. Frank, 5th Cavalry	88

Cavalry-Engineer Team Match:

First—7th Cavalry	942
Second—8th Engineers	923
Third—2nd Cavalry	921

National Engineer Regimental Team Championship:

First—8th Engineers	923
Second—13th Engineers	908
Third—1st Engineers	877

The "Plattsburgh Idea" Again

THE little city of Plattsburgh, on the Canadian border, became famous during the Great War as the site selected by General Wood and his supporters for the notable experiment in volunteer training, known as the "Plattsburgh Idea."

The American people have a tremendous prejudice, inherited from their European ancestors, against compulsory service in war, or compulsory training in preparation for war. Realizing, at the outbreak of the war, the probability of our becoming involved in it, General Wood devoted his energies to overcoming the national prejudice, and preparing the country for what he knew was coming. The two outstanding results of his efforts were the Plattsburgh volunteer training camps and the selective or compulsory service act of May, 1917. To these we owe the successful outcome of the war. The early Plattsburgh camps were the experimental laboratory for the Officers Training Camps in which we trained the many thousands of officers who led our forces on the battlefields of Europe.

In the Great War the principle of universal obligation to service was recognized in the form of law. It is recognized for all time, and in any future war of sufficient magnitude we will have compulsory combatant service. There is no question of that. And it is to be hoped that, as a result of our painful experiences, we shall have also *compulsory industrial service.*

But the prejudice against compulsory training in time of peace, the necessary preliminary to compulsory service in war, remains to be overcome.

The prejudice is natural, deeply rooted, and probably just. It can be overcome, not by oratory, invective and abuse, but by practical demonstrations of the advantages of proper military training. A splendid demonstration of this was given during the late war, but it was evidently not sufficient. The War Department is continuing the demonstration, and Plattsburgh is again in the limelight as the most notable locality at which the demonstration is being given.

Our military policy now includes compulsory service in time of war, a notable improvement. In time of peace it includes volunteer training in the Regular Army, National Guard, Reserve Officers Training Corps (the R. O. T. C.), and Citizens Military Training Camps. All of these are being carried out this year at Plattsburgh and other similar camps.

The R. O. T. C. is already well established, and includes in its junior and senior units approximately 100,000 boys and men. It is the most practicable and the cheapest method of providing suitable material for junior officers under our policy of volunteer training.

The Citizens Military Training Camps are having their first demonstration this year. It is planned to give the rudiments of a military education to about 10,000 volun-

Digitized by Google

teers. If the experiment proves a success it is hoped to increase this number from year to year until each summer will see about 100,000 men undergoing training. If these figures are realized it is conceivable that we may be able to build up a reserve of a million partly trained men within the age limits of the draft act. Many of these men will have passed through three successive camps (Red, White and Blue), and will have a good preliminary training as non-commissioned officers and officers. This scheme, however successful, cannot produce results comparable to those of universal training. But it can provide a good asset to the National Defense, and it can do much to overcome the prejudice against military training.

The summer training camp should be and must be regarded as a military kindergarten. The characteristic feature of the kindergarten is that the instruction is made so pleasant and entertaining that the children do not realize that it is work, but regard it as play. They receive their instruction in the form of a sugar-coated pill. This is perfectly proper and justifiable. Education should certainly be made as pleasant as possible, even when it is compulsory. We wish our children to have pleasant recollections of their school days. When the education is purely voluntary, as is the case with military training in America, it must be made pleasant and entertaining if it is to achieve any measure of success. This should accordingly be regarded as the mission of the officers who direct our summer training camps. The training administered should be considered as of secondary importance, or rather as something that will result as a matter of course in a successful camp. The camp must establish a reputation as a pleasant summer outing to which many young men will wish to come. When this is achieved, the success of the scheme is assured.

Knowledge and Wisdom

THE MILITARY ENGINEER has probably become characterized in the minds of many of its readers, by its continued insistence on the fact that the engineer who hopes to be successful in war, must have a knowledge of the fundamental principles and economies of the military art, as well as a knowledge of the technical work he will be called upon to perform.

An engineering structure or mechanical installation of any kind will not fully serve its purpose unless those who design, and erect or install it, are familiar with the purposes which the structure is to serve, and the conditions under which it is to be used.

In civil practice this essential knowledge need not all be possessed by one man. Consulting experts will be called upon to give advice on various phases of the work. If necessary, work may be suspended, pending an examination by the experts. Time is not always the chief element.

In war time, expert advice is certainly desirable, but will all too frequently be lacking. The consulting expert will not be at hand when he is needed, and the work must proceed without delay. The engineer must be his own consulting expert. Frequently, in fact usually, he must himself perceive the need for the structure, prepare the plans, obtain the materials and supervise the construction. He must be able to view his own work from every side. Any engineer in war is liable at any time, and certain sooner or later, to be thrown entirely upon his own resources, and to have nothing to consult except his own knowledge and experience. Such, in fact, is the usual situation in time of war, and the engineer must prepare to meet it. This any man of average talents may do, if he will remember that military structures and installations must be the last word in simplicity.

Further cumulative evidence of the truth of these statements is contained in Colonel Jackson's article on Engineer Supply, which appears in this issue. Colonel Jackson insists that a successful engineer supply officer must have a knowledge of both construction and combat. It should be quite plain that the engineer who is to be successful in either (engineer) combat, construction or supply service, must have a thorough knowledge of the economics of all three of these activities.

The bearing of all this upon the training of the engineer for war will be apparent. Profound technical knowledge is not essential, although it may be useful. It is not to be desired at a sacrifice of the qualities of adaptability and resourcefulness. What we need is plenty of engineers of average intelligence and training, men who have kept their eyes open and cultivated the faculty of observation, not allowing themselves to become narrowed by the too ardent pursuit of a specialty. We need men with sound fundamental ideas, a correct sense of proportion, a knowledge of good practice, open minds, high initiative, resource, determination and courage. In brief, we need men who can be depended upon to erect simple structures for simple needs, on their own initiative, in the minimum of time, under trying conditions, without calling for or expecting help from anybody—men who will produce results, make no excuses, and who will regard delay or failure as the only unforgivable sins.

It has been said that knowledge is power. It is so in a potential sense. We cannot *do* unless we *know*. But it is also true that too often "knowledge comes while wisdom lingers." Wisdom, or the ability to use one's knowledge effectively, is the great desideratum. It is not what we know but only what we do that counts in wartime. A mind stored with knowledge but lacking wisdom is like a great factory full of splendid tools and materials, but without the cunning artisans who alone can produce the commodities. It is better to have a moderate amount of knowledge with the wisdom to use it intelligently than infinite knowledge with no power of application. It is possible to cultivate wisdom, just as it is possible to amass knowledge, but the former is by far the more important, as well as the more difficult.

The engineer, whether in peace of war, should take advantage of every opportunity to increase his knowledge. But he must learn to think along common-sense lines, in true military fashion to "estimate the situation" that confronts him, decide upon a good plan of action, and carry it out with unwavering courage and energy. In this manner the man of average intelligence and information will achieve success. In no other manner can the best informed attain practical results, whether in peace or in war.

The Organized Reserves

THE Army of the United States consists of three components: the Regular Army, the National Guard, and the Organized Reserves. The first component having recently been reduced, it follows logically that additional reliance must be placed upon the two remaining components, in order that there shall be no decrease in the effective defensive strength of the nation.

"The organization of the Regular Army into a limited number of effective military units," said the Secretary of War recently, "will not only release a greater proportion of officers for duty with other portions of the Army of the United States, but will facilitate great economies in the maintenance of the peace establishment. As I interpret the intent of Congress in providing for the division of the country into corps areas, their primary object is to

Digitized by Google

form a decentralized organization for the promotion and development of the National Guard, the Organized Reserves and the Reserve Officers' Training Corps. It is my desire, therefore, that this function should be especially emphasized in the War Department."

Special Regulations No. 46, General Policies and Regulations for the Organized Reserves, have lately been published. These regulations are the result of several months' exhaustive study of the subject by officers of the General Staff, and will be read with great interest by reserve officers of all branches of the service.

The organization, training, and mobilization of the Organized Reserves are functions of the corps area commander. The normal allotment is three infantry divisions to each corps area, together with a proper proportion of corps, army, auxiliary and special troops. The allocation of units within the corps areas will be determined by boards that will include reserve officers, and the names, numbers and designations of divisions and subordinate units thereof that served in the World War will be preserved as far as practicable. Reserve officers will be assigned to units in the vicinity of their places of residence, with the exception of those whose special qualifications lead to their assignment to special duties and activities controlled exclusively by the War Department. This procedure is bound to result in the establishment of close bonds between the reserve units and the communities that will furnish their enlisted personnel in time of emergency. The assignment of reserve officers to units will also be made in such a way as to enable each officer to develop his military usefulness to the maximum.

Regular Army personnel will be assigned to the Organized Reserves on the following basis:

To the headquarters of each division—
3 General Staff officers,
1 adjutant,
1 supply officer, and
5 enlisted men.

To each regiment or equivalent organization—
1 officer, and
1 enlisted man.

An engineer regiment, for example, will be commanded by a reserve colonel and officered as far as possible by reserve officers. The officer of the Corps of Engineers assigned thereto will perform the duties of executive officer and will devote his entire time to the development of the regiment.

As to the individual obligations of reserve officers, it is provided that "to the extent permitted by appropriations for this purpose, members of the Officers Reserve Corps may be ordered to active duty for not to exceed 15 days within any one calendar year, and for further periods with their own consent." There is a further provision, however, to the effect that "in the exercise by the War Department of the authority given by law to require this period of active duty, due consideration will be given to the occupations and other civil duties and responsibilities of reserve officers." It thus appears that while the 15-day training period is regarded as an important factor in the development of reserve officers, it is not contemplated that reserve officers shall be called upon to sacrifice their business or other civil interests in order to undergo the training in question.

Lectures, conferences and correspondence courses will be arranged for the furtherance of voluntary training while on inactive status.

When on active duty the reserve officer will receive the same pay and allowances as an officer of the Regular Army of the same grade and length of active service, and mileage from his home to his first station and from his last station to his home, but will not be entitled to retirement or retired pay.

The foregoing are only a few of the salient points dealt with in Special Regulations No. 46, which will well repay careful reading and study by all reserve officers.

New Posts

The following Posts are now in course of organization:

Akron Post—Lieut. Sears S. Day, Lock Box 254, East Akron, Ohio.

Baltimore Post—Capt. John S. Doyle (E. O. R. C.), 309 Custom House, Baltimore, Md.

Boston Post—Lieut. Lewis A. Armistead, Room 701, 108 Massachusetts Avenue, Boston, Mass.

Cincinnati Post—Capt. Hugh J. Krampe (E. O. R. C.), 1608 First National Bank Building, Cincinnati, Ohio.

Denver Post—Mr. Charles H. Rankin, 700 Tramway Building, Denver, Colo.

Indianapolis Post—Capt. C. L. Harrod (E. O. R. C.), Public Service Commission of Indiana, Indianapolis, Ind.

San Antonio Post—Mr. Ray S. Quick, Box 262, San Antonio, Texas.

St. Paul Post—Capt. John F. Druar (E. O. R. C.), 512 Globe Building, St. Paul, Minn.

Minneapolis Post—Wm. P. Cowles, The Iowa Bridge Co., 317 McKnight Bldg., Minneapolis, Minn.

Silver Button Winners

A number of silver button winners have failed to advise the Secretary the character of emblem desired—button, charm or brooch-pin. If you have not as yet received your silver emblem, will you not promptly advise the kind you prefer so that an order can be placed with the manufacturers the latter part of this month.

Proposed Amendment of By-Laws Approved

The Board of Directors has unanimously approved the proposed amendment to Paragraph 1, Article VIII, of the By-Laws, which changes the date of the annual meeting of the Society from the Friday *preceding* the third Wednesday in January to the Friday *following* the third Wednesday in January. This paragraph as amended reads as follows:

"The annual meeting for the election of officers and for the transaction of other business of the Society shall be held in the city of Washington, D. C., on the Friday following the third Wednesday in January."

The object of the amendment is to bring the annual meetings of the Society of American Military Engineers (in Washington, D. C.) and the American Society of Civil Engineers (in New York) within the same week, thus enabling those who are members of both societies to attend conveniently both annual meetings.

Society Emblems

Orders may be placed with the Secretary of the Society for emblems at the following prices:

Material	*Button or charm*	*Brooch-pin*
Bronze	$0.75 each	$1.00 each
10k solid gold	5.00 each	5.50 each
14k solid gold	6.00 each	6.50 each

Activities of Our Local Posts

Detroit Post

MR. HARRY GARDINER, 708 Ford Building.

The adjourned meeting of June 1st was held in the Chamber of Commerce, June 20, 1921, at which time the following officers were elected:

President, Maj. Richard B. Hewitt;
Vice-President, Frederick H. Mason;
Secretary-Treasurer, Harry M. Gardiner;
Director, First Year, Col. E. M. Markham;
Director, Second Year, Col. Alfred Lovell.

Local organization being perfected, several very interesting talks and general discussion on objects of the organization were given by Col. Edward Heckel, Col. Alfred Lovell, Col. E. M. Markham, Major Hewitt and Frederick Mason.

All present being qualified, signed the application for charter for the local post, and the secretary was instructed to mail formal applications for membership.

William B. Stout gave an excellent resume of the development of airplanes with special detailed information on the liberty motor, during and since the war.

Col. Edward Heckel followed Mr. Stout with a much appreciated description of present and future plans of the Detroit Parks and Boulevards Department in improving harbor lines, etc., on Belle Isle. Several blue prints illustrating work completed and that yet to be finished on the site for the Scott Fountain, including approaches, were shown. Colonel Heckel also described the proposed method of handling refuse and dirt by building a new municipal dock on property recently purchased, so constructed as to allow teams and trucks to dump directly into scows underneath the dock, hereby effecting a larger saving in handling costs.

Col. Alfred Lovell of the University of Michigan, explained his conception of the benefits to be derived from membership in the Society, advising of his interest and the possibilities of large membership throughout the state.

Major Hewitt, whose efforts were instrumental in the organization of the local post, gave an excellent description of objects of the society, qualifications for membership, etc., with a plea for society co-operation from all.

General business being over, all present adjourned to the buffet room where an excellent luncheon thoughtfully provided was greatly enjoyed.

Meeting adjourned 10:30.

No further meetings will be held during July and August.

Why not a mission for each Post?

The following self-explanatory letter has been sent by the Detroit Post to each of its members:

Dear Comrade—

Have you read the activities of the other posts? A post has a mission; we have the post and we must decide as to what our mission is to be. A mission should be comprehensible and constructive, also one within our man power and financial ability to carry out, otherwise we court defeat.

To help us decide, let us have a heart-to-heart paper talk:

1. What work (one project) do you suggest for the post this year?

A.

2. Of what national engineering society are you a member?

A.

3. What are your present business connections?

A.

4. What work do you like best?

A.

5. Were you in the service during the late war? Arm and rank?

A.

6. What is your hobby?

A.

7. What is your ambition in the engineering line?

A.

8. What is your pet peeve? Social, Economic and Military?

A.

9. How much time can you give to the Society affairs?

A.

10. When and where were you born?

A.

These are personal questions, however, if you will think them over forty-eight hours, then fill in the answers and return promptly we will have a mission and a message for you at our next meeting. Use another sheet if you require more space.

Thanking you for your co-operation and looking forward to seeing you in the near future, I am,

Sincerely yours,

RICHARD B. HEWITT,
President.

New York Post

Maj. PERCY E. BARBOUR, 29 West 39th St.

On Saturday morning, May 28, sixty members of the New York Post, headed by General Langfitt, President of the Post, entrained at the Grand Central station for Garrison, N. Y., and thence by ferry to West Point. Through arrangements made by Maj. Percy E. Barbour, Post Secretary, a special railroad coach was provided and the party soon proceeded to smoke up. Col. Roger D. Black gave a series of informal short talks on West Point, and every one in the car was furnished with a copy of the latest annual report of the Superintendent of the Miliary Academy and a map showing location of various buildings and points of interest on the military reservation.

The details of arrangement and registration were in charge of a committee consisting of Maj. Edward L. Sherwood, Maj. W. E. Boughton and Capt. Samuel G. Hibben.

Upon arrival at the dock at West Point the party was divided into equads of five men each and marched to the Assembly Hall, and from there conducted about the reservation by Maj. Willis D. Crittenberger, Cavalry; Capt. George Von W. Pope, Infantry, and Capt. Henry C. Jones, F. A., each acting as liaison officer or guide for twenty visitors (four squads); the remainder of the morning was occupied by a walk taking in the buildings and grounds before joining the cadets for luncheon—two visitors being assigned to each mess table.

The afternoon activities began with an inspection of cadet quarters and company inspection; each of the twelve

Digitized by Google

tactical officers was accompanied by a squad of five members of the New York Post, following which the review was witnessed by the visitors, who were again in the hands of the liaison officers. After the review there was a most delightful organ recital, followed by a ball game between the cadet nine and Fordham University, both of which events were attended by the entire party. Following the ball game, Lieut. Col. Danford, Commandant of Cadets, addressed the party briefly in front of the Headquarters building, and last, but not least, was the tea and dansant at Cullum Hall. On the return trip Colonel Black gave an outline of the next year's program, which it was hoped would include another visit to West Point with perhaps a tactical ride or walk with the cadets.

The program for the day was arranged by Col. Thatcher T. P. Luquer and Col. Roger D. Black of the Program Committee in consultation with Brig. Gen. Douglas McArthur, the Post Superintendent, who invited the party to lunch with the cadets and very courteously arranged for the escorts and inspection.

Portland, Oreg., Post

MR. E. BURSLEM THOMSON, 321 Custom House.

At the annual meeting on June 14 the following officers were elected:

Capt. Frederick S. Cook, President; Capt. P. Hetherton, Vice President; Mr. E. Burslem Thomson, Secretary; Mr. F. C. Schubert, Treasurer; Capt. A. D. Monteith, Assistant Treasurer.

The annual meeting took the form of a social function, the members and guests of members bringing their wives, sweethearts or merely lady friends. The ladies brought a basket lunch, which took until about 8 o'clock to consume. Thereafter the meeting was held, consisting purely of election of officers. Flashlight pictures were taken of the group, and when the smoke of combat had cleared away, dancing commenced.

On Tuesday, June 21, there was a joint meeting of the retiring officers and the new officers. Policies were discussed for the coming year and papers, correspondence and cash transferred. We look forward to a very successful year and are expecting to have at least one problem to discuss each month. The map problem which appeared in a recent issue of THE MILITARY ENGINEER will be discussed.

Following the editor's suggestion, we will have a discussion of THE MILITARY ENGINEER, and hope to be able to bring out some suggestions.

San Francisco Post

Capt. DOUGLAS W. DODGE, 733 Rialto Building.

On the evening of June 28 the Society held a social evening at the Cliff House. Dinner was served at 7:30 in the north end of the main ballroom overlooking the Seal Rocks at four large round tables which were delightfully decorated. During the dinner the members present enjoyed dancing, which was continued after the dinner until late in the evening. Arrangements had been made for card playing on the lower floor, but the members were so well pleased with dancing that no one in the party desired to play cards.

The following members and their lady friends were present: Major Ward, Colonel Wing, Colonel Deakyne, Major Grant, Captain Dodge, Captain Miller, Captain Malatesta, Captain Tolbrook, Captain Toklas, Mr. Duncan, Mr. Landis, Lieutenant Colonel Hunt.

Major Ward, chairman of the Committee, was responsible for the success and enjoyment of the entertainment, which was heartily appreciated by all present.

Trip Over Properties of Spring Valley Water Company

Leaving San Francisco, Spring Valley Building, at 8:30 A. M., July 8, a party of members of the Post made an inspection trip by automobile over the properties on the San Francisco Peninsula of the Spring Valley Water Company. The members of the Post were the guests of the Spring Valley Water Company, through an invitation extended by Mr. S. P. Eastman, vice president and general manager, initiated by the suggestion of our member, Robert E. Child.

J. J. Sharon, assistant manager and engineer of the company, together with "D. R." Clemens and Theodore Wilder, personally conducted our visit.

The general route followed was to Lake Merced Pumping Station, through the Lake Merced properties to Colma, thence to San Andreas Dam, Pilarcitos Lake and Dam and Stone Dam, where party arrived about noon. At this point the company provided a lunch, for the excellence of which a memory will long remain, and for the preparation of which our members are indebted to "Bill" Yount and his staff. After lunch we viewed the Crystal Springs Reservoir and inspected the Crystal Springs Dam, thence to the Belmont Pmps, and return to San Francisco.

Copies of a reprint of an address by Mr. Hermann Schussler were distributed among the members, one of which is filed as a part of this record, and in which is contained the full description of our observations.

It was proposed that at our next regular meeting, which will precede the second portion of the Spring Valley Water Company trip, a paper illustrated by slides will be given us by Mr. J. J. Sharon, descriptive generally of the entire system, followed by a specific summary by Colonel Child, bringing out the particularly important points of military bearing.

The importance of this entire system is in connection with the defense of San Francisco and vicinity is immediately apparent, and the question has arisen whether the Headquarters have this property, together with all its vital points, so charted that a guard can be immediately placed on it for effectual protection in case of sudden emergency. If such preparation does not exist, would not the Department appoint a commission of reserve officers, E. R. C., to complete the necessary reconnaisance.

The members and guests present were as follows:

Fred C. Toklas, B. P. Miller, George W. Duncan, P. B. Delano, Colonel Wood, Wm. B. Hall, Col. Chas. B. Wing, C. A. DeCamp, R. E. Child, Lee Landis, C. W. Tilbrook, Lieut. Allen Hoar, U. S. N.; Robert Wing, Col. Herbert Deakyne, H. B. Truett, D. W. Dodge, Capt. F. D. Jones, Percy Burr, Lieut. Col. C. L. MacRae, U. S. N., and Maj. U. S. Grant 3d.

Letters expressing the appreciation of the Post, and of the members individually, were written to Mr. Eastman and to Messrs. Sharon, Clemens and Wilder.

The Entertainment Committee of the San Francisco Post, of which Mr. Thomas M. Ward is chairman, has arranged for a trip to Mt. Tamalpais and a picnic at Muir Woods for members and the ladies for August 21st. Through the courtesy of Colonel Williams, a member of the local post, the Northwestern Pacific Railway will attach a special car to its regular train leaving San Francisco at 9:45 A. M. It is planned to stop at Muir Woods for lunch and from there to proceed to Mt. Tamalpais, returning to San Francisco late in the afternoon.

New Orleans Post

Capt. E. H. COLEMAN, 1016 Hibernia Building, New Orleans, La.

The Post had a delightful outing August 20, with Maj. R. T. Coiner, the District Engineer, as their host, accompanying him on the steamer *Newton* on an inspection trip. visiting one of the nine levee-building machines operated by the Federal Government in the Fourth Mississippi River District in the construction of levees.

Training an Engineer Regiment

By

Lytle Brown

Colonel, Corps of Engineers

[The method of training an engineer regiment hereinafter described has been employed with excellent results in the Second Engineers at Camp Travis, Texas, Colonel Lytle Brown commanding. It appears to meet in a satisfactory way the varied and numerous conflicting demands which are made upon the regimental commander and which are inevitable under conditions now obtaining in most divisional camps. The method enables regiments to perform the construction work required by the division and at the same time affords opportunity for the instruction of the enlisted men in their duties as soldiers. It also gives the officers experience in handling their various commands.

The outline of the system as given below, together with some hints on training has been prepared from data furnished by the Commanding Officer, Second Engineers, Second Division.—ED.]

RECRUIT training in the Second Division was handled entirely by Division Headquarters until enlistments became so rapid that it was necessary to have the actual work done within the regiments. Training was directly controlled, however, by G-3, and an inspector from his office made frequent visits to all regiments, to assist with advice and to insure that instructions were being carried out properly. Each recruit upon assignment to a regiment had a recruit card prepared for him. This card listed all the subjects which the soldier should know before being assigned to full company duty. It embraced infantry drill through the School of the Platoon, First Aid, Interior Guard Duty, Courtesy and Discipline, Equipment, and the Articles of War. The recruit was tested once a week in the subjects listed on the card, and was marked proficient in such subjects as he could perform or explain satisfactorily. Upon qualification in all subjects, he was sent to the company for straight duty. This record system assured that every man was qualified in every subject considered essential for recruit instruction. Upon joining the company, the soldier's instruction was carried on in accordance with the company training schedule. These schedules covered one week's work and were based on regimental schedules covering a similar period, which in turn were based on general programs of instruction covering a greater length of time. The details of engineer instruction were left to the regimental commander. The basis for all engineer instruction in the regiment is Engineer Field Notes, No. 25, A. E. F. The subjects which were to be covered to enable a regiment to perform the functions prescribed by Engineer Field Notes No. 25, were listed, together with the amount of time which should be expended on each. All men were to be instructed in:

Communications,
Organization of the Ground,
Small Arms Firing,
Ceremonies,
Combat Instruction.

Selected men were to be trained in such subjects as demolitions, animal transportation, reconnaissance, etc. The weekly schedules were based, of course, on this general program.

There was, of course, a large amount of construction work required of the regiment by division headquarters, in the nature of barrack construction, athletic fields, target ranges, etc. This work was almost entirely of an engineering nature, and afforded an opportunity for the training of the command in engineer work.

The work was assigned to the organizations in the regiment, as explained later. Each company had a chart showing the amount of time each man had had in each of the subjects in which he was scheduled for instruction. This was, of course, to insure that all men should receive instruction in all of the subjects considered necessary in their training. The preparation of a qualification card for the average engineer soldier was given serious consideration, but this has not been accomplished because of lack of time. Units are tested for the adequacy and proficiency of their instruction, the lower units by higher commanders. It was not possible to determine the proficiency of each individual soldier by actual test in all the duties he was expected to be able to perform. It was possible, however, to determine by these tests of the men, the efficiency of their commander as an instructor. Thus two things could be assured, that the instruction the men were receiving was good, and that the proportion of time spent by any man on any subject was correct.

In the performance of work, the assignment was always by organization. Each task, no matter how small, was given directly to a battalion commander, and he was held responsible for the prompt, efficient completion of the job, although the work itself might actually be done under a sergeant or corporal. Work was always done by the task system. A definite amount of work was always assigned for each day, and only upon its completion were men released. Thus was assured proper organization of all work, proper inspection by higher commanders, and rapid, efficient work by the men.

The system briefly outlined above proved to be very successful, and gave very good results in the training of the regiment. There are numerous points in the Hints on Training which follow that go into greater detail on the practical workings of the plan.

Hints on Training

(*a*) Use the organizations as they exist for all training and all work; or conversely do not make special organizations for instruction purposes. Those who are responsible for the work of men in campaign must also be responsible for their training. A lieutenant must instruct his own platoon, a captain his company, etc. In the assignment of work, no matter how small the amount, assign the task

The Field Artillery Journal

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bi-monthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

to the next lower commander, and hold him responsible for results. That is, the regimental commander assigns to a battalion commander a task, possibly requiring only one squad to perform, and holds the battalion commander responsible for the proper execution of the task. If the task is large enough to require the entire regiment, the work should be divided between battalions, and then closely supervised.

(*b*) Inspections for results must begin at the top. The regimental commander must make his influence felt by inspecting personally all the work of the regiment.

(*c*) The greatest force in the hands of a company commander is personal knowledge of his men. In inspecting to determine the efficiency of a company commander as an instructor, the first step is to see that the company commander knows all his men by sight and can call them by name. If he cannot, there is no need of inspecting further. Either he has not acted as instructor, or he is totally ignorant of the first points of handling men.

(*d*) In all instruction of enlisted men (or any men) carry the instruction to the men in the manner Colonel MacNab has demonstrated in rifle practice. A man, properly instructed, knows his subject and can tell it in his own words. Having the man so reveal his knowledge is a test of his instruction. By impressing the men that such a test is coming, the difficult problem of holding their attention is solved. Each man must feel that at any moment he is liable to be called out by name before his squad, platoon, or company, and asked to repeat the instruction that has just been given. This method must be pursued throughout his course of instruction.

(*e*) If instruction is to have any personal appeal, an individual efficiency record of each man's instruction must be carefully kept to date in the company. It may be on a consolidated sheet or on individual cards or both. The sheet is best for display in barracks and should be kept posted under glass for inspection by all. Inability to keep such a record shows that something is wrong with the command as a school of instruction. The remedy may or may not be in the hands of the immediate commander; if not, then the situation should be brought to the attention of the next higher commander.

(*f*) All commanding officers should have a knowledge of the value of the force of the spirit of emulation among organizations as well as among individuals, and a free use of the publication of comparative results with the names of the responsible authorities, should be made in all accomplishments of real weight.

(*g*) The physical fitness of the soldier is a consideration of the first importance. All authorities from the highest to the lowest must show by their acts the appreciation of this fact. Athletics must be given a very high place in the training of the soldier. In commands of any size an annual athletic program should be adopted. The preparation for the events of this program should begin with companies; teams from companies should contest within the battalion; when the winning company is determined a team should be selected for the battalion, trained, and then battalion teams should contest for supremacy in the regiment. Then a regimental team should be chosen to compete in the contest within the division. Then a divisional team should represent the division, should it contest in the Corps Area. Generally, organized athletics for a team in a lower unit should at once cease when the team of the higher unit is selected. As a rule athletics should be highly varied; long baseball, basketball, or football schedules should not be made. If an an-

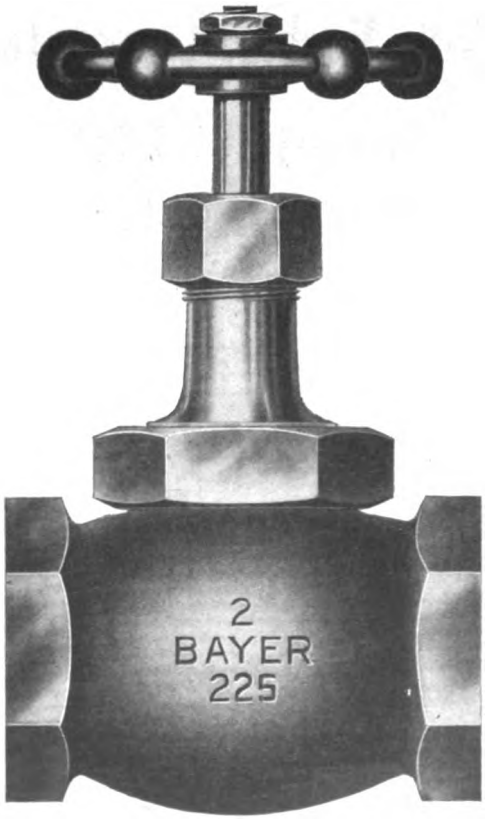
BAYER Valves

BAYER Valves are made in heavy-pattern regrinding globe, angle and check types, screw and flanged ends—all good for working pressures up to 225 lbs. Each one is guaranteed to meet the metal composition requirements of U. S. Navy Department specifications 46-B-8, June 20th, 1913, covering valve bronzes or composition "M."



Body walls are of liberal thickness, with a uniform distribution of metal. Valve seats are radial, and can be ground continually, thus prolonging the life of the valve indefinitely. Discs are made of a hard bronze composition; stems are unusually heavy with a greater number of accurately cut threads than usually found in valves of this type.

Naturally, continued satisfaction is the only logical result that can follow adherence to the BAYER standard. Send for our book "The BAYER Valve."

BAYER VALVE COMPANY

nual schedule of athletic games is not prepared by the larger units they will be made at random by smaller organizations and amount to but little. Athletics in the army has not been cultivated for as much as it is worth, due to the failure of higher headquarters to get out an annual forecast of the dates and events and games that they propose to hold. Once such a forecast is made it must not be changed except for unavoidable causes.

In athletic contests those in authority must not overlook the fact that there will be no encouragement to athletics unless there is provided, besides the contestants, an audience—the larger the better. The measures to secure the audience must be taken by those in highest authority. The audience must include the high authority. If it is company team contests, the battalion commander and his staff must be fully in evidence at the contest, and all of the battalion not engaged as contestants must be there.

All of the above points have been brought out by successful work in the Second Division in the Eighth Corps Area.

A good athletic field is a necessity at every station of importance. The events of an athletic meet should conform to the events of our national athletic games which are largely governed by the colleges of the land.

A good athletic team for a regiment is a great factor for morale. A prime young athlete is a model for clean living set before the eyes of all the men of the command, and a finer argument for such living than can be made by word of mouth.

(*h*) It is necessary for all in authority to recognize that the soldier, particularly the engineer soldier, is not a day laborer. He does not get the day laborer's wages and he does not have quite the liberty of action of a day laborer. But when a soldier works in peace, he must work just as he works in war, with speed. This is very particularly the rule with engineer soldiers.

The proper results in the line of work are gained by always following the task system. Tasks must be made light enough so that their completion can be assured by swift, efficient work in time to allow the man ample time for leisure and recreation. No daily task should ordinarily be set which requires more than four hours of vigorous sustained work for its completion, taking into account the skill of the men employed. Soldiers who are lazy and shiftless must be held to their work until it is completed, even though time for recreation be consumed.

Commanding officers must bear in mind that time and patience are required to finish works when tasks are made as light as they should be. The task system applied with the idea of producing instructed soldiers will probably not accomplish the same amount of work as if the men are handled as day laborers.

(*i*) Every piece of work performed by engineer troops must be regarded as a problem in organization methods and supervision, with the idea of securing efficient training in these things so essential to the proper performance of any task in time of peace or in time of war. Even a poorly performed piece of work will be instructive, if the faults are found out. If the faults are not found out, it may be the beginning of shiftless and inefficient habits.

The following appendices A to D, inclusive, are published as typical documents in use in the regiment:

A. Recruit Card,

B. Training Instructions for the year October, 1920-September, 1921,

C. Training Memorandum 43, 1920,

D. Training Memorandum 8, 1921.

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

Sauerman Bros.
1145 Monadnock Bldg., Chicago

APPENDIX B

Training Instructions for the Year October 1, 1920, to September 30, 1921, Second Regiment of Engineers

1. In accordance with General Orders No. 7, Headquarters Southern Department, and Memorandum No. 152, Headquarters Second Division, the following instructions are issued for the government of the training of this regiment, officers and men, for the year October 1, 1920, to September 30, 1921.

2. The year is divided into two periods: October 1 to June 30, and from July 1 to September 30. The first period will be largely devoted to the individual instruction of the men and officers in their duties according to grade and previous instruction. The latter will be largely devoted to their instruction by organization.

3. The instruction will be under the general supervision of the regimental commander. The next senior field officer assisted by the remaining field officers and specially designated officers will be responsible as directors of training for the whole training of the regiment.

These instructions will give the results to be accomplished and the means for their accomplishment. Such orders as are necessary to further carry them into effect will be prepared by the director of training and his assistants for the approval of the regimental commander.

Unit School

4. All schools in the regiment will be branches of the unit school, and will be—

(*a*) Schools for officers.

(*b*) Schools for non-commissioned officers and selected privates.

These schools will be formed for two distinct purposes:

(*c*) To prepare instructors for the proper execution of current schedules of instruction, and to secure in the command an intelligent comprehension of orders received.

(*d*) To prepare by general instruction, officers, non-commissioned officers, and selected men for the general duties in their grades, or to train them in specialties. Under this heading will be included any trade or vocational schools that may be established in the regiment. At present no trade school will be established in the regiment, when that trade is taught in the vocational schools established at Camp Travis.

5. There will be established at once a school for non-commissioned officers in each company which will include all non-commissioned officers who are available for company duty. It will meet daily, and the object mentioned under (*b*) will be secured by the best instruction that can be devised by the company commander; the object described under (*c*) will be secured as far as company commanders may under their own initiative prescribe.

6. There will be established at once a regimental school for non-commissioned officers, at which will attend at times to be prescribed, within the period October 1-June 30, all available non-commissioned officers of the regiment. These non-commissioned officers will be given twelve (12) lectures:

(1) Responsibilities of non-commissioned officers in relation to company officers and their relation to the enlisted personnel.

(2) Handling of men.

(3) Example of non-commissioned officers to the men under them. Deportment in barracks, at mess, off duty; proper mode of address; discipline.

(4) Summary and explanation of the orders of the Second Division bearing on the conduct of the enlisted personnel of the Engineer Regiment of the Division in campaign, in quarters, in camp and off duty.

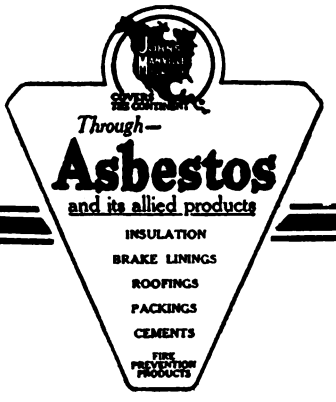
Digitized by Google

(5) Organization of the company and of working parties and the duties of non-commissioned officers therein.
(6) March discipline of a command on the road.
(7) The organization of the Division and the duties of the Engineer personnel, when attached to the various units thereof.
(8) Care of men in the field and in trenches; cleanliness, personal hygiene.
(9) Police of quarters; sanitary regulations of this camp, and in the field.
(10) History of the Regiment.
(11) The opportunities and advantages of continuous service in the Regular Army.
(12) The legal rights of the enlisted men; explanation of the various courts-martial, and of the Articles of War that particularly apply to the enlisted men.

Lecture No. 10 will be delivered shortly before Organization Day.

A meeting of the regimental non-commissioned officers' school will be called whenever in the judgment of the regimental commander, or the direction of training subjects may be best brought home to the entire command through this agency.

7. There is, and will be continued to be established in the regiment as a part of the unit school, the officers' school. This school will fulfill both the objects (*b*) and (*c*), but the study of matter to be covered by schedules will be made when the regiment is acting together under a detailed schedule of instruction, which is not intended to be the case generally. A detailed weekly schedule of the work of this school will hereafter be submitted by the director of training (see paragraph 10) of this regiment.



The subjects to be taught in the officers' school, and the period to be allotted to each, are as follows: The last day of each period will be the day of examination in the subject, unless that date falls on Saturday, Sunday, or a holiday, in which case the next prior available date will be the day of examination.

(1) Field Service Regulations—October 4-November 10.
(2) Administration, Company—November 11-December 1.
(3) Military Law—December 2-January 15.
(4) Military Hygiene—January 15-February 1.
(5) Rifle and Pistol Marksmanship—February 1-February 16.
(6) Military Topography and Map Reading—February 17-March 17.
(7) Duties of Engineer Divisional Troops in War—March 18-June 30.
(8) Minor Tactics—June 30-September 30.

8. Trade schools will be established within the regiment for such trades as are required in the military duties and which are not conducted by the Divisional Vocational Schools. These schools will have strictly regimental direction outside of companies. The companies will detail men either to the Vocational Schools of the Division or to the trade section of the unit school in accord with requirements deduced, from the following tables, which shows the number of qualified tradesmen of each class which should be in a company determined by percentages of the total enlisted strength, one being the minimum in any case, and major fractions counted units:

	Per Cent		Per Cent
Carpenters	10	Draughtsmen, General	1
Plumbers	5	Map Reproduction	1
Blacksmiths	5	Photography	1
Painters	5	Saddlers	1
Electricians	5	Surveyors	2
Farriers	1	Teamsters	6
Horseshoers	2	Motorcycle Drivers	2
Motor Mechanics	2	Truck Drivers	2
Draughtsman, Topographic	2		

Only one qualification can be given to a man in connection with the use of this table.

THE efficiency of Johns-Manville Products in severe service merely bears out their performance under laboratory tests conducted by Johns-Manville engineers. Every Johns-Manville product must prove itself correct in design, manufacture, and functioning before it is put on sale with the backing of Johns-Manville responsibility.

Asbestos and Magnesia Materials

Locomotive Lagging, Locomotive Spiral Pipe Covering, Locomotive Packings, including Air Pump, Throttle, Valve Stem, Cab Cock, Gaskets, etc.

Power Plant Specialties

Pipe Coverings for all classes of Service. High Pressure, Low Pressure and Sheet Packings, High Temperature Cements, Steam Traps, Insulating Cement, Electrical Supplies, Roofings, Industrial Flooring, Transite and Ebony Asbestos Wood, Transite Smoke Jacks, Refrigerator Car Insulation, Steel Passenger Car Insulation.

For Air Brakes on Locomotives and Cars

Automatic Slack Take-up, Packing Cups and Gaskets, Expander Rings.

9. The general training subjects which shall be covered in the instruction of the command as a whole in the period, October 1, 1920, to June 30, 1921, will be as follows and in about the progression as indicated. Instruction by company for the period, October 1, 1920, to June 30, 1921, as a rule:

All Grades

(1) Interior discipline and police.
(2) Care and nomenclature of the rifle.
(3) Personal hygiene.
(4) Calisthenics.
(5) General Orders for sentinels.
(6) Infantry drill, close order, to include the company.
(7) Use of tools, to include pick, shovel, axe and cross-cut saw; men to qualify once; amount of work in given time qualifying.
(8) Knots and lashings, individual qualification.
(9) Bayonet combat.
(10) Tent pitching.
(11) Making of the pack.
(12) Extended order drill to company inclusive.
(13) Signalling—in accord with War Department requirements.
(14) Interior Guard Duty.
(15) Musketry, full preparation for range firing—Supplementary Range Practice.
(16) Pistol—full preparation for range firing—Supplementary Range Practice.
(17) Gas defense.
(18) Regiment in ceremonies.

Non-commissioned officers and selected privates.

(1) Trench types.
(2) Revetments.
(3) Obstacles.
(4) Bridges, types floating and fixed; sub-types foot and all traffic.
(5) Explosives.
(6) Road construction and repair for military use.
(7) Light and standard railroad constructions.
(8) Water supply for division.

Period from June 30-September 30, 1921.

(1) Road march discipline.
(2) Road construction and repair.
(3) Bridge construction, all types.
(4) Ferries.
(5) Layout, defensive position.
(6) Trench construction, complete with revetments.
(7) Obstacles, construction.
(8) Machine-gun emplacements.
(9) Command post.
(10) Observation post.
(11) Trench drainage.
(12) First-aid Stations.
(13) Marking routes.
(14) Demolitions.
(15) Range practice.
(16) Regiment in ceremonies.

Non-commissioned officers and selected men.

(1) Engineer reconnaissance.
(2) Route sketch.
(3) Position sketch.
(4) Panoramic sketch.
(5) Minor tactics.

10. All instructions shall be by schedule prepared weekly. On Friday the director of training will submit to the regimental commander the schedule for the next week, which shall give the subjects to be taught on each day of the following week in companies, and in the unit school under regimental direction and the time to be devoted to each subject, with the authority or text to be used. On Saturday each company commander will submit to the regimental commander, in accordance with the director's schedule, a detailed schedule of the work of his company or school for the next week, giving, under the subjects to be taught, the

Digitized by Google

exact references to the governing texts or authorities which apply to the day's work, this in order that the instructors, and students as well, may prepare themselves for each period of instruction. The company commander or school director is best able to make the final sub-division of time to suit the progress of those under instruction, hence, the requirement as to detailed allotment of work under subjects.

The director of training must be governed in the weekly allotment of time to subjects by the average progress made, the importance of the subject, the total ground to be covered in the total time available, and the requirements as to time by higher authority.

Work for the Division

11. There will always be a considerable amount of work done by the regiment under the orders of the Division Commander. This work will, as far as practicable, be allotted to the regiment by company, each company commander being held responsible for the accomplishment of the work allotted to his company. Such work will take precedence over all training and regimental work. It will be done promptly and vigorously, and in such a manner as to give the best practice to all concerned in thorough, prompt, and well organized work, such as Engineer Troops must always be trained to do. Lazy, desultory and lagging endeavor on any of this work will not be permitted on any pretext. Let it be undertaken with the determination and the arrangements for prompt and effective completion.

The adjutant will keep a tabulation in chronological order of assignment of all such work, giving in the table a description of the work, the reference to the authority for its performance, the organization to which assigned, the responsible officer, the date of commencement of work, the probable date of completion and the actual date of completion. This table will be shown to the Regimental Commander, whenever new work is to be assigned, whenever any item is completed, and whenever the probable date of completion is exceeded.

APPENDIX C—Training Memorandum No. 43

Schedule for training for the week ending November 13, 1920.

	8:00 to 9:00 A. M.	9:00 to 11.30 A. M.	1:00 to 4:30 P. M.	2 to 4 P. M.	5 P. M.
Monday	Calisthenics Close Order Drill* School of Co. I. D. R.	Interior Discipline and N. C. O. School.	Interior Discipline and Police.	Officer riding Instruction.	
Tuesday	Offensive combat. The Company.* I. D. R.	Same	Same	Same	
Wednesday	Same*	Same	Same	Same	Battalion Parade.
Thursday	Advance, Rear, and Flank Guards** F. S. R.	Same	Same	Same	
Friday	Same**	Same	Same	Same	
Saturday		Inspection.		Half Holiday	

BAND.—8 to 9 A. M., play for drill; 9 to 11:30 A. M., practice; 1 to 4:30 P. M., individual practice and fatigue. Wednesdays at 5 P. M., Bn. parade. Saturdays at 9 A. M., review or inspection.

*All available men consolidated into one company. Company commanders will be changed during periods of drill.

**Each company sent out on different roads. To march out 15 minutes; return in formation for exercise selected.

PRIORITY OF WORK.—1, Roofs; 2, Mess halls, repairs to barracks, ditches, improvements, plots around barracks. General police must not be neglected in favor of work outlined above. (Sanitation also.)

By order of Colonel Brown:

W. H. CROSSON, *Captain, Corps of Engineers, Adjutant.*

APPENDIX D—Training Memorandum No. 8

Schedule of training for the week ending February 26, 1921.

	8:00 to 11:30 A. M.	1:00 to 2:00 P. M.	1:00 to 4:30 P. M.	2:30 to 4.30 P. M.
Monday	School of Company, Close Order, I. D. R. pars. 237 to 271 and pars. 43 and 44, N. C. O.'s School; also pars. 308 to 315 I. D. R. Instruction in Small Arms Firing, McNab System, p. 1-27. Exact subdivisions of work to appear in Company Schedules.	Officers' School. See Schedule of Lessons, and Field Training Problem.	Interior Discipline and Police. (See note).	Officers' Riding Class.
Tuesday	Same	Same	Same	Same
Wednesday	Regimental Work Drill (also 2-4 P. M.—Regtl. Athletics)			
Thursday	Same as Tuesday	Same as Tuesday	Same as Tuesday	Same as Tuesday
Friday	Same	Same	Same	Same
Saturday	Inspection (11-12 Lecture Serv. Club No. 4)		Half Holiday	

Wednesday.—Regimental Parade on Divisional Parade Ground at 5:15 P. M. Caps will be worn. Field and Staff Officers mounted.

BAND.—Play daily from 8 to 10 A. M., except on Wednesday, Saturday and Sunday, on recruit drill field, and from 1 to 4 P. M., as prescribed by Band Leader. On Wednesday the band will play at Regimental Parade on Divisional Parade Ground at 5:15 P. M., and at Divisional Consolidated Band Practice in the morning.

PRIORITY OF WORK.—1 Drainage; 2 Plumbing; 3 Walks; 4 Roads; 5 Repairs to Buildings. General police and thorough sanitation not to be neglected in favor of work outlined above.

RAINY DAY SCHEDULE.—Small Arms Firing. Inside band practice.

The Susitana River Bridge, Alaska Government Railway

The longest bridge span on the United States Government Railway in Alaska is the 504-foot steel through truss channel span of the Susitna River bridge, which was completed in February, 1921. Besides the main span the bridge includes two 121-combination Howe-truss flanking spans and two 70-foot combination pony Howe-truss end spans with 392 feet of trestle at southern approach and 28 feet at the northern approach, making a total length of 1322 feet. It is located 150 miles north of Anchorage and 264 miles north of the southern terminus at Seward.

The Susitna River has a heavy ice run in the spring that would carry out any timber pier, while concrete piers would have to resist not only the ice pressure but the undermining scour resulting from the ice jams forming against the piers. Comparative estimates for a main channel crossing of two 250-foot steel spans on three concrete piers and the single 540-foot steel span on two concrete piers were slightly favorable to the latter which was therefore adopted.

The combination of steel trusses and timber trusses in the same bridge was justified by the high prices of steel and concrete at the time of construction. It was cheaper to build all approach spans of timber and to make provision for possible renewal with steel and concrete when the life of the timber has reached its limit. For this reason the main piers were designed to support 200-foot steel flanking spans at some future time, each to replace the present 121-foot and 70-foot spans.

The Cooper E60 loading was adopted for the 504-foot span, E50 for the timber and E44 for the trestling, which has 14-foot spans. In the design of the steel span the 1910 specifications of the American Railway Engineering Association were followed mainly. Wind loading was an exception to this; the bottom lateral system was designed for 40 pounds per square foot on the area of train and floor in elevation, and on 1½ times the area of truss members of one truss not covered by train and floor while the top laterals were designed for 500 pounds per linear feet of span.

Test holes 60 to 75 feet deep to determine the nature of the foundation for the piers, disclosed compact sand gravel and boulders in layers of varying thickness, and capable of supporting the piers without foundation piles. An open caisson was used for the north pier excavation, and a cofferdam of Wakefield triple-lap sheet piling for the south pier. Excavation was started in the wet with orange-peel buckets operated by two stiff-leg derricks until hard material was struck; then the holes were pumped out and work was continued by laborers with pick and shovel filling dump boxes operated by the derricks. For both foundations, excavation was carried to an average depth of 25 feet below the ground. Drain ditches about 12 inches deep were maintained around the edges, being sloped to carry seepage water to a sump at the downstream end of the pit where one 5-inch and two 8-inch pulsometer pumps operated continuously in the lower levels of the work.

Concrete Work. Considerable difficulty was encountered in finding sand and gravel suitable for the concrete piers. Aggregate taken from pits in the vicinity of the bridge was not satisfactory, as samples showed humus. Several deposits along the railway line all showed the presence of this constituent in various amounts, except samples from a pit in a glacial moraine in front of Spencer Glacier, 56 miles north of Seward. This deposit tested clear and was used; 7 per cent of sand was added to the bank aggregate, which was deficient in this respect.

After a partial failure in one of the piers during September, 1920, caused by poor cement, the presence of humus in the aggregate and the low temperature of the air and water, special measures were resorted to in placing concrete in main piers.

When the cofferdam was unwatered, the bottom of the enclosure was under a 22-foot head of water from the river, and owing to the porous nature of the boulder and the gravel formation considerable water was forced through the floor of the pit. The enclosure was 33 by 69 feet and it was found impracticable to partition it off and place and hold concrete in the dry against the flow of water. As the low temperature of the water (35° F. in November) and the large area (2,277 sq. ft.) made it impracticable to place concrete under water by bucket or pipe methods, the following plan was devised to meet the conditions of cold running water and low air temperature. A large sheet of canvas was prepared in one piece, sufficient to entirely cover the bottom area and extend about 6 feet up the sides of the inclosure. This canvas was "formed-in" by wooden forms along the sides and ends, to provide a runway for water around the edges. Steam coils were placed around the sides of the pit inclosure and the entire space was housed in and made warm. Sand and gravel delivered on cars were heated by being dumped on a platform holding perforated steam pipe coils, and hot water was used in mixing.

Concrete was poured at the south pier, containing 1,456 cubic yards from October 24 to November 11, 1920, during which time temperature readings ranged from −2° to + 48° F. At the north pier, containing 1,520 cubic yards, the pouring was from December 1 to December 18, 1920, when temperatures ranged from −12° to + 34° F. The pit was kept unwatered, and the concrete was placed from chutes and pipes leading from mixer to pier. All concrete was given sufficient time to set before allowing cold water to come in contact with it.

Erection of Steel Channel Span. To hasten erection of the 504-foot span, it was necessary to proceed without waiting for completion of the piers. False work for this span had been driven from the north end. The north approach trestle, piers and falsework for timber spans were driven and a temporary deck laid. One of the 70-foot pony spans was used temporarily to span the excavation for the north pier, thus permitting the construction of this foundation.

Erection of steel started November 8, 1920, from the north end at panel point No. 2, a yard having been constructed on the north side of the river which was reached

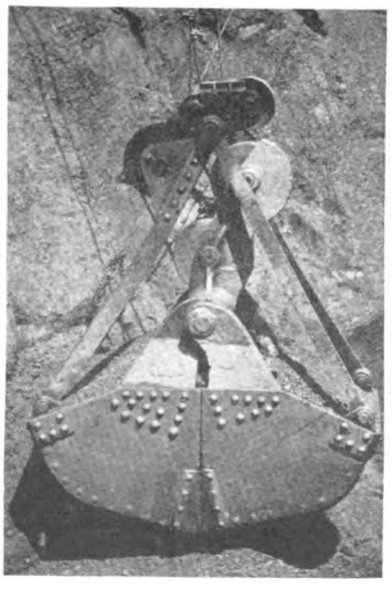
by means of the temporary trestle. Erection was continued to the south end and all steel except for the two north panels was assembled by December 15, 1920. Steel in these two panels which did not interfere with the 70-foot pony span was placed after December 25. As soon as this temporary span was removed, the rest of the steel was placed, completing the erection on January 8, 1921.

A 100-ton locomotive crane with a boom having extensions to make a total length of 85 feet was used for the erection, being supplemented in the yard by a 35-ton locomotive crane with 50-foot boom. The total weight of steel in the span is 1,803 tons. Only a little riveting was done after December 20, 1920, when over 90 per cent of the span was in place, but the work was then pushed until completion on February 9, 1921, during which time temperatures ranged from —42 to + 34° F. On some cold and windy days the riveters did not work; but on one occasion rivets were driven when it was —42° in the morning and —12° at quitting time. Rivets driven during very low temperatures were retested several times later in warmer weather and showed first class work. The total number of field rivets was about 42,200.

The span was swung February 2, 1921, and the first train passed over on February 6. The work of erecting the timber spans and finishing the trestle progressed simultaneously with the steel erection, so that the bridge was entirely completed and ready for service on February 16.

General supervision of the work was under Col. F. Mears, Corps of Engineers, chairman and chief engineer of the Alaskan Engineering Commission. The preliminary design of the 504-foot steel span and the design and details of the timber spans and foundation work were made by W. J. H. Fogelstrom, former bridge engineer for the Commission, assisted by F. H. Chapin, assistant bridge engineer. Final design and details of the 504-foot steel span were made by the American Bridge Co., which also fabricated and erected the steel. All designs and detail plans of steel work were checked and approved by Modjeski & Angier, consulting engineers, Chicago; Hildreth & Co., Chicago, performed the inspection of steel at mill and shop.—*Engineering News-Record.*



Marine Borers in San Francisco Bay

A committee of the American Wood Preservers' Association has published a "Report on the San Francisco Bay Marine Piling Survey," prepared in co-operation with the U. S. Forest Service and the University of California. This report is of much interest to engineers dealing with timber work in sea water.

The investigation was occasioned by a recent extension of the activity of marine borers to the upper arms of San Francisco Bay. As is well known, San Pablo and Suisun Bays receive a large inflow of fresh water from the Sacramento and San Joaquin Rivers. For this reason they were formerly practically free from marine borers. As their shores offer unusual facilities for the establishment of water-front industries, many structures have been built along them; all on untreated piling. Sporadic attacks of borers had been reported at intervals dating back to 1870, but no case was authentically recorded until 1914. In 1917 marine borers reappeared, and during the two years follow-

ADAPTABILITY FOR ANY KIND OF WORK

WILLIAMS BUCKETS

Whether it be in loading or unloading and handling all kinds of bulk materials, for dredging and excavating work, or for any of the many heavy capacities in which buckets are commonly employed, WILLIAMS BUCKETS may be relied upon thoroughly.

Williams Buckets

"Built to Dig and Last While Digging"

They live up to their name. They are built to give constant service. Built with large bearings and with well-guarded cables. They hold their alignment and stand the gaff in all kinds of digging and handling.

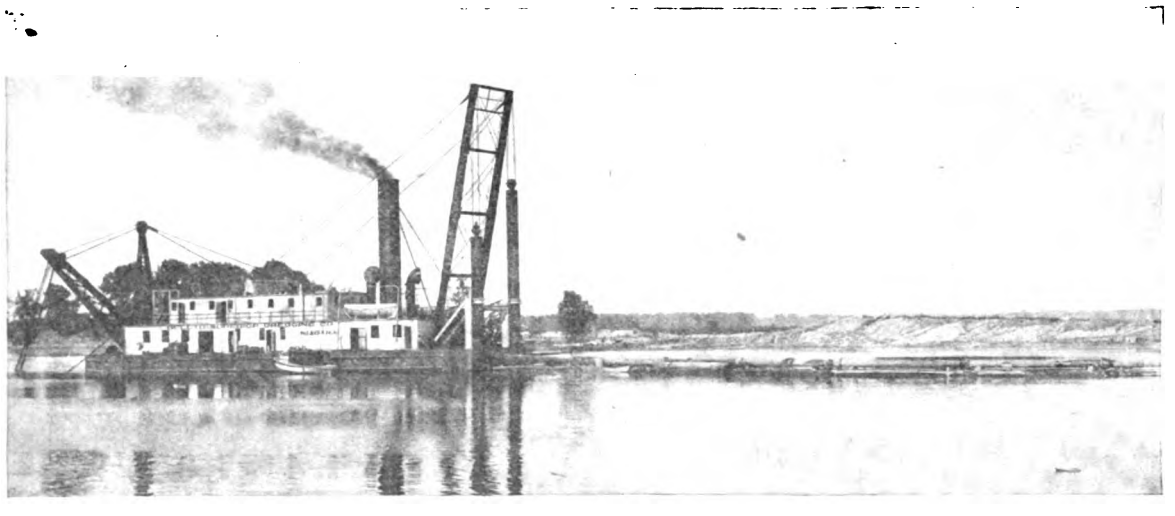
ing spread rapidly. By the latter part of 1919, widespread damage to wharves and similar structures had occurred.

The report is in three parts. The first, prepared by Mr. C. E. Grunsky, assisted by Capt. C. S. Jarvis, Corps of Engineers, deals with hydrography of the upper bay, and the causes leading to a recent increase in the salinity of the waters.

The second part, prepared by Prof. Chas. A. Kofoid, gives a very complete description of the borers infesting San Francisco Bay, their modes of attack, and their methods of propagation. As to boring mollusks, Professor Kofoid says that the well-known teredo (*Terēdo navalis*) is a recent acquisition in the bay, not having been discovered in 1910, when an examination was made. The variety long existent in the lower bay, and throughout the Pacific Coast, is a different species, much larger than the teredo proper. The new arrival will live in water less salty, so that the recent damage may be due to the introduction of the teredo navalis in conjunction with a decrease of the effective fresh-water inflow.

All boring mollusks propagate through free swimming larvæ, minute in size, which have a larval life of about a month; after which they attach themselves to the timber. A single borer will produce two million larvæ in a year, so that the spread of the pest is very rapid. The larvæ do not feed on the wood, but bore into the timber for protection, as a clam buries itself in mud.



Of crustacean borers, two species, one of which is the well-known limnoria, are reported to infest the bay. Crustaceans do not propagate through larvæ. The comparatively few young produced are ready to dig themselves into the wood at once. The limnoria spread locally therefore in much the same way as the mange spreads. The breaking away of fragments of infested wood, the wash of tidal waters, and occasional wanderings of individuals spread the infestion from timber to timber, and shipping carries it around the world.

The report points out that all ports are subject to repeated invasions of borers from other localities, through larvæ carried by sea currents or in the water tanks of steamers; and through infested driftwood, wooden vessels, and timber rafted by sea. It also brings out the interesting fact that barnacles, ordinary salt water mussels, and certain other marine growth are indicators of suitable conditions for the teredo. Where these are found the teredo is likely to spread if once introduced. The appearance of these parasites in upper San Francisco Bay is reported to be coincident with the appearance of the teredo.

The third part of the report deals with a survey of the protection measures that have been tried in the infested waters of the lower bay. Untreated Douglas fir will last but a few years, sometimes less than a year. An additional life of one or two years is to be expected when the bark is left on the piling, although this protection is fragile, and likely to be knocked off in spots before or after driving. One of the early forms of protection was the sheathing with copper or yellow metal from below the mud line to high water. While this treatment has produced good results, it is expensive, is subject to damage in handling and driving, from driftwood and from thieves after the piling is in place, and also to the danger that mud scour will expose unprotected wood.

Several types of protective coating (heavy bituminous or asphaltic paint, covered with burlap, felt, wire mesh, battens, etc.) have been tried. The committee concludes

that if piling is properly treated by one of these processes, and is not damaged by careless handling, a life ranging from five to eight years in quiet waters may be obtained. Otherwise such a life cannot be expected.

Concrete protection for wooden piles has been tried, with varying success. The committee gives the details of construction and the results secured by the various processes, and concludes that well constructed precast casings which have been in service for ten years show no evidence of deterioration and seem capable of long further life. Concrete pile jackets and cylinders cast in place give satisfactory results if properly constructed of suitable material. The difficulties in construction are such that the probability of success is less than in precast coverings. A number of failures are reported due to such causes as flooding of concrete while placing; mud and sand pockets, holes caused by arching of the concrete, laitance pockets; and the exposure of unprotected wood on account of dredging or scour.

Treated piling has been largely used in San Francisco Bay, and the committee was able to secure data of value covering structures involving a total of over 35,000 piles. It concludes that properly treated and carefully handled Douglas fir bearing piles may have a life of from 25 to 30 years. Poorly treated piles and those damaged in handling cannot be expected to last nearly so long. Most of the attacks on creosoted piling appear to have begun at spots where the shell of treated wood had been injured in handling and placing.

Precast re-enforced concrete piles have been satisfactory in these waters but none have been in use in this locality for a sufficient time to determine their ultimate life.

The report is published by the San Francisco Marine Piling Committee, of which Mr. F. D. Mattos is chairman. —*G. B. P.*

An Approved Solution

(See Military Engineer, July-August, p. 387.)

Problem No. 1—Military Bridges

Requirement 1—

The selection of the kind of bridge to be built is governed by the load, the nature of the obstacle, the materials available, the time available and the number of men available. These governing factors are laid down in the special situation.

There are two general classes of military bridges, viz.: floating and fixed. We may eliminate the floating bridge from consideration immediately because time, materials and men are available for building a more permanent type of bridge.

The types of fixed bridges to be considered are as follows:

(a) Simple stringer bridges,
(b) Suspension bridges,
(c) Truss bridges,
(d) Spar bridges,
(e) Pile bridges,
(f) Trestle bridges.

Considering each of these types in the light of the factors governing our selections, we arrive at the following:

(a) A simple stringer bridge is out of the question because the load is too great for the length of span and the size of timber available.

(b) Material is not available for a suspension bridge.

(c) It is possible with the material available to span the stream by a wooden truss bridge. Such a bridge will require more time to build than other types. It will necessitate skillful framing and accurate joining to develop its full strength. This type should be selected only in case we should find that another type will not suffice.

(d) A spar bridge is rejected as lacking sufficient strength and stiffness and being only temporary in character.

(e) A bridge supported on pile bents is possible, but should only be considered in case the character of the stream-bed is such that trestle bents can not be supported thereon. Pile driving requires special equipment and consumes time.

(f) In considering a trestle bridge the character of the stream bed is the governing factor here. The bed is such that the trestle can be supported without any elaborate preparation of trestle foundations in the form of cribs or piles and the velocity of the stream is not so great that there will be much danger of the material washing out from under the trestles.

There are, therefore, three possible types of bridge that could be erected at this location using the materials available. These are, the truss bridge, the pile bridge and the trestle bridge. Of the three types the trestle bridge is selected because it is the simplest in construction and requires the least amount of time to build.

Requirement 2—

Notes on Design

The trestles in the design on page 459 are considerably stronger than are required for the immediate load which the bridge is to take. Each trestle will support a load of about 12 tons including dead load, the load being limited by the ability of the trestle cap to support the loads brought upon it by the stringers. The bearing power of the stream bed is assumed to be about 2 tons per square foot. This trestle can be built and erected in about the same time that it would take to build one of 6×6 pieces so that no time is lost in gaining this additional strength and the result is a trestle that can be used in case it ever becomes necessary to alter the bridge for heavier loads.

The stringers are selected on the assumption that each stringer must take a concentrated load at its center equal to one-fourth of the axle load. The axle load is taken as 5,800 pounds which is the weight on the rear axle of the 1½-ton truck. The front axle of the truck is neglected because of the fact that the length of wheel base of the truck is 11 feet 6 inches and the length of bay of the bridge is only 15 feet.

While four stringers would carry the load, six are preferred because of the greater power of resistance thus given to the flooring.

The flooring is made of 4×8 pieces because such a floor can be more quickly laid than could a double layer of 2×8 pieces. A two-inch thickness of flooring will not stand the wear to which the bridge is to be subjected.

Handrails are omitted, although if the bridge is later to be used for the passage of men or horses in considerable numbers their addition would be advisable.

All joints in the trestles are made square in order to simplify construction. The outside posts of trestles are drift-bolted to the cap and sill and the inner ones are toe-nailed. Similarly the outer stringers are drifted bolted to the caps and the inner ones are toe-nailed. Each floor plank is spiked to all stringers although if unforeseen de-

Digitized by Google

lays occur they may only be spiked to alternate stringers. The wheel guards are fastened to the floor planks by lag screws spaced 4 feet apart. Longitudinal and transverse bracing are nailed to the trestles.

REQUIREMENT 3—

Prior to the arrival of the material the entire company will be employed on clearing away the wreckage of the former bridge, making measurements, and improving the ford just east of the site so that the wagons for hauling lumber may be put across the stream. At nine o'clock the organization of the company will be as follows:

Hauling detail—3 wagoners with teams and wagons.
Loading detail at cars—1 N. C. O. and 9 men.
Unloading detail at bridge—1 N. C. O. and 6 men.
Trestle building details—2 N. C. O.'s and 12 men.
Footing and abutment details—2 N. C. O.'s and 14 men.
Sawing and boring detail—1 N. C. O. and 8 men.
Carrying detail—1 N. C. O. and 8 men.

The above organization will hold during the first phase of the work which includes the time required to build the trestles and prepare their footings.

When the trestles are ready to be launched the following organization will be made and maintained until the end of the work. When any detail finishes the work allotted to it the members may be assigned to help out other details if necessary:

Hauling detail—As before.
Loading and unloading details—As before.
Sawing and boring detail—As before.
Carrying details—2 N. C. O.'s and 20 men.
Building details—2 N. C. O.'s and 20 men.
Total—7 N. C. O.'s and 66 men.
This does not include the regular details on the platoon tool wagons.

The bridge will be built from both ends simultaneously, there being a building detail of 1 N. C. O. and 10 men at each end with a carrying detail of 1 N. C. O. and 10 men. The N. C. O. in charge of the carrying detail will be placed under the orders of the N. C. O. in charge of the building detail. The building detail will perform all of the actual construction work from the placing of the trestles to the laying of curbs. The carrying detail being subordinate to the building detail may be used on the heavier work of construction where necessary, as for example in the launching of trestles. One lieutenant will be placed in charge of the erection of the bridge.

REQUIREMENT 4—

7 a. m. - 9 a. m.—Removing wreckage, preparation of ford and measuring for trestles.
9 a. m. -11 a. m.—Hauling material, building trestles and preparing footings.
11 a. m. - 3 p. m.—Launching trestles. Placing stringers, laying flooring and curbs, bracing and filling. One-half hour will be allowed for lunch during this period.

The estimated time of completion (3 p. m.) is based upon the assumption that the unloading of the railroad cars will commence promptly at 9 a. m. The first wagon load of timbers (which should be 8×8 pieces for the trestles) should be at the bridge site by 9:30. This will allow each trestle building detail 1½ hours for the completion of its trestle. During the third period 45 minutes are allowed for launching the trestles, 45 minutes for placing stringers (including the middle bay of which three stringers are placed from each end) and 2 hours for laying floor planks and curbs and putting in longitudinal bracing.

REQUIREMENT 5—

Tools Required	*Where obtained*
4 saws—2 man	Platoon tool wagons
12 saws—hand	do.
2 braces and bits	do.
6 augers ship 1 1-16	Platoon tool wagon and company reserve
8 claw hammers	Platoon tool wagons
8 rules—2 foot	do.
3 squares, steel	do.
4 tapes—50 foot	do.
4 chisels, framing	do.
2 mallets	do.
12 hatchets	do.
2 carpenters levels	do.
6 axes	do.
2 plumb bobs	do.
8 sledges	Platoon tool wagon and company reserve
2 adzes	Platoon tool wagons
6 blocks—8 inch	do.
10 picks	do.
20 shovels	do.
4 wrenches	do.
500 feet rope	do.
300 feet tracing tape	do.
3 escort wagons	Div. Eng.

Bill of Materials

14 pieces 8×8×14 (trestle posts, caps and sills and bridge seats)
18 pieces 6×8×18 (stringers)
6 pieces 6×6×16 (curbs)
74 pieces 4×8×12 (floor planks and end dams)
4 pieces 2×8×18 (transverse bracing)
4 pieces 2×8×22 (longitudinal bracing)
20 drift bolts 14″×¾″ (trestles and stringers)
26 lag screws with washers 9″ (curbs)
80 lbs. wire spikes 8″
10 lbs. nails 50 D

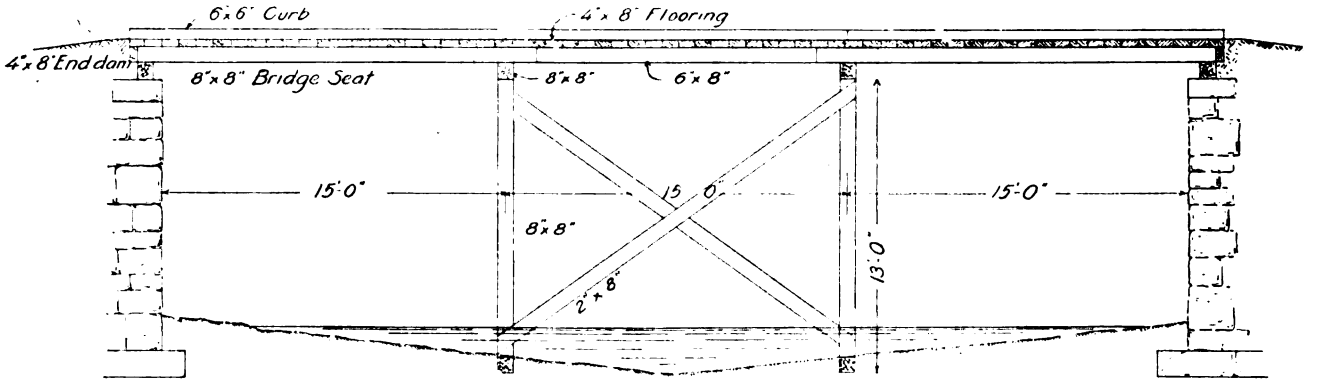
All material to be requisitioned from Division Engineer.

REQUIREMENT 6—

There is hardly any need for security measures in this case. Certainly there is no need therefore if the Blue army is to resume the advance the first thing in the morning, but of this we are not absolutely certain. The positions of our advance cavalry and advance guard are such that the only enemy troops against whom security is to be furnished will consist of cavalry which, if it gets this far in rear of our advance guards, will be fast moving and hence confine itself to open country. One automatic team and a corporal placed at the cut where the ACCOTINK STATION ROAD crosses the TELEGRAPH ROAD will therefore be sufficient and even this may be dispensed with after the main body of the Blue army advances.

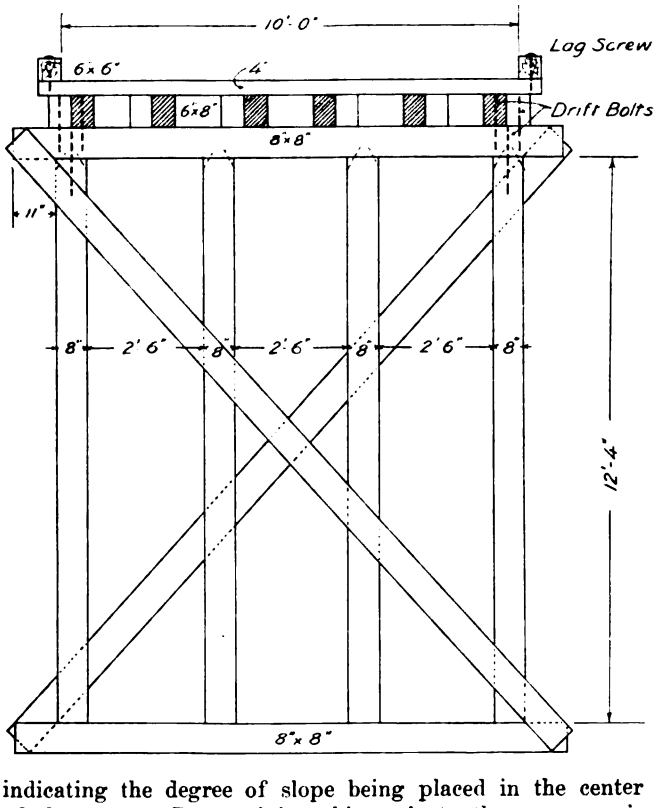
Solution to Questions on Map Reading

(See page 388, MILITARY ENGINEER, July-August, 1921.)



1. (a) 3 inches = 1 mile.

The representative fraction is given on the sheet as 1/21,120, which means that 1 inch measured on the map is equivalent to 21,120 inches on the ground. There are 63,360 inches in a mile. Therefore 1 inch on the map represents $\frac{21,120}{63,360}$ or 1/3 mile on the ground. Hence 3



Digitized by Google

inches on the map represent one mile on the ground.

(b) The abbreviation M. D. stands for Map Distances, and the scale underneath is called a scale of map distances. This scale shows the distance, on the map, between adjacent contours on slopes from 1° to 10°, the number

ELEVATION

indicating the degree of slope being placed in the center of the space. By applying this scale to the map one is able to express in degrees a slope which is represented on the map by the distance between contours. For any given degree of slope the length of the corresponding division multiplied by the denominator of the representative fraction gives the horizontal distance which one must travel along a slope of that degree in order to rise one contour interval or 20 feet.

2. (a) 280°
   (b) 287°
   (c) N — 73° — W

The above values are found as follows:

Through the cross roads 533 at Koons draw a true north and south line. This may be done with a triangle by drawing a line perpendicular to top boundary line of the map. Then draw a line connecting the cross roads with Centennial School House; place the center of a protractor over the intersection of these two lines and read the angle between them remembering that azimuths read from zero at the north through east, south and west to 360°.

At the bottom of the sheet is a small figure which shows the relation between the true north and magnetic north, the magnetic north being 7° west of true north. This is called the magnetic declination. Hence the angle measured in a clock-wise direction which the given line makes with the magnetic north is seven degrees larger than the angle which it makes with the true north.

Since the given line lies in the fourth quadrant the magnetic bearing is found by subtracting the magnetic azimuth from 360°.

3. (a) 522 feet. This occurs about 150 yards southeast of cross roads 500, the road passing over a divide at this point.

(b) 360 feet. This occurs at the bridge over the Monocacy.

(c) About 3 degrees at cross roads 476.

(d) About 7 degrees 750 yards southeast of cross roads 476.

These maximum grades are determined by finding the points where the contours are closest together along the road and applying the M. D. scale to the distance between adjacent contours.

4. Length of stride: 59.9 inches.

R. F. of this map: 1/8554.

Since the scale of his map is 1:10,000 the length of a 70-inch stride on the scale which he used is $\frac{70}{10{,}000} = .007$ of an inch. In order to plot 10 inches on his map he therefore must have taken $\frac{10}{.007} = 1428.55$ strides. The actual distance from cross roads 472 to cross roads 476 found by scaling it from the Taneytown sheet is 2376 yards = 85,536 inches. Hence the length of strike taken was $\frac{85{,}536}{1428.55} = 59.9$ inches. Since 10 inches on his map represents 85536 inches on the ground the R. F. of his map is $\frac{1}{8553.6}$.

5. Rate of horse: 4.3 miles per hour.

R. F. of his map: 1/14,246.

At the rate of 6 miles per hour, one minute on the scale used represents 1/10 mile = 528 feet. The length of a one minute division on a 1/20,000 scale is therefore $\frac{528}{20{,}000} =$ .0264 feet = 0.3168 inches. Therefore in order to plot 6

Digitized by Google

inches the sketcher must have ridden $\frac{6}{0.3168} = 18.95$ minutes. The actual distance is 2376 yards. In covering this distance in 18.95 minutes the correct rate of the horse must have been $\frac{2376}{18.95} \times \frac{60}{1760} = 4.27$ miles per hour.

Since 6 inches on his map represents 85536 inches on the ground the R. F. of his map must be $\frac{6}{85536} = \frac{1}{14256}$.

6. At the farmhouse about 800 yards east of cross roads 533. This is the highest elevation on the road. As it lies on the ridge line about midway between the 560 and 540 foot contours we may take its elevation as about 550 feet. Since this is higher than the observer's station and there is no higher ground along the road to the east of it the patrol will be obscured until it reaches this point.

7. No.

This may be determined either by constructing a profile along the line of sight or by inspection. If a profile is constructed it will be seen that the line of sight from the observer to the ford cuts two intervening ridges. It should not be necessary, however, to construct a profile in order to determine the visibility in this case. By inspection we can see that the ridge about 300 yards northwest of the ford must obscure it as this ridge is 40 feet higher than the ford while the total difference of elevation between the observer and the ford is 92 feet in a distance of 3,800 yards. In other words a ridge 40 feet higher than the objective must not be nearer to the objective than $\frac{40}{92}$ of the total distance in order to permit of visibility of the objective.

8. (a) No.

An inspection of the contours shows that they are grouped much closer together at the bottom of the slope than at the top, so that shots which will just graze the upper slope will be too high to strike an object at the bottom of the slope.

(b) Yes.

The elevation of the gun at the farmhouse is taken as 465 feet. The elevation of the cross roads is 472 feet, and there are no intervening ridges.

(c) Yes. On the ridge about 250 yards west of T-roads 419.

The slope of the line from the farm to the bridge is considerably steeper near the bridge. Hence the bridge will be obscured. The bridge is also beyond the 1,500-yard range of the gun. The gun must therefore be moved toward the bridge. In order for the gun to fire downward on a target the maximum descending slope of the ground along the range must occur immediately in front of the gun; that is, the contours must be closer together at that point than at any other. A location for the gun with such a slope to the front is found on the ridge about 250 yards west of T-roads 419. The elevation of this point is taken as 415 feet. The range to the bridge is 450 yards.

Problem No. 2—Demolition

Map References:

Mount Vernon Quadrangle U. S. G. S.

Northwest Section, Camp A. A. Humphreys 1:5000.

General Situation:

Two hostile forces have been in contact for the past week with their lines of outposts along Accotink Creek—Red, south, and Blue, north. The commander of the Blue force has decided to withdraw from this position.

Special Situation:

You are a lieutenant of Engineers assigned to a company of divisional Engineers of the Blue force. Your division is to withdraw along the Telegraph Road to the northeast. You receive orders from your Captain to prepare to obstruct the Telegraph Road at point 3,751 by means of a crater. The width of the road at this point between the drainage ditch on the up-hill side to the berm on the down-hill side is 25 feet. The roadbed is gravel. The earth underneath the roadbed is yellow clay with a small proportion of sand and gravel. T. N. T., Ammonal, 40 per cent Dynamite and Black Powder are available.

Required:

1. Explosive to be used and number of pounds required.
2. Method of placing charge or charges.
3. Method of firing the same.
4. Time and number of men required to prepare the mine and place the charge after the delivery of necessary materials to the site.

Note.—In the preparation for this problem the following text is given for study and references: Engineer Field Manual, Part V, Pars. 181-236.

Map Co-ordinates:

For the benefit of those who are unfamiliar with the use of rectangular co-ordinates for the designation of points in connection with map problems the following explanation of the system and the method of designation used will be given:

The system used on the Camp Humphreys map is the grid system, now prescribed in Army Regulations 100-15, Section IV. On all standard military maps the continental area of the United States is projected by means of the polyconic projection on seven zones of nine degrees extent in longitude and of indefinite extent in latitude. This division into zones of separate projection was found necessary in order to keep the errors inherent to the polyconic projection within reasonable limits. These zones are lettered A, B, C, etc., from east to west. In each zone a grid system is used in which the north and south lines are parallel to the central meridian of the zone and the east and west lines are perpendicular thereto. The origin of co-ordinates is taken in each zone at the intersection of the 40°-30′ parallel of latitude with the central meridian of the zone. The length of the grid divisions along the X and Y axes is 1,000 yards. In order to eliminate the use of negative co-ordinates to the west and south of the origin arbitrary values of X = 1,000,000 and Y = 2,000,000 are assigned to the origin. In any one zone, therefore, such as Zone A, a place on the earth's surface has an X and a Y co-ordinate which are fixed and remain unchanged no matter what the scale of the map upon which the place is shown. It is possible in such a system to designate the position of such a place down to the nearest yard, as, for example, X = 1,155,643; Y = 2,463,875, which would mean that the place in question is 155,643 yards east and 463,875 yards north of the origin. In actual practice the full designation is rarely used. To illustrate the manner in which the designation is contracted, taken as an example the point given above, whose co-ordinates are

X = 1,155,643,
Y = 2,463,875.

The last three figures in each co-ordinate indicate the number of yards which the point lies to the east of grid line 1,155 in one case and north of grid line 2,463 in the other. Hence, if we wish to designate the point to the nearest 10 yards, the last figure in each co-ordinate can be left out and the co-ordinates could be written as

X = 1155.64,
Y = 2463.88.

Digitized by Google

Or if it is desired to give the co-ordinates to the nearest 100 yards we might write

X = 1155.6,
Y = 2463.9.

In both cases the decimal point is used to separate the designation of the 1,000-yard grid line from the number of tens or hundreds yards beyond it to the place in question. The first four figures of the designation indicate the number of the grid line. On a map whose X and Y dimensions are not greater than 10,000 yards, the fourth digit from the left in each co-ordinate designation will occur but once. It is therefore possible on such a map to identify the grid line by means of this fourth digit. Hence the first three digits may be eliminated and the co-ordinates of the point might be written as

X = 5.6,
Y = 3.9.

Instead, however, of giving the X and Y co-ordinates separate they are combined, the X co-ordinate being written first and the decimal point being omitted. The designation of the point, therefore, is 5639. These four digits are all that are necessary in order to give the proper designation of a place to the nearest 100 yards on a map where the X and Y dimensions of the sheet do not exceed 10,000 yards. If, however, the dimensions of the sheet are greater than 10,000 yards, it is evident that the fourth figure in the full designation may occur—that is, here may be two grid lines on the sheet, the fourth digit of whose numbers are the same. In such a case it becomes necessary to give the third figure in the designation, and the proper way of writing the co-ordinates of the place to the nearest 100 yards is

55.6 — 63.9.

When it is desirable to give the co-ordinates to the nearest 10 yards of a place whose co-ordinates are given by means of four digits to the nearest 100 yards, it is necessary, in order to avoid confusion, to use decimals and dashes.

Thus the point 5639 when designated to the nearest 10 yards becomes

5.64 — 3.88

and to the nearest one yard, if necessary,

5.643 — 3.875.

If the co-ordinates of the place to the nearest 100 yards are written in the form

55.6 — 63.9,

and it is desired to designate the place to the nearest 10 yards, the co-ordinates will be written

55.64 — 63.88

and to the nearest one yard

55.643 — 63.875.

The system of designation described above is sufficient to unequivocally define the position of a place on any one map sheet. If several map sheets are used in a problem or operation covering an extended area, it is necessary to precede the co ordinate designation by the name of the map sheet, as, for example, Taneytown 5639.

Exercise in the Use of Map Co-ordinates.

The following exercise is given to enable the reader to gain some practice in the use of map co-ordinates. The use of a 45-degree triangle with the two legs of the triangle graduated in hundreds of yards, the zero being at the vertex of the right angle is recommended. The scale of the graduations should be 1:5000 for use on the Camp Humphreys Map (northwest section), to which the following questions refer:

(1) Give the co-ordinates of the farmhouse at Masons to the nearest 100 yards.

(2) Give the same to the nearest 10 yards.

(3) Where is the origin of co-ordinates of this map with respect to Pohick Church?

(4) How would you write the co-ordinates of the Kernan house to the nearest 10 meters?

(5) Suppose that the Kernan house were on a map sheet the same size as the present sheet, but on a scale of 1:20,000. How would you write its co-ordinates to the nearest 100 meters?

(6) What is the feature whose co-ordinates are given as 2418? What is the feature at 3.24 — 1.72?

(7) Give the co-ordinates to the nearest 100 yards of the following:

(a) Pohick Church.

(b) Intersection of Telegraph Road and Standard Gauge R. R.

(c) Cemetery in Accotink Village.

Military Art, Note 3

Map Problem No. 2. A Solution.

The following is a solution of Map Problem No. 2, which was published in the July-August issue of THE MILITARY ENGINEER, page 392:

First Requirement.

Detachments—

(a) One platoon and one motorcycle via Taneytown-Longville-Harney road to Piney Creek church.

(b) One platoon and one motorcycle via Taneytown-Bridgeport road to vicinity of Alexander house.

(c) Improvised mounted detachment to vicinity of road-fork 433, one and one-half miles south of Bridgeport, via road leaving Taneytown by southwest.

Reasons:

Major M has a rather large area to cover; he must keep it under observation, and he must be sure of getting messages from his detachments without delay, in order that he may transmit information to the regimental commander promptly.

The infantry forces are considerably stronger than any probable Red forces in the area. By taking posts at the points indicated they cover the general road system approaching Taneytown, from Koon's to Bridgeport, both inclusive, and so render reasonably safe the despatch of messages by the motorcycles. They are also sufficiently large to send out patrols large enough to go anywhere within the area that may be necessary.

The mounted detachment covers the roads south of the Taneyown-Bridgeport road and watches the frontier in the general vicinity of Stull's.

The infantry detachments are somewhat larger than he would send if this duty were likely to continue for several days. But this arrangement preserves the integrity of tactical units and, in view of the relatively large force which the detachment commanders will have, the actual fatigue on the individual men should not be great. No other duty is anticipated for Co. B tomorrow and Major M believes that the experience gained in marching in the probable presence of the enemy and the knowledge of the territory which the officers will obtain will prove of value later.

Second Requirement.

Major M sends his orderly for C. O. Co. B, Lts. B (commanding first platoon of Co. B) and C (commanding second platoon of Co. B), Lt. L (commanding the improvised mounted detachment) and Lt. D, the battalion adjutant (who has charge of the motorcycles). At 10:25 p. m., when they have all assembled in his tent, Major M dictates the

Digitized by Google

following verbal order, pointing to the map when roads and locations are mentioned and giving the officers time to orient themselves as he speaks:

(Note.—It is assumed that the information concerning the enemy and the Blues contained in the General Situation and Problem No. 1 is known to these officers and that Major M has informed them of his instructions to Co. A.)

"The following telephone message was received from the Regimental Commander at Littlestown at 10:00 p. m." (Reads his record of that message.)

"I shall send out three detachments.

"Lt. B, you will proceed with your platoon and one motorcycle by the Taneytown-Longville-Harney road to the vicinity of Piney Creek church. From there, by means of strong patrols, keep the area Piney Creek church-Koon's-Harney under observation and connect with Lt. C at the Alexander house.

"Lt. C, you will proceed with your platoon and one motorcycle by the Taneytown-Bridgeport road to the vicinity of the Alexander house, half a mile east of the Monocacy. From there send strong patrols to Harney via Pinehill Mill and toward Bridgeport and connect with Lt. L at road fork 433, two miles to the southwest. Do not attempt to enter Bridgeport in the face of strong opposition.

"Lt. L, you, with your mounted detachment, will leave Taneytown by the southwest and proceed via the Harner house to the vicinity of road fork 433, just mentioned. Maintain a lookout of two men to observe the country across the Monocacy and to the south and, about once an hour, send out a patrol of three or four men to get a more extended view from the 426-427 ridge, three-quarters of a mile to the west, and from hill 524, a mile and a half to the south. Relay your messages through Lt. C and, on returning, come by this road. (Fink, 456, 507, 490, Taneytown; south of the Taneytown-Bridgeport road.)

"Report to me here promptly the first definite information concerning the enemy and any later substantial development, such as a new body or material change in position of one previously reported. If no Reds have been seen by 1:00 p. m. send me a message to that effect at that time.

"Patrols will start from camp at 6:30 a. m. and will be back in Taneytown between 6:30 and 7:00 p. m. The men will go in light marching order.

"Lt. D, you will provide Lts. B and C with a motorcycle, each."

Map Problem No. 3—An Outpost

Maps.—

Gettysburg General Map.

Gettysburg 3-inch Map, Kingsdale, Taneytown and Emmitsburg sheets.

General Situation.

This problem is a continuation of Map Problems Nos. 1 and 2, which were published in THE MILITARY ENGINEER, Vol. XIII, No. 69, May-June, 1921, pages 302 and 303, and No. 70, July-August, 1921, pages 391 and 392.

Special Situation.

Same as Special Situations for Map Problems Nos. 1 and 2, with following additions:

Complying with the regimental commander's order to keep the general area Koon-Harney-Bridgeport-Stull-Taneytown-Longville-Koon under observation, Major M sent out the following forces, under light marching order, early on the morning of June 4th:

Detachment No. 1—First platoon Co. "B" and one motorcycle by the Taneytown-Longville-Harney road; to take post at Piney Creek church, send strong patrols to Koon's and Harney and connect with Detachment No. 2.

Detachment No. 2—Second platoon Co. "B" and one motorcycle by the Taneytown-Bridgeport road; to take post near the Alexander house, send strong patrols toward Bridgeport and to Harney, via Pinehill Mill and connect with Detachment No. 3.

Detachment No. 3—Improvised mounted detachment by the Taneytown-Harner house-489-433-Stull road; to patrol between Stull house and Alexander return by the road south and generally one mile distant from the Taneytown-Bridgeport road.

Co. "A" arrived at Taneytown from Silver Run at 10:20 a. m., without seeing any Reds.

By 5:00 p. m. the information received by Major M from his observation groups is as follows: Six or eight mounted men withdrew from Harney west across the Monocacy on the approach of the patrol from Piney Creek church. The crossing at Bridgeport was held in such strength that the patrol from Alexander made no attempt to cross. From the hill one-half mile north of Stull's, four to six mounted men were seen at several times during the day at hill 404, one mile to the west.

The regimental commander telephones from Littlestown that he has no further information of the enemy and that the orders for the regiment remain unchanged.

Required:

(1) Major M's outpost order for the night of June 4-5.

(2) Sketch showing locations and designations of the various elements of the outpost. (Trace outline from 3-inch map.)

(3) Tabulation showing number of men required for each element of the outpost and tactical unit or units from which each element is obtained. Account for the entire force assigned to the outpost by Major M's order.

References:

The following references, in addition to those listed at the end of Map Problems Nos. 1 and 2, should be studied in connection with the above problem:

Technique of Modern Tactics, Chapter X.

Field Service Regulations, pars. 60-88 inc.

General Subjects. Note 3

An Approved Solution Test on Infantry Drill Regulations

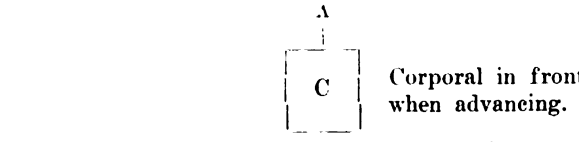
(See page 10, Military Instruction, Vol. XIII, No. 70.)

By Maj. Peter C. Bullard, C. E.

(References are to "Infantry Drill Regulations, Provisional, 1919.")

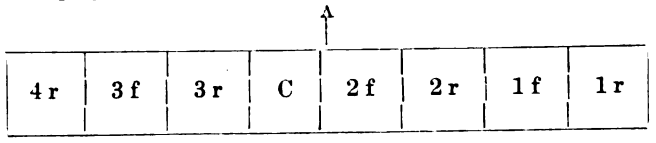
Question No. 1. Ref. Par. 106—

In the squad, seven (including the corporal) are armed with rifles, one with an auto-rifle. One rifleman is equipped with a grenade discharger. They are arranged as follows:



C 4 R	3 R	2 G D	1 R	front rank
4 R	3 A R	2 R	1 R	rear rank

C = Corporal
R = Rifleman
AR = Auto-rifleman
GD = Rifleman with grenade discharger
F = Front rank.
r = Rear rank.



Digitized by Google

Question No. 2. Ref. Par. 124—

The squad deployed alone:

Deployed as part of a larger unit.

Question No. 3. Ref. Par. 125—

The normal interval between skirmishers is 5 paces.

Question No. 4. Ref. Par. 119—

Being in line, to turn and march: 1. SQUAD RIGHT (left). 2. MARCH.

At the second command, the right-flank man in the front rank faces to the right in marching and marks time. The other front rank men oblique to the right, place themselves abreast of the pivot, and mark time. In the rear rank, the third man from the right, followed in column by the second and first, moves straight to the front until in rear of his front rank-man, when all face to the right in marching and mark time. The other number of the rear rank moves straight to the front 4 paces and places himself abreast of the man on his right. Men on the new line glance toward the marching flank while marking time, and as the last man arrives on the line both ranks execute FORWARD, MARCH, without command.

Question No. 5. Ref. Par. 185—

Being in column of squads, to form line of sections to the front: 1. Line of sections (so many paces), 2. RIGHT (left), 3. MARCH, 4. *Platoon*, 5 HALT.

At the third command, the leading section moves straight to the front or in the direction indicated by the platoon leader; it halts at the fifth command. The rear section is conducted in column of squads on the indicated flank and halted at the prescribed interval abreast of the leading section; if no interval be indicated in the command, it forms at section frontage from the leading section.

Question No. 6. Ref. Par. 210—

Being in column of squads, twos, or files, or section columns, to deploy as skirmishers: 1. *As skirmishers,* 2. MARCH.

The corporal of the leading squad moves in quick time straight to the front or in the direction indicated by the platoon leader. The leading squad deploys abreast of its corporal (par. 124). The center and rear squads of the leading section deploy abreast of the leading squad, the center squad on its right, the rear squad on its left, men running individually toward their places on the line as soon as disengaged from column. If the leading section consists of only two squads, the rear squad deploys on the right of the leading squad. The rear section deploys abreast of its leading squad and parallel to the line of the leading section as described for that section, the leading squad deploying in place. Unless otherwise directed by the platoon leader, the rear section gains a distance of approximately fifty paces from the leading section, standing fast or moving to the rear after deployment if necessary; if the platoon advances, the rear section follows the leading section, modifying its distance as required by consideration of cover. The platoon sergeant, section leaders and guides, and runners take their prescribed posts.

Squads may be deployed on one flank only of the leading squad of each section by the command: 1. *As skirmishers, right (left).* 2. MARCH. Executed as above described except that in each section the squads in rear of the leading squad of each section deploy on the right and abreast of the leading squad of the section.

Question No. 7. Ref. Par. 207—

The platoon runners are with the platoon leader.

Question No. 8. Ref. Par. 186—

Being in line of sections, to change direction: 1. *Platoon right (left).* 2. MARCH. 3. *Platoon.* 4. HALT. The right section changes direction to the right; the other section is conducted by the shortest line to its place abreast of the right section.

The fourth command is given when the right section has advanced the desired distance in the new direction; that section halts; the other section halts upon arriving on the line.

Question No. 9. Ref. Par. 215—

A section column is a formation in which the section is in column of twos with the leader at the head and the guide at the tail.

Squads are in the same relative order as in normal formation of the section in close order, corporals at the heads of their squads.

Question No. 10. Ref. Par. 249 and page 69.

1. *Squads right.* 2. MARCH.

An Approved Solution. Test on Military Law

(See page 10, Military Instruction, Vol. XIII, No. 70.)

By Capt. Ralph Millis, C. E.

(References are to "A Manual for Courts Martial, 1921.")

Question No. 1. Ref. Par. 198—

(1) The Articles of War. (2) The Federal Constitution. (3) Federal statutes as expressly mention courts-martial. (4) The Manual for Courts-Martial.

Question No. 2. Ref. Pars. 213 (a), *211* (b), *213* (c), *213* (d).

a. No; b. No; c. No; d. No.

Question No. 3. Ref. Par. 206—

a. No, has no bearing on this case.

Question No. 3. Ref. Par. 221—

b. No. Capt. B, who is available, should be called.

Question No. 3. Ref. Par. 222 (8)—

c. Yes. (Statement as to accused's intent or motive.)

Question No. 3. Ref. Par. 222 (10)—

d. Yes. (Statement of deceased person.)

Question No. 4. Ref. Par. 223a—

a. That the person now in court as accused is the same person described in the charges by name, rank, title, and organization.

b. That the person now in court as accused (irrespective of his name, rank, etc.) is the very person who did the act charged and to which act the witness's testimony will refer.

Question No. 5. Ref. Par. 254c—

(1) On cross-examination. (2) To abridge the proceedings, in leading the witness to the points on which he

Digitized by Google

is to testify. (3) When the witness appears to be hostile to the party calling him. Also (4) when there is an erroneous statement in the testimony of the witness, evidently caused by want of recollection, which a suggestion may assist. (5) Where, from the nature of the case, the mind of the witness can not be directed to the subject of the inquiry without a particular specification of it.

Question No. 6. Ref. Par. 225b-c—

In view of the military relations of the parties, the affidavit should be admitted only if it is clearly shown that it was voluntary, and made by the accused with a full knowledge of his rights. Corroborating evidence must also be introduced at some time during the trial.

Question No. 7. Ref. Pars. 237, 238—

When (a) the original has been lost or destroyed (b) the original is a public record required to be preserved on file in a public office, or (c) when the copy is of any record or paper in the War Department, any of its bureaus, or at the headquarters of an army, division, regiment, post, etc., and is authenticated by the impressed stamp of the bureau, office, or headquarters having custody of the original.

Question No. 8. Ref. Pars. 214, 290—

(a) By taking the stand as a witness in his own defense. (b) By making an unsworn verbal or written statement, personally or by counsel.

Question No. 9. Ref. Par. 289—

The recognition by the Court of certain facts, without requiring the introduction of evidence thereon as, for example, the ordinary divisions of time, the organization of the army, the contents of general and special orders of the War Department, etc.

Question No. 10. Ref. Par. 285—

Drunkenness is not an excuse for the crime, or justification for a finding of "Not Guilty," but it may preclude the presence of the deliberate intent required for the crime of murder, thus requiring the findings to reduce the grade of the crime to manslaughter.

Question No. 11. Ref. Par. Art. VI, Sect. 1

He should be tried by General Court. The maximum punishment is dishonorable discharge, forfeiture of all pay and allowances due and to become due, and confinement at hard labor for six months.

Question No. 12. Ref. Par. 366—

He forwards it to the appointing authority or his successor in command.

Question No. 13. Ref. Par. 294—

Voting is by secret ballot, the ballots being counted by the junior member, verified by the president, and the result announced by the president. Each member writes on his ballot, without signature, either (1) "guilty," or (2) "not guilty," or (3) "guilty, with exceptions or substitutions (setting them out in full on the ballot) as to each specification: and as to each charge (1) 'guilty', (2) 'not guilty', or (3) 'not guilty, but guilty of violation of the ------ Article of War,'" (setting it out). If the requisite number of votes of "guilty" without qualification is not received to convict the accused of the specification or charge, but one or more exceptions or substitutions are proposed on the ballots, the president reads such proposals to the court, and a vote is taken on each in turn, beginning with the one which the president considers the severest until all have been voted on, or one has been adopted. If none of the proposed exceptions or substitutions is adopted by the requisite number of votes, the accused is acquitted of that specification or charge. All ballots are destroyed as soon as the result is announced, unless some member of the court wishes to verify the count, when they are destroyed immediately after such verification.

Question No. 14. Ref. Par. 386—

He may (a) disapprove the sentence entirely, or (b) if the sentence is divisible, approve and order executed that portion within the legal limit.

Question No. 15. Ref. Par. 401—

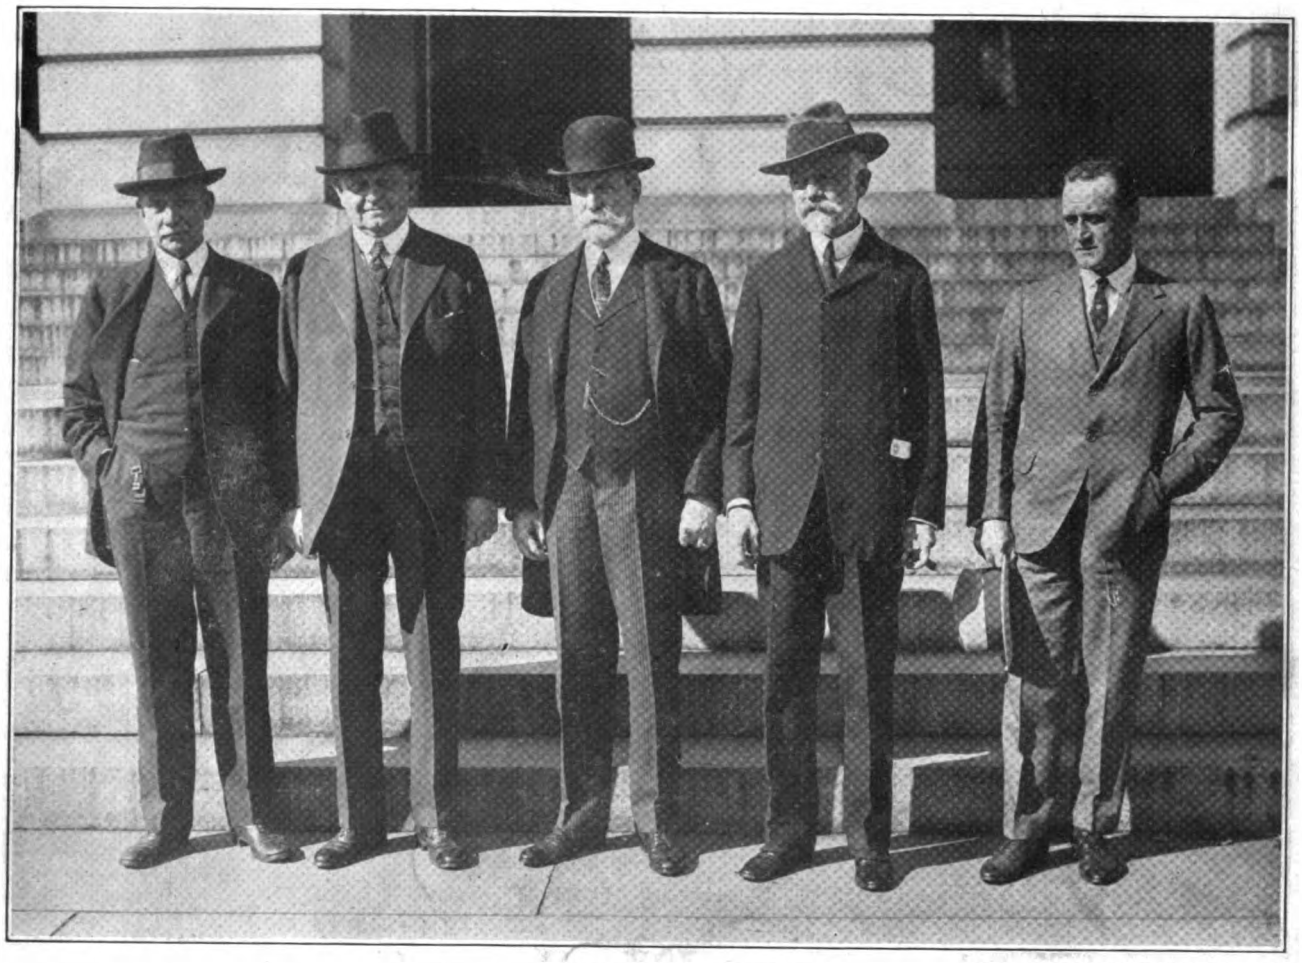
On the date on which the sentence was announced in open court; or, if it was not so announced, the date on which the sentence was adjudged by the court.

Questions on Military Hygiene

(Reference: Elements of Military Hygiene.—*Ashburn*)

Wt.	*No.*	*Question*
14	1 (a)	Describe two field methods of rendering water reasonably safe for drinking.
16	(b)	A small stream is the sole water supply for your company of mounted engineers. Name in order, going downstream, how you would segregate the water supply for its various uses.
16	(c)	Sketch a latrine cross-section suitable for use for a four-day camp. How should it be located with reference to the water supply?
10	2 (a)	Why are kitchens and latrines screened?
10	(b)	What is a typhoid carrier?
12	3	What is the difference between an infectious and a contagious disease? Give an example of each.
10	4	What is the necessity of thoroughly cooking pork?
12	5	How is malaria transmitted? How is its spread combatted?

Questions on Military Law



(Arts. 405 to 487 incl. Manual for Courts Martial, 1921)

No.	*Wt.*	*Question*
1	11	A man fraudulently enlisted in the army deserts the service. On trial for desertion he pleads his fraudulent enlistment in bar of trial, claiming that since his enlistment was fraudulent he is not subject to the jurisdiction of a court-martial. Should the court sustain the plea? Give reasons for your answer.
2	10	(a) Define "desertion." (b) What is meant by "short desertion."
3	10	Part I. A soldier is turned over to civil authorities, upon their application, to answer a charge of breach of the peace. Is he punishable for absence without leave for the period he is held by civil authorities: (a) If acquitted of the charge? (b) If convicted of the charge? Part II. A soldier on pass is held by civil authorities to answer to a charge of assault. Is he punishable for absence without leave for the period he is detained after expiration of his pass: (a) If acquitted of the charge? (b) If convicted of the charge?
4	9	(a) What is the distinction between "mutiny" and "sedition?" (b) What is the minimum number of persons who must be involved in a case to make it chargeable as mutiny?
5	8	A person subject to military law is charged with an offense. What are the determining factors in deciding whether he should be placed in arrest or in confinement (assuming that one or the other is believed advisable)?
6	10	(a) Who is authorized to sign charges and specifications? (b) What is his signature under oath intended to cover?
7	10	(a) Sufficient evidence is available to prove that a certain soldier destroyed or injured certain property belonging to a civilian. Is it possible for said civilian to obtain damages or redress by application to the military authorities? (b) If so, state how it would be done. (c) If not, state how redress could be obtained.
8	8	State briefly the difference between larceny and embezzlement?
9	10	(a) For what purposes are courts of inquiry convened? (b) What is the jurisdiction of courts of inquiry as to persons?
10	10	(a) In general terms, what classes of offenses are properly chargeable under the general article (A. W. 96—Conduct to the prejudice of good order and military discipline)? (b) What punishment can be awarded in case of conviction under this article?
11	4	What punishment is mandatory upon conviction of an officer for conduct unbecoming an officer and a gentleman? (A. W. 95.)

Maintaining the Motor Transport of A Field Army

By

M. D. Mills

Major, Engineer Reserve Corps, formerly of G-4, First Army, A. E. F.

[*Note.* In this valuable article Major Mills epitomizes the experiences of the A. E. F. in maintaining or endeavoring to maintain, the motor transport on which the success of all its operations so greatly depended. The subject is presented in a highly entertaining manner, which indicates that its author possesses "that saving sense of humor," which prevents physical and mental breakdown in the face of the trying conditions of war time. In this interesting and effective way Major Mills drives home the lessons of the war, and indicates the mistakes to be avoided in the the future, and how they may be avoided. We consider this one of the most important contributions which THE MILITARY ENGINEER has been privileged to make to the cause of the National Defense, and hope the article will be as widely read as its interest and importance warrant.—ED.]

IT has been said of the late Theodore Roosevelt that few men could remain indifferent toward him or could maintain a real neutrality in discussing his various utterances and actions, his being a positive character that aroused a strong partisan liking, or an equally strong opposition. Similarly, most men who even remotely came in contact with motor transport in France, developed positive and sometimes violent opinions commending or condemning the work of the Motor Transport Corps in maintaining the motor-driven vehicles of the A. E. F.

The reasons for this attitude are many and varied, but one of the commonest causes of criticism lay in the opinion of the average Yank, who back in peace time had ridden or driven in "flivvers," automobiles or trucks, that he knew about all there was to know regarding the operation of motor vehicles. As a result, the poor old M. T. C. staggered wearily on its way, judged, and generally found wanting, by the motor experts who made up the rest of the army.

Undoubtedly there was much reason for the belief that existed in many combat outfits, that the principal function of the M. T. C. was "to block the game." The medico who vainly scoured France in quest of front springs for Fords, and who in the meantime supported his ambulances on blocks of wood, and the artilleryman who daily watched his ammunition train dwindle and the number of quads tied up for lack of steering-knuckles grow, were not concerned with the fundamental causes of the failure to secure adequate spare parts. They only knew that apparently the divisional M. T. O. could do nothing for them and if, despite orders, they went to Langres or Verneuil they probably got no results, or if they did, it was because they begged, borrowed, or (most likely) stole parts that were on back order for some other outfit. In any event they probably formed a contemptuous opinion of the spare-part supply system, and as a result of their tales as to the number of cars, trucks, etc., parked at Langres and other points, the division G-1 bedeviled corps and army headquarters for additional vehicles, and refused to believe that the transport observed at the parks was on the way to equip some organization in worse shape than his own.

So many factors entered into each individual experience with motor vehicle maintenance in the A. E. F., ranging from the efficiency of the personnel and the operating conditions, to the make of vehicle used and the nearness of spare part and repair depots, that the observations of any one man represent generally his own limited experience and are valuable only in connection with the opinions of others to the end that, by a thorough discussion, different viewpoints and experiences will be developed, and practical improvement suggested. I am well aware that starting a discussion on such a subject as maintenance, is largely a case of rushing in where angels fear to tread. So bring on the anvil chorus!

As I see it, the essentials necessary to maintain properly the motor transport of an army in the field are:

1. *Standardization of vehicles by the assignment of the fewest possible makes and types consistent with operating requirements.*
2. *Proper operaton and inspection of vehicles.*
3. *Light repair facilities immediately at hand capable of making small repairs and adjustments "on the job" thereby forestalling extensive break-downs.*
4. *Overhaul facilities within the army zone where more seriously damaged vehicles may be turned in for repairs and a serviceable vehicle of the same make and type issued as a replacement.*
5. *Reconstruction facilities at the rear of the army zone capable of manufacturing parts and of rebuilding vehicles.*
6. *An adequate supply of spare parts and tools within reach of the combat units.*
7. *Well-trained and disciplined personnel.*

These seven essentials are so inter-related that it is hard to consider them separately in view of their collective effect. For ease of discussion, however, it is perhaps better to take them up individually.

Standardization of Makes and Types of Vehicles

It is unnecessary to take the time of engineers to dwell upon the advantages of standardization in relation to the upkeep of machines. As a result of our war experience it is now considered that the staff, supply, ammunition and evacuation requirements of a field army can be satisfactorily handled by nine different types of motor vehicles, viz, two types of motor cars, one type of motor cycle, one type of ambulance and five types of trucks ranging in capacity from three-quarter to five ton. (Tractors not included.)

Contrasting these actual requirements with the situation in France, we find a total of 162 different makes of vehicles in use by the A. E. F., these including many foreign makes for which it was not possible to secure spare parts. There are about 3,500 different parts in a motor vehicle of which approximately 1,500 parts are known as "parts common," such as bolts, nuts, brake lining, tires, etc.,

Digitized by Google

while the balance are parts peculiar to each make of vehicle. A stock of spare parts sufficient to have maintained the vehicles of the A. E. F. would have included 440,000 different items, of which 80 per cent were non-interchangeable. The difficulties of obtaining and keeping up such a stock under war conditions were insurmountable, and the actual records of the A. E. F. show that there were never over 87,000 different kinds of spare parts in France, leaving 353,000 different kinds actually required and not to be had. Under such conditions is it any wonder that the only practical way of repairing a vehicle was by looting the necessary parts from some more damaged vehicle of the same make, temporarily unguarded by its owners?

The early organization of divisions in 1917 and the beginning of 1918 saw a consistent attempt made to limit the cargo trucks within each division to one make. The 1st and 26th Divisions were largely equipped with A. E. C. (British) trucks; the 2nd and 32nd Divisions with the Packard; the 42nd with the Pierce-Arrow and the 3rd and 5th with the Peerless. The rapid arrival of later divisions in France with the ensuing shortage of transport prevented any further efforts at standardization, and the whole situation was made infinitely worse prior to the St. Mihiel offensive by the necessity for issuing the maximum possible equipment to the divisions and the corps and army troops that formed the First Army.

To equip the First Army with the required transport it was necessary, in addition to the equipment on hand within the army and ready for issue in the parks, to practically strip the S. O. S. of cargo trucks on short notice. This resulted in sending forward to an army preparing for battle a mass of transport of all descriptions and in all stages of serviceability. Undoubtedly, the S. O. S. made a conscientious effort to deliver the best possible vehicles, though this necessitated forwarding a great many makes and types of trucks not desirable for use in a combat area. Of the trucks received 14 per cent were rejected as absolutely unserviceable, and many of the trucks accepted were in an extremely dilapidated condition and would barely roll.

An idea of the general condition of these vehicles may be drawn from one typical experience as follows:

A convoy of 50 vehicles was forwarded from Bordeaux. The officer who took them protested verbally and forcibly against their being sent, stating that four out of the 50 were in a safe condition to undertake a hard journey. Of this convoy 36 vehicles were dropped by the wayside and salvaged, while ten (10) more were towed in by the exercise of considerable ingenuity, and the prediction that four would probably prove fit to make the trip was exactly justified.

With the transport from the S. O. S. and that which was already within the First Army, a re-distribution was effected in six days, whereby seventeen divisions, the corps supply trains and artillery parks of three corps, together with numerous units of army troops, were partly equipped, the degree depending largely upon the priority assigned them in the order of battle.

The short time available in which to carry out this distribution prevented any attempt at a homogeneous grouping, even by divisions, and as a result the First Army began the operations, which it was to continue until the armistice, with a mixed mass of transport in all stages of serviceability, and for much of which there existed few or no spare parts.

Conditions such as these could be eliminated in future by rigidly limiting the number of different makes of vehicles within the army to the required number of types. With the vast number of commercial vehicles existing in the United States, this could easily be effected in time of national emergency by commandeering for military purposes all serviceable, privately owned vehicles of the several makes selected as standard, either purchasing them outright or replacing them with non-standard makes.

Proper Operation and Inspection of Vehicles

Given proper operation of all vehicles, maintenance ceases to be a problem. Proper operation and inspection, meaning day-by-day care of the machine, proper lubrication of all moving parts, controlled operation on the road at proper speeds, and a system of inspection which will quickly check up any violation of these things, reduce the necessity for repairs to a minimum.

Maintenance and operation are so inter-related that it is fundamentally wrong to charge one branch of the service with the upkeep and repair of vehicles over the operation of which it exercises no control. Motor transport, excepting only the special technical and combat vehicles, exists for but one purpose, i. e., the most expeditious and economical movement of personnel and matériel between two points. Surely, for example, the actual movement of munitions is no more an artillery affair than is the movement of forage. Certain amounts of ammunition of various calibers are ordered forward from stockage at A to corps dump at B. The movement is purely an affair of transportation, and requires on the trucks not artillerymen, but truck drivers. It is the job of the commander of the stockage at A to see that the trucks get the exact ammunition called for on the order, and it is the job of the convoy commander to see that all his loads are delivered within the stated time to their destinations.

Similarly I have never been able to see the operation of ambulances in a different light, for their movement between the points specified requires drivers, rather than medical troops, and if the services of the latter are required for attention to sick or wounded in the ambulance, they should be sent along for that purpose. The locomotive driver who pulls a hospital train is certainly not a member of the Medical Corps. Why the driver of an ambulance?

Let us examine the situation within the combat forces of the A. E. F. Division staffs as originally organized did not include a representative of the Motor Transport Corps, for that corps did not come into existence, as far as the A. E. F. was concerned, until the late fall of 1917 and then only in the S. O. S. The motor transport within the division was assigned generally according to the tables of organization and was in the hands of the various organization commanders, being largely, however, in the four division trains and at division headquarters. Divisional methods of controlling the maintenance of this transport varied from highly efficient to the reverse. Even within the division, part of the trains were often ably handled and in fine condition, while the remainder were in bad shape. In other words, there existed no uniform practice or standard of inspection, and in few if any cases did any one authority within a division really control *all* the transport assigned to the command.

Motor transport officers were not assigned to corps and armies until June, 1918, and as soon as possible after that date M. T. C. officers were sent to the divisions. There at first they generally did not accomplish much, for on the average they had little rank and small experience as soldiers, and after being pushed well into the mud by the staff and organization commanders, were usually handed

Digitized by Google

the job of consolidating requisitions for spare parts. This situation improved, however, with the transfer of many older men to the M. T. C. making possible the assignment as divisional M. T. O.'s of officers who had made good as train commanders.

Passenger transport within the divisions was largely assigned to individual organization commanders and staff officers and in many cases was driven by favorite orderlies. It can be stated that a good many fine cars, including some with stars on the windshields, were ruined by this practice. Most of these officers insisted on the cars assigned to them being kept clean on the *outside,* but how many ever took the time to look *under* the hood?

Less trouble was encountered in the several corps and armies, for here there existed no prior organization, and the officers appointed as M. T. O.'s were generally officers of rank and ability. Pooling of passenger transport at these headquarters, less only the cars assigned to general and higher staff officers, was soon effected and this system was extended to most of the divisions during the fall of 1918.

The utter fallacy of looking to the several arms of the service for the selection, training and organization of motor transport personnel, was completely demonstrated in France. With the supply train manned by quartermaster personnel, the ammunition train by artillerymen, the ambulances and sanitary train cargo trucks by medical personnel, unbelievable indifference to the simplest motor transport practice was witnessed on every side and was almost totally beyond the control of motor transport officers. I do not believe that efficiency of operation will be possible of attainment until such time as all motor vehicles, excepting only combat and special vehicles, are operated and maintained by a single arm of the service, with all personnel, whether drivers or mechanics, drawn from, trained by, and looking to that arm for their promotion and technical control.

Facilities for Light Ordinary Repairs

While transport breakdowns and the necessity for repairs can be very materially reduced by proper operation, they certainly cannot be eliminated, even under garrison conditions. In the case of an army in the field there will exist a continuous demand for minor adjustments and repairs and the replacement of broken parts, which, if promptly attended to, will with little effort keep a large percentage of vehicles in a serviceable condition, while these same vehicles, if allowed to go on without attention, will soon need not light repairs, but a complete overhaul, necessitating tying up the vehicle for a period of several days.

To make the necessary light repairs within a division requires the presence of a small but completely equipped mobile machine shop, operated by a force of mechanics expert in the several lines of automotive repair and having at their disposal a stock of spare parts sufficient to maintain the division transport during the period of time necessary to obtain new parts from the rear.

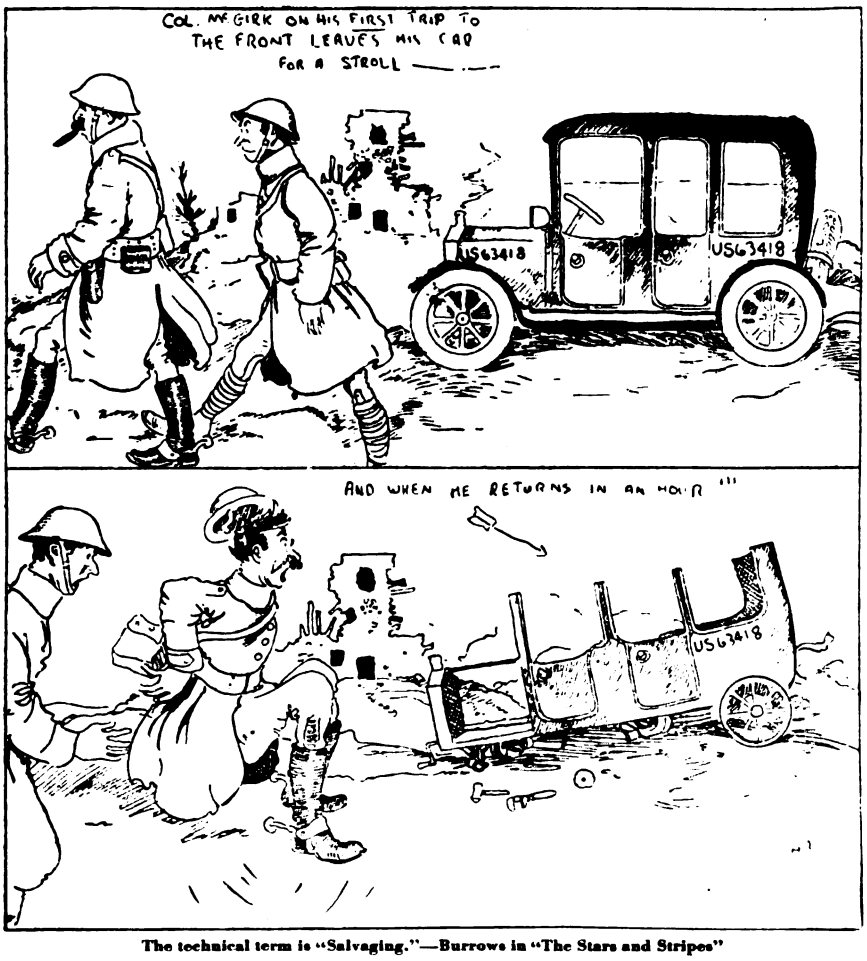
This work in the combat zone of the A. E. F. was performed (mostly *without* spare parts) by the very efficient machine shop truck units which were largely responsible for such maintenance as was possible. The name of these mobile units has been changed in the new Army of the United States to that of Repair Sections, and two of these sections, each consisting of an officer and eighteen men, will be responsible for the maintenance of division transport in the future. Each section will be equipped with a machine shop truck, a tire press, a wrecking truck, a spare-parts trailer, a tractor and certain cargo and passenger transportation, and the two sections will have between them a stock of spare parts sufficient to keep serviceable the motor vehicles of a division for a period of thirty days.

Facilities for Overhaul

The repair sections assigned to divisions must at all times retain their mobility, which practically forbids the acceptance of major repair jobs involving several days' work. This larger repair or overhaul work must be taken care of in bigger and better equipped semi-mobile shops situated far enough from the enemy's guns to prevent interference with the supply and troop movements in the forward zones, but not so far in the rear as to prevent damaged vehicles being quickly towed to the park for repair.

The French maintained a large repair park of this description at Bar le Duc, serving from this point the Second French Army in the Verdun Sector, and handling repairs, replacements, and, I believe, the issue of spare parts. Through the entrance gate of this park were towed damaged vehicles to be turned in for extensive repair, the drivers receiving in exchange a serviceable vehicle of the same type and make, with which shortly they rolled out of the exit on the way back to their organizations. The damaged vehicle was repaired and made serviceable and then held in the park for issue as a replacement. Such a system represents a minimum loss of transport to combat organizations but could only be put into effect where operation and maintenance are under the same general direction; otherwise the park would be swamped by the promiscuous dumping upon it of vehicles needing not overhaul, but simply intelligent care.

The first park built by the A. E. F. in the Zone of the Armies was the overhaul park at Langres. During the spring of 1918 this park handled some repair work for divisions in the training areas, but its main functions during this time were the issue of spare parts to the combat troops, the inspection and issue of new transportation assigned to these troops by G. H. Q., and the repair of vehicles salvaged and turned in as unserviceable.



At this time there were only four or five machine shop truck units with the divisions in the line, and none with the troops in the training areas. With no means at hand, therefore, for repair, and with few spare parts available, organizations were continually requesting authority to replace damaged vehicles. This *authority* was readily granted, but organizations soon discovered that there was no replacement. The reason for this was that new organizations were arriving much faster than was motor transportation; naturally all vehicles available for issue were gobbled up on initial assignments. The units demanding replacements did not know this, but soon discovering that they were getting nowhere, they adopted the practice of stripping damaged vehicles of all parts in order to keep other vehicles serviceable. This resulted in wrecks arriving at the overhaul park requiring not overhaul, but entire reconstruction.

This practice, due to the continual lack of spare parts, grew worse during the St. Mihiel and Meuse-Argonne offensives, and no one knows better than the man who has had the misfortune to have his car break down enroute, that vultures never gathered quicker over a fresh kill, or picked bones cleaner, than did the drivers and mechanics in the forward areas locate and strip a damaged car, truck or motorcycle.

During the process of equipping the First Army prior

Digitized by Google

to the St. Mihiel offensive, the chief motor transport officer of the army discovered that of 108 machine shop truck units then in France, 79 were in the S. O. S., and as a result of his efforts, 30 units were sent forward for distribution to the organizations of the army. The C.M.T.O. retained under his own control one machine shop truck and two tire presses, and with improvised personnel organized the provisional First Army supply and repair park. This park was first located at Toul, but for the Meuse-Argonne offensive it moved to the vicinity of Thiaucourt. The park was at this time increased to four machine shop truck units, five tire presses and one vulcanizing outfit, and became the point to which all spare parts for the army

The technical term is "Salvaging."—Burrows in "The Stars and Stripes"

were sent for distribution to organizations, and where organizations could send vehicles which they themselves could not repair. The park moved on November 10th to La Frana Ferme, near Nixeville. During the period from October 4th to December 4th this improvised park, partly housed in wrecked barns and partly in the open, handled a total of 841 vehicle repair jobs, and in addition pressed on 4,193 tires, vulcanized 1,875 tubes and 155 casings, repaired 121 radiators and handled 271 welding jobs.

The splendid work of this park is a convincing proof that the overhaul facilities of future armies should be part of the army itself and not an S. O. S. project. Under our new organization there will be an overhaul park (repair battalion) with each corps, in addition to two repair sections for the corps troops. The repair battalion, consisting of 1,238 officers and men, is a semi-mobile plant equipped with knock-down buildings and with machinery mounted on skids for portability. The equipment comprises all tools and machinery necessary for the repair of major units, and the capacity of the park is sufficient for the maintenance of 4,000 vehicles. At this park will be maintained a 90 days' reserve of spare parts for all units of the corps, and as the park has 24 cargo trucks it is possible at all times to move within short notice.

Reconstruction Parks

To care for the total reconstruction of badly damaged vehicles in the A. E. F. there was located at Verneuil, near Nevers, a completely equipped factory capable of building necessary parts of vehicles. This park was also the spare part depot to which all parts were forwarded from the base ports. Just what part this park played in the maintenance of the transport belonging to the combat armies I am not competent to say, for it was an S.O.S. project.

Under the new organization there will be assigned to each army three repair battalions organized into a reconstruction park. A fourth repair battalion will be utilized within each army as an overhaul park for army troops.

The Supply of Spare Parts and Tools

Of the several factors affecting the maintenance of transport which have been previously discussed, there is none that will stand out as clearly in the mind of any man who was responsible for the operation of motor vehicles in the A. E. F. as that of the supply of spare parts and tools. Literally, at times, "there was no such animal" as spare parts, and many a man scoured France, ofttimes vainly, in quest of certain parts required to keep his vehicles running.

Requisitions, sent to the rear in good faith, generally produced about 10 per cent of the needed parts on the day of issue, and to secure a part of the remainder it was necessary to beg, borrow, and steal. From all the testimony offered there were certainly some accomplished thieves in the army, especially in the matter of transport.

No more vivid description of existing conditions can be written than that described in a verse originally published in the *Stars and Stripes*, written by a sergeant in the M. T. C.:

The Absent Quad

The Quad truck waits without, my Lord!
  Without what, Captain Bunk?
Without the steering arms, my Lord!
  Without a lot of junk;
Without a vulcanizing patch,
  Without a nut or screw;
She's minus top and wheels and valves,
  She's shy a body, too;
Without a spring, a brake, a yoke,
  Without a horn to blare—
Good gracious me, it beats the Dutch,
  How much there isn't there!

We took her to the park repair,
  As perfect as could be,
Just wanted to adjust some screws,
  And now—ah! woe is me.
They swiped the lining, brake (ten feet),

Digitized by Google

They stripped the casings clean,
They monkeyed with her primer—
Oh, they acted awful mean!
But one thing saves the day, my Lord!
Our records can declare,
That though we didn't get a Quad,
The U. S. number's there.

Due to the great number of vehicle makes represented, and to the shortage of spare parts, it was not possible to develop a system of automatic supply of parts to the organizations of the army, but all supplies were issued only upon requisitions, which were forwarded through the C. M. T. O. of the army to the spare part depot at Langres. Such of the parts called for as were available were for a time forwarded direct to divisions by truck from the depot, but later each division was given a "drawing day" and on that day sent its own trucks to Langres. Either system would have been satisfactory had a stock of spare parts existed, though Langres was so far to the rear that the trucks were forced to make an unnecessarily long trip. After the establishment of the First Army Supply and Repair Park, spare parts for the army were forwarded to this park, where they were drawn by the organizations for whom intended.

One of the greatest handicaps in the issue of spare parts was the shortage of competent personnel in the supply division. Only 50 qualified spare parts men had arrived in the advance section by the last of October, 1918, and the few who were available were too often used for other than supply work to meet the almost continual emergencies existing through the summer. The same handicap applied equally to repair work and this at a time when great numbers of capable automotive mechanics were serving in the infantry.

Undoubtedly, however, had there been a really adequate supply of spare parts and tools from the United States, an organization, improvised perhaps, would have been effected to handle the distribution in the A. E. F. Much of this shortage was directly chargeable to the small amount of ocean tonnage allotted by the Transport Service to spare parts and supplies, in comparison to the amounts asked for. In addition there does not appear to have been very good co-operation and liaison between the motor transport headquarters in Tours and in Washington.

The automatic requisitions sent to the Chief of the Motor Transport Corps from the A. E. F., afforded ample information as early as August, 1918, as to specific serious shortages of tools and parts, but, though the system of automatics as furnished by the A. E. F. was apparently approved in Washington, orders for purchase and production in accordance therewith were not promptly placed, nor was the D. M. T. C. at Tours notified that the automatics submitted were not considered satisfactory, and that they were not being complied with. Instead, the authorities in Washington apparently developed a system of supply sets of spare parts based on the experience of the Punitive Expedition into Mexico, and forwarded a certain number of these sets for every 100 vehicles floated.

Between July and November 20,505 tons of spare parts and tools were floated out of 56,000 tons asked for, but, in spite of requisitions and protests from G. H. Q. of the A. E. F., nearly half of the tonnage floated consisted of certain solid tires and other supplies of which there already existed a stock in France sufficient to operate certain of the trucks for several years, while at the same time no attention was paid to requisitions for such supplies as Cadillac, Dodge and Ford tires, which were urgently needed.

Thousands of boxes of "supply sets" for different makes of vehicles were shipped to France, each box containing numerous kinds of spare parts on a ratio determined by experience tables prepared in the United States. The actual call for spare parts did not conform to this experience table and the result was, that to obtain certain needed parts it was necessary to open a large number of boxes to obtain a sufficient number of the particular article desired. Thus, heavy boxes had to be handled and opened, the particular part in question removed and the box closed and replaced in storage. Take for example the item of wrist pins for Packard trucks. There were five in each box, necessitating, in case 500 were required, that 100 boxes be opened for this article alone.

Another factor in the shortage of spares and tools among the combat forces of the A. E. F., lay in the development of the repair service in the S. O. S. which resulted in the first tools, accessories and parts being held at Verneuil and other points 300 miles in the rear. Few vehicles forwarded from the assembling parks had the necessary equipment of hand tools; the records show that over 20,000 vehicles were without tools.

Still another factor in the shortage of parts lay in the cumbersome purchasing system employed in the United States. Records in the War Department show that after requisitions for parts had been forwarded to the Purchase, Storage and Transport Branch of the General Staff for purchase, an average of 53 days elapsed before orders were placed with the manufacturer, and that after orders had been executed they often lay for days on the manufacturers' shipping platform, waiting for bill-of-lading.

Such a rigid system made it impossible to meet emergency demands for specific parts. As an example of this in the First Army, take the case of the Cadillac car. Three parts on this splendid machine gave trouble, these being the timing chains, the front springs and the wheel bearings. A shortage of these parts soon developed, with little or no apparent attempt made from the United States to correct the ratio of parts being shipped. As a result it became necessary to salvage from the First Army several fine cars which had nothing the matter with them excepting the lack of the above parts. Apparently, the Cadillac Motor Car Company received information as to these particular items of breakage only after the Armistice.

Any system for the supply of parts and tools for an army in the field to be effective, must be as automatic as the supply of rations, and it is apparent that it must be highly flexible to permit quickly changing the ratio of the different parts supplied to conform to actual requirements, which naturally will vary in different theatres of operations depending upon the roads and conditions of service. Further, the actual conditions governing the forwarding of parts to the various organizations require that but a single *kind* of part be shipped in each container to facilitate storage and issue, and that an adequate reserve of spares and tools be maintained in each corps and army.

This last essential is so evident as to require no discussion, and is of course to be implied wherever it affects the six preceding essentials.

The late war marked our first considerable use of gasoline driven vehicles for supply and combat purposes. With little or no previous experience to fall back on and in the confusion attending the organization of a great army in a limited period of time, it is small wonder that in both operation and maintenance much faulty practice should have developed. The real wonder is that we were able to do as well as we did. Out of the varied experience of many men, ranging from the depots in the United States to the front in France, it should now be possible, however, to develop a proper theory covering the use and upkeep of this new means of transport.

Fore and Aft of the Infantry

The 6th Engineers in the American Offensives of 1918

By

Donald Bennett Adams and **Albert Eli Crane**

Former Major, 6th Engineers, U. S. A. — Former Captain, 6th Engineers, U. S. A.

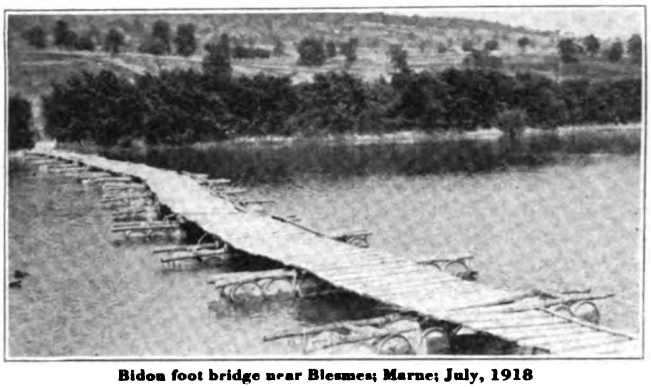
[*Note.* The following contribution by Major Adams and Captain Crane represents a type of article of which we would gladly see more in this journal. As a personal experience it is most interesting, and as an account of the things that engineer troops are actually called upon to do in "open warfare," it is most instructive. The apt title chosen well epitomizes the functions of engineers in the attack.

The period covered by this account, which saw the suppression of the Marne Salient and the Meuse-Argonne Offensive, witnessed the greatest activity, the largest numbers engaged, and the most notable achievements in the history of American arms. In these great events none of the American combat divisions was more actively engaged or acquitted itself with greater credit than the 3rd Division, "The Rock of the Marne." The authors give an entertaining picture of the part played by the 6th Engineers in the operations of the division. These activities are typical of those of all engineers with the combat divisions during these great offensives.—ED.]

THE service rendered by the engineers to the combatant forces might be divided into three parts. The first would cover the immense amount of work done in the S. O. S. areas, and would include everything from the building of ports to the establishment of rest areas for the exhausted units. The second might properly include the service with forces holding "quiet" sectors—position warfare. The third would cover the service performed under active combat conditions, where positions are held momentarily. What follows is taken from personal experience in the third class of service, and of course is confined to personal point of view, perhaps limited. These experiences may be of some interest and may perhaps clarify just what will and can be done in periods of confusion, high tension, at the best never out of artillery fire, and at the worst, under rifle fire.

In the ordinary course of events there is work to be done by the engineers previous to every attack. This always includes removing every obstacle which might impede the advance of the infantry and artillery. First of all, the opportunity presented in the usual lull before the attack must be utilized to assure the successful advance of those units lying immediately behind the front line. It often happens that one of these units actually forms the attacking force. At any rate the advance of all units lying to a depth equal at least to the limit of direct hostile observation must be made easy and certain.

During the night preceding an attack all roads in the sector, leading to the front, must be made passable for transportation. Bodies of horses and men must be disposed of, shell holes must be filled, or, if the road has been mined, a new piece of road must be built around the mine, or the hole bridged. Naturally a road is always mined at a fill, making the obstacle as complete as possible and the repair as difficult as possible. On the road leading north into Fismes—on the Vesle—a fill was blown out making necessary a trestle bridge not less than 20 feet long and 15 feet high.



In the advance in front of the Montfaucon, in the Meuse-Argonne campaign, it was known that when the Third Division should make their advance to take over the sector, the roads would barely take care of the horse and motor transportation. The simultaneous advance of the whole division excluded the infantry and machine gun units from the roads, and furthermore, these units were to advance beyond the points where large bodies could safely move on the roads. Starting at a point back of even balloon observation, paths for each of the advancing columns were cleared through the woods by the engineers. Thus the two infantry brigade columns and machine guns, arriving at a point where to be observed was dangerous, and where speed was essential, left the road free and open for wheel transportation and, led by engineer guides, advanced quickly and safely over paths marked by tapes. This advance was particularly successful and was made under cover up to within a short distance of the front, where there existed no cover of any kind. In making the paths, all obstacles such as stones and stumps were removed, small swamps and streams were bridged, some parts strengthened with corduroy and others merely drained. The speed and ease with which the advance was made and the manner in which the hastily constructed paths came up to all requirements, proved the entire merit of the scheme and justified the effort put forth.

The engineer, in assisting the advance of the infantry and artillery, encounters the usual artificial obstacles—almost always wire, and the multitude of natural obstacles such as swamps, rivers and vegetation. It is in overcoming the latter class, under fire, that the engineer finds his biggest job.

A few days after the Boche attack on the Marne, in July, 1918, the Sixth Engineers, attached to the Third Division, were called upon to get the infantry across the river opposite Mezy. The American side of the river was fairly flat with a gentle slope starting about a mile back. The Boche side was flat for only a few hundred meters and then rose abruptly, so that machine guns above could command all operations on the river. A company was detailed to rush a foot bridge across at this point. Furnishing their own covering party, the engineers forced the Germans back from the opposite side of the river. Then a bridge of gasoline "bidons" was thrown across under machine gun fire from the slope above. A deserted Boche ponton furnished the ferry for the landing party, which anchored the bridge to the opposite shore and held off the enemy. The bridge provided the means by which the infantry could begin their advance, whereupon the engineers immediately salvaged sufficient German ponton material to construct a parallel bridge sufficient in strength to carry the infantry supply and ammunition trains. This second bridge was put in operation in about 12 hours after the infantry attack had driven the Germans from the heights. Two companies of engineers then went to work on a more permanent bridge for the supply trains. With one company working from each bank, a bridge supported by piles, cribs and trestles was completed in 70 hours. This bridge could carry live loads up to ten tons.

During the advance to the Vesle, a large amount of road repairing and bridge building was done, but the next work in front of the infantry was done at the Vesle itself.

The division sector extended west from Fismes, joining the French at Villette. One company was ordered to provide a means of carrying the attack across the Vesle, the river at this point being about 20 feet wide, six or eight feet deep, and sluggish with abruptly sloping banks. One day and a night were consumed in making up the material for a "bidon" bridge, and the same night a hasty reconnaissance was made of the river. The bridge, completely built, was taken into Fismes on a truck under heavy artillery fire and then carried on the shoulders of the men along the main road just back of the front line. This road had been mined and was too close to the river to be safe

German entanglements; 6th U. S. Engineers encamped in woods in background; near Madelaine Ferme; Meuse-Argonne; Oct., 1918

for transportation. The bridge was carried to a position on front line and the infantry advance to the river prepared.

Owing to the difficulty in forcing ahead the covering party of infantry, the artillery had ceased to play on the opposite bank when the advance started. First went a wave of infantrymen, instructed to lie down on the bank on each side of the chosen position for the bridge. The bridge followed on the shoulders of the engineers, who were obliged to descend into and climb out of a precipitous railroad cut which had been well wired by the Germans. In doing this rifles and helmets continually struck against the empty metal bidons, making a great deal of noise.

We advise any reader who attempts to carry a bidon bridge into No-Man's Land to build the carrying pieces long enough so that the bidons cannot possibly be struck by rifles or helmets. The clang of a helmet on an empty bidon in No-Man's Land makes more noise than a brigade of artillery in action, or at least so it seems to those carrying the bidons. But nevertheless the bridge was slipped into place in less than fifteen minutes, securely anchored to the opposite bank, and made safe for passage. A bridge guard was left, and the outfit retired without having drawn any fire.

Further reconnaissance the same night furnished an interesting experience. Advancing along an old trail which the Germans had wired on both sides, a party of five arrived at the river bank and found the supports of an old bridge still in place, but with the flooring removed. On the opposite bank, the heads of a Boche outpost could just be distinguished. Such a mark could not be passed up, so the party indulged in a little rifle and pistol practice. Naturally, all the outposts in the sector opened up and the party was fortunate in getting away unharmed. A few nights later another party attempted to plank over the bridge, but suffered several casualties in the unsuccessful attempt, due to an enemy machine gun which commanded the path. The next attempt was made in broad daylight. Concentrated fire was diverted by an infantry attack and enough planks were placed by two engineer sergeants to allow the infantry to pass, although the bridge was covered by hostile machine guns.

Another reconnaissance in this sector proved the aptness of the title "No-Man's Land." An engineer officer was given an automatic rifle party to assist him in reconnoitering an old mill site between the front lines and opposite the junction of the French and American forces. While advancing along a narrow trail, the party was fired on. The riflemen immediately sought the protection of the ground and replied briskly to the enemy's fire. The only targets were the flashes of rifles and machine guns, and no one knew whether he was firing at French, German or American. After an extravagant waste of ammunition, the party withdrew without accomplishing its mission.

As to artificial obstacles, it was found that after several days in a position, the infantry liked wire along their immediate front, feeling its protection and confidently advancing through the lanes left in the wire, especially if the lanes were widened just before the attack. On the other hand, when the infantryman is advancing daily, he does not relish the idea of advancing through strange wire. It must be remembered that the engineer soldier was fed on barbed wire, that he appreciated its full value as an obstacle to the enemy. To the infantry, wire was primarily an obstacle to their advance, since the wire best remembered by him was that of the enemy.

In the Meuse-Argonne a belt of American wire was strung across the road just north of Cunel. The infantry from the commanding officer down, were so troubled by this obstacle, that a compromise was made and a single strand of wire used. In the weeks previous to the second battle of the Marne, the engineers in one regimental sector laid out an elaborate system of entanglements. But we received no encouragement from the infantry, and when July 15th arrived the wire had only been fairly started.

Just before the battle of St. Mihiel, the Commanding General of the Third Division gave to the Sixth Engineers the problem of finding a method of passing troops quickly over or through wire. The method devised was a mat of chicken wire, which was carried in a roll and pushed out over the entanglement as a carpet. On this the infantry could pass over the wire in a column of twos. The method

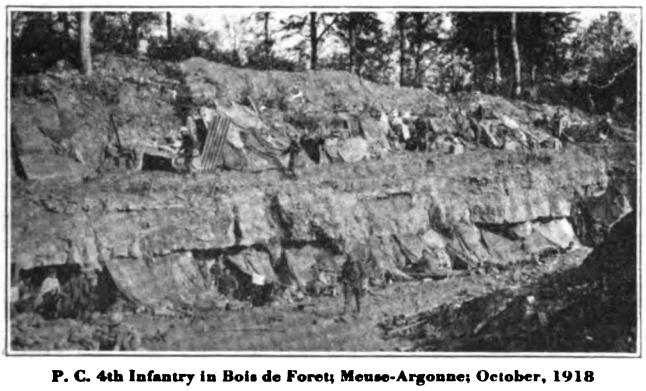
Road repair work; F Co., 6th U. S. Engrs.; Haucourt; Meuse-Argonne; Oct., 1918

was developed by the infantry as a drill, but as far as we know, it was not used in an attack.

In the fall of 1918, when the effective strength of certain divisions had been diminished, it was found necessary at times to use the engineers as infantry attacking troops. Arriving at the front, prepared to consolidate a position when taken by the infantry, if the infantry has met with a reverse, the engineers must, if there is a bare possibility, take the position and consolidate it as well. Following is an example:

On October 19, 1918, two companies of the Sixth Engineers were ordered to follow the infantry in an attack on

Digitized by Google



a small woods north of Cunel, the attack to take place the following morning. Fortunately the two engineer company commanders were ordered to division headquarters at the same time as the infantry officers, and were told the details of the affair.

The engineers, in their trenches as reserves, were somewhat delayed by shell fire at the start, but at two in the morning were able to draw wire, picks and shovels and to start forward. A thick mist and drizzling rain which held the gas in the woods also made the approach difficult. But finally arriving at a point about two hundred yards back of the front line, they dug in to wait for the zero hour. Shell fire was incessant, but rather few casualties resulted.

At the zero hour the engineers with their loads advanced in platoon columns and soon arrived at the jump-off trench on the edge of a small wood. Here it was found that only a handful of infantry had lived to cross the open space which lay between the jump-off trench and the objective, a long narrow wood perpendicular to the front. A half dozen of the infantry had crossed over and could be seen across the space, about fifty yards distant. The open space was covered at each end by machine gun nests, which neither the artillery barrage nor the attacking infantry had disturbed.

It was plainly "up to the engineers" to go on and try to take the wood. One company was despatched in single file at the most likely place and succeeded in crossing with few casualties, although at least one Boche machine gun was not over 75 yards away.

As soon as one platoon had crossed, it immediately advanced on the closest machine gun nests, and succeeded in cleaning them out, taking 40 prisoners. The platoon commander, Lt. Knox B. Birsey, was killed. But the crossing was made safer for the remaining men, and once over and under cover they reformed and prepared to advance into the woods. The plan of the Commanding General for the infantry was to be followed, an infantry officer who had crossed offering to bring up men to protect the flanks as the engineers went forward.

P. C. 4th Infantry in Bois de Foret; Meuse-Argonne; October, 1918

The advance of the Engineers carried them forward through the narrow wood for a distance of half a mile, in spite of a demoralizing machine gun fire directed at the woods from both sides. Part of a third engineer company had arrived in the woods, and had been rather badly used, its captain, C. D. Harris, being killed, and most of its other officers wounded.

It soon developed that the Boches, were entering the woods behind the engineers, so the line was faced to rear and the engineers fought themselves out back across the open again to the jump-off trench.

Two attempts to take the woods having failed, the engineers were ordered by the infantry regimental commander to form again, take the woods and hold it. Machine gun units were detailed to accompany the engineers and infantrymen filled out the depleted ranks of the engineers, who now formed as two companies. The reorganization had been actually carried out under machine gun fire from a point about six hundred yards distant.

Again the engineers started across the open, the first company encountering a line of Boche skirmishers. But this time the wood was taken throughout its entire length, and a heavy counter attack from the front was beaten off with the aid of the machine gunners.

Unexploded bomb; Fossoy; Marne; July, 1918

During the night the men dug in in groups of two to four at about 50-yard intervals along the edge of the wood. The following day an American advance on both sides took the commanding hills and straightened out the line. A fresh engineer company came up the second night, bringing tools, and wiring the woods against another frontal attack. Six days from the time the engineers entered the wood, the division was relieved, and went to the rear for a well-earned rest.

In general, the combatant engineer must be able to accomplish any sort of a technical job, and must be prepared to act as infantry when occasion demands. The ideal engineer company contains a large proportion of specialists, and invariably these men are the first casualties. Then new men must be developed to furnish the special details constantly required by the work at hand. A replacement who had been transferred from the infantry to the engineers gave his opinion of the sappers thus:

"Well, sir, it's like this. When I was a doughboy we would fight a little and that was very bad, but after it was over we had plenty of time to sleep and rest. Now in this engineer outfit we fought our way in here just like infantry, but now you have got us out here working like the devil all the time and we are just coaxing the Hun to shoot at us. I haven't had any time to sleep at all. Sir, I'm off the outfit, I want to go back to the infantry."

Our mission was to assist the advance of the infantry and artillery, and the measure in which we carried out the mission was limited only by our experience, ingenuity and physical ability. The engineer officer sins most who lets opportunity slip by unnoticed. He can not be smug and contented as long as one single combatant within his area is in trouble, and he must find the trouble. He must offer aid to the limit of his resources. He must anticipate situations and be ready to meet them. He must cautiously advise, and sometimes suffer for his zeal. But whether he digs an emplacement for the artillery or replaces the infantry in an attack, he must remember that in carrying out his mission he is one vital part of a huge machine, and one part which must function so well that it can be forgotten, so long as it continues to function.

"Mad Anthony" Wayne's Campaign Against the Indians in Ohio

1792-1794

By

H. L. Robb

Captain, Corps of Engineers

[*Note.* To the general reader this exceedingly well written account will be of interest as a record of a very important epoch in our national history, and of one of the decisive battles fought on the American continent.

For the military man this little sketch literally teems with the most valuable and important military lessons. It proves that lack of preparation, carelessness and indifference are sure to meet disaster, and that proper training and discipline, thorough preparation and skillful leadership are the essentials of success.

The success of General Wayne in this campaign stamps him as a military leader of the highest rank, and entitles him to the admiration and gratitude of his country. He took his duty seriously, prepared for it thoroughly, neglected no precautions, and when he finally struck, the force of his blow was irresistible, and the results immediate and far-reaching.—ED.]

THOUGH now nearly forgotten, and given only the most casual mention by the historian, General Anthony Wayne's campaign against the Indians in Ohio, constitutes one of the most inspiring and instructive chapters in our military history. A study of it reveals the display of competent generalship, and the application of sound military principles to a difficult problem, by a leader whom we have been taught to consider a reckless fire-eater, rather than a man given to painstaking preparations and the exercise of judgment and proper caution.

The following sketch of events preceding Wayne's campaign is given for the purpose of illustrating the relation of this affair to our national history.

In 1788, the first permanent settlement in Ohio was established near the mouth of the Muskingum river by a band of settlers, under the leadership of General Rufus Putnam. Friction with the Indians ensued, and a large number of lives were lost in numerous encounters between the settlers and the Indians. The larger part of the small regular army, then consisting of about 1,200 infantry, and a battalion of artillery, poorly outfitted and poorly paid, was sent to the vicinity of the settlement for the protection of the settlers.

General Joseph Harmar, a Revolutionary officer of excellent worth, was in command of the army. Harmar led an expedition against the Indians, and was defeated with considerable loss near what is now Fort Wayne, Indiana, on October 22, 1790. Although Harmar was personally exonerated, the command of the next expedition was given to General Arthur St. Clair. Preparations were begun for another punitive expedition in September, 1791. The new expedition was organized hurriedly and moved against the Indians in October. St. Clair was taken ill, measures of security were practically neglected, the militia deserted in large numbers, and as a final blunder, an entire regiment of regulars, under the command of Colonel Hamtramck, the most efficient officer in the expedition, was detached in the face of the enemy for the purpose of capturing some of the deserters. The finish of this ill-fated adventure came on the 4th of November, 1791. The army had camped for the night in two parties, separated by a creek. The militia forces were placed in the most exposed position. At dawn the savages fell upon the militia camp, with appalling whoops and yells, combined with the efficient use of the most modern fire-arms, which had been supplied to them by the British agents. The militia broke and ran, plunging pell-mell into the assembling force on the opposite side of the creek, throwing the whole force into confusion. The Indians, in the meantime, surrounded the entire camp and from all sides poured a murderous fire in the mass.

The panic-stricken men huddled together for protection and the slaughter was terrible. St. Clair, aroused from his sick bed, though so weak that he was unable to mount a horse without assistance, dashed around trying to arouse his men. In desperation the men finally attempted to charge their enemy and fight their way out. St. Clair at the head of one of these charges finally opened a gap through which the survivors poured in haste. The Indians were too busy pillaging the camp to pursue them far, and thus out of a total of about 1,400 engaged, 600 escaped, leaving 800 dead and wounded to the mercy of the savages.

The government was badly demoralized by St. Clair's defeat. The United States would have been glad to make peace with the Indians on almost any honorable terms. The nation was very poor and loath to undertake the heavy expenditure required for a real campaign. There was little national glory to be won even by a successful Indian war, and another defeat would have been a serious disaster. Every effort was therefore made to conciliate the savages but they, encouraged and supported by the British agents in Ohio, maintained a scornful and hostile attitude.

In the meantime Congress was persuaded to authorize an increase of the army, and money was provided for a new expedition, the head of which was to be appointed by President Washington. A nucleus for the army existed in the remnants of St. Clair's defeated army. One entire regiment of regulars had not been engaged in the final crushing defeat, as we have seen. The officers had, however, been either killed or, like St. Clair, had resigned in disgrace.

The problem of selecting a leader for the army was therefore considered at length by Washington. Most of the prominent Revolutionary leaders were either dead or too old for such strenuous service as was involved in the coming campaign. Lee, Morgan, and Wayne, appear to have been those considered most seriously. Of Wayne, Washington has left a memorandum of his opinion. He considered Wayne "vain, susceptible to flattery, brave almost to the point of rashness," and feared that he was "no economist." Nevertheless, "Mad Anthony" was undoubtedly the man for the task. He had the record of being one of the most successful leaders of the Revolution. In addition, he had had some experience in Indian warfare.

Digitized by Google

having led an expedition against the Creek Indians in Georgia at the close of the Revolution. He was an engineer by training, and a soldier by preference. At the time of his appointment, Wayne was about 47 years of age, and was in the prime of life, health and vigor. His personality and record were such as to inspire confidence in the men under him as well as in the country at large.

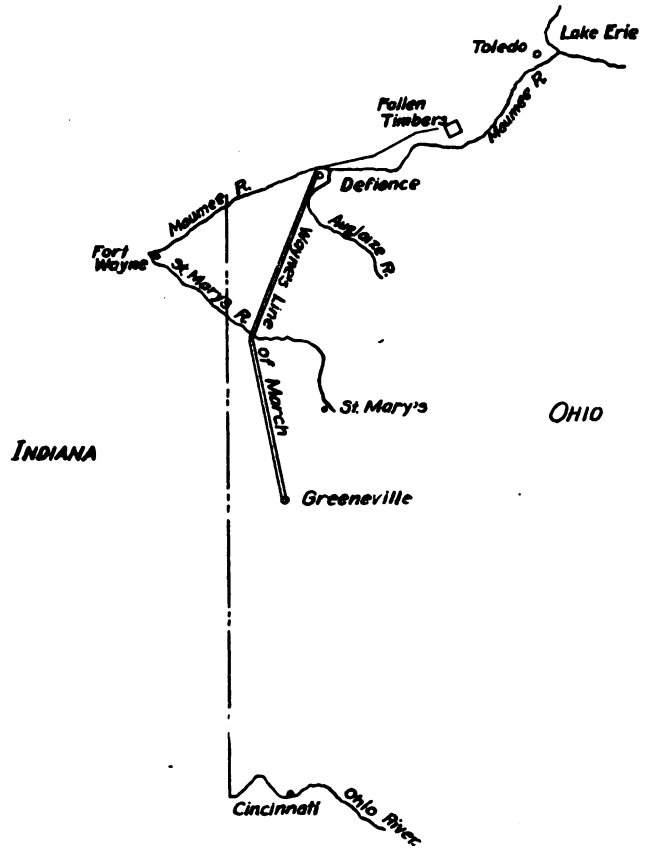
Immediately following his appointment, in April, 1792, Wayne proceeded to Pittsburgh, Pa., and established his headquarters at that place. He had made the stipulation, in accepting the commission, that he should not be required to move against the Indians until he was ready. He proposed therefore to receive recruits, and organize his force at or near Pittsburgh.

The organization authorized was one suggested by Baron Steuben, and is described in detail by General Upton in his Military Policy of the United States. Briefly, it was to be called the Legion of the United States. The legion was to be sub-divided into 4 sub-legions, each to be commanded by a brigadier-general, to have a strength of 1280 men; each sub-legion was organized into the following units:

1 troop of cavalry or dragoons.....strength	80
1 company of artillery.....strength	60
4 rifle companies, at 95 men.....strength	380
8 infantry companies, at 95 men.....strength	760
Total.....	1280

4 sub-legions at 1,280 men, grand total authorized, 5,120

This plan of organization was apparently carried out, but the total number of men was never more than about half that authorized, due to desertions and illness.



The burden of organization was at the start borne almost entirely by Wayne alone. In addition he of necessity had actually to conduct, personally, all drills both of men and officers. There is little record of the problems he faced at this time, but they must have been enormous, yet Wayne appears to have carried the burden with patience and self-confidence.

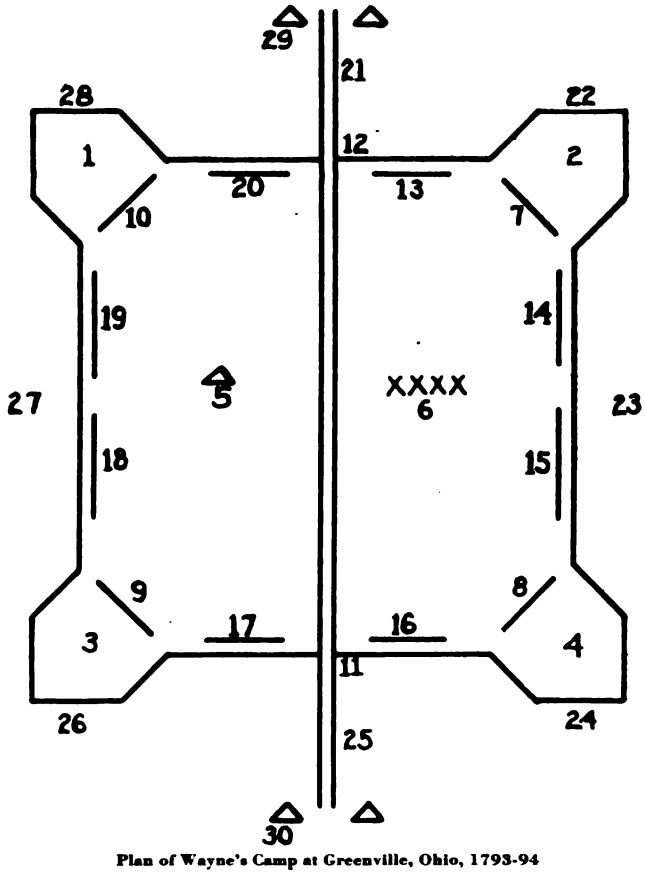
Recruits were shipped to him in large numbers, but many of them became panic-stricken as they neared Pittsburgh and deserted. Of Wayne's recruits one unfriendly observer remarks that they were "purchased from the prisons, wheel-barrows and brothels of the nation at foolishly low wages," and that taking them as a whole they were men who had "enlisted because they could no longer live unhung any other way." This estimate, undoubtedly a very harsh one, seems to be the original black eye, under which the much maligned regular soldier has suffered for many years. The problem of transforming these men into soldiers was probably as difficult a problem as any commander has had to face. Many of them were mere boys or weaklings, unaccustomed to handling the ponderous firearms of the period. Nevertheless, this group of men was gradually transformed into a disciplined army. Both officers and men grew into their tasks, and those who did not agree with the commander were eliminated from the commissioned personnel.

The points that were emphasized in this training period were: (1) the use of the rifle, (2) instruction in guard duty and (3) endless practice in charging, accompanied by blood-curdling whoops.

By March, 1793, Wayne was able to report that the morale and discipline of his command was at a high pitch. The men had acquired a confidence in themselves and their commander, which they never lost. In May, 1793, the Legion moved down the Ohio river by boat to Cincinnati, and established a camp about a mile from the city. Here they remained until October, while negotiations were being carried on by the government with the Indians in futile efforts to effect a settlement. The Secretary of War continually warned Wayne that he must be cautious and hazard nothing. This injunction was scrupulously observed by the general. His conduct and careful obedience to the governmental restrictions were not such common virtues at that time, and Wayne won the commendation of Washington, and the implicit confidence of the government by the restraint he practiced throughout the campaign.

On October 7, 1793, the Legion moved to the present site of Greenville, Ohio, where a fortified camp was constructed, and the army went into winter quarters. The

position of the Legion here was both a threat to the Indians and a protecting barrier for the settlers. During the winter, a fort was built on the site of St. Clair's defeat and called Fort Recovery. These fortifications were planned and superintended in part by Wayne himself. A sketch of the fortified camp at Greenville is shown for the purpose of illustrating how well organized the expedition was, and also to indicate somewhat of Wayne's skill as a military engineer.



During the winter Wayne caused a number of roads to be built through the forests, leading in different directions from Greenville, for the purpose of deceiving the savages as to his intentions. The savages were in the meantime keeping a close watch on Wayne, and all his movements were reported to the British agents in Northern Ohio. On June 30, 1794, the Indians made a savage attack on Fort Recovery, but were forced to withdraw after suffering some loss.

Wayne was now preparing to move against the savages, but was delayed by lack of supplies until the latter part of July. On July 26, 1794, he was joined by Major General Scott, an old Indian fighter, in command of about 1,200 mounted Kentucky militia. A number of experi-

Digitized by Google

enced Indian fighters and scouts had been induced to join the expedition also, and were of great service to the army.

On July 28th, the Legion left their camp at Greenville and instead of moving to the northwest towards what is now Fort Wayne, or the northeast towards Toledo, as the Indians had been induced to believe they would, a middle

course was chosen leading almost directly north to Defiance, Ohio. In eleven days the army marched 76 miles through a heavy forest, constructed a bridge 210 feet long across a swamp, built a fort at the crossing of the St. Mary's river, and cleared a road. Throughout the march no precaution for the safety of the command was neglected. The command marched in open order with a strong "front guard," and spies and scouts were kept well out to the front and flanks. These spies and scouts were able to capture, almost at will, individual Indians, and from the captives so made, much information was secured. Wayne was determined that he would not suffer the fate of Braddock and St. Clair. He showed his generalship by taking advantage of the services of the numerous white Indian fighters who were at home in the wilderness. On this march Wayne was severely injured by a falling tree while he was endeavoring to speed up the construction of the fort at the crossing of the St. Mary's river. He did not, however, allow his injury to delay the march for a moment. He had planned to plant himself in the heart of the Indian country before the savages knew that he had left his camp at Greenville. He did not succeed in this entirely, as a deserter gave warning of his approach, but the rapidity of his march impressed the Indians to such an extent that they nick-named him the "Whirlwind" and the "Blacksnake."

The Legion arrived at the junction of the Au Glaize and Maumee rivers on August 8th, 1794. The Indian inhabitants of the village at that point fled at the approach of the army. Here a week was spent in constructing a strong log stockade with four blockhouses as bastions. This fort was named Fort Defiance. A small garrison was left in the fort and on the 15th of August the army moved out again, marching down the north bank of the Maumee, and on the 18th, arrived at a point called Roche du Bout. The 19th was spent in constructing a rough stockade for the protection of all stores and baggage, and in making a reconnaissance of the Indian forces. The enemy was found to be encamped in a thick woods in the rear of the British fort at the rapids of the Maumee.

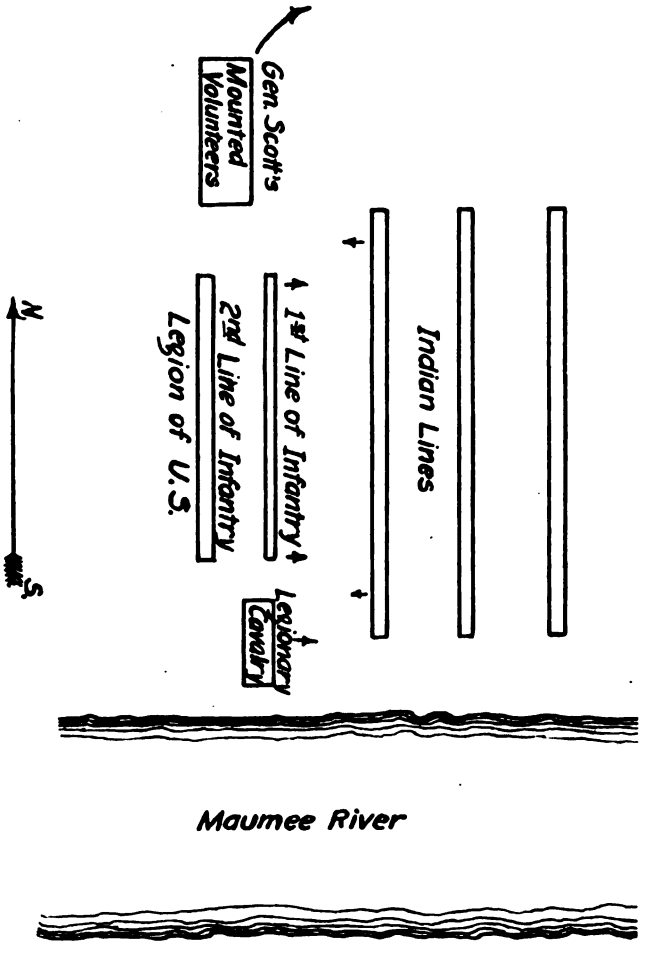
Wayne had previously dispatched a messenger to the Indians with a final offer of peace. This messenger returned with the answer that "if you will remain at Fort Defiance for ten days we will let you know whether we will be for peace or war." This insolent answer was not a correct representation of all the Indian sentiment. One of their most prominent chiefs, Little Turtle, called the attention of his fellow savages to the immense difference in the conduct of Wayne's expedition as compared with those of Harmar and St. Clair; he declared that "something whispered him" that the outcome of this coming encounter would be different than the previous ones had been. The hot-heads were in control, however, and Little Turtle's advice was rejected.

On the 20th of August, 1794, the Legion marched from their camp at 8 a. m. A battalion of selected men, from the mounted Kentuckians under Major Price, marched well to the front; a brigade of mounted volunteers under General Todd of the Kentucky militia, covered the left flank; the right rested on the river; and the remaining brigade of mounted men under General Barbee brought up the rear. The main body of the Legion advanced in two columns under General James Wilkinson and Colonel Hamtramck. The Legion advanced slowly throughout the forest until 11 a. m., when the advanced battalion was greeted

Wayne's March Formation prior to Battle of Fallen Timbers

with a heavy fire, thrown into confusion, and forced to retire on the main body in disorder. Wayne was prepared for just this situation, and at the sound of the first firing caused the Legion to be deployed in two lines. General Scott, with the two brigades of mounted men, was ordered to take a circuitous route and strike the enemy on their right flank; the Legionary cavalry, under Captain Camp-

Digitized by Google



bell, was directed to charge the enemy's left. The front line of infantry was ordered to charge with rifles at the trail, and to rouse the Indians from their cover in a mass of fallen timber, at the point of the bayonet, reserving their fire until this had been done. The second line was ordered to follow and support the first.

The Indians were formed in three lines, at right angles to the river, and were well covered by a mass of fallen timber, as stated before. They directed a heavy fire on the Legionary troops while they were forming for the attack, and endeavored to repeat their tactics of the battle with St. Clair's army, when they had so successfully surrounded a force larger than their own. But Wayne was too quick for this to succeed. On the Legion's right the cavalry charged with "broad swords swinging," the horses jumping over the fallen trees, and rammed their way pell-mell into the savage ranks. In the center the front line of infantry advanced with equal impetuosity and vigor; the Indians were able to deliver only one volley before, with a shout, the soldiers were upon them. The savages broke and fled; as they fled the infantry fired at their backs; if they attempted to halt the infantry pounced upon them with the bayonet. So complete was the success of the first charge, that only the cavalry and the first line of infantry were able to take part in the actual fight. The Indians were pursued through the woods to the very walls of the British fort, where they had taken shelter. The entire action lasted only 40 minutes. Less than a thousand Americans actually took part. The number of the enemy was about 2,000, including about 400 whites, Canadians, and renegades. The American loss was 107 men killed and wounded, the enemy loss was about twice that many.

This battle was the most complete and important victory gained over the period of 40 years' warfare to which it put an end, and the only one of any importance in which the Indians lost more than their foe. The results of the battle were far-reaching; the war spirit of the Northwestern Indians was subdued, as well as growing restiveness of the many other frontier tribes in New York and in the South, who had been watching the progress of the American army in Ohio. The Indians learned that no great reliance could be placed on British protection, the superior power of America was at last made manifest to them and they came forward to sue for peace. The voice of the anti-war faction which had risen to such heights as to embitter the life of Washington, was stilled for a time. Great Britain was induced to sign a treaty confirming American rights in the Northwest.

The concluding events of Wayne's campaign are of no special military importance. He laid waste the Indian country along the Maumee, destroyed even the British agents' houses and fields up to the very walls of the British fort at the rapids of the Maumee, while the British commander was forced to look on, powerless to stop him. The army then returned to Defiance and proceeded to Fort Wayne, Indiana, where that fort was then constructed. The following summer the Indians signed a formal treaty of peace at Greenville.

The weaknesses of St. Clair's expedition are a lesson suitable for embodiment in a military primer, while the strength of Wayne is only emphasized by a statement of these weaknesses. The principal weakness or fault of the St. Clair expedition was the choice of the leader. For this Washington was largely to blame, as much as he is to be praised for the choice of Wayne. St. Clair was elderly, in poor health, had a reputation in the Revolution which, at best, indicated only mediocrity, and a propensity to failure. The poor quality of his troops was a second flaw, though under a lengthy training these same men in many cases became real soldiers. The third and principal error made, was in the presumption that an army could be organized and become effective in the short space of two months or less, which was all St. Clair was given for his task. The final massacre of St. Clair's force even then was due to the criminal lack of any measures for information and security. No scouts were sent out, no

Wayne's Formation for Battle

attempt was made to learn anything of the enemy's whereabouts, and even the camps were guarded by only a few sentinels, apparently posted close to edges of the camps.

For Wayne, we can have only admiration for his competence. He accepted the leadership of what was popularly regarded as a hopeless undertaking, and carried it through to completion and success. His success was built on the solid foundation of adequate preparation and able leadership. For the two years preceding the battle of Fallen Timbers, the Legion was undergoing a steady training in the fundamentals of the soldier's profession. From the beginning, an information and security service was in force. The aid of the frontiersmen was enlisted to keep the army informed of the doings of the savage enemy. On the march, the same measures that would be adopted today under similar circumstances, were adopted to preserve the army from ambush. When the army halted, they "dug in" and prepared to hold the objective gained. The men in ranks saw and understood all these things and by so doing, gained that intangible but priceless asset of an army, morale, without which they would have been lost, but with which they were able to crumple, at one blow, the Indian foes of the Northwest.

Colonel Mason M. Patrick, Corps of Engineers, Appointed Chief of the Army Air Service

Col. Mason M. Patrick, Corps of Engineers, whose portrait appears as the frontispiece of this issue, was on October 4, 1921, appointed Chief of the Army Air Service, with the rank of Major General.

The appointment is a recognition of the conspicuously efficient service of General Patrick as Chief of the Air Service of the A. E. F., and will be a cause of gratification to the engineering profession generally.

Mason M. Patrick was born in West Virginia, December 13, 1863. He was appointed to the Military Academy from his native State in 1882, graduating No. 2 in class of 1886.

On graduation, General Patrick was assigned to the Corps of Engineers, in which he rose to the rank of colonel on March 24, 1916.

In his service as an officer of the Corps of Engineers, General Patrick enjoyed a widely varied experience, both civil and military, which fitted him to perform with conspicuous success the important duties which devolved upon him during the World War. At various times he served as District Engineer Officer at Norfolk, Va.; Wilmington, N. C.; Detroit, Mich.; Cincinnati, Ohio; Memphis, Tenn.; in charge of the U. S. Lake Survey; Secretary of the Mississippi River Commission; Division Engineer; raising the wreck of the *Maine;* instructor at West Point; assistant in the Office of the Chief of Engineers; Commanding Officer Post of Washington Barracks; commanding the 2d Battalion of Engineers, Chief Engineer of the Army of Cuban Pacification, commanding 1st Regiment of Engineers.

When the U. S. entered the World War, General Patrick was one of the first to proceed to France, sailing August 7, 1917, from New York, as colonel of the famous 1st Engineers, which regiment he had organized and trained.

Shortly after his arrival in France, Colonel Patrick was promoted to the rank of brigadier general. He was successively appointed to the positions of Chief Engineer of the Lines of Communication, Commanding General of the Lines of Communication, and Director of Construction and Forestry. In this latter capacity he was charged with the direction of all engineer construction in the A. E. F.

General Patrick's chief contribution to the winning of the war was as Chief of the Air Service, A. E. F., to which position he was appointed on May 29, 1918, and shortly thereafter promoted to the rank of major general. In the face of extraordinary difficulties he thoroughly reorganized the Air Service, placing it on an efficient working basis. In addition to his regular duties he served on various important boards and commissions, including the Inter-allied Aviation Committee and Munitions Council.

In recognition of his many and conspicuous services General Patrick was awarded the distinguished service medal and was likewise awarded decorations by England, France, Italy, and Belgium.

His last assignment to duty with the Corps of Engineers was as Commanding Officer of the Engineer School, U. S. Army, and the post of Camp Humphreys, Va. Since the inception of the Society of American Military Engineers, the interest and enthusiasm of General Patrick have been an important factor in its development.

Subsidence of River Banks

By

H. McL. Harding

MR. H. McL. Harding, Consulting Engineer, City of Natchez, Mississippi, has furnished a very interesting paper, of which the present article is an abstract, on the subsidence of river banks, as affecting terminal and other waterfront improvements. It is regretted that limitations of space prevent the publication of the paper in full.

After an investigation and study of waterfront conditions at a number of cities on the Mississippi and Ohio Rivers, the author concludes:

First. The river bank and levees may subside, as a consequence of the transportation of the subsoil by the flow of underground water, at points where the bank is not eroding, and even where accretion is taking place. The underground flow may be due to springs, lakes, or natural drainage.

Second. The underground water, whatever its source, on reaching a wholly or partly impervious stratum of clay or rock, may flow above this stratum in a narrow course, causing a gully in the banks or a bayou; or may spread fanwise, and convey away earth and sand, leaving voids and cavities in the soil above the impervious stratum. Supporting columns of material, which have resisted the slow moving water, may remain. There may be several impervious layers with softer material between them, and consequently separate underground streams at different elevations.

Third. When the underground flow is small, or at a great depth, a long period of time may be required to produce a marked subsidence. The earth may arch so as to prevent, for the time being, any settlement.

Fourth. A rise in the river will fill the voids and cavities with water both from the river itself and from the underground flow from the land. So long as the rise lasts, no settlement results. However, the layers of soft earth become saturated, and their weight increased. When the flood recedes, the underground flow is augmented in volume and velocity, more material is transported, the voids increase, and then comes the subsidence of the surface, gener-

Digitized by Google

ally following a falling river stage. When the supporting earth columns or arches are slowly removed, the surface subsidence is gradual; otherwise it may be quite rapid, often several feet in twelve hours or less. Much depends on the character of the soft strata. It may be gumbo clay, which, while ordinarily resistant, becomes fluid when saturated with water, and then flows or is squeezed out.

Bank subsidence is therefore due to underground flow or drainage from the rear, either alone or in combination with water from the river discharged during a falling stage. The river water cannot be kept out of the subsoil if there is underground flow from the land. The subsidence in swamps due to subsoil movements requires a different treatment.

The author cites a case where the bank consisted of a stratum of impervious blue clay (erroneously called soapstone) overlaid with gravel, sand and marl. The blue clay stratum extended about 13 feet above local river datum, and had a depth of more than 80 feet. Above the clay was first a layer of gravel containing about 40 per cent sand, then a layer of sand, and finally of marl. The total depth of the overlying material was from 20 to 30 feet. The bank extended back from the river several hundred feet to high bluffs. Buildings and accessories of a municipal public utility occupied a frontage of about 600 feet along the river. There had been a spring flowing to the river in considerable volume through the northern end of the property, but it had been stopped by filling and revetment. The flow of underground water through the central and southern portion of the frontage, which was previously only a small seepage, then greatly increased, and the bank undermined and fell away. Various attempts were made to check the sloughing, by cinder filling, brush, concrete walls to keep out river water, etc., but with no good result. The protective works were undermined by the ground water coming from the land.

In another case, in a different locality, settlement of the levee and the land in rear of it was experienced on a frontage where a foreshore was being deposited in front of the bank, and where no erosion or sloughing of the bank was experienced. A large drain was constructed for diverting the drainage from the southern part of the city frontage to a point beyond the city limits. Since its construction there has been no change in the elevation of the levee in this section, but in the northern portion, where no drain has been provided, there is still a continual subsidence.

After giving other instances, the author recommends the following corrective measures:

First. That borings be made to determine the existence of impervious strata and their depths, and to determine the presence or absence of underground flow. These borings should be on a line in rear of the area, and on lines perpendicular to the banks at its limits. They should extend to impervious material, which is generally found at no great depth.

Second. If water is found at a reasonable distance below the surface it should be diverted by drains into the river, so that it will not flow under the area affected. The drains may be porous drain pipes with open joints, laid in broken stone. They should extend along the rear of the area to be protected, and have suitable outlets to the river.

Third. Lines of stakes, parallel and perpendicular to the river, should be set and their elevations taken to determine surface movement and subsidence.

The author explains that the above is only a general outline of the necessary procedure.

Discussion

Charles L. Potter

Colonel, Corps of Engineers

I have read with interest Mr. Harding's article and particularly his suggested method of investigation and treatment. The method of investigation is sound. His method of treatment (drainage) is good, in the cases where it can be applied. In some cases, however, it is impossible to apply such methods.

It is also not always practicable to determine that a locality needs treatment. At Helena, Ark., some years ago, a section back from the river bank subsided bodily. On this bank there is the usual bank revetment, consisting of a wide willow mat up to about low water, and a loose rock pavement above. It is true that borings would have shown an underlying stratum of sand; but the fact that the bank revetment had remained unchanged for years, would have indicated that this locality would be safe for structures of moderate weight. When the sudden subsidence occurred, there was no movement in the bank. This would indicate that the undermining occurred entirely away from the immediate bank. It is inconceivable that sand, away from the bank, could be moved toward the river and leave the bank fully supported. It was the view of the Mississippi Commission that the sand was carried away laterally and not toward the river. In this case exploration would have indicated no real danger; and treatment, if any had been undertaken, would probably not have been carried out in the right direction.

Another case, which the commission is now studying, is at Memphis. At this place the city has built a terminal at the top of a high bluff and connected by an incline with a floating barge at the river. It is not a case of locating a terminal, but of trying to save an existing structure. The river bank slopes to about high water (35 to 45 feet on the Memphis gage) where it is surmounted by a nearly vertical bluff 50 to 60 feet high. Borings at the foot of this bluff show no impervious stratum for 60 feet (30 feet above to 30 feet below the zero of the gage). It is practically all sand. Slight cavings from the bluff at high water indicated that they might be due to direct action of the river on the underlying sand. But some distance up river the Frisco tracks leading to the terminal have been damaged, and their connection with the terminal threatened, by such decided caving that it cannot be believed that it is due to the action of the river. This stratum of sand is found in wells in the lower parts of the city—quite a slope back from the bluff makes a back portion of the city lower than at the bluff—and it is invariably found to be water bearing.

Many years ago the Mississippi River Commission reveted this bank to the extent of an underwater mat. This mattress work has remained unchanged, even opposite the deep caving threatening the Frisco tracks. The sloughing occurs above low water. The upper bank paving was not added, since the low water line was nearly up to the bluff when the mats were put in. The bluff has since gradually receded until there is now a fair slope from low to high water. The commission has decided to pave the upper bank for some distance either side of the terminal with concrete, providing for carrying away of the water along the lower edge of the concrete by an open gravel-filled ditch. This, if it stands, will prevent direct action of the river on the sand stratum. If the water in the sand has not too much head (and it should not, since it is not held in any other direction so far as is known) it is believed

Student Military Training

An Address by

The Honorable John W. Weeks
Secretary of War

Presented at Lehigh University, October 8, 1921, by Major General James G. Harbord, Deputy Chief of Staff, on behalf of the Secretary of War.

THIS is a day set apart at Lehigh University for the expression of a tribute of appreciation and gratitude to those to whom the University owes its origin and its upbuilding in the fifty-five years of its existence.

Lehigh University has been and is noted for its promotion of matters of national public service. I am therefore glad to have this opportunity to speak on the subject of Student Military Training here, because the time has now arrived when it is possible to speak of military training in the schools and colleges as a part of a comprehensive program of national defense. I am particularly glad to speak on this subject at Lehigh University because Doctor Drinker has not only been one of the pioneers in developing student military training but through his leadership he has had no small part in organizing and developing the public opinion that has finally crystallized into a settled national military policy.

In my capacity as Secretary of War I am officially disposed to emphasize the importance of student military training from the standpoint of its value to the national defense. It means an assured supply of highly intelligent reserve officers. It means that the requirements of national service are to have proper consideration in the education of our future thinkers and men of affairs. It means that a new public value is being developed in the graduates of our schools and colleges. It means a more intelligent public opinion with reference to military economics and international affairs. This alone will justify student military training in the minds of all patriotic citizens.

But student military training does not involve a sacrifice for the public good without return to the individual. It has a positive educational value for each student. Our most eminent educators have agreed that, aside from its physical benefits, time devoted to the military studies in the R. O. T. C., is fully entitled to credit in the general scheme of mental culture. The student of engineering will be a better civil engineer for some knowledge of the military applications of his profession to the nation. In subjecting themselves to the discipline which is essential to military teamwork, young men soon learn the real secret of modern civilization which depends upon the combined action of human beings to common ends.

There is also a distinct moral advantage in the contemplation of patriotic service to the nation and in preparing to meet its obligations. But perhaps the greatest benefit of military training is found in the opportunity it gives a young man to develop his gift of leadership and to acquire a sense of its responsibility. No man can prepare himself to serve his country in war without making himself more valuable for all of the relations of civil life. The student who avails himself of the opportunity offered by the military department of this University will graduate a better man for himself, for his family and for his country. He will go out better prepared for peace as well as for war.

The progress of military training in our schools and colleges is already most encouraging. At the close of the past academic year, the total enrollment in the Reserve Officers' Training Corps was 90,811. There were 227 Senior Units with 5,025 students enrolled in the Advanced Courses and 39,228 students enrolled in the Basic Courses. There were 116 Junior Units with an enrollment of 46,558. Of these Junior Units, 51 with an enrollment of 34,472 were organized in the High Schools of the country. Of the 5,025 students in the Advanced Courses, 1,069 qualified for commissions in the Officers' Reserve Corps at the close of the academic year.

I am particularly impressed by the record of Lehigh University during the past year. The total enrollment in the University's R. O. T. C. was 545. It is expected that this year's enrollment will be about 700, with at least 70 in the Advanced Courses. Lehigh sent 17 advanced students and 130 basic students to this year's R. O. T. C. Camp at Plattsburgh. I am informed that the Lehigh students had a higher average of marks than those of any other institution represented at the camp. This gave Lehigh the Efficiency Cup. The Seventh Company composed exclusively of Lehigh men was officially rated as the best company at the camp. The Eighth Company with a fifty per cent membership of Lehigh men, was rated as the second best company in the camp. The Lehigh Rifle Team won the Intercollegiate rifle match and with it the honor of representing the R. O. T. C. Units of the 1st, 2nd and 3rd Corps Areas in the National Matches at Camp Perry.

It is my good fortune to be the first Secretary of War who has been able to announce the establishment in time of peace of a national defense organization sanctioned by the Congress and defined by the President of the United States. It has always been understood that in the event of serious national emergency we would expand a small professional peace Army into a great non-professional War Army. The defect of this policy in the past has been that we have always deferred the organization of this national War Army until danger has actually come. Our new national defense law does not change the type of this traditional American institution. It simply prescribes that the defect be corrected—that our traditional Citizen Army be organized in time of peace so that the actual units which may be required upon mobilization shall be permanently constituted and localized. This is the realization of Washington's words to Congress in 1790, when

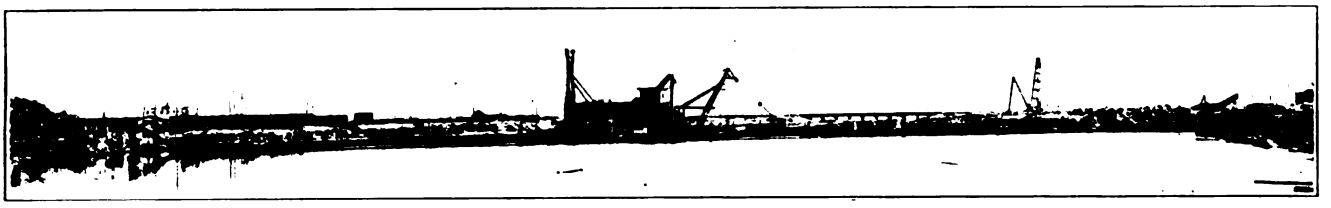

Fig. 2, 36-inch siphon assembled ready for lowering

Inverted Siphon in Sewer System

By

Burt Harmon
Captain, Engineer Reserve Corps
Formerly Junior Engineer, Engineer Department at Large

Note.—In a letter accompanying this article the U. S. District Engineer at Los Angeles (Maj. E. D. Ardery) says:
"There is enclosed an illustrated paper on a sewer siphon written by Capt. Burt Harmon, Engineer O. R. C., who, as Junior Engineer of the Engineer Department at Large, was in local charge of the Silt Diversion Works for the protection of Los Angeles and Long Beach harbors, California, and who designed and installed the necessary alterations in the Long Beach sewer system where crossed by the new river channel.
"The 36-inch siphon was installed at the same time as the 27-inch pipe, not only because the United States desired to complete its share of the work pertaining to the diversion project, but also because in heavy rains enough storm water finds its way into the sewer to exceed greatly the capacity of the 27-inch pipe, in which cases it, for brief periods, overtops the wooden partitions and uses the other pipe also
"While standard practice would indicate a minimum slope of about one per thousand for a 36-inch sewer, and perhaps one and a half per thousand for a 27-inch sewer, the 27-inch side of the siphon described above is operating successfully with a slope of about one in twelve hundred."—ED.

AN inverted sewer siphon that may be of interest to engineers by reason of its length and exceptionally flat grade was built during 1920 by the United States Engineer Department at Long Beach, Calif. The siphon, as part of an existing sewer, was made necessary by the construction of silt diversion works for the protection of Los Angeles and Long Beach harbors.

The silt diversion channel has a bottom width of 530 feet and a depth of 14 feet, with side slopes of one on one and a half. It passes through the industrial district of Long Beach and intersects several branches of the former sewer system, including the 48-inch outfall sewer to which all the others were tributary through pumping plants. To avoid unnecessary channel crossings all the smaller sewers are intercepted by a new one paralleling the channel and emptying into a sump, from which the sewage is pumped into the outfall sewer before it crosses the channel.

The problem before the designers was to provide a structure that would (1) maintain a scouring velocity with the present minimum flow in the outfall—approximately one-eighth its total capacity—and (2) be sufficiently elastic to provide for future increase in flow up to the ultimate capacity of the outfall. As the sewer is below flood height, a bridge was considered impracticable. Pumping was obviously undesirable. The only alternative was a siphon.

The siphon as constructed (Fig. 1), consists of two welded steel pipes 27 and 36 inches in diameter, laid 7 feet below the bottom of the channel. The horizontal distance between manholes is 611.4 feet, and the total length of the siphon pipes is 619.1 feet, of which 32 feet at each end is inclined (Fig. 2) on a grade of 2 horizontal to 1 vertical. The total fall is 0.50 foot. This very flat grade required that the intake be so constructed as to cause as little obstruction to the flow as possible. For this reason no gates were placed at either end of the siphon, the diversion from the 48-inch pipe to the siphon pipes being made by curved wooden partitions in the manholes.

The invert through the manhole is semicircular, and so designed that when the natural flow in the 48-inch sewer is just equal to the capacity of the 27-inch pipe under the head available, without increase by backwater, the area of the cross-section of the stream is the same at all points between the end of the 48-inch pipe and the beginning of the siphon proper. The same method was followed in designing the 36-inch side. The upper sides of the inclined pipes were prolonged into the manhole so that the floating material will enter them without colliding against a vertical wall. The discharge manhole follows the lines of the intake.

Fig. 1. Intake manhole showing siphon pipes in position prior to completion of channel bank

It is estimated that the 27-inch pipe alone will care for the increase in flow for perhaps two years without creating an undue amount of backwater in the approaching sewer. The diversion partitions will then be replaced by others already prepared to confine the flow to the 36-inch pipe, the sewage being by-passed into the channel while the change is being made. When the capacity of the 36-inch pipe shall have been reached, the second partition will be removed and the flow passed through both pipes, the capacity of the two being approximately that of the 48-inch outfall.

Digitized by Google

The method of placing the pipes is shown in Fig. 3. The pipe was built in 50-foot sections with flange couplings. A trench was dredged across the channel, and a trestle with bents 50 feet apart driven along it. Screws 1½ inch in diameter and 18 feet in length, with the lower end bent into a hook, were placed through the caps of the trestle over the center line of each pipe. The pipe was assembled suspended by slings from these screws. It was then lowered by turning the nuts on the screws simultaneously, the pipe being filled with water from the city mains as it was submerged. When both pipes were in place, they were covered with earth to a depth of 1 foot, and the trench then filled with broken concrete to the level of the channel bottom. This fill was permitted to settle for about six weeks, when the screws were removed and the piles cut off near the top of the concrete fill, the stumps being left for additional security.

Fig. 3. 36-inch siphon being lowered

The siphon has been in operation for eleven months without either lodgment of floating matter in the manholes or indications of deposit of sediment in the pipe.

Superiority of the American Automatic Pistol

A singular corroboration of the claim that the American .45 caliber automatic pistol furnished by the Ordnance Department during the World War was far superior to similar hand weapons in use by other armies is found in two incidents related in the *Cavalry Journal* for July, 1921.

The first is a reprint from the French *Revue de Cavalerie* of May-June, 1921, in which Colonel Loir recounts an encounter between a French and a German patrol. The German patrol of six troopers under command of a commissioned officer was surprised by the French patrol and immediately abandoned its leader, hotly chased by the French patrol except for the non-commissioned officer in charge who remained behind to enter into single combat with the German officer. As the French patrol followed in pursuit of the Boche, they passed in file at a gallop in front of the German officer, and according to Colonel Loir:

The latter fired and hit three horses with three shots at a distance of 30 paces. The French non-commissioned officer, armed with his lance, galloped down upon him and charged him. The officer fired a fourth round, which left a very visible mark on the leather leggin of the non-commissioned officer, and springing aside he avoided the lance. The non-commissioned officer threw his horse about and charged the second time. The officer fired a fifth round, which glanced along the thumb of the lancer's bridle hand, again bounded back, and a second time avoided the shock. With admirable obstinacy, the non-commissioned officer a third time came back to the charge. The officer fired a sixth ball, which, like the five others, found its mark and hit the horse in the point of the shoulder, passed under the skin, and lodged under the saddle, where we found it some days later. A third time he avoided the shock. Undaunted, always master of his horse, and retaining his presence of mind, the non-commissioned officer again made an about and charged for the fourth time. The German then lost his head, believed that he had no more cartridges (he had two more), turned and bolted. Naturally he was struck at once to the ground by a blow of the lance in the back.

The fate of this German officer, armed with a German pistol, who, in spite of the fact that he registered six hits out of six shots with a weapon whose efficiency he backed with his life, was eventually struck through the back with a lance is in striking contrast to the incident related by Capt. Ernest N. Harmon concerning the part played by the Second Cavalry in the St. Mihiel offensive in September, 1918. In proceeding toward Vigneulles he states:

The men were falling back to the cross-roads in good order, when suddenly a machine gun opened up on the column from a small trail leading from the main road on the right. This was on our unprotected flank. The Germans had allowed our patrols to go by and had brought their guns to the edge of the woods as the column started back. All the men opened fire on the machine-gun crew with their pistols as they passed. All rules as to flank men only firing from column of fours were forgotten. All men fired, with the effect that the crew of three men were all killed. Of course, the horses broke into a gallop. The head of the column, being without a leader, dashed past the cross-roads before an officer could get in front. A second machine gun opened fire from the left. The crew hardly fired before they were all killed by the fire of the troops as they passed. Both guns were about twenty yards off the road. The time of firing was short. However, the only reason many of our men were not killed is the fact that the aim was low as for infantry and our column was moving so fast. No commands to fire were given our men; the firing was done from a sense of self-preservation, and was effective. After this incident the men had all the confidence in the world in their pistols.—*Army Ordnance.*

Robert's Rules of Order

How many engineers know that the author of "Robert's Rules of Order" is one of their own profession, that he is a civil engineer and a retired member of the Corps of Engineers of the United States Army and at one time Chief of Engineers, holding the rank of brigadier general? This man, now in his eighty-fourth year, is living a vigorous life at his home in Oswego, N. Y. His book was published in 1876 and was immediately accepted as the standard authority on parliamentary law. The sales have increased yearly so that to date over 650,000 copies have been sold. A new book by General Robert appears this month entitled "Parliamentary Practices" and still another will be published next year called "Parliamentary Law."—*New York Times.*

The Greek Offensive of July, 1921

By

M. C. Shallenberger, U. S. A.
Military Attaché, U. S. Embassy, Greece

[NOTE.—In view of the confusing and often highly inaccurate and unreliable accounts of the Turko-Grecian War which have appeared from time to time in the public press, this informing account of an important phase of the Greek operations by an eye witness, who is also a trained soldier, will be of interest even to the non-military reader.
Major Shallenberger observes, but he also interprets that which he observes in the light of previous experiences of warfare.
We are especially gratified at his testimony as to the conduct of the troops toward prisoners and enemy civilians, proving that war may be conducted in a humane manner, and that brutality to the helpless is not essential to the success of military operations As the evidence on this point is direct and first hand, we have no reasons to doubt the truth of it.—ED.]

General Scheme of the Offensive

DURING the month of June the Greek staff had organized five regiments from reservists, who were used to replace the divisions which were holding defensive sectors and engaged in the duty of guarding the occupied area and line of communication work. The 11th Division had been withdrawn from the Ismid sector and moved to the Brusa sector, the 12th Division had been sent over from Turkish Thrace, having been relieved by two regiments of reservists. By this operation the Greek general staff had available for the offensive eleven divisions, which were organized as follows:

First Corps—
1st Division.
2d Division.

Second Corps—
5th Division.
13th Division.

Third Corps—
7th Division.
10th Division.

Northern Group—
3d Division.
11th Division.

Acting Directly Under Army Orders—
9th Division.
12th Division.
4th Division.
1st Cavalry Brigade.

Army Troops—
One Regiment of heavy artillery, 120-mm. guns.
Two groups, 6-inch howitzers.
2d, 3d and 4th squadrons aeroplanes (24 planes).
One squadron from the navy (5 planes).

Total combatant force for operations, 150,000 men, 271 guns, 29 planes.

The Turkish force opposing the Greek troops consisted of fifteen known infantry divisions, and possibly two others, plus three cavalry divisions. These were organized into five groups of three divisions each, a total combatant force of 80,000 men and about 140 guns.

The Greek plan of action had for its objective the occupation of a line beyond the railway running from Bilejik through Eske-Shehr to Afium Kara-Hissar. The Turks had so strongly fortified the defile running from Bilejik to In-Eunu that to attempt to again pass by that route was not attractive. The route through Kutahia was, therefore, decided upon. The Greeks then purposely allowed the information to leak out that they were going to march from Ushak through Kutahia or Eske-Shehr. Newspaper reporters and foreign observers found this information everywhere, so that it soon became common all through the Orient that the Greeks were going to follow this route in the next offensive. The Turks made use of this information and commenced the fortification of Kutahia, facing their fortifications to resist the movement from Ushak.

In the first days of July the Greeks announced that they were going to attack, and assembled seven divisions and the cavalry brigade at Ushak. They made no attempt at concealing them, and allowed the Turkish aviators to come over and observe and photograph them. At the same time they assembled four divisions at Brasa, which were apparently to march against In-Eunu.

On July 8, the 9th Division marched from Ushak via Gediz on Kutahia in four columns, each column made long for the purpose of deception, and the 11th and 3d Divisions commenced to march in the direction of In-Eunu. On the same date the 3d Corps, consisting of the 7th and 10th Divisions, which had been secretly moved to Southwest of Brusa, commenced to march on Kutahia by the trails passing over and to the west of Mt. Olympus. The bulk of the army, that is the remaining six divisions and the cavalry brigade, were marched in two night marches from Ushak to Toulum Bonar. During this time the Turkish aviators were not allowed to approach the Greek lines and all movement was kept secret. On July 10 the Greeks issued the first communique which announced the progress of columns moving north from Ushak and those moving east from Brasa. No mention was made of the other forces. On July 10, the 1st and 2d Corps moved north from Toulum Bonar, having as the objective the left flank of the Turkish position which they were to take by envelopment, while the 3d Corps from Brusa was to turn the Turkish right flank. On this same date the 12th and 4th Divisions marched against Afium-Kara Hissar. The cavalry brigade marched between the two forces.

It is thus seen that the operations against Kutahia were to be that of a maneuver in which the Greeks, by giving out false information, caused the Turks to take up positions which could be turned by their columns moving from unexpected directions.

It was very evident that the Greeks had carefully prepared for this offensive in every detail Whether the credit belongs to the King and the Great General Staff, headed by General Dousmanis, or to General Papoulos and his staff, is difficult to say, but every feature seemed well prepared. About 1,500 trucks had been assembled at Toulum Bonar, Ushak and Brusa which were the advance bases, to insure

Digitized by Google

supply, also about 2,000 camels had been requisitioned, and several thousand ox-carts. The sanitary service had prepared hospitals at these three bases and sanitary trains to handle the wounded. Every department was functioning well and calmly.

The Battle of Kutahia

The troops advanced against the Kutahia defenses without much resistance until the 14th, on which date the covering troops were encountered and real fighting commenced. Before this time, however, columns marching against Afium Kara-Hissar found little resistance and occupied the town on the 13th. A small battle was fought on the 12th on the positions west of the town. When it was seen that little resistance was to be encountered the 12th Division did not enter the town, but turned at once to the north, moving in general east of the railroad. The 4th Division occupied the town and remained there because the Turks attempted to counter-attack and retake the town, but were driven off and fled to the north. After that there was little action in that sector. The cavalry brigade moved to the right of the 12th Division, and marched throughout the rest of the operations on its right flank.

On July 15, the left flank of the Turkish positions was assaulted by the 1st and 2d Corps with success, the 5th Division completely passed the flank and secured a foot-hold on a commanding position well in rear. On the 16th the Turks attempted to drive back the 5th Division by a counter attack made with three of their divisions. This counter attack was repulsed only after very severe fighting, in which the 5th Division had about a thousand casualties, but they remained masters of the position, which completely turned the left flank of the Turkish defenses. On the same day the 3d Corps, in an all-day battle, captured the positions on the Turkish right and progressed in the direction of Kutahia. The divisions in front pressed the attack only lightly. Thus on the 16th the Turk found both his flanks turned, and decided to give up the whole of the position. He commenced the retirement of his entire force in the afternoon of that day, and by midnight the last of the Turkish troops had passed out of Kutahia. The 10th Greek division entered the town the next day at noon, followed closely by the 9th Division.

As soon as it was seen that the Turkish lines had been turned, the 2d Corps received orders to change direction, and marched against Siedi Ghazi. This they commenced on the 17th.

The Turkish evacuation was extremely well executed. It was accomplished quickly and completely. Very few prisoners or matériel fell into Greek hands. The 3d Corps captured four guns, and eight guns were abandoned by the Turks during the pursuit. It is not believed that the number of prisoners taken would reach a thousand. During the 15th and 16th between 2,500 and 3,000 Turkish wounded passed through Kutahia, while probably one thousand passed by other routes. The Greek casualties in this battle amounted to a little over 3,000. Thus the battle casualties were about equal, with a slight advantage to the Greeks. However, during the retreat the Turkish soldiers took occasion to desert in great numbers. The inhabitants of Kutahia and other villages stated that this was done by wholesale. The town of Kutahia did not suffer at all from the operation.

While no decisive result was arrived at on the field of battle, a serious shock was given the morale of the Kemalist troops, for Kemal had assembled here his best divisions, which thought by reason of their strong position to stop the Greek troops. The Greeks took this position all too easily for the Turk to receive any credit in its defense, and his precipitous evacuation caused his organizations to break up, giving discontented soldiers an opportunity to run away.

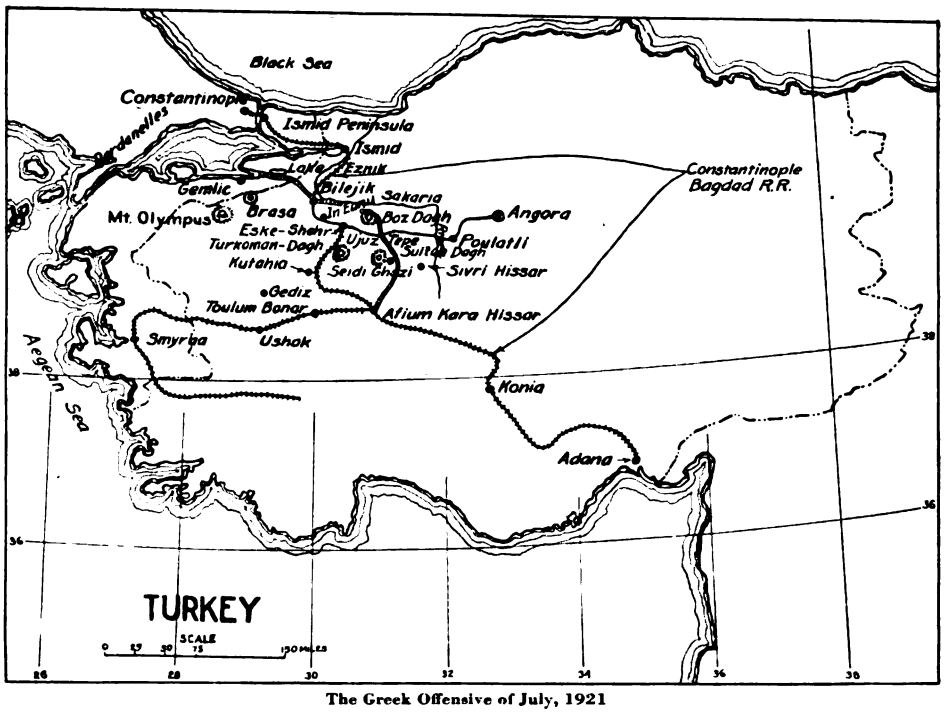
The Greeks pursued the Turkish columns as rapidly as possible, but only unimportant rear-guard actions were fought until the entry into Eske-Shehr.

The Battle of Eske-Shehr

On the afternoon of July 19, the Greek 3d Corps moved to the attack of the position in front of Eske-Shehr, but found it unoccupied and entered the city that night at 8 [illegible]. The town of In-Eunu was occupied that afternoon [illegible] p. m. Thus the whole Turkish garrison from that [illegible] p. [illegible] gone. The inhabitants stated that they had about 4 [illegible] evacuation on July 17, the day of the fall [illegible] troops left Eske-Shehr by train at 5 district had [illegible] visions pushed on beyond commenced the eva[illegible] the city still occu- of Kutahia. The last [illegible] the two divi- p. m. the 19th. as to have

On July 20, the 7th and 10th Div[illegible] Division the city and found the hills surrounding [illegible] etween pied by the Turks, and orders were given to [illegible] ayed sions to take the heights on the following day, so [illegible] ar- a covering position. Thus on the 21st, the 10th [illegible] 0th was prepared to attack the heights east of the city, b[illegible] the railroad and the main road, but its attack was de[illegible] until the afternoon because the cavalry brigade which [illegible] rived that morning was to take part on the right of the 1[illegible] Division, and it was not yet in position for attack. The 7t[illegible] Division was awaiting the attack of the 10th Division before pushing farther up the railroad and up the Boz-Dagh. The 9th Division had been assigned to the 3d Corps as reserve, and was halted a short distance west of the city. The Greek 1st Corps had crossed the Turkoman-Dagh, and was facing the heights of the Sultan-Dagh. The Greek 2d Corps was approaching Seidi-Ghazi.

The Turks had evidently prepared to surprise the Greeks by a strong counter-offensive, hoping to entrap a large number in Eske-Shehr and roll up the balance of them in the mountainous country. The Turk had concentrated his entire force in the hills facing the Greek lines, and commenced a strong counter-offensive all along this line, between 10 and 11 o'clock on this day, July 21. The Turkish troops were disposed as follows: The 1st Division, 3d Caucasus, 11th Division and 3d Cavalry Division to the north of Eske-Shehr, at the foot of Boz-Dagh; the 24th, 4th and 41st Divisions in the hills east of Eske-Shehr; the 61st, 23d and 5th Caucasus Divisions on the Sultan-Dagh, facing west; the 12th Corps in position west of Seidi-Ghazi. The Greek staff counted two other divisions and two cavalry divisions as present, but their positions were unknown to the writer. They probably were in reserve. The strongest efforts were made against the Greek left, which the Turk hoped to envelop and cut off the retreat in the direction of In-Eunu, and against the center, which he wished to pierce, thereby cutting the only other route leading from Eske-Shehr.



The scheme was bold, but a good one, and was a surprise to the Greeks. But the Turk unfortunately found the Greek quite ready for a fight, since they themselves were everywhere preparing to attack on that day, and consequently all troops were well in hand. The Turkish attack drove back the advanced detachments, but as soon as the Greek main forces were deployed the attack was everywhere checked and the Greeks themselves immediately took the offensive and soon had the Turks on the run. The Turk in his endeavor to push through his part of the attack had committed all of his forces to the action and when the Greeks began to push him back he seemed to have no reserves to cover his

Digitized by Google

withdrawal. Thus late in the afternoon his lines completely gave way and his troops fled from the field in all directions and in great disorder. The Greek columns were immediately ordered to pursue, which they did all night long, so that by morning the Greeks had advanced their lines everywhere about 20 kilometers, the Turk having been unable to offer any resistance. The Greek lines were pushed forward the next day again without resistance, until present line was occupied, which was the line the Greeks wanted for the defense of that area.

The booty from this battle was considerable, 40 guns were taken, and over 5,000 prisoners. The Turkish killed and wounded were conservatively estimated at 5,000. The 23d, 41st and 3d Caucasus Divisions suffered particularly severely. The Greek cavalry brigade found occasion to charge the 41st Division, mounted, and killed over 400 with the sabre. The commander and staff of that division were captured. The Chief of Artillery of the 23d Division was captured, together with 1,500 men from that division. The Turkish 11th Division attempted to move down the railway toward Eske-Shehr and was caught in flank by the artillery fire of the Greek 10th Division, which caused the Turkish 11th Division to withdraw without playing much of a part. The Turkish troops in front of the Greek 1st and 2d Divisions suffered very heavy casualties, the extent of which is not exactly known.

The result of the whole battle was a very serious defeat for the Kemalist Army, and gave the Greeks their much-desired opportunity to deal the Kemalists a good blow. The casualties on the Greek side were comparatively light, numbering a little over a thousand in all.

The Greek Offensive of July, 1921

General Results of the Offensive

On July 23 operations ceased, leaving the Greeks in possession of a strong line about 50 kilometers to the east of Eske-Shehr. This completed the operation which had Eske-Shehr for its final objective. The Greek lines now commenced on the Sea of Marmora near Gemlik and extended to Lake Iznik-Guel and Bilejik, thence following the heights east of the railroad and crest of Boz-Dagh, crossing the railroad to Angora at Ujuz-Tepe, south along a series of heights about 140 kilometers east of Seidi-Ghazi to Afium-Kra Hissar.

The Greeks captured in all 50 guns of various calibers, a large quantity of rifles, and about 6,000 prisoners. This number will be probably increased when the final count is taken, since the number of prisoners and deserters was increasing daily and pieces of artillery were being found abandoned in various places.

The most important result was a serious blow dealt to the prestige of the Kemalist movement and to the morale of the troops. His army, which had been so much vaunted by the French and Italian press, was unable to offer any serious resistance to the Greek troops. When one considers the rapidity of the Greek advance one cannot help but admit that the Greek movement was rather brilliant. The various strongholds of the Kemalists fell in very rapid succession. For example, the real movement commenced on July 10; on July 13 Afium Kara Hissar fell; on July 17 Kutahia fell; on July 19 Eske-Shehr fell; on July 21 the entire Kemalist army was given a decisive defeat. Thus in eleven days all of the Kemalists' strongholds had fallen, and the Greek troops had made an advance of 200 kilometers by the shortest line.

The remnants of the Kemalist Army were concentrating at Sivri-Hissar and in the heights north of the railroads. The next real line of defense, which is the defense of Angora, is that of Poulatli, behind the Sakaria River. From airplane reconnaissance and other sources it would seem that Kemal has there about 40,000 men, which is what remains of his army of 80,000 at the commencement of operations.

Observations

The most striking feature of the operations was the mobility of the Greek divisions and their great marching powers. The Greek divisions were about 13,000 strong, but all of their transportation was so arranged that no roads were necessary for their advance. All of the divisional transportation was on the backs of burros, mules or camels. By this means the divisions were able to march and maneuver over mountain ranges and in places which seemed incredible; for example, the 7th Division, which became the left flank division, throughout its entire march on Eske-Shehr of over 300 kilometers by the map, but actually over 400 kilometers, never had a road worthy of the name, and many times the division would have to pass in single file over the trails. In spite of these difficulties, it was always in its place and even in advance of the line. I, myself, on July 19, saw this division advance 50 kilometers in the face of the enemy. Other divisions, such as the 12th, made remarkable records in marching, but I did not personally witness them.

It was by means of the mobility of its divisions that the Greeks were always able to envelop or out-flank the Turks, and the Turks were so fearful as to their line of retreat that the least threat at it always caused them to give way.

Digitized by Google

Both sides evidenced good fighting qualities in battle. The Greeks always attacked with great zeal. The Turk also showed every evidence of being a very brave and clean fighter. The greatest fault of the Kemalist army was its lack of real organization. There seemed to be no bottom to it.

The artillery did not play such an important part in this operation. Only at Kutahia was the fighting in prepared positions, at all other places the fighting was in the open and was generally the fight of the infantryman. The Kemalist artillery appeared to me to shoot better than that of the Greek, but they seemed to shoot sparingly as if they did not have a plentiful supply of ammunition. Outside of Kutahia the Greek heavy artillery never arrived in time to take a real part in engagements. Artillery fighting was done with the mountain artillery, and such field artillery as would arrive in time.

The fighting seemed to conform exactly to the principles of our training before the World War. When objectives had been assigned to units plenty of initiative was allowed to the commanders. The importance of commanders being near the front was very apparent; the distances and difficulties of communication made it impossible for commanders far in the rear to take advantage of the rapidly changing situation. Only the commanders who stayed close to their troops were able to advance rapidly. This feature also showed the importance of small and active staffs with all units. Only simple orders had to be given, but they had to be given quickly and clearly. The division and corps commanders practically lived in their automobiles, and when at a halt their headquarters consisted simply of a few tables in a house or tent on which to spread out their maps and write their orders. Typewriters were practically unseen. Red tape did not exist.

In general, it may be said that the Services did their part satisfactorily. The sanitary service had to do its business in the open with simple field equipment, but seemed to be as good as could be expected; the most difficult feature was the transportation of the wounded over the long and poor roads in trucks.

The food supply was very simple, since the Greek soldier seems to get along on very little. Bread was practically the only thing they sent up from the rear. The regiments and divisions drove herds of sheep, goats and cattle behind their columns, thus bread and meat was the ration, but it seemed to be all that these soldiers required.

The ammunition service, which was handled by the artillery, was maintained from the base to the corps by trucks. Each corps and division had a large train of mules and camels which carried the reserve supply for their units. At no time were the Greeks ever lacking in the supply of ammunition, as these trains were always on the spot.

The conduct of the Greek troops toward the inhabitants and the Turkish prisoners was very proper. They had received orders at the commencement of operations to conduct themselves in that manner, and I neither saw nor heard of any cases of cruelty. Also, the conduct of the Kemalist army was as good as could be expected. The Turkish inhabitants, to my surprise, greeted the Greek troops in a very friendly and hospitable manner. They had been told that they would be massacred, and were at first frightened, but as soon as they found this was not to be the case, they seemed glad apparently of the Greek occupation, or rather they were glad that the Kemalists had gone. It seems that the Kemalist occupation had been rather severe on the Turkish as well as the Christian population. They continually were demanding money, clothes, horses, men and everything until the peasants were sick of it all. The expression of this sentiment was heard not in a few instances only, but in so many that one could not help but be convinced of its sincerity. The Greek soldiers were required to pay for everything they took, and when it was found that this was the case, all shops and stores were immediately opened, goods appeared from all manner of places, and a lively business ensued.

Neckar-Danube-Lake Constance Canal

By

Const. J. Centmaier, M. E. E. E.

Esslinger on the Neckar, Germany

THE Reichstag and simultaneously the legislative bodies of several German States have a short while ago passed bills providing for extensive appropriations for several new waterways in Germany. Among the new-planned arteries in the network of artificial watercourses the Neckar Canal will be the most important. Connecting later on the Danube and Lake Constance, it will form, after completion of the Rhone waterway through Switzerland, the missing link between East and West, North and South of Europe.

Beginning at Schwenningen in the Black Forest of Southern Germany and ending at Mannheim on the Rhine, the River Neckar is one of the principal tributaries of this large European waterway. The Neckar forms the most important stream in the State of Wurttemberg, with a total length of 225 miles (367 kilometers) and a total fall of about 2,000 feet. The first part of the canal will be from Mannheim up to Plochingen. The former is the foremost industrial and commercial center of southern Europe, the latter a very important branch point, the junction of the railway lines to Bavaria and Switzerland. The first part of the canal will be about 120 miles long (Mannheim-Plochingen by train at present approximately 140 miles) with a total fall of about 525 feet and about 26 locks. It will be built for a traffic of nearly 10 million tons per year and for vessels up to 1,200 tons capacity. The width of this waterway will be 115 feet, tapering to 88 feet in width at the bottom, at an average depth of 12 feet. The locks will be about 380 feet long, with gates 40 feet wide, so that vessels up to 2,000 tons capacity can pass in the future. For the purpose of an easy judgment of the importance of this waterway as a source of power it may be stated that the whole waterpower gained on this first part of the river will be about 100,000 horsepower and nearly 600 million kilowatt hours per year.

Digitized by Google

The connecting link between Plochingen and Ulm on the Danube will be about 62 miles long, the section Ulm-Lake Constance about 70 miles. The crossing of the high plateau of the Suabe or Rough Alb will have a summit elevation of 1,760 feet above sea and 950 feet above the Neckar at Plochingen, to be reached by a series of locks located approximately 2 to 3 miles apart. All these locks will be in duplicate—that is, two chambers side by side. The dimensions of the locks will be the same as are planned at present for the first section. The river Lone will empty into the summit of this mountain part, aided by a pumping system near the City of Ulm. It is also planned to tap the Danube by means of an 18-mile tunnel passing through the Rough Alps, taking about 20 cubic meters per second and gaining by this method about 125 kilowatt hours yearly.

The most important towns along the first section of the canal line are Mannheim, Heidelberg, Heilbronn, Stuttgart, besides many smaller ones, Neckarsulm, Cannstatt, Ober, and Understurkheim (with the Daimler Works, manufacturers of the Mercedes automobile), Esslingen (large factories for tools and machinery, Dicks' file factory, Mueller's presses). Later on the industrial towns Goppingen, Ulm, Friedrichshafen, will fall into the canal zone. Mannheim is the most Americanized city in Europe in having streets and blocks built in American manner; it has also the biggest inland harbor in Europe. The trade and industries of the stretch from Mannheim to Ulm are second to that of the industrial and commercial center of Germany at Duisburg, Essen, etc., alone.

The Neckar-Danube-Lake Constance Canal will serve an enormous area. After completion, it will connect the North Sea with the Black Sea by means of the projected Rhone Canal, the Mediterranean with the two former. The canal, with its extensions, will then serve as a very cheap medium of transportation for the export and import of all nations of Europe and of the world.

The above data and figures convey some idea of the enormous importance and the sure coming volume of traffic flowing through this new artery and the widespread effect it will have upon the commerce between East and West, North and South.

The Neckar Canal Shares Company, a semi-public stock corporation with a capital of nearly one million marks will issue bonds with 5 per cent interest besides shares. Supported by the German nation, the three States—Wurttemberg, Baden and Hesse—the enterprise will grant the guaranty of the bonds by the nation and the three named States. As a further security the right of mortgage upon the power plants is provided for.

Up to this date the subscriptions for the capital stock show a very marked interest among industrial and commercial circles, so that the work already begun in several places will soon be carried on on a large scale.

Increased Enrollment in Engineer R. O. T. C.

The healthy growth of the Engineer Reserve Officers Training Corps is shown by the increase of 50 per cent in enrollment as compared to last year. Twenty-one units are now in operation.

	Basic	Advanced	Total
Enrollment Oct. 1, 1920	2,110	356	2,466
Enrollment Oct. 1, 1921	3,096	572	3,668
Increase over 1920	986	216	1,202

Orientation

By James A. Maher

In teaching topography to the military student the necessity for keeping himself oriented cannot be emphasized too much. Whether a command is in motion or at rest the officer in command should know his exact location at all times and he can only know this if he has kept himself oriented with relation to his point of departure. It is true that some persons have the "mule sense" highly developed but the majority need the importance of this prerequisite of movement borne in upon them by careful teaching.

It is not only necessary that the officer know his position with reference to the units in his immediate vicinity but he should know it with reference to the whole terrain.

This knowledge will enable him more quickly than anything else to grasp the import of orders that may be more or less obscure in wording, which is often the case, owing to verbosity or lack of clear expression on the part of the writer of them.

It will not answer to have himself located only with reference to the units with which he is in contact. He should have a general idea of the whole occupied terrain and a particular one of his immediate surroundings, neither of which he can get clearly in mind and fixed there without keeping himself at all times oriented. He can then more readily interpret the orders he receives and more clearly and precisely express those which it may be necessary for him to issue.

Test of Rods Grouted Into Concrete

Some tests to determine the holding power of rods grouted into concrete were recently conducted at the Georgetown Bridge, Washington, D. C., with results as tabulated below:

Depth to which grouted	*End of rod upset or plain*	*Age of grout when tested, days*	*Pressure recorded, tons*	*Bond stress per sq. in. at failure*	*Failed by*
2 ft.	Upset	11	18	424	Eye breaking
2 ft.	Plain	11	26	614	Eye breaking
2 ft.	Upset	12	36.5	861	Eye breaking
2 ft.	Plain	12	33.5	740	Rod pulling out
3 ft.	Upset	11	33.5	526	Eye breaking
3 ft.	Upset	12	44	692	Rod breaking
3 ft.	Plain	19	45	708	Eye breaking
3 ft.	Plain	19	45	708	Eye breaking
4 ft.	Upset	19	47	740	Rod breaking
4 ft.	Plain	19	47	740	Rod breaking

Rods used were 1⅛-inch diameter deformed steel, half of them with the end upset to a diameter of 1¾-inch, the other half with the end left plain. The outer end of the rod was bent into a loop, to take a 3-inch diameter shaft, and clamped with cable clamps.

Rods were grouted into horizontal holes 2½ inches in diameter with neat cement grout mixed just thin enough to permit it to run freely through a 1½-inch pipe. The pipe was withdrawn gradually as the hole was filled with grout. The rod was then pushed into place, displacing part of the grout, and the opening of the hole around the rod closed with waste. After the grout had set sufficiently, the waste was pulled out and the hole plugged with neat cement mortar.

Rods were pulled with hydraulic jacks, the pressure being indicated on the pump gage. Cable clamps did not hold as well as was expected with the result that in most cases the rod was broken in the eye by a combination of bending and direct tension. Low pressure of the first two tests was due to clamps not being drawn tight enough.

The pressure gage on the pump has been calibrated and corrected readings are given above.

The Engineer R.O.T.C. Camp of 1921, at Camp Humphries, Va.

By

Lucius D. Clay

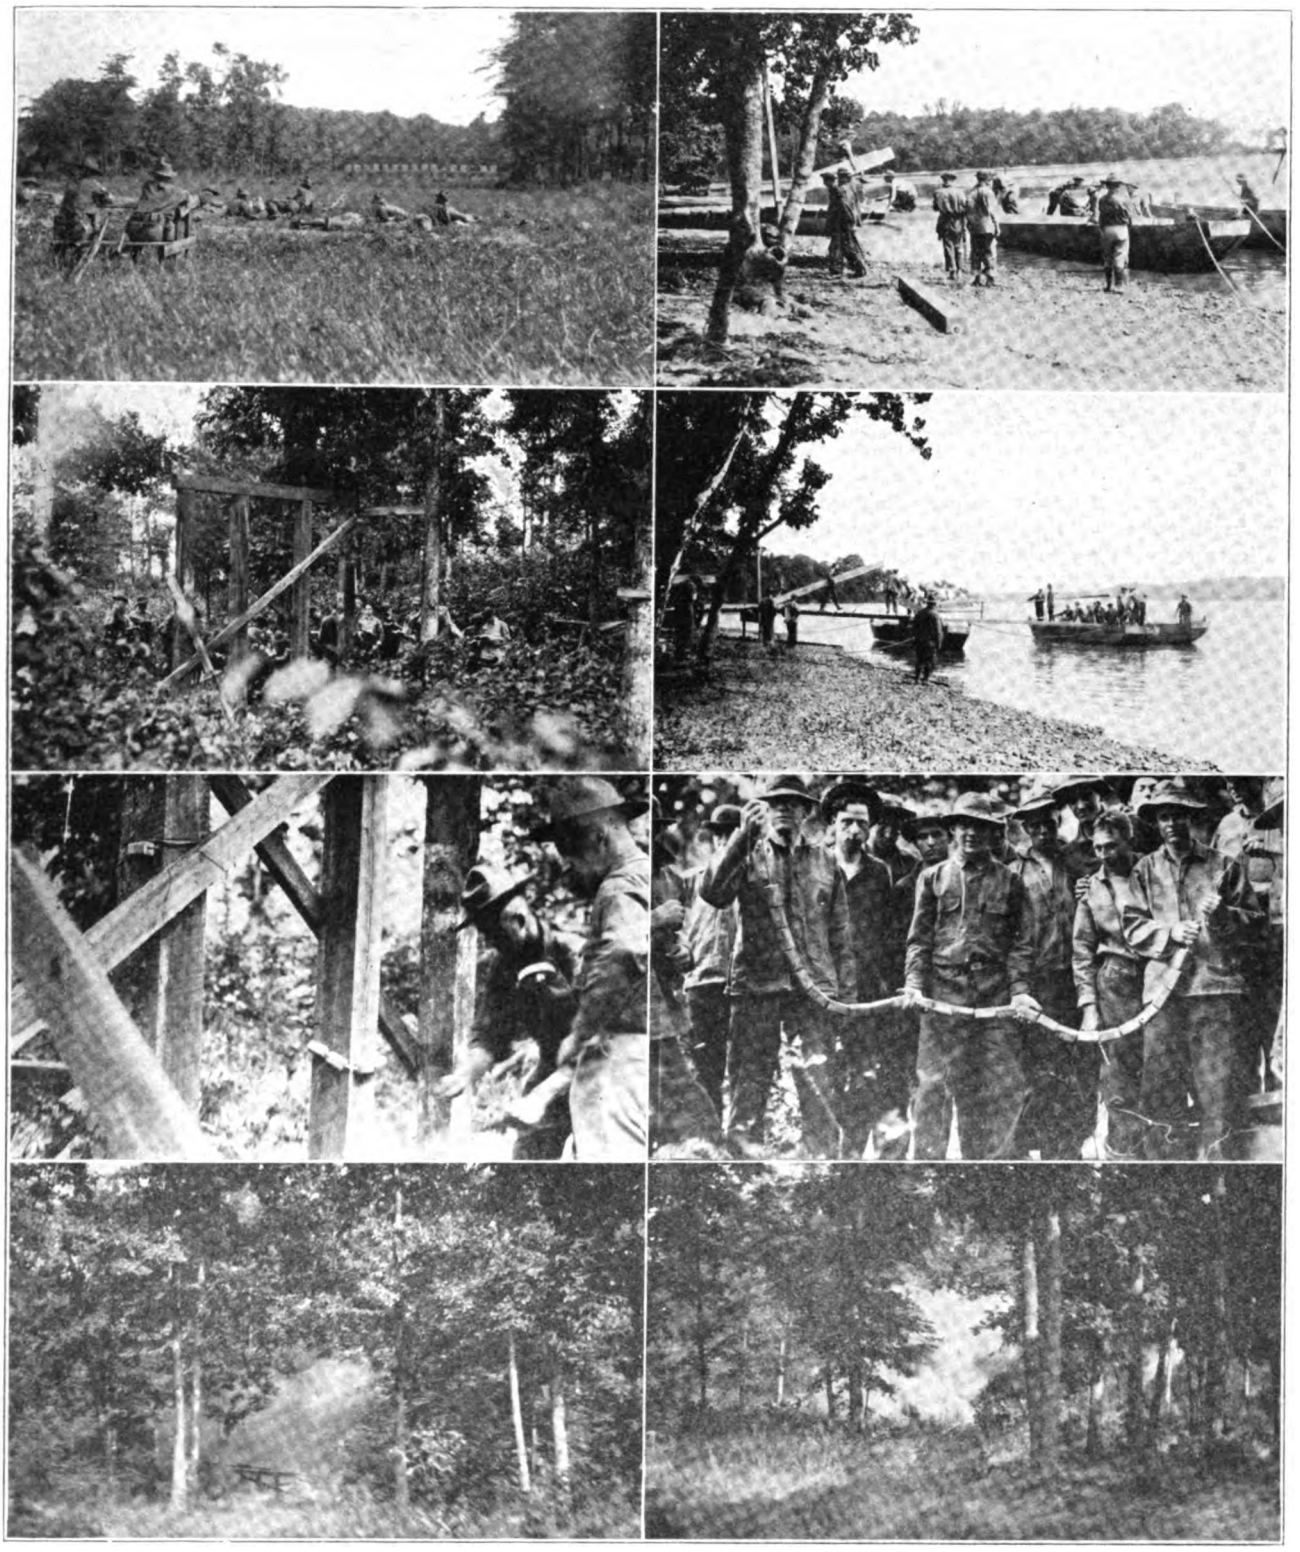
Captain, Corps of Engineers

On June 16 there were assembled at Camp Humphreys, Va., for the 2d Annual Encampment of the R. O. T. C., 620 engineering students, representing nineteen colleges and universities in all parts of the country.

There can be no better measure of the success of a voluntary movement such as the R. O. T. C. Camp than the increase in the number in attendance from year to year. The first of these camps was held in the summer of 1920 at Camp Humphreys. It was described in an illustrated article in THE MILITARY ENGINEER, in which the author, Capt. W. D. Styer, confidently predicted the success of the movement. This prediction was fully justified at this year's camp. That every student at the first camp went home a "booster" for the R. O. T. C. is rather plainly indicated by the gratifying increase of nearly 200 per cent in the attendance at the second camp.—ED.

THE following technical institutions had students enrolled at the camp: Massachusetts Institute of Technology, Yale University, Carnegie Institute of Technology, Virginia Military Institute, Virginia Polytechnic Institute, Alabama Polytechnic Institute, University of Alabama, University of Tennessee, University of Cincinnati, Rose Polytechnic Institute, University of West Virginia, University of Illinois, Iowa State University, Iowa State College of Agriculture and Mechanical Arts, University of Kansas, Missouri School of Mines, Colorado School of Mines, California Institute of Technology, and Oregon Agricultural College.

When the students reported to the camp, they were assigned to companies according to the number of years of military training they had received at their schools. In general, students who had completed more than two years' work at schools were assigned to Advanced Companies, while students with less training were assigned to Basic Companies. The men started reporting on June 16. The remainder of that week, consisting of three days, was devoted entirely to organization, physical examination of the men, assignment to the proper companies, fitting uniforms, issuing equipment, etc. With this accomplished, the way was paved for the actual course of instruction to start on the following Monday, free from interruption.



The course as originally contemplated was to be of six weeks' duration. However, due to shortage of appropriations, the actual course as given was cut to five weeks. The first week's work was devoted to the training of the infantry soldier, and also to a review of the work covered theoretically in the colleges, and practical handling of engineer equipment. This week's course was practically the same for both Basic and Advanced Companies and included infantry drill, physical training, bayonet fighting, preliminary target practice, rigging, military bridges, demolition, ponton work, and first aid. The day was divided into three periods—the first period, from 7:15 a. m. to 8:30 a. m., was devoted to infantry drill, physical training, and bayonet fighting. The second period ran from 8:45 to 11:30 a. m. and from 1:00 to 4:00 p. m. It was devoted chiefly to engineering training of a military nature. The third period was from 4:00 p. m. until taps, and was entirely at the men's disposal to use for recreational purposes. Parades were held twice a week, with daily guard mounts.

The second week of camp life saw a radical change for the Basic companies, for this week was designated for training on the range. The rifle range is located about five miles from the camp proper, and the march served as an opportunity to work in a small tactical problem. In the range camp itself, life was made as comfortable as possible in a temporary camp, in order that the minds of men would not be diverted from the range practice. The men were established in comfortable pyramidal tents and were messed in screened and covered mess halls. During this week all of the students were first required to fire the regular army preliminary or instructional course, and then to fire the regular record course. Every effort was made to teach the student not only how to handle the rifle, but also how to teach others marksmanship and confidence in the rifle. In keeping with this idea, advanced course men were developed as rapidly as possible, and instructed in the duties of a coach, and then assigned to do actual coaching on the firing line. In addition to rifle instruction and range firing, all advanced students were given instruction in the automatic pistol and allowed to fire the record course.

Men who successfully qualified in the various grades of marksmanship were later given the badges of their grade by the Camp Commander. Considering the short period of instruction available for preliminary target practice, the number of qualifications was entirely satisfactory. Nevertheless, all was not work on the range. The old Potomac backs up and winds about the camp, forming many bays and estuaries. One of these bays is sufficiently close to the range to allow swimming and boating, and, in addition, athletic contests were encouraged. At night almost every squad tent was a miniature theater—devoted to musical entertainment ranging from the plaintive tones of the violin to some deep-noted freshmen yodellers. During the week, one night was given over to an explanation and display of pyrotechnic signalling devices, while the final night was used for a night march back to the camp proper and for a night tactical problem. The advanced companies followed the basic companies to the range in two sections—the first section attending during the third week of camp and the second section during the fourth week. On the whole, the range work was satisfactory from every viewpoint. The men, having that inborn American love for the rifle, were eager for instruction, and as a result were well pleased with their week of firing on the range with service ammunition.

During the second week, while the basic companies were on the range, the advanced companies were proceeding rapidly with their infantry and engineering training. In fact, the remaining period of camp life was devoted to infantry and engineering drills with particular emphasis always placed on the methods of applying the principles of civil practice to military necessities. For the advanced

course, the last week was devoted to special courses in engineer terrain exercises based on fitting the students' college course in with their military training and thus improving the theoretical side of both by actual practical work.

Lampert foot-bridge—Construction

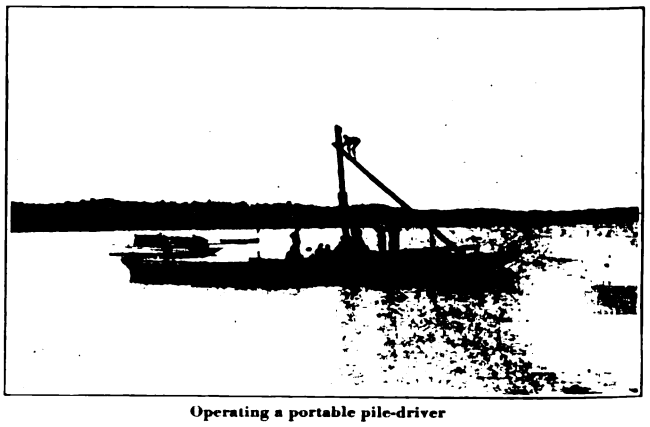
Drills were of a varied nature, designed to insure the continued interest of the students and fresh enthusiasm of the instructors. They included instruction in infantry drill,

Students inspect rigging



Students operating a searchlight

physical training, bayonet fighting, first aid and gas, demolitions, fortifications, rigging, bridges, mining, preliminary target practice, range firing, minor tactics, and special engineering problems. All engineering drills were given as far as possible in the form of problems, and as such called for actual solution in the field. The students were quick to see the value of such training in their own engineering study, and as a result thoroughly appreciated and enjoyed the instruction.

Bridges—Lashing spars

Operating a portable pile-driver

In both the engineering and military aspects of training, the true purpose of the R. O. T. C. to train our educated citizenship to become potential leaders in military capacities was fully recognized. To aid in securing this result, to develop leadership and initiative, advanced students were assigned to basic companies as non-commissioned officers and officers, and, whenever practicable, all parades and ceremonies were handled entirely by the students themselves.

A true appreciation of the value of the course of instruction as herein outlined can best be obtained by a resumé of its purpose. This can be expressed for this, the second engineer camp, exactly as it was expressed for the first camp, exactly as it will be expressed for all camps. Capt. W. D. Styer, C. of E., in his article in this magazine on last year's camp, well describes this purpose: "The course of instruction for the camp was planned and ar-

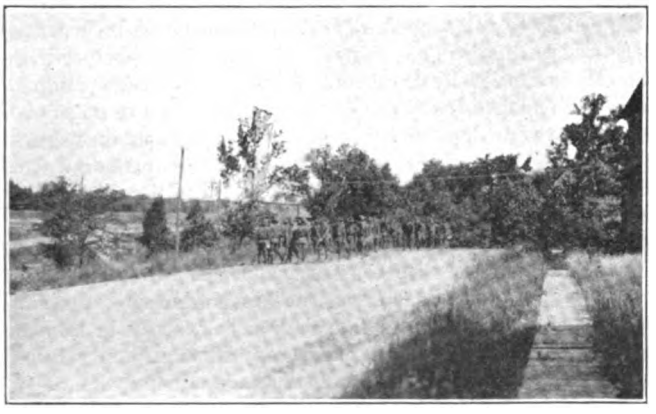
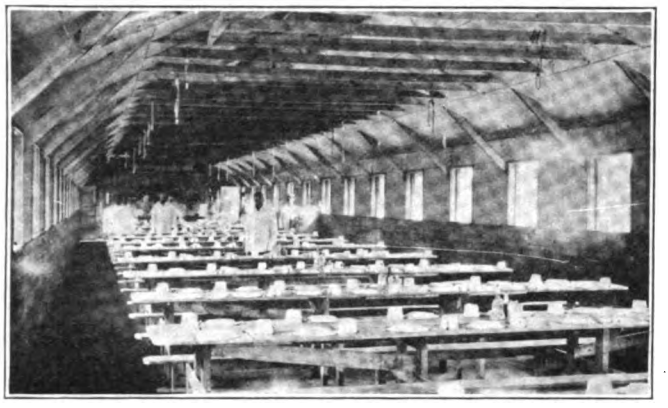
ranged with the following object in view: To make the course interesting as well as instructive; to cover a maximum amount of practical work, leaving the bulk of the theoretical instruction to be covered at the institutions; to



R. O. T. C. battalion parade

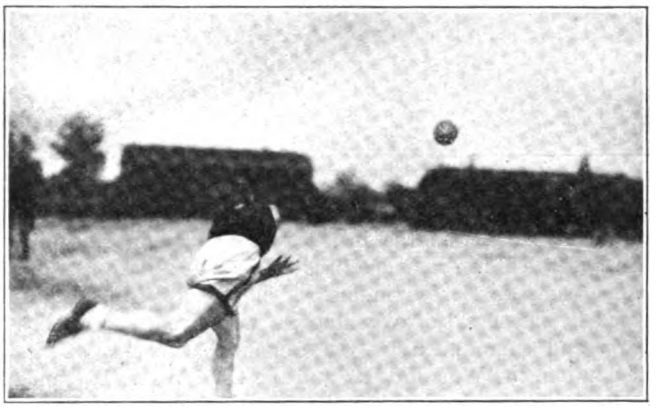
give instruction in phases of engineer work which, due to lack of proper facilities, cannot be handled at the institutions; to instill in each student a high sense of discipline,

As they arrived



to develop qualities of leadership, initiative, and resourcefulness by placing the maximum amount of responsibility upon the individual; to teach the students to be *instructors,*

A tactical walk



and to give practical instruction in the problems of the military engineer, the solutions of which will be of value to the student in his preparation for his future career in his chosen field of engineering." Such has been the purpose of the instruction courses at our past two summer camps, and such must always be the purpose to keep the Engineer R. O. T. C. Camp firm on the foundation it has built for itself.

The R. O. T. C. is a phase of military training of vital importance in our National Defense Policy, for it provides

A company mess hall

our potential reserve of trained officers for future emergencies. It is a voluntary course of instruction in military art given in practically all of our colleges. The attendance

Putting the shot—The track meet

at a summer camp is also voluntary until the student has decided to remain in the R. O. T. C. for his full four years of college work. Hence, if camp attendance is to be kept

Service Club—The recreation center

on the increase (and this is very important as the work in the camp is essential to round out the theoretical work at the schools), the camp must be made a pleasant memory in the minds of all attending. To secure this result the camp must be more than a success from the viewpoint of instruction given and received; it must give the student a live sum-

Digitized by Google

mer of work and play; it must provide all varieties of recreational and athletic diversions to offset the rigid course of instruction.

Not the least of the advantages of this camp are the meeting of young men from various parts of the country, and the close association in which they find themselves. An exceptional opportunity is afforded for the interchange of ideas, and the broadening effect of contact of different minds and varying personalities.

The site of Camp Humphreys is ideally suited to the purposes of the engineer camp, both by reason of the exceptional facilities for instruction and the pleasant summer outing afforded the students in this beautiful and historic spot. Engineer officers and troops in ample numbers are

Off for a ride

available to assist in the instruction, and engineer equipment, complete in every detail, is at hand for use.

The camp is located in historic northern Virginia, hallowed by memories of Washington, who lived and worked there, and surrounded by the famous battlefields of the Revolution, the War of 1812, and the Civil War. It stands upon a plateau overlooking the beautiful Potomac River, scarcely four miles from Washington's home at Mt. Vernon, and seventeen miles (one hour by rail, water or automobile) from our Capital city, Washington, the Mecca of America. The atmosphere of such an environment is stimulating and elevating.

The advantages of frequent visits to Washington and of real use of this opportunity to see our National Government at work was impressed on the students, with the result that a large percentage of them made frequent visits to the Capital City. Then, the Fourth of July brought with it a three-day holiday over the week end, and enabled many of the men to make trips to the various beaches near Washington, or to Baltimore, to Philadelphia and New York.

Another advantage of proximity to the National Capital, the headquarters of our government, was the opportunity afforded the students to listen to the views of some of our most progressive thinkers, both within and without the service. Reviews were held for Col. M. L. Walker and Col. Mason M. Patrick, the two camp commanders, and the students were privileged to hear the views of both on the future of the R. O. T. C. Each Sunday night the Camp Theater was the scene of a "get-together" party under the influence of the Camp Chaplain. After a few minutes of devotional exercises, short addresses on interesting subjects were made by distinguished speakers. These addresses were followed by excellent picture shows. Among the most interesting addresses during the summer were a talk on the old Army by General McCaw, a talk on the American Mission in Armenia by General Harbord, and a short talk by Professor Tilden of Yale. As a final honor, the R. O. T. C. was reviewed by General Pershing, who, after the review, personally presented commissions to those men qualifying for them on the completion of the camp. General Pershing addressed the men and expressed his satisfaction with their excellent appearance and marching. In addition, he told them of his own interest in the future of the R. O. T. C. and of its real importance in the new policy of National Defense. Such visits and addresses had a most wholesome effect on the morale of the camp, as they impressed on each student how he can play his part in the general scheme of national preparedness, and also emphasized the importance of the work in the R. O. T. C.

In addition to these attractions of sightseeing, etc., every possible means of making the camp attractive to the men was utilized. Each company had a building fitted up with magazines, papers, books, games, stationery, and a piano for recreational purposes. The Camp Service Club was opened to all students, and the Officers' Club was thrown open to the advanced course men. An exchange was opened in the heart of the camp. A weekly hop was held at the Service Club under the direction of the camp hostess; girls were invited from Washington by the hostess, with such happy results that the hops were always popular and the men made many pleasant acquaintances to renew in town during the week ends. Athletic competition on a company basis was encouraged, and a variety of equipment was provided. An inter-company baseball league was soon functioning, and a camp team was organized to play the 13th Engineers. A tennis tournament, a track meet, and a swimming meet were held at various times during the camp, with suitable medals for the place winners. As many horses as were available were placed at the disposal of the students, and many used the opportunity to enjoy horseback visits to the many places of interest surrounding the camp. As a final wind-up to the recreational side of the camp, the entire personnel held a picnic on the banks of the Potomac, with swimming and boating as diversions, and on the last night each company held a farewell banquet, at which the work of the camp was reviewed and the company spirit solidified into an active campaign for next year's engineer camp.

The true success of this, the second Engineer Camp, cannot be definitely determined until the students have returned to their institutions. The spirit that they carry back with them, as developed by the campaign for next year's camp and the attendance thereat, will be the true measure of success. However, the immediate results of the camp were highly gratifying. The men were eager for instruction, willing to work, and amenable to strict discipline. They were impressed with the scope of activity of military engineering and were able to form their own ideas as to how to adapt civilian practice to military needs. In addition, they were given practical experience in engineering problems in such a way as to add to their college work in their chosen field of engineering. The camp ended in universal satisfaction, and the enthusiasm of the students who attended the second camp speaks well for possibilities of the third camp. This satisfaction was secured by the loyal cooperation of the entire personnel of the camp and because each and every student on the last day of camp could truly say that he had spent a summer with the R. O. T. C., filled with profitable work mixed in the proper ratio with plenty of social and athletic activities; that on looking back over the five weeks of military training, he could say "Well done."

Are We Really Building An Officers' Reserve?

By

John A. Miller, Jr.
Member S. A. M. E.

[Note: If our peace time army is reduced to an inadequate maximum to cope with our next emergency, what will be our method of procuring officer personnel for that emergency? Were the expedients resorted to in 1898 and 1917 entirely satisfactory? These, and many more similar questions must present themselves, not only to the army but to the vast majority of our population. It is that majority which inevitably "pays the price." In this well considered article the writer constructively criticizes methods of the past, while recommending ways and means for the future. It should be read by every person—Regular, Reserve or Civilian—interested in the maintenance of peace.—ED.]

EVER since the years immediately following the Revolutionary War, it has been the policy of this nation in time of peace to keep a military establishment of much smaller size than would be necessary to cope with a serious emergency. But it is only recently that there has been any general interest in schemes to provide a reserve force to supplement the Regular Army in time of need. As a result of the war, however, numerous suggestions have been offered and some experiments tried along this line. It is a problem which men in all walks of life are now carefully studying, and it seems not improbable that in time a satisfactory solution will be reached. Meanwhile, a frank discussion among those who have had personal experience with different phases of the situation, may bring forth new ideas or confirm the old ones.

The problem of creating an organized army reserve has so many ramifications that a thorough understanding of the entire subject would be impossible without very long study. However, the question is susceptible of division into two major parts—the training of a reserve force of commissioned officers and the training of a body of enlisted men. By confining the discussion to the first phase of the problem, and especially to the matter of training reserve Engineer Officers, the situation may be simplified to such a point that a few definite conclusions are attainable.

Any man who has held a commission in the engineers, whether as an officer of the Regular Army or as an emergency officer, is probably more or less familiar with the methods that have been followed heretofore to create a body of reserve officers. Nearly all of the emergency men were themselves the graduates of training camps organized for that purpose. Many of the regulars have become quite conversant with the subject as instructors to the camps or through association with emergency officers during the war.

A careful and thorough analysis of the methods that have been used, and the results that have been achieved, would be of great interest and profit, and would no doubt suggest possible improvements. Such studies have in fact already done something of the sort. But the difficulty met in basing a program for the future upon a consideration of the achievements of the past is that new and radically different ideas, however good, are unlikely to be introduced.

It may be worth while, therefore, to look at the question of creating a body of reserve officers, without regard to the attempts that have already been made to solve the problem, and with particular attention to the mental process of the man to be trained. To do so it is necessary to start at the very bottom, and to consider not only the possible methods of training, but also the proper qualifications and the available resources of personnel.

To begin with, what are the requisite qualifications of a commissioned officer of engineers? They appear to be of four kinds—physical, mental, professional and military. The proper physical standard is for the medical men to decide upon. Suffice it to say that there seems to be no good reason why an officer should be expected to have a physique superior to that of his men, and it may be doubted if the policy is a wise one of rejecting for commission a man qualified in all ways except physique, and accepting the same man for service in the ranks. This happened occasionally during the recent war and probably lost to the army the service of some very capable officers.

The determination of a proper standard of mental qualification is less simple, but of even greater importance. An active mind, accustomed to the consideration of affairs, and quick in weighing relative values, is of more use in the army, as in civil life, than a mind which has become a mere storehouse of accumulated facts. Experience has shown that a poor plan well executed will often succeed, while even the best plan will certainly fail if indifferently carried out. One of the most pithy sections of the Infantry Drill Regulations says to do any intelligent thing in an emergency, but do not hesitate. An officer should be a man who can be relied upon to choose a fairly intelligent plan, and carry it out. For this is needed the ability to observe, consider, decide and execute. The basis of selection should therefore be mental training rather than specific knowledge of particular subjects.

But an engineer officer nevertheless must have a certain amount of definite information on technical subjects. The ordinary conditions of service with combat engineer troops do not demand highly specialized professional education. A general understanding of the fundamental principles of science, in combination with a mind trained to consider and apply such knowledge, is sufficient to meet the usual requirements. Probably most of the graduates of any first-rate scientific school would possess the proper mental qualifications for an engineer officer, as well as the necessary professional knowledge. The few technical graduates who might be temperamentally unfit for the work of the army could be easily eliminated, and the able practical man without scientific education could be included by careful selection.

There are undoubtedly a large number of men who have the physical, mental and professional qualifications requisite for an engineer officer. But unfortunately only a comparative few have also a considerable fund of military

Digitized by Google

knowledge and experience. This is not acquired in any of the ordinary pursuits of life, and a special effort must be made if one would become thoroughly qualified in this particular. It may be said that the military training of reserve officers is the crux of the whole problem of organizing a supply of competent leaders for an emergency.

Starting from the assumption that in a future war the army is going to immediately require the services of a much greater number of commissioned officers than are included in the permanent military establishment, the first question then concerns the possible sources from which men can be obtained, properly qualified in the four respects just mentioned. The number who can be promoted from the ranks of the Regular Army is limited. There are not a great many enlisted men who possess the necessary mental and professional qualifications. The fact that these men sometimes lack the social polish which is expected of the commissioned officer is, of course, no argument against their selection if they are otherwise fitted. At the old army game the Regular Army non-coms are without superiors, but in the face of an unexpected and unusual situation, the rules of the game as they know it are useless to solve the problem, and the mind trained to cope with such conditions is frequently lacking. It is certainly very desirable that a man of ability in the ranks should be promoted to be an officer, but it would be folly to suppose that mere length of service will insure the necessary qualifications.

As the number of engineer officers to be obtained by promotion within the engineer service is limited, so also is the number to be had from among the emergency officers of the past war. The possibilities of the latter method depend entirely upon when the next emergency occurs, and if it be not soon, which everyone hopes it will not be, the number of former officers available will hardly be very great. It must therefore be from among the engineers in civil life without actual military experience that the largest number of leaders of the future will come.

At the present time the body of available engineers in civil life is composed of two groups, a small organized minority in the National Guard and in the Officers Reserve Corps, and a vast unorganized majority. While under existing circumstances the engineer officers of the National Guard have a good chance to practice what they may have already learned, and under the proposed army reorganization the Reserve Officers will have a similar chance to keep up to date in military matters, yet in neither case is there discernable much opportunity for a man without any experience to acquire a thorough military education. And that is the real problem, for, as has been said, the ranks of former officers cannot be depended upon to furnish sufficient experienced leaders in a future emergency. It appears, therefore, that even the organization now in existence is insufficient without a program to give satisfactory military training to men entirely devoid of it. The same program would be equally useful in training men outside of the present organized reserves.

There are two general methods now being followed to that end—the R. O. T. C. units at many colleges and universities and the summer "Plattsburg" camps. Just how successful the student courses in military training have been, and how well they will continue to function, is not easy to tell without thorough study. But experience at one camp of the Plattsburg type has convinced the writer that it is difficult, if not wholly impossible, to get in that way all the training that a man needs to be successful as an officer. It seems improbable that the university military courses are more successful.

For a man thoroughly acquainted with any subject to teach that subject to a man who knows nothing whatsoever about it is never an easy matter. It is extremely difficult for the instructor to understand, unless he has had long experience at teaching, which subjects need most emphasis. Things which he takes as a matter of course are often the hardest for the student to grasp. In considering possible ways of giving satisfactory military training to the great mass of engineers eligible to be officers in a future emergency, the mental attitude of the student is worth serious study.

To begin with, a Reserve Officer should be thoroughly familiar with infantry drill. This, however, is no great problem for an intelligent man. Engineer drill, although slightly more complicated, can be readily mastered. Administration is a less simple problem. The ways and means of administration in the army require study before they can be thoroughly understood. By diligent application, however, one may expect to get a satisfactory working knowledge of this subject, simultaneously with infantry and engineer drill.

A wide range of information that the Reserve Officer should have, however, can be got neither from books nor from the experience of an ordinary training camp. Under this head come the problems of field service—what to do if the picket line breaks at night, how heavily the escort wagons can conveniently be loaded, where to build the incinerator, and a thousand other matters, not particularly important in themselves perhaps, but in the aggregate vitally affecting the efficiency of the command. In addition there are the problems of military discipline and morale. One must know how to be a soldier, in order to understand what to demand of another soldier. One must know when and how to insist upon the rigid obedience of the very last letter of an order, and when it is better to be a little lenient. These things can be learned from no text book, and it is very difficult, if not quite impossible, to acquire such knowledge during the short period of a training camp.

A layman might think that a military education could be acquired from careful study of proper manuals, as many people, indeed, believe that a college education is gotten wholly in the classrooms. But in neither case is that the true situation. The effect of university training is not to be gauged by a puzzling questionnaire, nor is knowledge of Infantry Drill Regulations an index to a man's military ability. The least successful army officer of the writer's acquaintance was letter perfect in text-book learning. Those who have been in the army know that a part, at least, of military training must be absorbed from experience, and that for men without any experience a special solution of the problem must be found. Reserve Officers, unused to the details of army life in the field, must be equipped with sufficient knowledge to cope with the situations that are sure to arise. Increasing the duration of the annual training period is not the answer. If this were possible it might produce the desired result, but obviously men engaged in civil professions cannot spare a long time every summer.

But if the mountain cannot come to Mohammed, Mohammed must go to the mountain. The army must go to the engineer who is unable to get away from his business, and must give him a chance to become familiar with its workings without interruption to his daily tasks. This the Regular Army cannot do, but the National Guard can and should offer an opportunity for a man to get sound practical military experience. At first thought one may see huge obstacles in the way of such a plan. All the evils

Digitized by Google

that have undoubtedly existed in this organization would be incorporated into the training of Reserve Officers, one thinks. But this need not be so. Certain units of the Guard could be specially designated as training units for officers. They should be commanded by experienced men of outstanding ability. Politics and irrelevant social considerations should be absolutely eliminated. The full performance of duties by the men would become a privilege instead of an obligation because the army would be in the position of conferring an honor upon the deserving rather than in the position of receiving the services of patriotic citizens while giving small recompense in return. The time spent in a high-grade training unit of the National Guard would be more valuable than an equal amount of time spent in a summer training camp, because experience has shown that short periods of instruction spread over a long space of time are more satisfactory than the same amount of continuous instruction. The mind fails to assimilate knowledge after a certain saturation point is reached, and an interval must be allowed for the information to be filed, so to speak, before any more teaching is done.

Moreover, in such an organization the prospective officer would have a chance to learn the intangible and indefinable things concerning the army while proceeding with the routine training. He would of course have the same chance in an officers' training camp, but in the latter instance so much has to be crammed into a short period of camp life, that the student is apt to become confused, and miss a great deal that cannot be taught directly from a text book. In the National Guard, however, he would have a chance to get his bearings after a few weeks and begin to take mental notes concerning the way things should be done. The weekly drills would serve well to keep constantly in the forefront of his mind all the detail of army life in garrison, and the occasional week-end hikes would do as much as can well be done to give field service experience. In addition there would be the same two weeks of camp in summer, and if properly conducted, this period could be quite as profitable as the two weeks now customary for Reserve Officers to spend at training camps. In fact a National Guard camp could easily be the more profitable of the two because the men, having previously mastered the minor details, would be able to receive field service instruction with a broader outlook than that of men who were trying to learn the elemental and advanced subjects simultaneously.

Let it not be supposed that such an officers' training unit of the National Guard, commanded by experienced and capable soldiers, with intelligent earnest men in the ranks, free from political or other baneful influences, is an impractical idealistic dream. Units have existed in that organization, and some continue to exist, which very closely approach the type described. From them came a great number of officers for the army in the war with Germany. The single cavalry troop in which the writer formerly served furnished nearly one hundred commissioned officers to the army in the recent emergency. The possibility of selecting some of the high class units of the National Guard as special training organizations for Reserve Officers, deserves serious consideration as one way of solving the problem to giving thorough military instruction to men qualified to be leaders in time of war.

Another method, however, is even more promising. It answers the most difficult question concerning the military training of civilians; how to give instruction and experience in the subjects which cannot be studied from books. In brief this method consists in giving temporary commissions in the Regular Army during peace time to graduates of approved colleges and universities. By this means, as by the use of the National Guard, high grade men could get some actual field service experience prior to the outbreak of war. The mountain would come to Mohammed in this case, before it became too firmly established to move.

That such a suggestion is likely to be received with limited enthusiasm in some quarters can easily be imagined, for at first glance it might appear to place on an equal footing the graduates of civil institutions of learning and graduates of the United States Military Academy. To a certain extent that might be the result, but the equality would be more superficial than real, and would be of temporary character in any event. A not dissimilar condition confronts the college graduate when he first goes to work. He finds himself no better off than men of far less technical training and scientific knowledge. It seems hardly fair that his education should have given him only equality with them. But he soon finds that the man who has missed the advantage of a college education has improved those years by gaining practical experience. Until the technical man has begun to accumulate a similar fund of experience he deserves scarcely to be on an equal footing. However, he should on account of his trained mind, be able to learn more rapidly the practical side of his business, and eventually go much farther than the untrained man is likely ever to go.

The parallel is close in the case of the graduate of the Military Academy and the ordinary college graduate. In the first place it must be admitted that a large part of a cadet's time at West Point is spent learning precisely the same things that a man learns in any good college. If a period of intensive military instruction follows immediately upon graduation from the civil institution, the man so trained compares not unfavorably in many respects with a graduate fresh from the Military Academy. Neither has the well rounded ability of an older officer, yet either should be able to handle the problems of a lieutenant. In the long run the man from West Point, because of his more thorough study of military subjects, may be expected to succeed better in the army than the man with civil education, exactly as the technical man eventually outstrips the purely practical man. This is entirely as it should be for the basis of the whole plan is that the ordinary college graduate should enter the army only temporarily before commencing in earnest his real life work.

The British Army follows a somewhat similar plan. Its success depends largely upon the careful selection of men for appointment to the army. There appears to be no reason why such an arrangement would not work satisfactorily in the United States Army. At the time a man graduates from college he often has no very clearly defined plan for his immediate future. A year or two in the army would benefit him in many ways. It would broaden his outlook upon life, as has been incontrovertibly shown by the experience of many during the last few years. It would bring him into close contact with men and ideas that he might never otherwise encounter. It should solidify the development of character and give him poise. At the termination of the period of his temporary appointment as an officer he would return to civil life richer in experience, in knowledge of human nature, and prepared at any future time to assist in the solution of the problems of a military emergency.

Nor would this plan be without profit to the army itself. It would gain for a time the services of many of the best young men of the country who do not wish to take up the profession of arms permanently. But more important

Digitized by Google

than the mere service by which the army would profit, is the sympathy that would be gained. Unfortunately, the people have in the past understood their soldiers very poorly. Even now there is much misconception about military matters. But with a steady stream of young men going from colleges and universities into the army and later returning again to civil life, a very powerful leaven would be widely distributed throughout the population, and would inevitably produce a better understanding and closer co-operation. At the same time an invaluable reserve of trained officers would be established.

Much would depend upon the right selection of the graduates of civil institutions of learning. One doubts if the ordinary mental examination, no matter how stiff, would discriminate successfully between those adapted to such service and those who would be misfits. But the army has now become so skillful in the selection of personnel for its various activities that one may safely dismiss this as a minor detail.

Possibly the arrangement would provide more officers in time of peace than would be really needed. In that case the difficulty would be met by detailing more of the permanent officers to the War College, to staff duties, to the School of the Line at Leavenworth, or in any one of many ways that seemed desirable to the War Department. The great outstanding advantage would be that men of the best sort, already educated to be leaders, would receive a thorough fundamental military training and would be prepared to respond to the country's call in time of need, knowing the work expected of them, and able to perform it.

A very important phase of the problem of training additional army officers for an emergency must not be overlooked. Under the most favorable circumstances it will hardly be easy in war time to secure as many properly qualified men as one would wish. Rather than commission men who lack some of the important qualities, it would seem better to be extremely economical in the use of officers. By this is not meant some absurd scheme of keeping them out of danger, such as the Germans were said to have used, but simply to be careful in the assignment of officers, so that a trained mind will not be wasted upon a job that does not require it. Sometimes it seemed in France that commissioned officers were used where sergeants or corporals could have functioned with equal efficiency. There were reasons for this situation, and a thoughtful person would not waste time in criticism of faulty minor details of a gigantic undertaking so successfully conducted, unless some lesson were to be learned therefrom.

But an impartial consideration of such details may show how to avoid little mistakes another time. If the commissioned officer is a man of superior training and ability, as he should be, and usually is, the work done under his supervision ought to be more efficiently performed than work done without such supervision. When the undertaking is important, skillful superintendence is needed, but if the able executives are assigned to unimportant work, there will be a shortage when bigger jobs come along.

In order to assure the careful performance of important duties, the army has habitually insisted upon the presence of officers at certain times and places. But during the war, new conditions developed demanding additional supervision by commissioned officers. It was difficult to separate the more important work from the less important, and to distribute the available officers to the greatest advantage. Some commanders made little attempt to discriminate and used the phrase, "an officer shall be present" as a sort of formula to be included in every order. When organizations lacked a full complement of officers, it sometimes happened that literal adherence to instructions would have required the same officer to be in two or more places at one time.

The French, always keen observers of American methods, laughingly asked, "For what have you sergeants and corporals? Your officers do all the work." The training and encouragement of non-coms to supervise minor details will simultaneously increase the dignity and importance of their position, and reduce the number of commissioned officers needed. Only if this be done, will it be possible for the supply of competent Reserve Officers to fill the demands of a serious emergency.

One other phase of the situation is worthy of careful thought. If a competent force of Reserve Officers is to be built up, the men of the highest caliber in civil life must be attracted to it. There are some difficulties in the path, and it is well that they should be frankly considered. No one who served as a commissioned officer during the recent war will deny that the relations between the permanent officers and the temporary officers were sometimes not harmonious and sympathetic. Sufficient time has now elapsed, however, for one to look at the matter without the antagonism that prejudiced opinion at the time.

One understands easily the reasons why Regular Officers sometimes distrusted the Reserve Officers. A highly specialized profession was swamped by the influx of a great number of outsiders with little or no previous military experience. The time devoted to their instruction had been so short that nothing like proficiency was to be expected. Under the pressure of the emergency it was necessary to take strangers right into the bosom of the family. Such a proceeding cannot but be embarrassing for both stranger and family. To make matters worse some of the outsiders rudely abused the hospitality, even rather patronizing their hosts. This was, happily, the exception rather than the rule, but the majority suffered for the sins of the minority. At the beginning, the temporary officers were quite humble and willing to learn from their more experienced associates, the regular officers. To be told at that time how things were done in the army was what they expected. But time should have separated the objectionable ones from the many others, and the latter ought not to have continued to suffer on account of the deeds of the former. Each individual had his virtues and his shortcomings.

So it was very exasperating to a temporary officer after two years of service to be charged with all the faults ever found among his class and to be credited with only the virtues which he had personally demonstrated. It did not seem sometimes that the temporary officer was ever really accepted into the family. He was with the army but not of it, and was too often tolerated as a sort of necessary evil for the duration of the emergency. From this fundamental attitude of toleration rather than acceptance, sprang most of the incidents that bred antagonism between Reserve and Regular. Those commanders who rebuked and humiliated the junior officers in front of the men would hardly have acted in that way toward officers whom they regarded as co-workers. One single incident will serve to illustrate the point. A certain colonel, after warning his officers that the company streets were not clean enough, and finding somewhat later that a little dirt yet remained, turned out all of the commissioned officers of the regiment to be a detail that personally policed the area while the enlisted men looked and laughed. It is hard to imagine what idea lay behind this order. Certainly it was detrimental to discipline, stirred up antagonism that lasted many months, and made even more difficult for some time thereafter the not easy work of those officers. Had the

Digitized by Google

colonel regarded his temporary officers as associates in a joint undertaking, such an incident could not have occurred.

Experience shows that the way to encourage good work is to treat the worker as a partner in the enterprise. Imagine the feeling of a Reserve Officer during the third year of his military service who was told by a Regular, "In the army, we think thus and so." Was it not clear that the permanent officer did not consider the temporary officer to be really "in the army" at all, and never would so consider him? Yet after all the army is not a thing apart, composed of beings from a different world, moving in a mysterious way. It is the army of the people, and the farmer in his field, the mechanic in the mill, and the officer at the head of his company should all have a common interest in its welfare.

No good end is now served by cherishing the memory of incidents that caused friction in the past. But it is necessary to frankly face the facts in considering how to avoid a repetition of this antagonism. No satisfactory reserve force can be built upon a foundation of toleration. The situation demands more than that. The civilian must understand that the army is composed as Kipling's soldier says of "single men in barricks, most remarkable like you," and the army must know that the civilian engineer is "most remarkable" like them.

Therein lies the great advantage of a scheme that will bring into closer contact the best minds of the every day world and the best minds of the military world. To a certain extent the method of utilizing some parts of the National Guard as training units for officers, might accomplish this object. One cannot remain out of sympathy with a vast organization of which he himself is a part. Moreover, the cost would be comparatively small and no great divergence from precedent is involved. But the desired goal would be very much more closely approached by the method of making temporary appointments to the commissioned personnel of the army from among the promising graduates of approved colleges and universities. A much more real contact would be established between the leaders in the army and the leaders in civil life. The cost would be more and the divergence from precedent greater, but the final good would be increased proportionately.

It is always difficult to estimate exactly the result that will follow the attempt to execute a new plan. One hesitates to assert that certain advantages will surely be gained. Yet by a careful analysis the probable effect can be fairly accurately forecast. This is particularly true when the analysis is made by different persons who view the situation from various angles. It is not with any assurance of success if tried, that either of the foregoing plans is suggested to solve the problem of creating a large force of reserve officers of the army, but rather they are proposed in the hope that one view of the question may suggest ideas to persons holding other views, and that a free discussion may bring forth suggestions to satisfactorily solve the question.

Counter Intelligence in the Field

By

Evarts Tracy

Lieutenant Colonel, Engineer Reserve Corps

[*Note.*—Colonel Tracy speaks with authority on the subject which is the title of this article, and what he has to say will be of interest to all our readers. He served with the A. E. F. throughout our participation in the World War, and as consulting expert on camouflage, Camouflage Officer of the First Army, and Professor of Camouflage at the Army Engineer School (A. E. F.), his activities in his chosen line covered the entire area occupied by the A. E. F., from the battle line to the base ports. His great practical knowledge of the subject, his unbounded enthusiasm and persistence, combined with tact, diplomacy and persuasiveness, were important elements in the development of an efficient camouflage service in the American Army. Colonel Tracy's interest in camouflage has not ceased with the conclusion of hostilities, as this article will show. In a few words he lays down some important practical principles for our future guidance.—ED.]

CAMOUFLAGE, French police slang signifying disguise, became during the war the most overworked word in two languages.

Mere disguise or concealment is by no means the whole of what has been called camouflage, which really is Counter Intelligence in the Field. What may be called Tactical Camouflage, which starts with map reconnaissance and ends with camouflage discipline (if it ever ends), is the most essential part of the whole work.

It has its greatest value for artillery, and the writer believed, even before the end of the war, that artillery camouflage should be entirely an artillery function, and should be taught to all officers and enlisted men just as carefully as any other branch of their work.

"Strength in a defensive battle depends essentially on the precautions taken to conceal from the eyes of the enemy all our means of fighting. The fighting means (trenches, dugouts, machine gun and battery emplacements) will *surely* be destroyed if they appear on the enemy's aerial photographs." (Signed) "General Sixt von Arnim, Commanding IV Army." So thought the Germans, as evidenced by this captured order.

"I would as lieve go into action without ammunition as without camouflage; I consider one as essential as the other," said Major General Summerall, after long experience in action.

The writer, after much discussion with artillery officers, took up the matter of instruction at field artillery camps with the Chief of Field Artillery, and with Capt. Homer St. Gaudens, E. O. R. C., volunteered to go to any of the artillery camps this summer and be of whatever service possible in conducting firing practice under war conditions from the counter intelligence standpoint.

There was, under the present conditions, no provision for giving reserve officers active duty status, but the Chief of Field Artillery issued instructions to proceed to Camp Knox and give whatever assistance was possible to the students and regular troops there.

As there were artillery R. O. T. C. students from nineteen universities for the summer camp, it was thought that the opportunity for teaching these men who would form the nucleus of the field artillery reserve in emergency, was great. Instruction was also ordered for the Basic School of Field Artillery and the regular brigade of artillery there stationed.

The instruction given consisted of: First, lectures on

Digitized by Google

the theory and practice of counter intelligence illustrated by lantern slides from both terrestrial and aeroplane photographs taken during the war. These showed plainly both good and bad instances of concealment and the corresponding results; Second, reconnaissance and choice of positions in varying terrains and the placing of the guns, wiring of paths and approaches, overhead concealment, defiiade screens, auxiliary positions for ammunition supply, command posts, kitchens, dugouts and latrines, and most important of all, so-called "camouflage discipline."

The main points in the lectures were discussed somewhat as follows:

The first thing necessary in approaching this subject is for one to free himself from all the popular conceptions of camouflage, the spectacular stuff, scene-painting fakes, protective coloration of animals, painting guns and vehicles, etc.

After long experience, the relative values of the factors entering into successful concealment were decided as follows:

Reconnaissance and choice of position	45 per cent
Camouflage discipline	25 per cent
Correct installation of camouflage material	20 per cent
Camouflage material used	10 per cent

The main idea is to so conceal your batteries that you may damage the enemy before he damages you. If you have even an hour's advantage in this way you may do incalculable damage to the enemy.

The ultimate value of a battery is its potential power for damage to the enemy at the time of the crisis, in the hour of its mission. Personnel and matériel, if destroyed, can be replaced, but the lost hour of opportunity in battle never returns.

The choice of position is paramount. Of course a battery must be where it can fulfill its mission, but one often saw during the war, a position taken, utterly impossible of concealment, when within one hundred yards was an ideal position.

The study of aerial photographs is of the greatest importance, as well as obtaining aerial views of positions before and after occupation. If the position shows on the photo it is time to move, leaving the old one for a dummy. The French say *"Une batterie vue est une batterie perdue."*

The lens, in many respects a more perfect instrument than the human eye, is a most accurate observer. It sees everything, forgets nothing, and records every object in its exact relation to every mark on the terrain, so that the transference to the map is easy and accurate.

Always tie in your position to something which shows an irregular blotch on the photo, even if it be no more than low bushes, weeds or a patch of different colored grass.

Overhead cover is then more difficult to detect. Avoid regularity, echelon your guns at unequal distances. One spot on a photo, irregular and of slightly different color may be bushes or weeds, but four in a straight line and at equal distance simply spell Good-night.

The making of tracks when bringing up guns, approaches for personnel, and promiscuous tracks from billets, dugouts, kitchens and latrines, are the most deadly signs commonly seen about a battery, and resulted in the destruction of more positions and material than any other cause during the war.

A gun or battery itself would rarely show on an aerophoto taken under war conditions. It is the signs of occupancy which are dangerous. Tracks and blast marks are the two surest signs that a position is occupied and active.

If a road must be made where it is visible, never stop it at the position, continue it and let it lead to some logical objective such as another road, a farm, or lose itself in woods, and *keep* it open, use it at night so the enemy will not detect the fact that part of the road is not in use.

In the field work at Camp Knox a regular sergeant and four men were detailed every day, and from twenty to fifty students for the actual work on positions.

There were three positions for firing used, and at each position two batteries were placed, one under concealment and one in the open. We had, therefore, three batteries which were placed in widely varying terrain, one at the edge of some low woods, just off a road, an ideal spot, good approaches, good locations for ammunition and dugouts along the road—altogether ideal as there were many other patches of woods in the near neighborhood so that it would be impossible to know just which one to shell (a solitary patch of woods is of course suspicious *per se*).

Another position had two guns under single trees, needing no overhead cover, while the other guns of the battery were at irregular distances in patches of bushes, and were covered. All were on an existing path.

The third position was on the edge of a huge blackberry patch and all guns required cover. Blackberries were ripe, a condition very bad for track discipline. I had the same condition once on the other side with blueberries and in a few days we had to move the battery.

We were confronted with the entire lack of matériel for concealment. This I considered a distinct advantage in instruction as it is the most likely and usual situation in war, and it is good to show men how to take advantage of whatever may be in the surrounding country.

There were miles of old telephone wire on the ground and we set our details to bringing it in. It was not as good as No. 9 or 10 annealed, but it served the purpose of overhead framework and for wiring off paths.

The first thing done was to wire off authorized approaches, anyone going outside was disciplined.

Details were then set at work tearing down the woven wire fences from the farms on the reservation, and these made our superstructure. Natural vegetation, branches and weeds furnished the final cover. Blast marks were taken care of by low wire entanglements with branches thrown in upright. These of course had to be constantly replaced.

One man was detailed as camouflage sergeant for each battery, his duties being to preserve the camouflage discipline, replace withered foliage, tighten wire, etc., asking for a detail from the battery commander when necessary. Aerophotos were taken both before and after the positions were occupied, and no evidence of occupancy was visible on them. It is a most important principle of successful camouflage *to preserve the former appearance of the terrain.*

The men, both students and regulars, were keen on the work, and were careful to observe all necessary precautions. We had just enough violations of discipline to serve as examples, mainly ammunition wagons leaving shell-case litter at entrances to positions.

With the increasing development of aircraft, counter-intelligence in the field becomes daily more important. I have just heard it is to be made a strong point of at the French maneuvers this autumn. I believe for us, its future lies in three things:

1. Choice of position.
2. Camouflage discipline.
3. Use of natural materials.

Transportation by Inland Waters in the Campaign In Mesopotamia*

By

Lt. Col. L. J. Hall, R. E.
Digest by L. E. Lyon, Major, Corps of Engineers, U. S. A.*

A WORK on river transportation in the British campaign in Mesopotamia has recently appeared in England. This book, entitled "The Inland Water Transport in Mesopotamia," compiled by Lieut. Col. L. J. Hall, of the Royal Engineers, under the direction of Brig. Gen. R. H. W. Hughes, Director of Inland Water Transport, Mesopotamia Expeditionary Force, is published by Constable and Company, Ltd., London. The volume opens with a Foreword by Maj. Gen. Sir G. F. MacMunn, Inspector General of Communications, Mesopotamia Expeditionary Force, under whose orders the Inland Water Transport operated. General MacMunn pays a high tribute to the work accomplished by the Inland Water Transport under most difficult and trying conditions. In this campaign transportation by water took on a greater importance than transportation by railroads. Ordinarily railroads dominate in transportation questions. Only rarely is a campaign undertaken in which rivers and canals present the best or the only immediate solution of the transport problems. The campaign in Mesopotamia was one of these. Lieut. Col. Hall gives a most painstaking account of the river transport operations in connection with the operations in Mesopotamia after August, 1916. Only brief reference is made to the transport operations and difficulties prior to that date, because previous to that time no distinct Inland Water Transport Service existed. The Royal Engineers brought it into being about that time. Water transport facilities had been deplorably inadequate and in an unsatisfactory state. They were becoming worse with the arrival of additional forces and the increase of distances as the troops advanced from their base at the head of the Persian Gulf. Only after persistent appeals and recitals of the difficulties encountered did the British War Office come to a realization that to keep its army in Mesopotamia supplied with the necessities of life and munitions a large and well-managed river transport service must at once be brought into being and operation. But when it did come to this realization it filled all demands made upon it and gave the officers in the field charged with that work its full support. The predicament of General Townsend, besieged at Kut, was instrumental in driving home the lesson that a poorly organized and inadequate river service made up of makeshift craft handled by inexperienced men would not suffice. It had become apparent that a large and well managed river fleet was essential to the success and even existence of the troops.

The streams utilized were the Tigris and the Euphrates, the Shatt-el-Arab and a few tributaries of these streams; principally the first-mentioned, upon which is situated the city of Bagdad. The word Mesopotamia signifies "the land between rivers," and is applied to the plain situated between the Tigris and Euphrates rivers. These two rivers have their origin in the Armenian highlands and flow in a southeasterly direction towards the Persian Gulf. They unite at Kurna (spelled Qurnah on the map), 108 miles above the Persian Gulf, where they form the Shatt-el-Arab, which empties into the north end of that gulf. Kurna is considered the head of ocean navigation.

The Mesopotamia Expeditionary Force was operating in Turkish territory. Its enemy was the Turk and its objectives were Bagdad and Mosul, and the Turkish Army. Its base was at Basra, 62 miles beyond the head of the Persian Gulf, and was approached through that gulf. The campaign was an operation in a secondary theater, but no doubt formed an important part of the larger strategical plans of the British War Office.

River transportation became dominant from the beginning. The British encountered almost no resistance up to the taking of Kurna. After the taking of Kurna, the need of additional river transport was sorely felt and became more serious and acute as the campaign advanced, notwithstanding the continual additions of plant and personnel to the river transport activities. Military operations began in 1914. An Inland Water Transport Service was not organized until August, 1916, after costly attempts at improvising such a service.

The magnitude of the river operations is shown by the following table of the river fleet in commission at various dates from the time the Inland Water Transport of the Royal Engineers took over the duty of river transportation to the date of the Armistice:

Classes of vessels	September, 1916	March 31, 1917	*Dec. 31, 1917	Nov. 11, 1918
Self-propelled vessels	138	242	358	446
Barges	134	315	585	774
Motor boats	95	187	356	414
Total	367	744	1,299	1,634

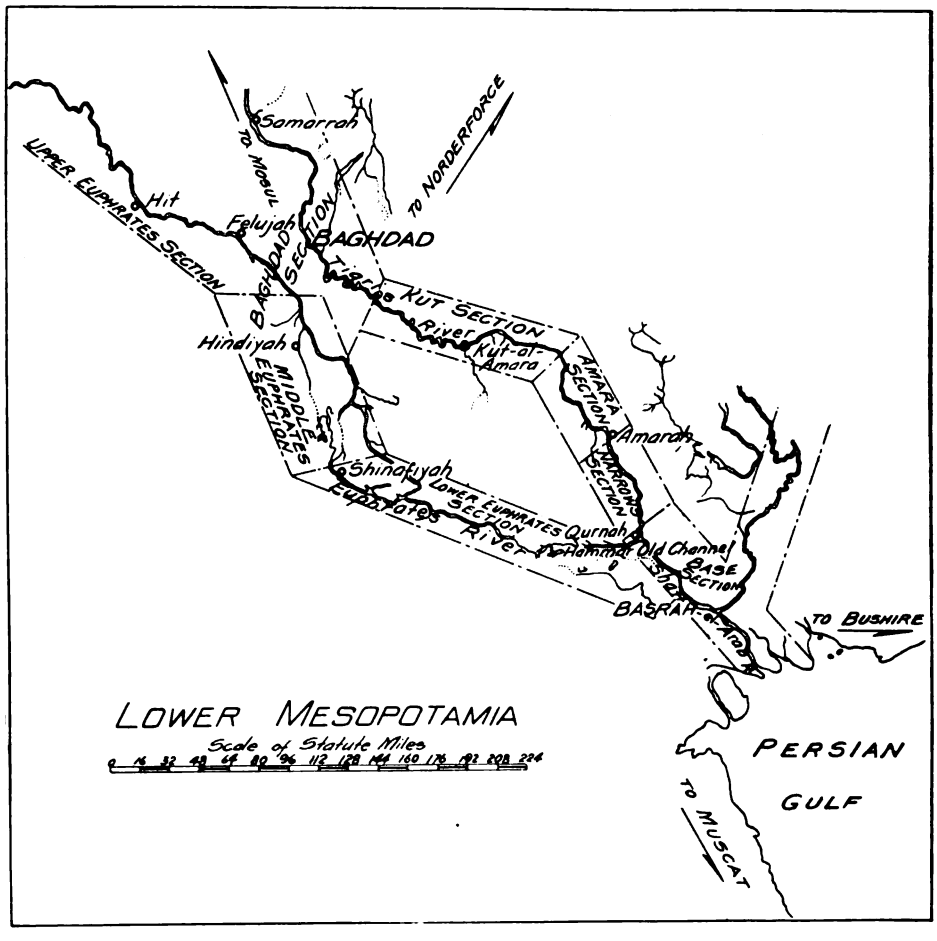
*At time of taking of Bagdad.

The personnel engaged upon the various phases of Inland Water Transport work at certain dates from December 31, 1916, to the date of the armistice, was as follows:

*This review by Major Lyon is of special interest as indicating the variety of duties which fall to the lot of the military engineer in time of war. It also indicates that inland water transportation is by no means obsolete, but still finds useful application in localities where railroad development is backward. It can frequently be placed in operation in much less time than would be required to build railroads.—ED.

Digitized by Google

Grade	Dec. 31, 1916	Dec. 31, 1917	Nov. 11, 1918
British Officers	292	703	804
British Warrant Officers	19	51	99
British other ratings	1,445	2,277	2,596
British West Indians	427	382	392
British African or Eastern races	16,338	42,640	41,940
Total	18,521	46,053	45,831



For purposes of administration, the work of the Inland Water Transport was divided into departments, all departments reporting through heads of departments to a Director. These departments consisted of Transport, Dockyards, Construction, Craft Reerection, Vessels, Marine Engineering, Accounts, Stores, Buoyage and Pilotage, Native Craft. Conservancy and Reclamation, and Personnel.

The Department of Transport was the operating department. All other departments were for the purpose of assisting it and facilitating its work. The name of each department is descriptive of the class of work upon which it was engaged.

In addition to the departmental organization described, the administration of the Inland Water Transport work was divided into geographical sections, in order to attain more direct supervision. The head of each geographical section acted in the capacity of the agent of the Director, Inland Water Transport, and also as the agent of the head of each of the departments. He was responsible to the Director, Inland Water Transport, for the satisfactory operation of all Inland Water Transport activities in his section. Officers from each department served under the section head and were responsible to him for the work belonging to their departments. At the same time these officers were responsible to their department head at Headquarters for the proper performance of their special duties.

As soon as a barge or a boat entered a section the head of the section became responsible for its prompt movement, loading or discharge in his section, and was assisted in this duty by officers from the transport and other departments. If a vessel required repairs to its machinery while in a particular section, the head of the section caused the repairs to be made through officers stationed in his section and representing the department charged with the repairs to be made. In the same way if a channel in a section required marking with buoys, the officers of the Department of Buoyage and Pilotage stationed in the section and reporting to the head of the section directed the work. The map shows the limits of the geographical sections.

The officers of the Inland Water Transport were designated by the titles of Director, Deputy Director, Assistant Director, Deputy Assistant Director, and Officers, in addition to their military rank. The Director was in command of the entire service. He was assisted by a Deputy Director and Assistant Director at his Headquarters, and a Deputy Director as Chief Engineer who was held responsible to him for all construction and engineering work. A third Deputy Director represented the Inland Water Transport at General Headquarters and directed the service's activities in the advance. The heads of departments and of sections were Assistant Directors and Deputy Assistant Directors. Officers in charge of branches of departments and of sub-sections were also designated Deputy Assistant Directors. The commissioned strength was as follows:

Director	1
Deputy Directors	3
Assistant Directors	15
Deputy Assistant Directors	36
Officers	715
Reserve	34
Total	804

The tonnage carried by the Inland Water Transport in 1916 was 117,882; in 1917, 1,231,398; and in 1918, up to the date of the armistice, 1,532,834 tons, making a total of 2,882,114 tons from the beginning of operations under the Royal Engineers to November 11, 1918.

As the campaign progressed, grave doubts arose in 1917 as to the advisability of relying entirely upon the Tigris for transportation in the low water seasons. It was feared that the river would fall to such an extent as to interrupt

Digitized by Google

for an unduly long period the transport of supplies in the quantities required. The construction of railways paralleling the river between certain points, and also from the Tigris to the Euphrates, was decided upon. A railroad was built from Bagdad to Kut, one from Basra to Amara, another from Bagdad to the Euphrates, and some shorter lines. At no time was the territory between Kut and Amara covered by a railway, and the Inland Water Transport carried all supplies between these two points during the entire period of the British campaign and occupation.

A conception of the transport difficulties encountered by the British upon arrival in Mesopotamia may be formed from General Townshend's statement in his book entitled "My Campaign in Mesopotamia," in which he describes the territory immediately above Kurna as having the appearance of our Lake Michigan. The Tigris was in flood at that time, and the river overflowed the banks on both sides, leaving visible only islands formed by high ridges and knolls here and there. General Townshend also describes one of his first attacks upon the Turks as having been made from a large fleet of native boats prepared for the purpose. The Turks occupied high ground, and the high waters of the river cut off all approach except by boat.

The work of the Inland Water Transport in Mesopotamia differed from similar work on the Western Front in France and Belgium, in that the Mesopotamian Expeditionary Force was operating upon unimproved rivers, very distant from industrial centers and sources of supplies, while the Inland Water Transport on the Western Front was upon improved rivers and canals to which supplies could be brought from England in a few hours. In Mesopotamia the rivers were the only means of transport from the outset, and the forces to be supplied depended entirely upon the rivers for their support. On the Western Front the water transport was auxiliary to railroad transportation, and although it relieved the railroads to a great extent at a time when the supply of railroad cars and locomotives did not equal the demand and when congestion was continually occurring upon the railroads, the forces supplied were not absolutely dependent upon it. Again, river and canal craft already existed in large numbers upon the waterways and such additional craft as were needed were constructed in England and had to journey but a short distance. The craft used on the Western Front were more nearly all of one type, that is, standardized canal barges which were towed by tugs, while the craft used in Mesopotamia were of all descriptions. Self-propelled boats were used to a greater extent in Mesopotamia than in Belgium and France, where the greater part of the tonnage was carried in river and canal barges in tow of tugs. The average tonnage of the boats used in France and Belgium was much higher than those used in Mesopotamia, where liberal use was made of the native boats having a carrying capacity of less than 50 tons.

The administration of the British Inland Water Transport in Mesopotamia and on the Western Front were very similar, each being controlled by a Director, under whom operated Chiefs of Departments and heads of geographical sections. On the Western Front the supervision of the moving craft was much easier, on account of the roads and towpaths following closely the banks of the rivers and canals. Officers traveling on motorcycles on these towpaths exercised constant supervision over the movements of craft, and took immediate measures to keep the craft moving in case of accidents or delays.

While the British modeled the administration of their Inland Water Transport along lines similar to those which would be followed in a commercial organization, the French, who also operated an Inland Water Transport service, followed more strictly military lines. In the French service water transport by barges was based on company administration. Each company had assigned to it certain territory to be covered, and was provided with the necessary barges and equipment. The bargemen and other personnel needed in the operation of the barges belonged to the company, and were directed and cared for by the company commander. The tonnage handled by the French was vastly smaller than that handled by the British, and was confined largely to the transportation of road material. These companies operated mostly upon the canals and smaller rivers. A large amount of water transportation was done by the French upon the Seine, but this traffic was handled by civilian bargemen and barges requisitioned for the purpose. The American Expeditionary Force also operated an Inland Water Transport in France. The 57th Engineers, functioning in the Transportation Service, were engaged upon that work. Large additions were contemplated to the organization when the Armistice rendered expansion unnecessary. Most of the transport work done was upon the Seine, but operations were also conducted upon the canals in the central and eastern parts of France. The work on the Seine was very urgent, and required all available barges in connection with overseas freight and freight from England received at the ports of Le Havre and Rouen. Railroad freight cars could not be secured at these ports except in small numbers, and barge transportation was depended upon for the evacuation of freight for the American Army arriving at these ports. Most of this freight was barged to river ports in the environs of Paris and then trans-shipped by railroad to its destination. Railroad cars for trans-shipment were more easily obtained at Paris, on account of that city being a large consuming center. The American Inland Water Transport was administered along lines similar to those used by the British.

It is evident from a perusal of this book that it was written as the work of the Inland Water Transport proceeded. It has therefore taken the form of an official review of the work done rather than of a book intended for the general reader. It will appeal especially to those who were connected with Inland Water Transport during the World War, but it has not thereby lost all interest for the general reader. It is to be regretted that in connection with the descriptions of craft, difficulties overcome, and statistical matter contained, the author has not dwelt more upon the general plan of the campaign and pointed out more fully and specifically the connection between the work of the Inland Water Transport and the operations of the combatant forces. Transportation by water assumed a greater importance and was a more dominant factor in the Mesopotamian campaign than in any other campaign in history. It is fortunate that Lieut.-Colonel Hall has put the achievements of the Inland Water Transport in Mesopotamia on record in his book. The book is a valuable one, and as General MacMunn remarks in his foreword: "The record of the Inland Water Transport, Royal Engineers, should remain as a text book and pattern for many generations to come."

Panama Canal Revenues and Expenses

During the fiscal year ending June 30, 1921, the excess of revenues over cost of operation and maintenance was $2,712,000. This was the fourth consecutive year in which the Canal has earned an excess of revenues over expense of operation and maintenance. This excess was sufficient to wipe out the last of the deficit that had resulted from slides in Gaillard Cut in earlier years and to leave an excess for the entire period of Canal operation of $420,000.—*Panama Canal Record.*

Student Military Training

(Continued from page 480)

he said, "To be prepared for war is one of the most effectual means of preserving peace. A free people ought not only to be armed, but disciplined; to which end a uniform and well-digested plan is requisite."

This simplifies and defines the problem of preparedness for all of us and it particularly defines the purpose and objective of the training system in our schools and colleges. It has always been the mission of the Reserve Officers' Training Corps to train young men to serve as officers in the event of emergency. In the past this mission has been vague and its obligations uncertain. It has always been understood that they would serve as officers in such an Army as we might require in the event of war. But that Army did not exist as a vital national institution and therefore the reserve officer could have no definite conception as to the unit with which he might serve or the character of duty which might be expected of him.

The important constructive features of our military law were originally contained in the so-called Wadsworth Bill which was prepared by the Senate Military Affairs Committee during the last session of Congress. This Bill provided for a National Citizen Army and for a system of universal military training through which all of the units of that Army would be filled with trained men with an ample surplus for replacements. The military system proposed in this measure was similar in form to the military system of Switzerland but adapted to American conditions. This bill was not accepted in its entirety by Congress. Congress did provide for the national Citizen Army composed of the National Guard and Organized Reserves but it rejected compulsory military training. It provided, however, in the Citizens' Military Training Camps, for the germ of a national system of voluntary training. Through the development of these camps and of the system of training already established in our schools we may hope that the day is coming when every young man who is willing to take it will have an opportunity to prepare himself for service in one component or other of the Army of the United States. Under universal training all of the units of the Army of the United States would be filled to overflowing. Under voluntary training the number of trained citizens will of course be less, but I believe that we may reasonably expect enough of them to maintain the Regular Army and National Guard at effective strength and to provide the officers, non-commissioned officers and specialists and a considerable number of the private soldiers required for the units of the Organized Reserves.

It is impossible to predict the number of young men who will undergo voluntary training. But I take it that as the system develops a number of influences will tend to increase its popularity. In the first place with an organized Citizen Army localized and officered in time of peace, it must soon become apparent that only those can hope to lead in war who prepare themselves for the responsibility of leadership in time of peace. Therefore, the young man who aspires to be any higher than a rear rank private upon mobilization will be impelled to prepare himself for leadership in time of peace. Another influence and I think a most potent one, will be the gradual development of the idea that it is the proper action for every self-respecting young American to give a portion of his time during his youth to preparation for effective service if his country should ever need it. I expect to see the development of a feeling of *Noblesse oblige* that will spur all patriotic young men to prepare for national service.

With our military policy and organization definitely settled by law, the mission of the Reserve Officers' Training Corps is clarified. We can now say that the young men of the Reserve Officers' Training Corps are being trained to serve in a definitely organized Army of the United States. After they receive their reserve commissions they will have an opportunity to join definite territorial units organized and established in the neighborhood of their homes. They will be officers of local units of the organized Citizen Army. They will know precisely what is to be expected of them upon mobilization. This will enable each reserve officer with the greatest possible economy of time to prepare for his assigned mission. This means more definite organization for the nation and a more precise understanding of the obligation incurred by the individual citizen soldier.

In the future, when a graduate of the Reserve Officers' Training Corps receives his commission and returns to his home he will find in that vicinity an organization either of the National Guard or of the Organized Reserves with which he can identify himself. His duty of preparedness will thus crystallize into the very definite duty of helping to prepare this particular organization for service in an emergency. When he joins this unit he will probably find enrolled in it older men of his acquaintance who have served in the World War and it will be a part of his mission to receive from them and to transmit to the future, the experience and traditions of the great War Army of 1918. He will report to this unit as a junior officer but a well defined pathway of promotion will be open to him, through which, if he has the time, the ability and the industry, he can prepare himself for the highest rank and the greatest responsibility in any future emergency.

The establishment of this national military organization will go far towards funding the cost of the World War as a permanent national investment. At several times in our past history it has been necessary at great cost of money and energy to create a great national military organization and then, after the emergency, we have demolished that organization without making any provision for making it available for the next generation that may be subjected to the burden of war. It is the great feature of our new military law that this defect in our national policy is corrected for all time. In our new organization we will actually perpetuate the principal military units that fought in the World War. We will assign each such unit to a definite locality. We will enroll in these units those veterans of the neighborhood who are willing to serve for a time until they can be replaced by younger men. The initial officer corps of this great Citizen Army will thus be provided by the veteran officers of the war. The problem of the R. O. T. C. has become the well defined problem of providing gradual replacement for this veteran officer corps. In any future emergency, mobilization will not be a process of hasty organization and classification of millions of untrained and unprepared men but the much simpler process of filling the ranks of organized units assigned to definite localities and provided with competent officers and non-commissioned officers.

I have explained that the new law provides for an Army of the United States comprising the Regular Army, the National Guard and the Organized Reserves. It is very important for all of us to form a clear conception of this force as a whole and of its several components. The Regular Army comprises those organized military units which are always ready for immediate military service and it also includes the corps of professional officers and enlisted

Digitized by Google

men who are required to train and develop the Citizen Army which comprises the National Guard and the Organized Reserves. The sub-division of this Citizen Army into two separate parts is a logical one. But there should be no rivalry between these two parts. The National Guard is that part of the Citizen Army prepared for any sudden emergency as a first re-enforcement of the Regular Army and is composed of those citizen soldiers who voluntarily assume that special obligation. The Organized Reserves will comprise those citizen soldiers who obligate themselves to serve only in the event of a great national emergency. There must be a harmonious relation between these two forces. The proper development of either should advance the development of the other. Those young men who desire continuous military service for a time will find their place in the Regular Army. Those who desire service only in periods of emergency but who are prepared for any emergency will find their place in the National Guard. Those who are able to obligate themselves only in the event of a great war will find their proper place in the Organized Reserves. In practice there should be an interchange of personnel between these two forces. Every young man who desires to become a member of the Army of the United States and who is free to take the special obligation involved, should be encouraged to enter the National Guard. Later, the same man, when business and family obligations restrict his freedom for military service, will transfer to the Organized Reserves.

There has been an impression in some quarters that the development of the Citizen Army will tend to reduce the importance of the Regular Army. It is indeed true that by the development of effective citizen forces, we make it possible to reduce our regular establishment to a safe minimum. But the development of the Citizen Army in time of peace provides the greatest field for constructive work that our regular officers have ever had. Considering the Army of the United States as a whole, the Regular Army forms the keystone of the arch. But its trained officers and men serving in institutions like this and with the National Guard and the Organized Reserves form the cement which binds all of the members of the structure into one complete and permanent whole.

Thus we find that the Reserve Officers' Training Corps has a more definite mission than was anticipated at the time of its inception. It was proposed then to prepare young men for an undefined service in the event of an emergency. It is proposed now, under the new law, to prepare young men to be officers in a definitely organized Citizen Army. The Reserve Officers' Training Corps will always be one of the most important agencies for training our citizen officers but it will not be the only agency. Through attendance at training camps and by actual membership in the Organized Reserves and National Guard, any young American with sufficient ability and industry will be able to prepare himself for a commission in the Citizen Army whether he is able to go to college or not. With this conception in mind it is important that we should not permit the R. O. T. C. to regard itself as a separate agency of preparedness. It is an important part but only a part of the machinery for developing leaders for the Army of the United States. Its members should, therefore, take every means of identifying themselves with the National Guard and Organized Reserves. I take it that the time is coming when many young men who come to college expecting to prepare themselves as reserve officers will come as members of the local military organizations formed at or near their homes. They will come here and enjoy exceptional opportunities to prepare themselves for leadership. But they will retain their identification with their home organizations and they will return to these organizations after their graduation. Their real title to leadership will be determined there.

Today the Government of the United States is determined to take such measures in time of peace as a prudent nation should take, not in the interest of, or with the thought of military aggrandizement, or military aggression against other nations, which the sentiment of our people and the fixed policy of our Government forbid, but in the interest of the preservation of peace among the nations of the earth, and the War Department appeals to the Universities and Colleges—the Institutions of Higher Education in our land—to give effective aid to this end by giving our intelligent educated college-bred men such reasonable means of military training and knowledge as will make better men of them, and prepare them to efficiently serve the country if need should arise.

Personals

All members are cordially invited to submit contributions to this column.

Col. LYTLE BROWN, Corps of Engineers, has been transferred from the 2d Engineers at Camp Travis, Texas, to Fort Leavenworth, Kansas, for duty as instructor at the General Service Schools.

Col. THOMAS H. JACKSON, Corps of Engineers, has been ordered to Kansas City, Mo., for duty as Instructor, Engineers, Missouri National Guard

Col. CHARLES W. KUTZ, Corps of Engineers, upon being relieved from his duties as Engineer Commissioner, District of Columbia, by Colonel CHARLES KELLER, has been ordered to Cincinnati, O.

Col. LEWIS H. RAND, Corps of Engineers, has been transferred from Camp Lewis, Wash., to Memphis, Tenn.

Col. THOMAS H. REES, Corps of Engineers, has been transferred from San Francisco, Cal., to Honolulu, T. H., for duty as Commanding Officer of the 3d Engineers.

Col. CLARKE S. SMITH, Corps of Engineers, has been transferred from Fort McPherson, Ga., to Camp Jackson, S. C., for duty in connection with the Organized Reserves.

Lt. Col. PAUL S. BOND, Corps of Engineers, has been transferred from New York City to Cleveland, Ohio, for duty as instructor, Engineers, Ohio National Guard.

Lt. Col. W. GOFF CAPLES, Corps of Engineers, has been relieved from further duty in connection with recruiting at Fort Logan, Colo.

Maj. HARRY F. CAMERON, Corps of Engineers, has been transferred from Florence, Ala., to Honolulu, T. H., for duty with the 3d Engineers.

Maj. FREDERICK B. DOWNING, Corps of Engineers, has been transferred from Los Angeles, Cal., to Washington, D. C., for duty in the Office of the Chief of Engineers.

Each of the following-named officers of the Corps of Engineers has been relieved from his present assignment and has been assigned to the organization specified:

Major Raymond F. Fowler, from the 9th Engineers to the 2d Engineers, Camp Travis, Texas.

Captain Peter E. Bermel, from the 2d Engineers to Engineer Training Company No. 8, Camp Bullis, Texas.

Captain EUGENE M. CAFFEY, to Engineer Training Company No. 1, Camp A. A. Humphreys, Virginia.

Captain FRANK M. S. JOHNSON, from the 4th Engineers to Engineer Training Company No. 9, Camp Lewis, Washington.

Captain JOHN B. LA GUARDIA, from the 7th Engineers to Engineer Training Company No. 5, Camp Jackson, South Carolina.

Warfare Is Evolutionary, Not Revolutionary

THE account of the operations of the Grecian army which appears elsewhere in this issue will be convincing proof to thoughtful persons that the methods of warfare have undergone no radical change as a result of the World War.

It was certainly not to be expected that the principles and methods which have been gradually and progressively developed during thousands of years of continued conflict would be completely upset and rendered obsolete in a single war of four years' duration.

Man is a conservative creature, even when he makes war, and the laws of nature are unchangeable. All the arts and sciences which we know today have been gradually and slowly developed during many years of patient, plodding research and experiment. The steam engine, the aeroplane, the dynamo, the automobile, were not conceived and created over night. They were not even independent inventions, but painfully slow developments by many men. The tea kettle preceded the steam engine, the kite preceded the aeroplane, the bird on the wing and the autumn leaf whirling through the air preceded the kite.

No industry has ever been "revolutionized" by any one man or any one invention. Our material civilization and all its component arts and sciences have followed the law of evolution. Violent changes are disturbing, they are against nature, and the race as a whole frowns upon them. There is no machine or method in use today whose evolution may not be traced over a period of many years.

The methods of warfare are based chiefly upon the nature of man, which certainly changes more slowly than anything else in the world, if indeed it has ever changed. Warfare is a composite of all the arts and sciences, and accordingly the most radical development in any one science can effect but a slight change in the all-including science of war.

There was nothing revolutionary in the developments of the World War. Nearly all the machines employed, certainly the most important ones, had been invented, used and highly developed prior to the conflict. They were further developed and employed in increased numbers during the course thereof.

Yet it is always the case that these plain lessons of history are thrown aside by many persons, in favor of some wild obsession. We were told during the war that a few submarines would render all surface navies obsolete. And as if this were not enough to dispose of them, a few recent experiments in bombing with aeroplanes have caused some wild enthusiasts to announce the doom of the battleship, and to advise that we build no more of them. Some thoughtless persons who have not sufficiently studied the law of evolution in all human developments, have in-

Digitized by Google

formed us that the next war will be fought entirely with tanks. Others of the same unthinking class say it will be fought entirely in the air. Still others assure us that it will be settled by poison gas, with which we shall all be wiped out.

The facts are that all future wars like all those of the past, will be fought by men. And the more numerous and the better trained and equipped these men are, the better will be their chances of victory. Tanks, aeroplanes, poison gas, will form part of the equipment—of less importance than rifles, machine guns and artillery. Man will never devise any instrument of warfare which will take the place of and render obsolete the human element, the fighting machine devised by the Creator.

Whether the persistent circulation of these unsound theories is studied, pacifist propaganda or the result of mere ignorance, they are always hailed with delight by an apparently large number of our people. Mr. Lincoln said you can fool some of the people all of the time, and more recently Mr. Barnum observed that "the people like to be fooled."

The eternal hope that we will find some cheap substitute for the soldier and the battleship is one manifestation of a desire very close to the American heart—to get something for nothing. It is the same hope that causes many people to believe the wonderful cures announced in patent medicine advertisements and to use such medicines even after they have been pronounced frauds by the medical profession, who know the facts. It is the same unthinking people who furnish the money for wild-cat investments and thus help to perpetuate that curse.

It is the duty of those who have studied the evolution of civilization and of warfare and who know the facts, to be on their guard to protect the nation against the dangers of the false theories touching the vital matter of the national defense. If we are to disarm let us at least do so with our eyes open, fully appreciating the risks that we are taking, and not in the false belief that a poison gas factory can take the place of an army and a navy.

Object of the Society of American Military Engineers

THE object of the Society of American Military Engineers and of its journal, THE MILITARY ENGINEER, is to promote harmony amongst and between military engineers in and out of the regular service, in the interests of the national defense. And such, we believe, has been the real motive of every article and argument that has appeared in our columns. Certainly we should suppress or advise the revision of any writings calculated to tear down rather than to build up the harmony and esprit de corps of our Society as a whole.

The ultimate object of this harmony is *efficiency* in the service of the country. This cannot be built up by flattery alone, nor do any of us desire the American Military Engineers to degenerate into a mere mutual admiration society. There is probably no man living who does not need a little honest criticism now and then to jar him out of his ruts or loose from his too fixed ideas along certain lines. The criticism must be honest and constructive, given in a spirit of helpfulness, and accepted in the same spirit.

All of us enjoy honest praise and appreciation. And it is helpful. But we should also be thankful for honest criticism, grateful to those who point out our mistakes or shortcomings, thus giving us the opportunity to correct them.

The "military mind" may be, and is sometimes born. But in general it is the result of the training which the individual has received. An exclusively military training like any other training of an exclusive nature, may have a narrowing influence. The successful military engineer must be a broad-minded man. The profession demands men of this type. We are broadened by professional and social contact with men in other lines of endeavor. In our Society, consisting as it does of engineers of varied experience in many civil and military lines, the opportunity for such contact exists. It must be "exploited" to the utmost. A free interchange of information and ideas, honest praise where such is due, honest criticism of a constructive nature, are the means to our end. It is not "military minds," but broad minds which we seek to develop, minds whose point of view commands the entire horizon. Such is the composite mind of our Society, and such we desire to have the mind of each individual member.

Our Society was not organized solely for the training and benefit of the civilian engineer who may be called to the colors in case of war. Association with civilian engineers during the late conflict, and the opportunity to observe their methods and learn their point of view, resulted in a marked increase in the efficiency of the regular Corps of Engineers. An appreciation of this fact by the regulars gave rise to a desire to continue this helpful association after the close of the war. And our Society resulted from a mutual desire for a continuance of pleasant and profitable relations between engineers in and out of the service. It has already justified the hopes of its founders, and there is more reason than ever for its perpetuation and growth.

Our future armies, like our A. E. F. in the World War, will consist of a mixture of professional military men and civilians with only a small amount of military training. The military mind and the non-military mind must co-operate in a common cause. To bring these two classes together and to hold them together in time of peace, to enable each to appreciate and in the greatest possible measure to share the point of view of the other, thus paving the way for more effective co-operation in time of war, is the aim and purpose of our Society. This basic idea cannot, we believe, be too often repeated.

The Unknown Soldier

On the tenth of November there lay in state in the rotunda of the Capitol at Washington the body of an unknown and unidentified American soldier, brought from France to be buried with the highest military honors among the nation's heroic dead in the National Cemetery at Arlington.

A company of soldiers from the 13th Engineers stood guard while organizations representing the multitudinous activities of America's citizens held special services in honor of the dead and laid floral tributes upon the coffin. All day long and far into the night a steady stream of people filed through the rotunda and paid tribute in awestruck silence to the remains that symbolized the sacrifice made by scores of thousands upon the fields of France.

During the morning Colonel C. H. Birdseye, E. O. R. C., and Major R. W. Crawford, C. of E., laid upon the coffin the floral tribute of the Society of American Military Engineers, consisting of a wreath of green with a center of white roses upon which a castle was raised in red roses.

Emotion craves outward expression, and nothing could have been more fitting than this ceremony as an opportunity for the expression of an emotion that has filled the hearts of all since the days when casualty lists brought their terrible news daily into hundreds of homes.

Even in our short and comparatively peaceful history, occasions such as this have not been infrequent. And always with the emotion of grief over the dead has been mingled the high resolve that the dead shall not have died in vain.

For the first time in our history, however, there exists a definite military policy which, if faithfully carried out, will insure that either there will be no war, or, if war must come, that it will be carried to a victorious conclusion with the minimum expenditure of human life.

Activities of Our Local Posts

Buffalo Post

HENRY P. JONES, 540 Federal Building

A meeting was held July 6, 1921, at the University Club of Buffalo, N. Y., with an address by Major Wm. E. R. Covell, District Engineer, U. S. Engineer Office, Buffalo, N. Y. Application made for charter and plans discussed for perfecting organization.

Albert F. Krause was made temporary President and Henry P. Jones temporary Secretary-Treasurer.

Minneapolis Post

H. V. BURNETT, 526 McKnight Building

This Post has completed its organization and has elected the following officers:

President—Captain William R. Lee.

Vice-President—Captain O. F. Woodrich.

Secretary-Treasurer—Captain William E. Clark.

Application for charter, signed by twenty-five members, has been made to the parent Society.

The chairman appointed S. W. Farnham, Philip A. B. Bellin and M. T. Northey as a membership committee of three, to call on eligibles for membership.

Col. E. H. Marks, Corps of Engineers, U.S.A., whose station is Duluth, Minn., spoke on Organization, and instructed the members present in the best method of procedure.

New York Post

PERCY E. BARBOUR, 29 West 39th St.

The first meeting of the season was held on November 1st at the Engineering Societies Building, 29 West 39th St. Major Douglas W. Johnson, of Columbia University, gave a very interesting and instructive lecture on "The Strategy and Tactics of the Great War in Their Relation to Geographical and Geological Features of the Theatre of Operations." Numerous lantern slides were shown.

Major Johnson has written a book on this subject which is attracting wide interest and attention.

Plans were made for an interesting winter program.

Portland, Oreg., Post

E. BURSLEM THOMSON, 321 Customhouse

The August field trip of the Post was to Forts Stevens and Canby, as guests of the United States Corps of Engineers and Major Wing of Fort Stevens. Fourteen members left at 9 A. M., August 6th, on the Engineer boat *Woodland*. A stop was made for inspection of the government dredge *Wahkiakum* at Kalama, Wash. At Altoona the party transferred to the U. S. Engineer boat *Vigilant* and continued on to Astoria. Reaching Astoria about 6 P. M., dinner was had at the Weinhard Hotel, after which the party were taken to Fort Stevens, landing about 8 P. M. Here the members were assigned very comfortable quarters in the barracks. The members showed a complete disregard for the sounding of taps, being busily engaged at the time, in true army fashion, in card games and anecdotes typical of barracks life. Early Sunday morning a fine ride was enjoyed across the Columbia River to Fort Canby where the party was shown over the older fortifications and especially the emplacements recently completed by Major Park. Returning to Fort Stevens for lunch, the party was met by Major Wing, who devoted the entire afternoon to a trip of inspection over the fortifications, accompanied by a most interesting and instructive explanation of the defenses of the mouth of the Columbia. The workings of the large gun emplacements, fire control stations, mortar batteries and the war game room were most interesting and thoroughly enjoyed by every member present.

After another good army meal the party left on the *Vigilant* transferring at Altoona back to the *Woodland*, where all passed a pleasant night, reaching Portland at 8 A. M., Monday, August 8.

This trip was undoubtedly the most enjoyable and instructive one yet made by the Post and our sincere thanks are due to both Major Park and Major Wing of Fort Stevens for making the trip both pleasant and instructive.

Many of our members being away on vacation, the regular business meeting was postponed until September.

The September meeting of the Society was held at Elk Rock on Tuesday, September 13, 1921, at the invitation of the Hauser Construction Company. An excellent opportunity to view the work of the tunnel construction being done by the S. P. Ry. Co., was obtained. This work is under contract by the Hauser Construction Company, Major Kenneth Hauser being in direct charge of the work for the contractors.

The 24 members and eight guests present were treated to an excellent dinner, served on the old steamship *Potter*, which is being used by the contractors as a barracks for their workmen.

Two military problems were prepared and analyzed for the members by Major Mayo and proved very instructive.

The program committee decided to invite some of the officers of the army stationed in and about Portland to attend the next meeting with the view to propounding a comprehensive traffic problem relative to this particular district. The solution of this problem is to be divided into various subjects to be apportioned to various committees from among the membership. It is believed that a problem of this nature will occupy the interest of a large number of the members for several meetings, and should prove of great practical value.

The October meeting of the Society of American Military Engineers was held at the University Club on the 11th. The meeting was preceded by a club dinner at 6:30 which was enjoyed by 23 members and guests.

The meeting was of unusual interest, plans being discussed and formulated for an extensive study of the traffic problem in Oregon in relation to an assumed attack of an enemy on the western coast line. The development of the problem will be of interest to all members, and the information gathered will be of public value whether in peace or war.

The following officers of the U. S. Army were guests of the Society:

Colonel Whitworth, Chief of Staff for 96th Division; Colonel Cavanaugh, Major Mayo and Captain Tansey, Corps of Engineers; Colonel Dentler, Instructor to the Oregon National Guard, and Majors Andrus and Peake, Aides to Colonel Whitworth.

The advice and experience of these officers was of great assistance to the Society in drawing up their plans, and Colonel Whitworth kindly consented to draw up an outline of the proposed study for discussion at the next regular meeting.

Counter Intelligence in the Field

(Continued from page 498)

Discussion

By

H. S. Bennion

Major, Corps of Engineers
Formerly Chief Camouflage Officer, A. E. F.

Colonel Tracy has outlined in a very satisfactory way the camouflage question. It was new to us and our period of active operations was so short that its relative importance and the best way to handle it were left more or less unsolved at the close of the war. But we learned much and must profit thereby. Some of the salient points are given below.

In the first place, it is important that all troops have an understanding of the subject and are properly trained in its application before they undertake active operations. It is hopeless to expect a few trained specialists to camouflage the operations of a large body of men when the activities of each one of thousands of men is tending to disclose the operations; and it is equally hopeless to expect troops in battle to remember and to act in accordance with instructions hastily and imperfectly given them just before the fight. The first time they forget everything and do only those things which have become habitual or are instinctive. The second time they are strongly inclined to do the things they did the first time and thereafter they are scarcely amenable to instruction.

The best way to learn how to camouflage is to study the means and methods of obtaining intelligence and of disseminating it. If this is thoroughly understood, the means of defeating the enemy's intelligence system will often suggest themselves.

The theory of camouflage is simple but its proper application is very difficult. Resource, ingenuity and common sense in abundance, study and experience, and a high state of discipline are required. It is essentially a game of wits where you must do the outwitting. The early ideas of it, developed by not too practical artists and dressed up and shaped by imaginative but uninformed writers, must be discarded and it must be considered as a phase of the old military problem of concealment and deceit.

The importance of camouflage depends directly on the development of the air service, of the intelligence service, and of artillery and, since it is safe to assume that these activities will increase greatly in effectiveness, our officers should study the subject with care and our troops should be trained in it. The execution of camouflage requires the expenditure of time and labor and perhaps materials and transportation. It seriously restricts operations and therefore it is essential that all officers understand the subject as well as they understand other military problems with which they have to deal so that when confronted by a situation they may be able to make an intelligent decision as to what sacrifice to make in the interest of camouflage.

The action of Colonel Tracey and Captain Saint Gaudens in giving their time to instruct at Camp Knox was most commendable and should produce excellent results. The enthusiasm with which these two men undertook the work is almost as valuable as the training they gave in practical camouflage.

Subsidence for River Banks—Discussion

(Continued from page 479)

that this treatment will be effective. It will be seen that Mr. Harding's proposed method of drainage will not apply, there being no impervious stratum to act as the bottom of the drainage system, and the high bluffs preventing its installation. In the narrow limits between the river and the bluff, no great disturbance of existing conditions can be allowed.

Another method of preventing the movement of underlying sand has been found to be effective. It sometimes appears that the head necessary to move the sand is produced from a pond or swamp behind. This case can be handled effectively by surface drainage.

It is not believed that there is much to support the theory that the river water enters the sand at high water, and that its return to the river, as the water falls, carries out the sand. Most of these sand strata carry their own water, particularly in the wet season when the river is high. The effect of the high river is to hold back the water in the sand—prevent its escape. Then when the river falls the water is allowed to escape, carrying with it the sand. The effect is the same and it might be argued that the point is immaterial, but it has a bearing on the treatment. Many think that an impervious treatment to keep the river from supplying water to the sand will solve the problem. The water is in the sand, with a head equal to or greater than the fall that has taken place in the river, and therefore any attempt to stop the sand movement must be instituted against the water in the sand and not to prevent the river from supplying the water to the sand. The usual argument that the river water does the damage is believed to be unsound. That is true only to the extent of direct river action in washing away the sand. Other than this the river's only offense is that it rises and prevents the escape of the water naturally in the sand. It does not supply, in the general case, the water that does the damage.

Hints to Speakers

The following hints were suggested to speakers at the Illinois Short Course in Highway Engineering.

1. Don't apologize for your presence as a speaker. If any apologies are needed, let the management make them.

2. Don't tell the audience you are a poor speaker. If it is true, it will be found out soon enough.

3. Be brief. The orator who preceded Abraham Lincoln on the program at Gettysburg talked over two hours. Today we don't remember who he was or what he said; Lincoln spoke a few words, and those immortal thoughts are a part of the life of every American. Draw your own conclusions.

4. Marshal your facts. The best extemporaneous speakers are those who have planned in advance what they intend to say and how best to say it.

5. Make every word hit the mark. If a word is not necessary, don't use it. You are not singing a swan song; you are presenting engineering facts.

6. Be heard! If you prepare the best information of the day, and then smother it by swallowing your voice, mumbling your words and slurring your syllables, your effort will be a rank failure. Every engineer can yell cross section readings for six hundred feet; he can therefore make himself heard by a thousand people. Remember that if you are too quiet, the appointed coach in the rear will yell "louder."

7. Keep within your time limit. The other fellow may have a few valuable things to say also.—*Professional Engineer.*

ACTIVITIES OF OUR LOCAL POSTS

(Continued from page 506)

San Antonio Post

Lieutenant Ray S. Quick, Post Office Box 262.

On August 9th a preliminary meeting was held, attended by 27 members of the Society. Col. Edgar Jadwin was elected chairman and Lieut. R. S. Quick acting secretary. Following a talk by Capt. Elliott Vandevanter in which he outlined some of the features of other Posts, a motion made by Col. F. G. Chamberlain to form a San Antonio Post was carried. A committee consisting of Col. Chamberlain, Maj. E. W. Ropes, Capt. Vandevanter, Lieut. J. C. Adams and Lieut. A. T. Colwell was appointed to draft a constitution and by-laws. A motion was made and carried that charter memberships be held open for two weeks.

At the second meeting of the Post held on August 28, three applications for membership were received and the organization completed. A constitution and by-laws were adopted and application for charter, signed by 54 members, was prepared for transmission to the parent Society,

The following officers were elected:

President, Col. Edgar Jadwin; First Vice-President, Col. W. B. Tuttle; Second Vice-President, Col. F. G. Chamberlain; Treasurer, Maj. W. N. Vance; Secretary, Lieut. R. S. Quick; Director, Maj. R. F. Fowler; Director, Lieut. Joseph A. Dodge.

A committee consisting of Maj. Fowler, Capt. C. B. Falley, Capt. V. H. Browning, Capt. Anderson and Alfred G. Ranney was appointed for the purpose of securing new members and arousing interest in the Post and its purposes.

San Francisco Post

Douglas W. Dodge, 733 Rialto Building

San Francisco Post of the Society is doing things.

The daily press of San Francisco recognizes that the Post by the Golden Gate is doing more than merely getting together at intervals, of evenings or around the lunch table, to chat of "over there" reminiscences, and has detailed reporters to attend the meetings of the Post and record its activities and plans. Particularly have the San Francisco *Chronicle* and *Journal* exhibited this interest, the former paper having detailed Mr. R. E. Quinn, one of its writers who served overseas with the 23d Engineers, to attend San Francisco Post sessions and luncheons, and accompany the Post on military inspection trips, to "cover" them in his paper.

This is as it should be. The public should be informed of the work the Society is doing in keeping alive general interest in those vital things that have to do with the National Defense. That public apathy towards essential military activities which has been manifest after all of our national conflicts should not be allowed to continue this time. Co-operation of the daily press, enlisted and maintained by live-wire publicity committees in every local Post, will be a powerful factor in wiping it out.

Inspection of Spring Valley Water System

The members of San Francisco Post, with officials of the Spring Valley Water Company, of San Francisco, as hosts and guides, spent two Saturdays in making an exhaustive military reconnaissance of the city's water supply. July 16 was taken up with an inspection of the properties of the company—reservoirs, pumping stations and pipe lines—down the peninsula from the city, west of San Francisco Bay. July 30 was given to a similar trip over the Alameda County or "east-bay" watershed and properties of the company—the Calaveras reservoir, the famous earth dam that slipped its clay core out into the lake two years ago, the Sunol sand-filter beds, the noted and beautiful Sunol "Water Temple," the pumping stations at Pleasanton and Belmont, the Niles Canyon weir dam, and the system of two 22-inch and two 16-inch ball-joint submarine pipes that carry beneath southern San Francisco Bay and to San Francisco exactly one-half the city's total present available water supply—21,000,000 gallons daily out of the total of 42,000,000.

The inspection trip was a corollary to the work undertaken by San Francisco Post in studying that essential factor in the problem of the city's defense against a hostile force approaching by land from the south, the specific defense of the city's water supply, essentially a military engineering problem, and one that would be laid upon the Corps of Engineers at the very outbreak of hostilities with a foreign power that would menace the Pacific Coast.

At the meeting of the Post Thursday evening, July 28, Col. R. E. Child led a discussion of the military aspects of this factor in the San Francisco defense problem, following an interesting stereopticon talk on the engineering features of the Spring Valley Water Company's system by Mr. J. J. Sharon, Assistant Manager and Engineer of the company.

The problem in question is now being concretely worked out under the direction of a committee, the personnel of which is as follows: Col. Herbert Deakyne, C. of E.; Col. Robert E. Child, E.R.C.; Lieut.-Col. Charles B. Wing, E.R.C.; Major A. R. Ehrnbeck, C. of E.

In conjunction with this problem, the more general one of preparing a system of military maps of the San Francisco region of the Pacific Coast, from a point 75 miles north of the metropolis to one that distance south, and east to the San Joaquin and Sacramento Rivers, has likewise been undertaken by San Francisco Post under the general supervision of the following committee: Capt. Addison N. Clark, E.R.C.; Capt. C. A. De Camp, E.R.C.; Mr. H. B. Truett.

In this broader work, the objective will be to provide instruction in the art of military mapping for the benefit of military men not now familiar with such work—Regular Army, Reserve and National Guard officers and men—and for cadet organizations and similar bodies.

In all of our work we are proceeding with the knowledge and approval of Headquarters, Ninth Corps Area, and it is our aim not only to secure valuable training for our members but also to make definite contributions that will be of value to the Corps Area in its study of the military problems with which it will be confronted in the event of emergency.

Yet it's not all work and no play for San Francisco Post. Each alternate meeting (i.e., every other month) the meeting takes the form of a luncheon at a popular restaurant, and business and war play second fiddle to congenial good-fellowship. Ladies' night and social hikes in which the ladies of the knights participate have been a feature of the Post's activities throughout the spring and summer.

Nor was the Spring Valley water reconnaissance allowed to be too serious a matter by the Spring Valley officials, who, when they play host, do so royally. The piece de resistance of the Peninsula trip was a trout dinner de luxe. That of the Alameda County trip was a barbecue beneath the trees at the Sunol water temple, presided over by Manager Sharon, Superintendent George Pracy and George Espey, not overlooking Chef Gee Fong, who, a comedian as well as a famous cook, was distracted to provide enough roasting ears and ash-baked potatoes, likewise barbecued mutton, plus that which gurgleth and gleameth a ruby gleam when it poureth from the bottle, for that famished flock of engineer officers. It may be added that everything on those long tables was grown or—er, manufactured—on the Spring Valley premises.

Trip to Muir Woods and Mt. Tamalpais

On Sunday, August 21, our party, including twenty-five members and ladies, left San Francisco at 9:45 a. m. on the N.W.P. ferry. At Sausalito, the ferry terminal, we were provided, through the courtesy of the Northwestern Pacific Railway, with

Digitized by Google

a special car in which we proceeded to Muir Woods under the escort of Mr. Ingram, the vice-president and general manager of the Mount Tamalpais Railway Company. At Muir Wood Tavern we were provided with an excellent lunch through the prior arrangements of the Entertainment Committee, and continuing under the personal escort of Mr. Ingram, ascended to Mount Tamalpias over the "Crookedest Railroad in the World."

A great value is being attached to these occasional social trips of members with their families and friends. This trip was the second social undertaking of the Post, and the effect is most plainly evident. Wives and families of different members are becoming well acquainted and a considerable spirit is being manifested in our membership and purpose, and especially notable is the interest and support that is being given by the wives that the members shall do everything possible for the success of the Post.

Plans for Instruction in Mapping.

The necessity for adequate instruction of all officers in map reading and map making was strikingly brought out by Major L. M. Adams in his article on "Map Reading," in the July-August number of THE MILITARY ENGINEER.

The committee appointed to develop a plan for carrying on instruction along these lines has taken the matter up with the Ninth Corps Area and will make a report at a later date.

Dinner to General Wright.

Shortly after the arrival in San Francisco of Major General W. M. Wright, the commanding officer of this Corps Area, he was tendered a public dinner, to which all reserve officers were bidden. Our own members made up two large tables of approximately twenty men. We are keeping in very close touch with headquarters and as matters of information of interest to our members arise notices are sent to them, which always are considerably in advance of the official distribution. In this way Special Regulations No. 46 have been distributed.

State Highway Inspection Trip.

On October 20th a luncheon was held, and on October 22d a tour of inspection was made over the state highway from San Francisco to Santa Cruz and through Redwood Park and the Big Basin territory to gather data of a military aspect on the highways for the defense of the bay regions should an emergency arise.

Colonel John H. Skeggs of the California State Highway Commission acted as guide for the party and explained the obstacles it was necessary to overcome in building the roads.

Among the members of the post who made the trip were Colonel Herbert Deakyne, engineer officer of the San Francisco district; Colonel Thomas H. Rees, engineer officer of the Ninth Corps Area; Colonel Lee Rand, Presidio; Major Thomas M. Ward, Captain L. D. Jones, C. A. DeCamp, Captain B. P. Miller, Captain Walter E. Buckingham, Captain Douglas W. Dodge, M. J. Lyon, Colonel R. E. Child and Captain C. W. Backe.

Problem on Defense of Water Supply System.

The committee on water supply defense has submitted the following problem:

General Situation:

War has recently been declared and the hostile forces (Red) have advanced up the Santa Clara Valley and hold a general east and west line across the valley from the base of the foothills two miles south and east of Milpitas, through Santa Clara to Calabazas Creek and via that creek to the foothills. Red army consists of about 40,000 men with a small air force.

Special Situation (Blue):

The Blue forces, composed of hastily mobilized troops from nearby posts are holding a line about a mile north and roughly parallel to the enemy.

It is expected that the Reds will try to destroy the water supply to San Francisco by artillery fire, air raids, and penetration of the Blue lines by raiding parties or individuals. No land attack is expected from the west, and shore defensive forces are able to keep off landing parties from the Golden Gate southward of Halfmoon Bay.

One regiment of Engineers under Colonel "A" has been concentrated near Belmont. Two companies of Engineers without transportation, under Major "B," will arrive at Niles tomorrow morning at 6 o'clock, with instructions to report to Colonel A for orders.

All troops of other arms are required in the line. About 1,500 civilians are available for labor work with the Engineers. Colonel A has authority to commandeer any needed auto trucks with drivers.

The Commanding General has issued an order to Colonel A to proceed at once with his regiment to the construction of such defensive structures as he deems necessary for the protection of the water system on the west side of San Francisco bay exclusive of the City of San Francisco proper. He is to furnish Major B with transportation and labor, and order him with his two companies to construct the necessary defensive works for the San Francisco water system east of San Francisco bay.

Required:

1. A definite statement of the mission (Colonel A).
2. A definite statement of the plan of action adopted (Colonel A).
3. Written orders of Colonel A to Major B for carrying out the work required east of San Francisco Bay.
4. Written orders of Colonel A to subordinates of his regiment for carrying out the work west of San Francisco Bay.
5. Written orders of Major B to his subordinates.
6. Location of defensive works on map (U. S. G. S. sheet).
7. Sketch designs of defensive works.
8. Estimate of materials required.
9. Estimate of labor required.
10. Estimate of time required.

Denver Post

Lieut. Col. CHARLES H. RANKIN, Room 4, Building A, Denver Tramway Co.

This Post has completed its temporary organization and has made application for charter to the parent Society. The following officers have been elected:

President, Col. Joseph C. Taylor; Vice-President, Maj. Charles Larson; Secretary, Lt. Col. Charles H. Rankin; Treasurer, Captain George B. Clark; Assistant Treasurer, Maj. R. R. Mayther.

Baltimore Post

STEUART PURCELL, City Hall

A meeting was held at the Engineers' Club on November 1st, at which Col. Jenks G. Jenkins, E.O.R.C., presided. The organization of the Post was completed and constitution and by-laws adopted.

Major F. C. HARRINGTON, C. of E., Engineer, Third Corps Area, made an address in which he outlined the steps that have been taken to date for the establishment of units of the Organized Reserve in the Third Corps Area, with particular reference to the engineer units.

Major W. H. Lanagan, Corps of Engineers, on duty in the Office of the Chief of Engineers in Washington, spoke on the

Digitized by Google

history and objects of the S. A. M. E. and the close relation that it bears to the engineer units of the Organized Reserves.

Colonel Jenkins emphasized the fact that civilian engineers even though not members of the E. O. R. C., could by affiliation with the Society and the local Post do much to further the cause of National Defense.

Washington, D. C., Post

E. P. Ellis, U. S. Coast & Geod. Sur.

By courtesy of the Chief of Ordnance a demonstration at the Proving Ground at Aberdeen, Md., was given on November 2d to the Washington Post of the Society of American Military Engineers. A large delegation from the Post was met upon arrival at Aberdeen by Capt. K. L. Brown-Jones whom Col. H. W. Schull, the commanding officer, had directed to explain the work that is being done at the Proving Ground.

The most striking exhibits are two 16-inch guns, one of which is mounted on a disappearing carriage. This gun has an effective range of 35 miles and is the most powerful one in existence. The disappearing carriage has proven completely successful in actual use, its principal advantage being the concealment of the gun emplacement which it accomplished very successfully prior to the employment of aircraft for observation purposes. Camouflage is a more effective means of concealment from overhead observation than is the disappearing carriage.

An interesting exhibit is the famous French 75-millimeter gun and those of the same size developed in this country during and since the war. Although the French 75 was perfected as long ago as 1897 it was used without change throughout the war by France and her allies. That the Ordnance branch of the United States Army has made important improvements in artillery is indicated by the fact that the French 75 gun had a range of only 8,000 yards while that of the new U. S. 75 is 15,000 yards. The latter is also much superior to the French original by reason of greatly increased elevation and ease of manipulation.

As the value of artillery is largely dependent upon the quickness with which it can reach the scene of action, the development since 1918 of the caterpillar tractor as a gun mount has been a notable advance in ordnance. An inspiring sight is a battery of artillery dashing into action with drivers urging the horses on with lash and voice, but the actual progress is slow and halting. Less thrilling but more impressive was it to see modern 6, 4 and 3-inch high-powered guns moving towards their stations at 20 and 25 miles an hour and ready to fire as soon as they had taken position.

Great as have been the improvements in ordnance matériel, the changes now being introduced in sea coast defense are nothing short of revolutionary. Specimens of the heavy 12-inch naval guns mounted on railway trucks that were used by Admiral Plunkett against the Germans were exhibited at Aberdeen, together with improved trucks and mounts designed in this country since the close of the war. The success of this type of artillery has suggested its employment in seacoast defense. Plans have been formulated that provide for the construction of concrete emplacements at suitable points adjacent to or within reach of railways. Guns mounted on railway trucks will be parked at strategic points from which they can quickly be dispatched to any section of either coast that may be threatened by a hostile fleet. Coast artillery regiments can be maintained intact at the strategic points, the advantages over the prevailing custom of breaking up the regiment into numerous detachments being self-evident.

The development of the use of Aircraft for bombing has not been neglected at Aberdeen. A Handley-Page airplane capable of carrying a 4,000-pound bomb has been built at the Proving Ground. This is the largest bomb that has ever been projected by any means and its destructive power is so great that its effect is irresistible whether on land or sea. The bomb has proven completely successful in tests.

While the development of new ideas in ordnance is an important function of the Proving Ground, the real task of the plant is the testing of all guns and ammunition used by the army. Every gun is subjected to the strain of charges 15 per cent in excess of those used in actual service.

The Proving Ground has important work to perform and those who designed the layout and equipment planned generously, and with a view to meeting the enormous demands of a great army. There can be no doubt that as long as our country maintains an army, and just so long as there is a possibility of another war the work at the Aberdeen Proving Ground should go on and the plant be fostered and developed so that it may function fully and without delay should another great emergency arise.

Seattle Post

J. M. Clapp, Burke Building.

The members of the Seattle Post of the Society of American Military Engineers were highly honored on Monday night the 17th of October at the Assembly Rooms of the Chamber of Commerce by Colonel John Millis, Corps of Engineers, U. S. Army, who made an informal address.

Colonel Millis was a visitor in the city for a few days in attendance at the convention of the World's Port Authorities held at the New Washington Hotel last week where he was to present a paper on "Regulation of the Great Lakes."

Although his itinerary included his attendance at the Coast Ports Convention held in Vancouver, B. C., on the 17th and 18th, Colonel Millis very generously stopped over a day to meet with the Seattle Post, and his talk proved highly interesting to the forty or fifty members present.

Colonel Millis will be remembered as District U. S. Engineer at Seattle from 1900 to 1905, when he left Seattle for a tour of duty in the Philippine Islands where he had charge of the Defenses of Manila harbor and the river and harbor work there. This is the Colonel's first visit to Seattle in sixteen years.

During Colonel Millis' tour of duty in this district he started the work on the Lake Washington Ship Canal; continued the construction on the Gray's Harbor Jetty System; the Rainier National Park Road; the Harbor work at Everett and Bellingham; directed the survey for the road and trail work in Alaska and had charge of the other engineering work of the Department, scattered over eastern and western Washington, Idaho, Montana and Alaska.

The description of his trip to the Philippines from Seattle, via the Northern route, Japan and China and later his homeward voyage by way of Singapore, Mandalay, India, Ceylon, the Red Sea, Egypt and the Mediterranean proved most interesting to all present, who gave him the closest attention.

Aside from the description of the scenery and the habits and customs of the inhabitants of the various countries he visited on his trip, he touched briefly on some of the engineering features he observed, including the great break-water at Colombo, the ponton bridge at Calcutta, the Suez Canal and the irrigation works at the Nile.

The Colonel's description of the changes he noted in Seattle after his long absence, of the changes of the business center of Seattle and the construction of the various buildings and other improvements, many of which had been made for ten years or over, made all present realize what wonderful progress the city had made and that Seattle was still in the "March of Progress." His lecture made all present feel contented with Seattle.

All were happy to note that there had been very little change in the Colonel during his absence and all united in expressions of pleasure for the talk he had given them.

At the conclusion of his address, a rising vote of thanks was tendered him.

The Seattle Post of the American Military Engineers sincerely hopes to have the Colonel with it again and that sixteen years will not elapse before his next visit.

New Posts

The following Posts are now in course o forganization:

Akron Post—Lieut. Sears S. Day, Lock Box 254, East Akron, Ohio.

Baltimore Post—Major Steuart Purcell, E. O. R. C., Highways Division, City Hall, Baltimore, Md.

Boston Post—Lieut. Lewis A. Armistead, Room 701, 108 Massachusetts Avenue, Boston, Mass.

Cincinnati Post—Capt. Hugh J. Krampe (E. O. R. C.), 1608 First National Bank Building, Cincinnati, Ohio.

Indianapolis Post—Capt. C. L. Harrod (E. O. R. C.), Public Service Commission of Indiana, Indianapolis, Ind.

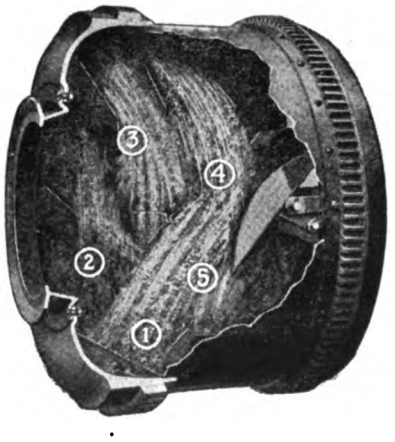
Kansas *for* KOEHRING

SEVENTY-NINE per cent of all the contracts let for the building of hard surface highways in Kansas in 1919, 1920 and 1921 to date, have been or are being built with Koehring Pavers. Such an almost universal choice by Kansas contractors speaks more eloquently of the value and worthiness of Koehring Pavers than pages of advertising could possibly do.



Here are the statistics:

Total number miles of concrete road let to date in Kansas	181.349
Total number miles of brick road let to date in Kansas	60.043
Total mileage of hard surfaced roads let	241.392
Mileage paved or being paved with Koehring machines	191.309
Mileage paved or being paved with all other machines	50.083
Percentage of Koehring paved roads	79.249
Percentage of roads paved with all other machines	20.752

Of the 181.349 miles of concrete roads let, 137.224 miles, or 75.668% are Koehring built roads. And of the 60,043 miles of brick roads let, 54.085 miles, or 90.077% are constructed with Koehring pavers.

The customer is the final judge of worth. And 79% of the state hard road builders of Kansas back their judgment that the Koehring Heavy Duty paver is the paver of absolute dependability.

Koehring re-mixed concrete is DOMINANT strength concrete.

The Field Artillery Journal

Official Organ of the

United States Field Artillery Association

The U. S. Field Artillery Association was organized in 1910, and is composed of officers of field artillery of the Regular Army, the National Guard, and the Officers' Reserve Corps, and other persons interested in field artillery.

The Field Artillery Journal is published bi-monthly by the Association. Each number contains approximately one hundred pages of technical information of value to officers of all arms of the service, although of course of particular value to those who are interested in the development of field artillery.

Subscription price, $3 per annum, including all dues. Single copies of the magazine, 75 cents.

Address—

The Secretary
United States Field Artillery Association
War Department, Washington, D. C.

Personals

(Continued from page 503)

Captain TATTNALL D. SIMKINS, from the 9th Engineers to the 18th Engineers, Camp Bullis, Texas.

Captain KENNETH M. MOORE, to Engineer Training Company No 2.

First Lieutenant HOWARD V. CANAN, from the 12th Engineers to Engineer Training Company No. 5.

First Lieutenant CHARLES D. JEWELL, from the 12th Engineers to Engineer Training Company No. 6.

First Lieutenant WENDELL P. TROWER, from the 12th Engineers to Engineer Training Company No. 7.

Maj. FREDERICK W. HERMAN, Corps of Engineers, has been transferred from Louisville, Ky., to Camp Dix, N. J, for duty with the 1st Engineers.

Maj. PAUL A. HODGSON, Corps of Engineers, has been transferred from the 3d Engineers to the 14th Engineers, Manila, P. I.

Maj. THOMAS B. LARKIN, Corps of Engineers, has been transferred from Washington, D. C., to Tokyo, Japan, for duty as Assistant Military Attache, American Embassy.

Maj. CHARLES E. PERRY, Corps of Engineers, has been transferred from Camp Dix, N. J., to Washington, D. C., for duty in the Office of the Chief of Engineers.

Maj. XENOPHON H. PRICE, Corps of Engineers, has been transferred from Cambridge, Mass., to Washington, D. C.

Maj. GEORGE J. RICHARDS, Corps of Engineers, has been transferred from Camp A. A. Humphreys, Va., to Memphis, Tenn.

Maj. THOMAS M. ROBINS, Corps of Engineers, has been detailed as a member of the Board of Officers to consider a system of National Highways in connection with the rural post roads.

Maj. BREHON B. SOMERVELL, Corps of Engineers, has been ordered to report by letter to the Commanding General at Fort Howard, Md., for temporary duty in the District of Columbia in connection with court-martial duty.

Maj. HENRY H. STICKNEY, Jr., Corps of Engineers, has been transferred from Camp Meade, Md., to Cincinnati, O.

Maj. HARRY M. TRIPPE, Corps of Engineers, has been transferred from Camp Grant, Ill., to Columbus, O.

Capt. CLARENCE L. ADCOCK, Corps of Engineers, has been assigned to the 13th Engineers, Camp A. A. Humphreys, Va.

The following-named officers of the Corps of Engineers have been ordered transferred from the 4th Engineers to the 6th Engineers: Captain AUBREY H. BOND, Captain CLARENCE S. JARVIS, Captain SAMUEL H. HARRICK, Captain JOHN G. LITTLE, Captain FRANK W. MOORE, Captain KERYN AP RICE, Captain STEPHEN C. WHIPPLE, First Lieutenant WILLIAM H. WHEELER, First Lieutenant LESLIE H. GROVES, Jr.

Captain BENNETT H. BOWLEY, Jr., and Captain HARLEY LATSON have been relieved from their present duties in the Hawaiian Department, effective upon the completion of their present tour of foreign service.

Capt. WILLIAM H. CROSSON, Corps of Engineers, has been ordered transferred from Camp Travis, Texas, to Camp A. A. Humphreys, Va., for duty with the 17th Engineers.

Capt. SAMUEL L. DAMON, Corps of Engineers, has been ordered transferred from the 2d Engineers to the 13th Engineers, Camp A. A. Humphreys, Va.

Each of the following named officers of the Corps of Engineers has been relieved from his present duties at the station indicated and has been detailed as Assistant Professor of Military Science and Tactics at the institution specified:

Captain NOTLEY Y. DUHAMEL, from Camp Meade, Maryland, to the Carnegie Institute of Technology, Pittsburgh, Pa.

Captain ROBERT D. INGALLS, from Camp Pike, Ark., to Alabama Polytechnic Institute, Auburn, Ala.

Hayward Buckets

Quick as a Flash

—open the jaws of a Hayward Clam Shell Bucket when the closing line is slacked. And the load begins to discharge at once —a smooth, swift, well-directed dump. Digging, the jaws bite into the material at an angle that means speed and a load which piles clear up to the power wheel hub.

This is bucket action that insures fast, economical work.

Refinements of design and construction prompted by over 40 years of bucket-building experience are incorporated in Hayward Buckets—the "reason why" for Hayward Bucket efficiency.

Catalog 43 is a little booklet picturing and describing Hayward Buckets of all types in contracting and engineering work. Write for it.

Captain WALTER L. MEDDING, from Camp Jackson, S. C., to Missouri School of Mines, Rolla, Mo.

Captain WARREN A. LYON, from Camp Lewis, Wash., to University of Illinois, Urbana, Ill.

Captain WILLIAM C. ATWATER, from Camp Meade, Maryland, to Johns Hopkins University, Baltimore, Md.

Captain ROBERT H. ELLIOTT, from Camp Benning, Ga., to Iowa State College, Ames, Ia.

Captain F. RUSSELL LYONS, from Camp Grant, Ill., to Virginia Polytechnic Institute, Blacksburg, Va.

First Lieutenant DAVID A. D. OGDEN, from Camp Pike, Ark., to Massachusetts Institute of Technology, Cambridge, Mass.

First Lieutenant ARCHIE T. COLWELL, from Fort Sam Houston, Tex., to Rose Polytechnic Institute, Terre Haute, Ind.

First Lieutenant JAMES G. CHRISTIANSEN, from Fort Sam Houston, Texas, to Oregon Agricultural College, Corvallis, Ore.

First Lieutenant JOSEPH S. GORLINSKI, from Camp Benning, Ga., to University of Tennessee, Knoxville, Tenn.

First Lieutenant DOSWELL GULLATT, from Fort Sam Houston, Texas, to California Institute of Technology, Pasadena, California.

Captain LEONARD B. GALLAGHER, Corps of Engineers, has been assigned to the 1st Engineers, Camp Dix, N. J.

Captain LLEWELLYN B. GRIFFITH, Corps of Engineers, has been transferred from Washington, D. C., to Cincinnati, O.

Captain WILLIAM S. KILMER, Corps of Engineers, has been ordered attached for duty to the 2d Battalion, 3d Field Artillery.

Each of the following-named officers of the Corps of Engineers has been relieved from his present duties at the station specified after his name and has been ordered to Camp A. A. Humphreys, Va., for assignment to duty as student at the Engineer School:

Captain ALBERT C. LIEBER, Jr., Boston, Mass.; Captain GEORGE J. NOLD, Cincinnati, O.; Captain ROBERT M. COPELAND, Washington, D. C.; Captain CLAY ANDERSON, Camp Dix, N. J.; Captain FRANK B. HASTIE, Camp Grant, Ill.; Captain PHILIP T. COFFEY, Camp Pike, Ark.; Captain ALVA H. PERKINS, Camp Grant, Ill.; Captain ELLIS E. HARING, Camp Dix, N. J.; Captain LEROY W. CUMMINGS, Camp Grant, Ill.; Captain THEODORE B. PARKER, Camp Jackson, S. C.; Captain ROBERT C. HUNTER, Camp Pike, Ark.; Captain EDWIN P. KETCHUM, Blacksburg, Va.; Captain MARSHALL J. NOYES, Washington, D. C.; Captain GEORGE A. GEIB, Washington, D. C.; First Lieutenant JOHN C. ARROWSMITH, Cincinnati, O.; First Lieutenant CONRAD P. HARDY, Los Angeles, Cal.; First Lieutenant LEWIS A. MURRAY, Columbus, O.; First Lieutenant ROY P. BISHOP, Camp Pike, Ark.; First Lieutenant PHILIP B. BRUTON, Camp Pike, Ark.; First Lieutenant ROBERT F. GILL, Camp A. A. Humphreys, Va.; First Lieutenant ROY W. GROWER, Cincinnati, O.

Captain LEONARD LUNDGREN, Corps of Engineers, has been transferred from New York City to Camp A. A. Humphreys, Va., for duty as Instructor at the Engineer School.

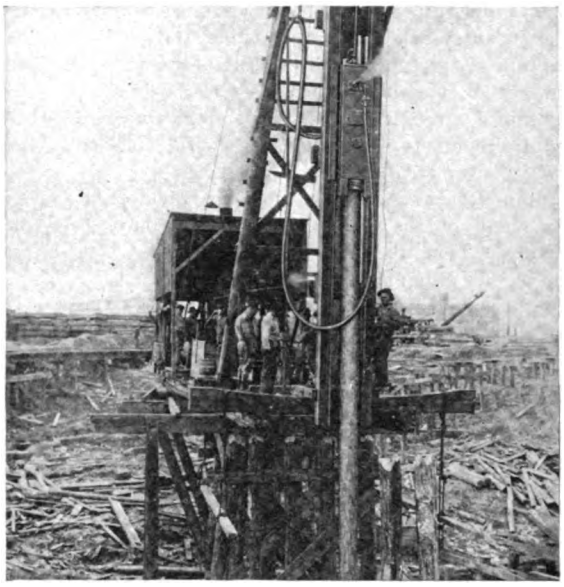
The following changes in the assignment, station and duties of the officers of the Corps of Engineers have been ordered:

Captain DAVID MCD. SHEARER, from the 1st Engineers to Engineer Training Company No. 1, Camp A. A. Humphreys, Virginia.

Captain HAROLD G. LYONS, from the 2d Engineers to the 17th Engineers, Camp A. A. Humphreys, Va.

Captain HENRY B. POST, from the 2d Engineers to the 17th Engineers, Camp A. A. Humphreys, Va.

First Lieutenant FABIUS H. KOHLOSS, from the 7th Engineers, to the 2d Engineers, Camp Travis, Texas.



First Lieutenant Arthur J. SHERIDAN, from the 9th Engineers to the 1st Engineers, Camp Dix, N. J.

First Lieutenant PETER P. GOERZ, from the 9th Engineers to the 17th Engineers, Camp A. A. Humphreys, Va.

First Lieutenant WILLIAM C. BENNETT, Jr., from the 9th

SAUERMAN Dragline Cableway EXCAVATORS

Digging from under water

Conveying gravel to plant

Dredging river channel

—dig, convey, elevate and dump in one continuous operation, entirely controlled by one man.

The development of Sauerman Dragline Cableway Excavators can be traced to the need for a machine which would dig over long spans and to depths beyond the reach of the dipper arm of a steam shovel or the boom of a boom dragline excavator.

How successfully our machines have answered this need is testified to by the hundreds now in use by sand and gravel producers, railroads, mining companies, contractors, etc.

The long reach of dragline cableways makes them particularly economical and efficient for digging materials from under water, and they are often used instead of pumps or dredges.

When undertaking any work involving excavating material and conveying a distance of 200 to 600 ft., it will pay you to investigate our equipment. Catalog on request.

"What and Why is a General Staff"

Discussion

Eben Swift
Brigadier General (Retired)

In the May-June number of your magazine there is an article entitled, "What and Why is a General Staff," by Donald H. Connolly, Major, General Staff. On page 225 the following statement appears: "In 1906 Major Morrison (now Major General) revolutionized the educational system of the army by putting into effect at the Leavenworth School a definite system to prepare officers for the tactical command of troops and General Staff duty."

Major Morrison assumed charge of the Department of Military Art at Fort Leavenworth on August 15, 1907. (See Report of Commandant for the year 1907-8.)

There is a belief among many of our officers that the most important development in the educational methods of our army was due to the adoption of the "Applicatory method of instruction." If this is true it may be in the interest of history to state some facts bearing upon that subject.

Between the year 1893 and the close of 1906, Captain (and Major) Eben Swift, U. S. Army, was on duty at the Fort Leavenworth schools for about six years. During that time he acted as Assistant Instructor and Senior Instructor in Military Art; as Assistant Commandant and Acting Commandant, he prepared the work here listed:

1. Lecture. Field Orders and Reports, April 2, 1894.
2. Map Problems, June, 1894. The march of a detached brigade of all arms from Fort Leavenworth against an enemy on Big Stranger Creek. There were six requirements included in the orders for the movement. Other problems followed, based on the French edition of Griepenkerl, April, 1896.
3. Lecture. Field Orders, Messages and Reports, November 22, 1895.
4. Translation. The War Game Simplified. Verdy du Vernois, 1897. Published by Hudson Kimberly and Company, Kansas City.
5. Essay. The Lyceum at Fort Agawan. Journal of the Military Service Institution of the United States, March, 1897.
6. Lecture. Introductory to the Course in Military Art at the Infantry and Cavalry School and Staff College, Fort Leavenworth, Kansas, September, 1904.
7. Course of Instruction for the Department of Military Art for the year 1904-5. (See Report of Commandant.)
8. Lecture. Orders, November, 1905.
9. Course of Instruction for the Department of Military Art for the year 1905-6. (See Report of Commandant.)
10. Translation. A Tactical Ride. Verdy du Vernois, 1906. Printed at the school.

The first lecture on orders was the basis of the following lectures on the same and kindred subjects, the last of which was officially adopted by order of the Secretary of War, for the guidance of the Regular Army and the Organized Militia, July 10, 1906.

The Map Problem in June, 1894, seems to have been our first problem of the kind, requiring the systematic issue of Orders.

The Essay in 1897 was an analysis and a plea for the introduction of the Applicatory System of Instruction into our army.

The translations in 1897 and 1906 were intended as text books for two out of the three district branches into which the Applicatory System was divided. The British translation of Griepenkerl became available in December, 1896. It covered the third branch and caused work on an American translation to be abandoned temporarily.

The lecture of September, 1904, was an announcement that the Applicatory System was adopted. The schedules showed the details of the course.

Colonel Arthur L. Wagner, the Assistant Commandant, wrote a long memorandum for the Commandant, on December 28, 1903. Referring to the school he said: "Its curriculum is not up to the standard that had been attained by the old institution which was discontinued at the outbreak of the Spanish War." (See Report of Commandant, 1904, page 87.) Whether we entirely agree with this criticism or not, it is plain that the school was still handicapped by a lack of text books in the several branches of Applied Tactics. The best books of the kind in the military world of that day were formally adopted in 1904-5-6. The principles therein contained were fixed by daily recitations, and the students were thus prepared for the original work which followed.

Major Boughton conducted the instruction of the Infantry and Cavalry Class from January 3 to August 15, 1906, and of both classes for the year 1906-7. Major Morrison had the course for five years following. During all this time and up to the present, a steady improvement has marked the progress of the Fort Leavenworth Schools.

Maintaining the Motor Transport of a Field Army

(Continued from page 469)

Discussion

By

Brainerd Taylor
Major, Quartermaster Corps

"Maintaining the Motor Transport of a Field Army" by Major M. D. Mills, Engineer R. C., presents in the main a very fair and conservative picture of one of the most trying and dangerous situations in the A. E. F. during the World War. I have always believed that had the war continued a few months longer great disaster must surely have overtaken an army so extended into enemy territory as was ours, with its principal means of field mobility in the condition described by Major Mills. The failures to observe the "seven essentials" which Major Mills gives in italics, in his sixth paragraph, could have had but one end, that which would have followed the paralysis of motor mobility of an army greatly extended from its forward bases and deployed in front of a powerful enemy.

Major Mills' idea that "Efficiency of operation is not possible of attainment until all motor vehicles, excepting only combat and special vehicles, are operated and maintained by a single arm of the service with all personnel, whether drivers or mechanics, drawn from, trained by, and looking to that arm for their promotion and technical control" is the crux of the whole situation. In any serious competition requiring a high order of mechanical mobility for its personnel and material, the employment of a corps of specialists is inevitable if superiority of mobility over rivals or opponents is to be gained and maintained. With the accomplishment of a homogeneous motor transport organization most of the other difficulties described by Major Mills would rapidly disappear. The change of opinions from dissatisfaction to satisfaction among those who depend upon motor transport for their mobility would be very great in a reasonably short time, because they would control not just so many vehicles and drivers, but an effective local motor transport service in the thoroughly organized units detached from, and with all the support of, a highly specialized service possessed of equipment, trained personnel and authority to meet all the mechanical requirements of motor vehicles in the field.

Intelligent handling of automotive spare parts, effective and adequate replacements, minimizing the necessity of shop repair and gaining a maximum of vehicle life, are all inseparably bound together within the technical functioning of a single transportation service. Who and what are transported and for whom or for what purposes personnel and material are transported, have very little to do with the question of gaining and maintaining superiority in motor mobility. These matters belong purely to the *business* functioning of a transportation service, and while of paramount importance to the military establishment, their successful transportation when and where needed depends absolutely on successfully meeting the mechanical requirements of vehicles.

The business of a motor transport service is to give passengers and shippers or personnel and material transported the most effective and economical mobility required by their special missions or uses. This primary purpose is ultimately defeated when any part of the technical functions, especially vehicle operation and control of driving personnel, is surrendered by the technical organization to the passengers or shippers that it serves.

The turning over of freight trains to shippers, or consumers, or the turning over of artillery without artillerymen to the infantry for operation, would be no less extravagant and ineffectual than our present system of turning over motor vehicles, with or without personnel, to any other service for operation than the specially organized motor transport service.

In justice to the Motor Transport Corps, which struggled bravely and patiently under the great disadvantages cited by Major Mills, to give the greatest possible service to the armies in the forward areas, I wish to correct an erroneous statement in Major Mills' article. The "Provisional First Army Supply and Repair Park," referred to by him, was not organized in the First Army and by it located first

Seattle Post Endorses American Cable Project

On May 28, 1921, the Seattle Post of the Society of American Military Engineers met and on the conclusion of the regular business, a resolution was offered and unanimously adopted as follows:

"Recognizing the commercial and strategic value and importance of an all-American cable between the United States of America and the Orient, *Be It Resolved That*: The Seattle Post of American Military Engineers in meeting assembled do indorse the efforts now being made by Senator Wesley L. Jones and the Washington delegation in Congress for the construction of an "All American Cable" via the shortest practical route between the United States of America and the Orient. That copies of this resolution be mailed to Senator Jones, Senator Poindexter and our Congressmen at Washington and to the Secretaries of all Posts of Society, including the parent office of the Society."

Proposed Amendments to Constitution and By-Laws

At the last annual meeting of the Society, a committee consisting of Lieut. Col. G. A. Youngberg, Lieut. Col. C. H. Birdseye, and Major W. O. Tufts was appointed to consider a resolution passed by the Chicago Post in October, 1920, reading as follows:

"Whereas, the Society of American Military Engineers is organized for preparedness, promotion of good citizenship and the furthering of friendships created during the World War, it is desired to open the doors of this Society to the young men who will be the future citizens of the country.

"Therefore, be it resolved, that the parent Society be requested to consider such a change in the Constitution as will add another class of members called Junior Members."

Subsequent to that meeting, the question has also come up concerning the establishment of student chapters, which question was referred to the same committee for consideration.

The committee accordingly suggests the following:

Amendments to Constitution

Amendment No. 1. After the word "Associate" insert the word "Junior," so that this section shall read:

"1. *Classification.* The membership of the Society shall be classified as Active, Associate, Junior and Honorary."

Amendment No. 2. Re-number sections 4 and 5, so that they shall bear the numbers 5 and 6 respectively.

Amendment No. 3. Insert a new section 4, as follows:

"4. *Junior Members.* Male persons not less than fifteen, nor more than twenty-one years of age shall be eligible to junior membership: *Provided* that no such person shall be deemed a junior member unless he shall also be a member of a junior post or section, as provided in the By-Laws of the Society."

Amendments to By-Laws

Amendment No. 1. Article IV. Number the existing section No. 1.

Amendment No. 2. Add a new section, viz.:

"2. *Student Sections.* Male persons duly enrolled as students in engineering or technical courses in educational institutions, being eligible to associate membership, may form student sections, subject to conditions described in Section 1 of this article: *Provided* that the annual dues of associate members, who are also members of such student sections, may, by a majority vote of the Board of Directors, be fixed at less than the annual dues for active members; *Provided further* that the number of copies of THE MILITARY ENGINEER and other publications sent to such units shall be fixed by the Board of Directors, according to the cost of publication and the amount of money paid in by such student sections."

Amendment No. 3. Add a new section, viz.:

"3. *Junior Sections.* A junior post or section to be composed of junior members only may be organized in affiliation with any (senior) local post or section, upon favorable vote by such (senior) post or section. The name of such an affiliated junior post or section shall be the same as that of the (senior) post or section with which it is affiliated, except that the word 'Junior' shall be inserted at the proper place in the title, to distinguish it from the (senior) local post or section proper. Subject to the general supervision of the (senior) local post or section, exercised through such persons or agencies as the latter may direct, each such affiliated junior post or section shall establish its own rules of government and procedure, which shall conform to any regulations which may be promulgated by the Board of Directors. The number of copies of THE MILITARY ENGINEER and other Society publications to be sent to such units shall be fixed by the Board of Directors according to the cost of publication and the amount of money paid in by such junior sections."

Comment

The reasons for the proposed amendments relating to the establishment of student chapters are obvious.

The objects to be obtained by the amendments relating to junior members merit some explanation. At first glance, this might appear to be a variation of the Boy Scout idea, and competition might be introduced; but there is a period between the ages of fifteen and twenty-one when a boy is too old for Boy Scout work, and too young to go to college, and during this period it is possible that some useful work might be done by junior organizations of the Society. It is the opinion of the Committee, however, that junior members of this class should not be admitted unless they can be united into junior posts or sections under the direct supervision of a senior post

or section. It is believed that local posts can do a great deal to further the interests of the Society and to recruit future members, by interesting themselves in the Boy Scout movement in their communities, aiding in the instruction of the Boy Scouts, and introducing engineer work that is interesting, and still within the mental grasp of young boys. When these boys become too old for Boy Scout work, they can readily be interested in the junior posts of the Society and eventually, upon reaching their majority, may become active or associate members, according to their technical qualifications.

Local posts should interest themselves in the student sections, and particularly in the Engineer units of the Reserve Officers' Training Corps established at the various educational institutions of the country. They are recognized elements of the Military Reserves of the country, and their support and growth are directly in line with primary objects of the Society.

As a matter of necessity, dues for student members and for junior members will be very low, and will not pay the cost of publishing THE MILITARY ENGINEER, so that one copy can not be sent to each such student or junior. It is planned, therefore, to send to each student section, or to each junior section, such number of copies as is covered by the funds received. That is to say, for each five dollars paid in the National Society by sections mentioned, a copy of THE MILITARY ENGINEER will be sent to the Secretary of the section. The amendments are worded as to give the Board of Directors a wide discretion in the matter, and if the funds of the Society warrant it, the number of copies may be increased any time.

Recommendation

The committee recommends that the amendments to the Constitution and By-Laws, together with necessary explanatory comment, be submitted to a vote of the membership of the Society, as provided by Article VI of the Constitution, and Article XII of the By-Laws.

GILBERT A. YOUNGBERG,
Lieut. Colonel, Corps of Engineers,
Chairman of the Committee.

C. H. BIRDSEYE,
Lieut. Colonel, Officers' Reserve Corps.
Major W. O. TUFTS.

Nominations of Officers for 1922

Report of Nominating Committee.

In transmitting a list of nominations for President, First and Second Vice-President and for six directors to serve for three years (of whom two represent the Regular Army, two the Reserve Corps and two the membership at large), the Nominating Committee has followed its understanding of the by-laws (Art. VIII, pars. 4 and 5) and restricted the nominations to a single list.

In order that the list might best fulfill the committee's policy both geographically and selectively, the following letter was addressed to the Secretary of each local post in the country so far as listed in the September-October number of THE MILITARY ENGINEER:

"October 1, 1921.

"At a meeting of the Nominating Committee of the Society of American Military Engineers held in Washington, September 30, for the purpose of making nominations as provided in the by-laws (Article 8, Paragraph 4, etc.), it was unanimously agreed to invite suggestions from local posts throughout the country. Nominations are to be made for President, First Vice-President, and Second Vice-President to serve for one year and for six directors to serve for three years, of whom two shall represent the Regular Army, two the Reserve Corps and National Guard, and two the membership at large.

"As a policy governing nominations, this Committee feels that the best interests of the Society warrants the election of a President and First Vice-President from among candidates living in or near the Washington headquarters, but that the Second Vice-President should represent middle or western country. In making nominations for the six vacancies in the Board of Directors, the committee feels that the representation in the West should be increased.

"In order that the Nominating Committee may have the benefit of local sentiment, I should be glad to receive from you by October 21, or preferably earlier, a list of those members of the Society who, in the opinion of the officers of your Post, are especially qualified for the duties of the positions as above outlined. The names submitted should be accompanied by local addresses together with status as to membership (Regular, Reserve, or at large). Your co-operation along these lines will be helpful to the Committee and will tend to make its report more representative of the thought of the Society at large.

"Your attention is also called to a clause in the by-laws (Article 8, paragraph 5) whereby a nominating letter signed by ten members and reaching the Secretary of the Society by December 1st will formally place such names in nomination."

This letter is being sent to the secretaries of all local posts. posts."

The replies received were largely based upon special meetings held by the local posts for the purpose of making such recommendations, and inasmuch as approximately 50 per cent of the Society membership is represented through its local sections your committee feels that it has obtained in the short time allotted, a large degree of representative opinion.

The Nominating Committee after full consideration of all names suggested, submits the following nominations for the offices as specified:

For President—Lt. Col. G. A. Youngberg, R. A., Washington, D. C.

First Vice-President—Lt. Col. J. P. Hogan, R. C., New York City.

Second Vice-President—Capt. Douglas W. Dodge, R. C., San Francisco.

For two directors (Regular)—Col. E. M. Markham, Detroit; Major C. T. Leeds, Ret., Los Angeles.

For two directors (Reserve)—Col. E. A. Gibbs, Pittsburgh; Lt. Col. H. P. Ralston, New Orleans.

For two directors (at large)—Col. E. J. Spencer, St. Louis; Major Joseph Jacobs, Seattle.

In submitting the above list the committee has the assurance that each name below and including the office of Second Vice-President, has the indorsement of the local post represented.

Very truly yours,

W. M. BEAMAN,
Secretary, Nominating Committee.

Nominating Committee:
Brig. Gen. Harry Taylor, R.A., President.
Col. John Stewart, R.C.
Maj. W. M. Beaman, R.C., Secretary.
Capt. E. P. Ellis, A.L.
Capt. Robert Coe, A.L.

(Continued from page 518)

at Toul, then at Thiaucourt and finally at Frana Ferme near Nixeville, as stated. In compliance with the provisions of an A. E. F. order requiring the Chief Motor Transport Officer of the Advance Section to "keep contact" with the armies in his front, and after consultation with the Chief Motor Transport Officer of the First Army, two advance service mobile repair parks and spare parts dumps were organized from personnel and material assigned to the advance section overhaul parks at Langres and at Neufchateau. These advance agencies of the Motor Transport Corps, S. O. S., were sent up into the army area to operate under the orders of the Chief Motor Transport Officer of the Army with instructions to keep close contact with the main body of which they were a part, namely the Motor Transport Corps of the Advance Section, through its nearest overhaul parks and spare parts depots, for support and supply in meeting the immediate and urgent needs of the army. The first park and dump were located at Toul for the First Army. They remained at Toul and were later taken over by the Second Army. The second park and dump, first located at Commercy, were moved at once by the Chief Motor Transport Officer, First Army, to Thiaucourt and thence to La Frana Ferme; it remained and moved with the First Army. These were distinctly efforts of the Motor Transport Corps of the S. O. S. to render greater and more effective service to the armies under very great difficulty and confusion, due to very faulty motor transport organization throughout the army. That army policies of taking over and controlling everything in army areas robbed the Motor Transport Corps, S. O. S., of the credit for this effort and practical assistance, should not be forgotten in view of Major Mills' opening paragraph in which he pictures the Motor Transport Corps as "staggering wearily on its way, being judged and generally found wanting."

G. R. Young
Major, Corps of Engineers

I have few comments to make on Major Mills' very excellent article. Major Mills was in direct touch with the problems he discusses throughout the fighting period of the First Army. His efficiency in "begging, borrowing or stealing" spare parts, all of which he practised with persistence and success, is unquestioned by any who knew him; also his ability in handling a difficult and thankless job.

Regarding "operation," Major Mills is evidently a strong advocate of centralized operation. I concur in this heartily. But I would like to know more of his ideas with respect to the operation of ambulances, and in general of "combat" trucks. There are several degrees of operation which can be practised by the M. T. C. If he means that ambulances in a division, for example, are to be handled directly by the M. T. C. as are supply train trucks, I think he goes too far, not only because it is perhaps bad organization theory, but because the medical department would strenuously object. Everyone wants to operate his own vehicles. If this natural jealously is disregarded too much, the M. T. C. will get a universal reputation for interfering beyond its province, which will make trouble for itself. And in the case of ambulances, I think there are sound organizational reasons for letting their movements in detail be controlled by the medical authorities.

For strictly centralized operation, the line should be drawn at what I have called "supply transportation"—the cargo trucks that handle large and varying amounts of miscellaneous supplies—the old supply and ammunition trains, supply columns, trains of artillery parks, etc. Beyond that —say for ambulances, motorized combat trains, or engineer trains—the M. T. C. should make a fight to have the personnel belong to the M. T. C. and be trained by the M. T. C., but should leave their handling to the corps they serve. The principal interest of the M. T. C. is efficient handling and care of the individual vehicles. Its personnel on such vehicles should be in much the same situation as a medical detachment with a small infantry outfit. The division surgeon trains them, pins on their collar ornaments, and oversees their manipulation of pills, but does not order their movements as he does those of a field hospital.

There is a real line between "supply" and "combat" transportation, analogous to that between the railway trains that enter a city terminal and the taxicabs that leave it. Centralized operation, the railroad system, must stop somewhere. The best place for it to stop is with the assimilation of the large, uniform truck groups that move supplies or men in bulk. If it goes further it will get into organizational difficulties; and equally important, will injure so many susceptibilities that it will have to retire from the field.

Perhaps this is Major Mills' idea also; he is not definite on the point, and I want simply to have it made clear.

Major Mills rightly emphasizes the importance of mobile repair units. In open warfare, say on this continent, they will be the mainstay of the repair system. Can't he abolish the spare-parts "trailer," though? Trailers, unless very small and light, are out of place in a mobile combat force. The example of the heavy "mobile" ordnance machine shops is proof enough. As to overhaul parks, or repair battalions, it seems to me an open question whether their mobility justifies attachment to a corps; but no doubt this point has been considered by the thoroughly experienced maintenance personnel of the M.T.C. Whether armies, corps, or S.O.S. operate the overhaul parks, I think it should be the doctrine that a vehicle sent to them is *lost* to the owner, who receives (we hope) a replacement, the original vehicle being repaired and placed in general stock; whereas in the advance mobile repair units, the *individual vehicle* is repaired and returned to its owner.

Major Mills speaks with feeling of the practice of stripping damaged vehicles. I suggest a remedy. The first case I saw of this was in Mexico, in 1916. My immediate commanding officer was using a Ford car. It was in bad condition, and finding an abandoned Ford ambulance by the road, he removed from it a number of parts. He was later called on officially to state what he had taken, and why. He replied in substance that he had taken everything he could carry, and regretted it was not more; the reason being that it was the sensible thing to do. This little affair was an omen of conditions in France; and I think that the officer in question was (as usual) right. It is the sensible thing to do, within limits. I suggest for criticism the idea that when authority is obtained to salvage a vehicle, it include authority to strip the vehicle. It will be done anyhow; if the salvaging organization is too pious to do it, others will before the wreck gets back to the rear. The salvaging organization will probably have others of the same class of vehicles, so that the parts obtained will be of real value to them. The reconstruction park, where the vehicle will eventually go, will of course have additional trouble and expense. But it is down by the base of supplies, where parts are more plentiful, whereas up front they will *always* be in demand. This, of course, should apply only to vehicles in such bad shape that they are sent out of the fighting zone altogether, back to the big immobile parks at the bases.

Digitized by Google

Major Mills is very mild in his remarks about the supply of parts and tools from America to the A. E. F. An M. T. C. board, principally of officers of the A. E. F., investigated this on their return from France, and their report is on file in Washington. The condition they found, as to disregard of the expressed needs of the A. E. F., delay and red tape in filling requisitions, etc., was probably chargeable more to the system than to any individual. It was a condition of disgraceful inefficiency.

Applications

This list contains the names of only those applicants from whom formal applications have been received between July 15 and October 20, 1921:

Adams, Lieut. James C., 618 Avenue B, San Antonio, Texas
Anderson, Lieut. Amil A., 70 John Sedgwick, Newcastle, Wyo.
Anderson, Lieut. Jos. W., 2730 Portland Ave., S. Minneapolis, Minn.
Atterbury, Gen. W. W., Broad Street Station, Philadelphia, Pa.
Atwater, Capt. Wm. C., Johns Hopkins University, Baltimore, Md.
Augustus, James M., 151 S. Light St., Springfield, Ohio.
Aurandt, George M., 1005 Twenty-seventh Aye., Altoona, Pa.
Balch, Lieut. Elwyn C., 195 Broadway, N. Y. City.
Barber, Major E. L., 1228 Sixteenth Ave., San Francisco, Cal.
Barton, Lieut. F. Eugene, 412 Bellevue Ave., Oakland, Cal.
Bates, Capt. Guy, 9 Fernwood Rd., Summit, N. J.
Baur, Lieut. George, 2732 Bedford Ave., Brooklyn, N. Y.
Bellin, Capt. A. B., 4420 Washburn Ave. S., Minneapolis, Minn.
Berry, Sgt. Carl C., Post Hqrs., Marine Barracks, Paris Island, S. C.
Best, Lieut. Richard D., 4700 Berkley Ave., Louisville, Ky.
Bickford, Capt. John W., Gilboa, N. Y.
Blanchard, S. E., Care Camp Utilities, Camp Knox, Ky.
Bouton, Charles W., Prattsville, N. Y.
Boyce, Lieut. Marvin R., 322 McCormick Bldg., Chciago, Ill.
Bowles, Maj. Hardy, 71 25th St., Elmhurst, L. I., N. Y.
Brayton, Capt. Wm. M., 111 N. Kenilworth Ave., Oak Park, Ill.
Brennan, Lieut. John T., 39 Eighth Ave., Brooklyn, N. Y.
Brooks, Capt. Frank W., Jr., 100 Jefferson Ave., E., Detroit, Mich.
Brown, Capt. Alfred T., 2 Mable Hill Ave., N. Y. City.
Burden, Maj. W. W., 1236 Goodfellow Ave., St. Louis, Mo.
Busch, Capt. G. Walton, 823 Fox St., N. Y. City.
Butler, Capt. Jesse V., Huntsville, Texas.
Byonton, Lieut. Henry B., Blacksburg, Va.
Callahan, Lieut. J. L., 814 N. Meridian St., Indianapolis, Ind.
Camet, Lieut. J. J., 311 Lincon St., Carstadt, N. J.
Carson, Maj. Matthew B., 56 N. Bartram St., Atantic City, N. J.
Chase, Hugh Donald, Unity, Me.
Chittenden, Capt. A. F., 4106 Burke Ave., Seattle, Wash.
Clark, Lieut. J. W., Troy, N. Y.
Clarkson, Maj. John L., 757 Drexel Building, Philadelphia, Pa.
Cleary, Lieut. C. Norman, 2815 Grand Concourse, Bronx, N. Y. City.
Cole, Capt. Donald, 624 McKerchey Building, Detroit, Mich.
Cole, Wesley, Signal Office, Ft. Howard, Md.
Coleman, Maj. John B., 152 Taber Ave., Providence, R. I.
Collier, Sgt. Frederick W., 2353 N. Talbot St., Indianapolis, Ind.
Corbin, Lieut. Malcolm D., 92 Nevada Ave., E., Detroit, Mich.
Cresson, Capt. H. C., 3102 Shattuck Ave., Berkeley, Calif.
Cruse, Capt. R. E., Troy, N. Y.
Davis, Jesse G., Jaser, Ala.
Dayton, Capt. R. B., 40 Maple Ave., Morgantown, W. Va.
Diver, Mortimer L., Box 69, San Antonio, Texas.
Dixon, Chas. Y., 337 Federal Building, Dtroit, Mich.
Donnelly, Lt. Joseph B., 6155 Jefferson St., Phila., Pa.
Dowling, Angus M., Denmark, S. C.
Doyle, Harry K., Rosedale, Miss.
Drips, Lieut. A. N., 813 S. Anderson St., Tacoma, Wash.
Drury, John D., 45 Lamoille Ave., Bradford, Mass.
Duff, Capt. Levi B., 1104 Empire Building, Pittsburgh, Pa.
Duncan, Geo. W., Jr., 58 Sutter St., San Francisco, Calif.
Dunn, Charles P., care Skagit River Power, 110 Cherry St., Seattle, Wash.
Eistetter, Lieut. Leo A., Apdo. 40, Tampico, Tamps, Mexico.
Feldes, Lieut. Col. R. A., Gibson, Ind.
Fisk, Maj. J. H. P., Walsenburg, Colo.
Focardi, Capt. Pier L., Army Supply Base, Boston, Mass.
Foster, Lieut. E. J., P. O. Box 315, Laredo, Texas.
Fox, Capt. Philip, Cohasset, Mass.
Freeman, Capt. John G., Brawley, Ca.
Frenzell, Lieut. E. H., 305 W. Olive Ave., Redlands, Cal.
Froebel, Lieut. G. S., 918 Union Nat. Bank Building, Houston, Texas.
Gamble, Winfield S., 1312 Terry Ave., Seattle, Wash.
Gardiner, Harry M., 2223 Euclid Ave., W., Detroit, Mich.
Gartner, Roy G., Madison, W. Va.
Geist, Lieut. A. Joseph, 276 Fifth Ave., New York City.
Gillingham, Lt. Geo. O., Lakehurst Proving Ground, Lakehurst, N. J.
Goedike, Capt. John G., 317 La Fitte St., San Antonio, Texas.
Gordon, Capt. Douglas, 88 Myrtle St., Lynn, Mass.
Gotwals, Maj. John C., Juneau, Alaska.
Graves, Walter J., 1600 R. E. Exch. Building, Detroit, Mich.
Gregory, Maj. H. W., 1310 E. Jefferson, Boise, Idaho.
Griggiths, Geo. E., Grand Gorge, N. Y.
Guiteras, Maj. H. G., Iowa State College, Ames, Ia.
Hall, G. D., Sunnyside, Wash.
Harding, Capt. George M., Wynnewood, Pa.
Haring, Capt. Ellis E., 1st Engineers, Camp Dix, N. J.
Harrison, Lieut. John J., 3422 Minnesota Ave., Duluth, Minn.
Hawley, John C., 841 David Whitney Building, Detroit.
Hazlehrigg, Maj. Thomas H., 1227 W. 29th St., Indianapolis, Ind.
Henny, D. C., 1006 Spalding Building, Portland, Oreg.
Herkness, L. C., 208 S. 3d St., Philadelphia, Pa.
Hines, Capt. P. R., 703 Lewis Building, Portland, Oreg.
Hoaas, Lieut. Ole G., 5th Engineers, Camp Meade, Md.
Hoffman, Lieut. J. E., 672 Mansfield Pl., BBrooklyn, N. Y.
Jansky, Frank W., 4009 Castleman Ave., St. Louis, Mo.
Jones, Capt. F. D., Fort Mason, Calif.
Jones, Sidney G., 4732 Garfield Ave. S., Minneapolis, Minn.
Kelly, Capt. Frank J., 1112 E. Capitol St., Washington, D. C.
Kennerly, Lewis, 607 King St., Selma, Ala.
Kern, Lieut. Francis X., 4344 Boone St., Manayunk, Philadelphia, Pa.
Kerns, Maj. Samuel M., 1076 Cerritos Ave., Long Branch, Calif.
Labarre, R. V., 610 Genesee Bank Bldg., Flint, Mich.
Lane, Capt. Harry, 60 E. Broad St., Clumbus, Ohio.
Laughinghouse, Lt. N. R., March Field, Riverside, Cal.
Lees, Capt. Franklin B., Pier 3, Hoboken, N. J.
Light, John J., 222 W. Beavr Ave., State College, Pa.
Liscom, A. Clark, Phillips Manor, Eliot Station, Detroit, Mich.
Lloyd, Lieut. Col. Arthur H., Esmont, Va.
Lockwood, Clement L., 178 Nehoiden Rd., Waban 68, Mass.
Loder, A. E., 917 Bell Building, Montgomery, Ala,
Lynch, Lieut. Louis C., Gainesville, Fla.
Lyon, M. J., 1900 Vallejo St., San Francisco, Calif.
Malloy, John F., 307 Prospect St., Morgantown, W. Va.
Marburg, Lieut. Edgar, 1st Engineers, A. F. in G.
Markham, Capt. John H., Sutico, Wash.
Mason, Frederick H., 614 Moffat Building, Detroit.
Meyer, Lieut. Harry, Camp A. A. Humphreys, Va.
Miller, Hubert S., 611 E St., Centralia, Wash.
Miller, John D., 97 Red River St., Austin, Texas.
Monro, Lt. Wm. L., Jr., 5840 Wilkins Ave., Pittsburgh, Pa.
Mooney, Lieut. George T., 4411 Kemper Ave., St. Bernard, Ohio.
Motz, Thos. B., 1211 Syndicate Trust Building, St. Louis.
Murphy, T. F., U. S. Geological Survey, Wash. D. C.
Nelson, Maj. Wm. H., 4210 Bagley Ave., Seattle, Wash.
Nettleton, Lt. Elwood T., 29 Huntington St., New Haven, Conn.
Noble, Lt. Geo. H., 30 Gould Ave., Patterson, N. J.
Noerenberg, Maj. Clarence E., 401 L. A. Ry. Bldg., Los Angeles, Calif.
Nold, Capt. George J., Fort Thomas, Ky.
Oehmann, Maj. John W., Room 110, District Bldg., Washington, D. C.
Orbeck, Martin J., 507 Walnut St., Ann Arbor, Mich.
Ostlind, Lieut. B. B., 415 Sixth St. S., Marshfield, Ore.
Owen, Capt. Elijah H., 404 McKerchey Building, Detroit.
Page, Capt. Donald William, The Ambassador, Washington, D. C.

Map Problem, No. 3—A Solution

The following is a solution of Map Problem No. 3, which was published in the September-October issue of the MILITARY ENGINEER, page 462.

First Requirement—

Major M assembles Capt. B, commanding Co. "B;" Lt. D, commanding the 3rd platoon of Co. "B," and Lt. A, the battalion adjutant, in his tent and issues the following verbal order at 5:10 p. m., indicating on the map the places mentioned:

"Our detachments along the border report that the enemy has had small mounted patrols west of Harney and Stull's today and that the crossing at Bridgeport is held in comparative strength.

"The regimental commander telephones that he has no further information of the enemy and that the orders for the regiment remain unchanged. This battalion remains in its present camp tonight.

"Lt. D—Your platoon and one motorcycle will compose the outpost, under your command. Place outguards covering the roads from Kingsdale, Harney, Bridgeport and Crabster and send occasional patrols along the southeast edge of town. In case of attack, hold a line on the outskirts of the town. Have your outguards in position by 6:00 p. m. and submit sketch of the outpost to me by 6:30.

"Capt. B—Give Lt. D's men supper before they go on duty and send out hot breakfast tomorrow morning. No fires will be allowed at the outguards.

"Lt. A—Have the motorcycle now outside report to Lt. D at once. Arrange for two of your supernumerary drivers to report to Lt. D at 6:00 p. m. and relieve the present driver during the night.

"My headquarters will remain in its present location."

Second Requirement—

Outguard No. 1 (one squad) at cross roads 400 yards northeast from S. H.

Outguard No. 2 (two squads and one sergeant) at roadfork 491, one-half mile northwest from S. H. Places auto rifle covering each road and maintains double sentry at night; single sentry in day. During day sends cossack post forward to hill 507.

Outguard No. 3 (one-half squad, with auto rifle) at road cut 500 yards southwest of S. H.

Support (remainder of outpost) at main cross street. Posts single sentry. Furnishes three visiting patrols of three men each. Route: Support to Outguard No. 1; south and west around town to Outguard No. 3; east and north around the town to Outguard No. 2; back to support.

Third Requirement—

Outguard No. 1 (Sentry Squad)	Double sentinel	6	
	Corporal	1	
	Supernumerary	1	
	Total	8	—1st squad 1st Sec.
Outguard No. 2 (Picket)	Double sentinel	6	
	Corporal	1	
	Supernumerary	1	
	Total	8	—2d squad 1st Sec.
	Extra squad, in support	..	—3d squad 1st Sec.
	N. C. O. in charge	.....	—Sec. leader 1st Sec.
Outguard No. 3 (Cossack Post)	Single sentinel	3	
	Corporal	1	
	Total	4	—½ 1st squad 2d Sec.
Support	Outpost commander	....	—Platoon leader
	Patrols, leaders	3	—Platoon sergeant Sec. guide 1st Sec. Sec. guide 2d Sec.
	Privates, 3 at 2 each	6	—2 platoon runners ½ 1st squad 2d Sec.
	Support, main body, two squads	.....	—2d and 3d squads, 2d Sec.
	N. C. O. in charge	.....	—Sec. leader 2d Sec.
	Outpost commander's orderlies	2	—Platoon runners
	Motorcycle drivers.		

Note.—Support posts running guard (one man, one hour tour) from the 2d and 3d squads 2d Section.

Map Problem, No. 4—An Advance Guard

MAPS—

Gettysburg General Map.
Gettysburg 3-inch Map, Taneytown and Emmitsburg sheets.

General Situation—

This problem is a continuation of Map Problems Nos. 1 to 3, published in previous issues of the MILITARY ENGINEER.

Special Situation—

Same as for Map Problems Nos. 1, 2 and 3, with the following additions:

The outpost, composed of the 3rd Platoon of Co. "B," was established at 6:00 p. m., June 4th, on the outskirts of Taneytown, one outguard being at roadfork 491, on the Taneytown-Bridgeport road. By 6:45 p. m. the observation

Digitized by Google

groups had returned to Taneytown, bringing the following additional information concerning the enemy:

A mounted force of 75 to 100 men entered Bridgeport from the direction of Emmitsburg about 5:00 p. m., but made no effort to cross the Monocacy. About 5:15 p. m., as a Blue Infantry patrol was leaving Harney to join the platoon at Piney Creek church, a mounted force of 30 or 40 men entered Harney from the west and apparently remained there.

At 7:30 p. m. Lt. S, from regimental headquarters at Littlestown, arrived at Taneytown in a motor car and gave Major M a secret dispatch.

At 8:00 p. m. Major M assembles his company commanders, the battalion adjutant and Lt. S in his tent and issues the following verbal order:

(Note.—It is assumed that all information concerning the enemy stated to this point has been communicated to the officers of the battalion and to Lt. S.)

"A Blue patrol from Littlestown found Two Taverns held today by a hostile force estimated between a platoon and a company. Our secret service reports that the Red mobilization at Waynesboro is proceeding somewhat faster than we expected and that a movement toward Emmitsburg in the next few days is not unlikely.

"The following general plan of campaign is confidential to the officers assembled here. Our War Department plans an immediate advance on Emmitsburg, the 1st Infantry seizing and holding the crossings of the Monocacy until the arrival of reinforcements from Westminster.

"Our regiment advances on Harney tomorrow afternoon.

"This battalion will march to Bridgeport tomorrow and seize the crossing of the Monocacy.

"The advance guard will be composed of Co. 'C' and the mounted detachment, under command of Capt. C, and will clear the street crossing at the west corner of this square at 6:30 a. m., marching by the direct road on Bridgeport.

"The main body, in order of march, Co. 'A', Co. 'D,' Co. 'B,' (less 2d Platoon), will follow the main body at 500 yards.

"Outguards will be withdrawn at 6:20 a. m. and the outpost platoon will take its proper place in column at the first hourly halt.

"The train, escorted by the 2d Platoon of Co. 'B,' will march in the order, battalion combat train, water carts and rolling kitchens, ration-and-baggage wagons, and will follow the main body at 300 yards. Wagons will report to Lt. T of the escorting platoon at the street crossing south of the school house between 6:15 and 6:25 a. m.

"I shall be at the head of the main body."

To Lt. S:

"On your return to Littlestown, please inform the regimental commander of the gist of this order."

To the Bn. Adjt.:

"Give the necessary instructions for the combat train and inform Lt. L, Lt. T and the outpost commander of so much of this order as concerns them."

To Captain C:

"I suggest that you consult with the officers who were out near the frontier today and obtain any information of value which they may have concerning the terrain."

Required—

1. Captain C's estimate of the situation.
2. His orders.

Note.—Reveille on June 5th has been prescribed for 5 a. m.

References:

Same as for Map Problems Nos. 1 to 3.

Military Engineering, Note 4

Problem 3—Organization of the Ground

MAPS:

Mount Vernon Quadrangle U. S. G. S.
Camp Humphreys 1:5000, North Section.

Texts: E. F. N. No. 13. A.E.F.

General Situation—

The James River is the boundary between hostile states, Blue (North) and Red (South). The Red Army having mobilized more rapidly than the Blue, has invaded Blue territory and has defeated the Blue forces in three engagements, the last one being near DUMFRIES on QUANTICO CREEK. The Blue Army is retreating in good order along the roads running northeast towards ALEXANDRIA. The victorious Reds are pushing vigorously forward with the purpose of capturing WASHINGTON, the Blue Capital. Blue reinforcements have arrived from the North and Blue High Command has decided to organize a defensive line east of ACCOTINK CREEK until their forces are sufficiently reorganized and reinforced to permit taking up the offensive. A rear-guard delaying action on OCCOQUAN CREEK holds the enemy on this line for four days, permitting a partial organization of the position chosen by the Blues for defense.

Special Situation—

The 1st Blue Division (1st, 2d, 3d and 4th Regts. of Infantry) is assigned to the sector on the left of the line. The 1st Infantry occupies the sub-sector from the road running east through Accotink to a line from 3125 to 4535, with the 1st and 2d Battalions in front line and the 3d Battalion in Regimental Reserve.

Orders from Headquarters, 1st Division, for the organization of the position have prescribed the following:

(a) The general location of the outpost line along the east bank of ACCOTINK CREEK; of the firing line, along the forward slopes of the hills just northeast of the Standard Gauge railroad; and of the regimental reserve line, from a point 3742 along the forward slope of the hill at MASON FARM, thence in front of the woods to point 5717.

(b) Sub-Sector Boundaries; that between the 1st Infantry and 2d Infantry being given in the first paragraph of this "Special Situation."

(c) Limits of battalion centers of resistance; the dividing line between the 1st and 2d Battalions of the 1st Infantry being along the line 4016; 6330.

(d) That each battalion shall hold the outpost line by squads detached from the platoons in the front line.

(e) That battalion commanders, after consultation with each other, shall arrange for flanking fire by machine guns across the intervals between the centers and along the front lines.

You are an engineer officer assigned to the 1st Engineers. Your Colonel (the Division Engineer) sends for you. After explaining the situation outlined above, he adds: "I want you to report to Major X, Commanding Officer of the 1st Battalion, 1st Infantry, to assist him in planning the organization of his battalion center. You will find Major X at the railroad trestle at 4422. Report to him there."

Required—

Your recommendation to Major X concerning the following:

(1) Final location of firing, support and battalion reserve lines.

(2) Location selected for machine guns and principal obstacles.

(3) Location and strength of combat groups.

(4) Location of company and battalion posts of command.

(5) Location of approach trenches.

Digitized by Google

Instructions—

(1) Assume that two machine guns of the regimental reserve are emplaced on the hill at 5127 to fire down the ravine.

(2) The Infantry Battalion has a headquarters company, three rifle companies and one machine gun company. Each rifle company has a headquarters section, and three platoons of two sections each. Each section has three squads, each squad having one automatic rifle, making 18 automatic rifles per company.

The machine gun company has two platoons of two sections each. Each section has two machine gun squads, making 8 machine guns with the company.

(3) Show information in red on the 1:5000 map of Camp Humphreys using conventional signs given in Figs. 3, 4, 5 and 6, Engineer Field Notes, A.E.F. No. 13.

An Approved Solution of Problem No. 2—Demolitions

(See MILITARY ENGINEER, September-October 1921, p. 457.)

(1)

Four explosives are available, viz.: TNT, ammonal, 40 per cent dynamite and black powder. The last named of these explosives, black powder, is especially adapted to use in land mines because of the effect of its slow action and because in such work it is possible to give it the proper amount of tamping. Its use will save the other explosives which can be used on a greater variety of work to which black powder is not adapted because of the difficulty of giving it proper tamping. The greatest objection to the use of black powder in this case is its susceptibility to moisture. This objectionable feature can be met by water proofing the mine chamber.

The quantity of black powder required depends upon the size of crater which will effectively block traffic along the road. The road at this point lies along the side of the valley and is in side hill cut and fill. A crater with diameter equal to the width of road, 25 feet, will effectively block the road for some time because the slope of the country on both sides makes the construction of a detour quite difficult. To blow a one lined crater of 25 foot diameter will require placing the charge at a depth of 25 feet. A crater this deep is hardly necessary in order to block the road effectively. By using a two lined crater there will result an obstacle 25 feet wide and 13 feet deep, which will delay the enemy as long as would a crater of 25 foot depth, if we assume that he would be forced to bridge the breach in the road in both cases. A two lined crater or common mine is therefore adopted. The L. L. R. is 13 feet. The amount of explosive is determined by using Table II, page 421 EFM. The earth is assumed to be the equivalent of hard sand. Multiplying the cube of the L. L. R. by the factor .042 given in Table II for hard sand and a 2 linel mine we obtain 92 pounds as the quantity of 50 per cent dynamite required. If we assume black powder to be about one-third as powerful as 50 per cent dynamite we should therefor use at least 276 pounds of powder. Increasing this 10 per cent gives 300 pounds, which will be the charge used.

(2)

A shaft 3′×3′ will be put down at the east side of the road to a depth of 13 feet below the surface of the road. From the bottom of this shaft a branch gallery (3½ feet by 2½ feet) will be driven to a point beneath the middle of the road. At the end of the gallery a mine chamber 2′×2′×2′ will be constructed to take the charge. The center of this chamber will be directly under the center of the road. It will be lined with boards and tar paper in order to keep out the moisture. The charge will be tamped by closing the chamber and gallery with sand bags filled with earth and wedged into place and by throwing earth back into the shaft.

(3)

Time fuse will be used in firing the charge. Duplicate sets of fuse will be used to insure against failure, both being lighted at the same time. Each set will consist of the proper length of fuse to lead from the mine chamber to the top of the shaft. At the end in the mine chamber the fuse will be split and surrounded with finely granulated powder. The fuses in passing through the gallery and up the shaft will be encased in iron water pipe to protect them from moisture and abrasion.

(4)

The depth to which the shaft at the side of the road must be sunk in order to reach a point 13 feet lower than the surface of the road is about 8 feet. The length of the gallery from the bottom of the shaft to the entrance to the mine chamber will be about 18 feet. From the table on page 405 EFM. it is seen that one N. C. O. and 4 miners can put down 8 feet of shaft in about 6 hours. From the same table we see that one N. C. O. and 5 men can drive 18 feet of branch gallery in 9 hours. It will take an additional 2 hours to excavate and prepare the mine chamber, thus making a total of 17 hours of work before placing the charge. Placing the charge, tamping and filling in will require 4 more hours. It, therefore, will take 1 N. C. O. and 5 men working 21 hours to complete the mine ready for firing. It would be preferable to do all the work by daylight unless the work is urgent. The trees on the east side of the road will conceal the men working at the top of the shaft from aerial observation. In case the requisite number of men is available it would be well to detail 2 N. C. O.'s and 10 men to the work and use them in two shifts.

Solution to Exercise in Use of Map Co-ordinates

(1) Co-ordinates of farm house at Mason's to the nearest 100 yards may be written as single number without decimals or dashes as follows: 4339

(2) If, however, it is desired to write the co-ordinates to the nearest 10 yards, decimals and dashes must be used as follows: 4.34-3.95.

(3) Pohick Church is 150 yards west of grid lin 601,000 and 200 yards south of grid line 1,792,000. Since the co-ordinates of the origin have the value $x = 1{,}000{,}000$ and $y = 2{,}000{,}000$, Pohick Church is 398,850 yards west of the origin and 208,200 south of the origin.

(4) The co-ordinates of the Kernan house in yards are $x = 602{,}830$; $y = 1{,}793{,}480$. Expressed in meters this becomes $x = 551{,}230$; $y = 1{,}639{,}960$. Hence the co-ordinates to the nearest ten meters may be written 1.23—9.96.

(5) If the present sheet were on a scale of 1:20,000 there would then be chance of a 10,000 meter error if only one figure were shown before the decimal in each co-ordinate. The co-ordinates of the Kernan house on such a sheet would then be written to the nearest 100 meters as follows: 51.2 — 40.0.

(6) At 2418 is a dwelling house and well on the military crest of a ridge. 3.24 — 1.72 is a point just below the wood line on a ridge running about east and west.

(7) (a) The co-ordinates of Pohick Church to the nearest 100 yards are written as follows: 1118

(b) Of the intersection of the Telegraph Road and Standard Gauge R. R.: 2337.

(c) Of the cemetery in Accotink: 4519.

General Subjects, Note 4

Questions on Interior Guard Duty

(Reference: Manual of Interior Guard Duty, 1914.)

No.	Wt.	
1	5	When does the tour of the officer of the day cease?
2	10	How does a sentinel give the alarm in case of fire? In case of disorder?
3	5	Normally from what person or persons does the officer of the day receive orders?
4	12	What does a sentinel armed with a rifle do (in the simple general case) when an officer crosses his post?
5	8	What words does a sentinel use to challenge a mounted party?
6	10	Who releases garrison prisoners whose sentences have expired and when does he do it?
7	10	Who is ordinarily authorized to order the confinement of a soldier?
8	10	What does the sentinel at the post of the guard do after challenging and receiving a response?
9	10	Between what times does a guard turn out for compliment?
10	10	What should a sentinel do in case a prisoner attempts to escape?
11	12	Enumerate three forms of punishment given general prisoners for bad conduct.

Questions on Military Law

(A Final Test on "Manual for Courts-Martial, 1921")

No.	Wt.	Question
1	2	Who are competent to serve as members of courts-martial?
2	2	Who may be tried by special courts-martial?
3	3	What is the gist of the affidavit of a person preferring charges?
4	2	If a soldier comes to you and confesses a crime, is his confession sufficient for preferring charges?
5	5	State briefly what is required in an investigation of charges by an officer detailed for the purpose?
6	5	What proportion of votes of the members present is required for each of the following (answer by tabulation, as (a) 3/5): (a) Conviction of absence without leave. (b) Sentence to death. (c) Conviction of crime which may involve not more than 20 years' confinement. (d) Sentence to 10 years' confinement. (e) Sentence to life imprisonment.
7	3	When is a reporter authorized: (a) For a general court-martial? (c) For a special court-martial? (c) For a summary court-martial?
8	2	If a member who has been absent during the taking of evidence is allowed without objection to sit on the remainder of a trial, what precautions should be taken?
9	2	What is the effect of a tie vote on: (a) A challenge? (b) An objection? (c) A motion? (d) A finding?
10	5	A soldier kills a man in the District of Columbia. He is tried by a general court-martial and convicted of manslaughter. May a court of the District of Columbia try him for murder? Give brief reasons.
11	4	A battalion commander directs that a man who has been A.W.O.L. be restored to duty. May he be later tried for desertion? Give brief reasons.
12	2	Write the oath that is administered to a witness.
13	2	What is a plea to the general issue?
14	5	When is a deposition permitted?
15	4	What is a plea to the jurisdiction? Name two grounds for such a plea.
16	4	What is a plea in bar of trial? Name two effective pleas in bar of trial.
17	2	Who ordinarily signs the record of a general court-martial?
18	3	What is the rule as to the introduction by the prosecution of evidence to prove the bad character of the accused?
19	5	What is meant by "res gestae"? Illustrate by an example.
20	5	Distinguish between a "confession" and an "admission against interest." In considering admissibility of evidence, why is this distinction important?
21	3	Define (a) Leading Question; (b) Double Question. Under what circumstances can double questions be used in the examination of a witness?
22	3	In a case not capital, the Trial Judge Advocate requests permission to introduce as evidence a deposition properly taken at the instance of the prosecution. He states, however, that he wishes to offer only the first part of the deposition, omitting the last half. What action should the court take on this request?
23	4	Pvt. A is "found drunk on duty" (A.W. 85). While drunk on duty he assaults Pvt. B. The company commander, not knowing of the assault, sentences Pvt. A for drunkenness on duty, to company punishment, which Pvt. A performs. Later, charges are preferred against Pvt. A for the above-named offenses, viz.: (1) Violation of the A.W. 85, in being found drunk on duty; (II) violation of A.W. 93, in assaulting Pvt. B with intent to do bodily harm. State whether Pvt. A can be legally tried by a court-martial (a) on Charge I; (b) on Charge II. Give reasons, in brief.
24	3	What is meant by the "Reviewing Authority"? What action, in general, may he take on a sentence adjudged by a court-martial under his jurisdiction?
25	3	What are the elements of fraudulent enlistment?
26	3	(a) Define desertion. (b) Under what circumstances is it unnecessary for the Trial Judge Advocate to prove the specific intent?
27	4	An officer is ordered by his commanding officer to make an inventory of certain company property and submit a report thereon at 11 a. m. on the following day. At 11 a. m. on the day specified in the order the junior officer is found drunk at his quarters and the inventory has not been made. Is the delinquent officer guilty of— (a) Disobedience of lawful command of his superior officer (A.D. 64)? (b) Neglect of duty (A.W. 96)? (c) Drunkenness on duty (A.W. 85)? (d) Failure to obey lawful order of superior officer (A.W. 96)?
28	3	Name three of the ordinary acts which constitute disrespect toward a superior officer within the meaning of A.W. 63.
29	3	(a) What is the nature of the conduct contemplated in A.W. 95 (conduct unbecoming an officer and a gentleman)? (b) Give two examples.
30	4	Civil authorities make due application upon a commanding officer to have delivered to them a certain soldier of the command charged with crime. Under what circumstances (in time of peace) may said commanding officer refuse to deliver the soldier?

An Approved Solution—Test on Military Law

(See Page 20, Military Instruction, Vol. XIII, No. 71)

By Maj. Cleveland C. Cee, C. E.

(References are to "A Manual for Courts-Martial, 1921")

Question No. 1. Ref. Par. 405—

The Court should not sustain the plea. By the 54th A.W. a man fraudulently enlisted is subject to trial by court-martial for such fraudulent enlistment. This shows that he is subject to the jurisdiction of a court-martial. In general, it is contrary to public policy to allow a person to plead one crime or offense in justification of another.

Question No. 2. Ref. Par. A.W. 28—

(a) Desertion is absence without leave accompanied by the intention, either (1) not to return, (2) to avoid hazardous duty, or (3) to shirk important service.

(b) Short desertion covers cases (2) and (3) in the definition of desertion given under (a).

Question No. 3. Ref. Par. 412—

Part I. (a) No. (b) No.

Part II. (a) No. (b) Yes.

Question No. 4. Ref. Par. 417—

(a) Mutiny imports a resistance to lawful *military* authority while sedition implies a revolt against lawful *civil* power.

(b) Two.

Question No. 5. Ref. Par. 420—

(1) The gravity of the offense. (2) The character and reputation of the accused.

Question No. 6. Ref. Par. 420½—

(a) Any person subject to military law. (b) Signature under oath signifies either that he has personal knowledge of, or has investigated, the matters set forth, and that the same are true in fact, to the best of his knowledge and belief.

Question No. 7. Ref. A.W. 105—

(a) Yes.

(b) See A.W. 105.

Question No. 8. Ref. Par. 443—

In embezzlement the original taking of the property was lawful or with the consent of the owner, while in larceny the felonious intent to steal or purloin the property must have existed at the time of the taking.

Question No. 9. Ref. Par. 451—

(a) 1. For determining whether there should be trial by court-martial in a particular instance.

2. For informing and advising superior authority in cases which appear not to call for trial by court-martial, but for some other military or administrative action.

3. For the vindication of character or conduct.

4. For inquiring into the correctness of the action of classification boards in classifying officers in Class B as not to be retained in the service.

(b) Officers and soldiers only.

Question No. 10. Ref. A.W. 96—

(a) Disorders and neglects to the prejudice of good order and military discipline, conduct of a nature to bring discredit upon the military service, and crimes or offenses not capital, when not covered by a specific article.

(b) Such punishment as a Court-Martial may direct, subject to limits of punishment prescribed by Executive Order.

Question No. 11. Ref. A.W. 95—

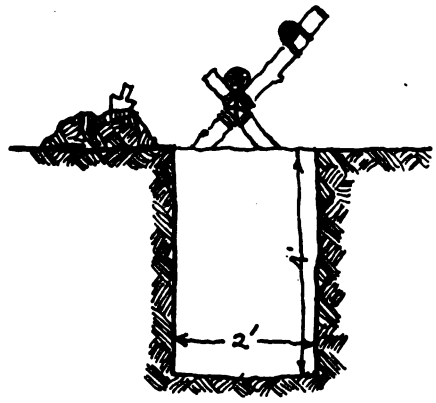
Dismissal from the service.

An Approved Solution—Test on Military Hygiene

(See page 20, Military Instruction, Vol. XIII, No. 71)

By Maj. Alfred L. Ganahl, C. E.

(References are to "Elements of Military Hygiene," by Ashburn)



1. (a) By boiling and by chemical treatment. The latter, in the field, would ordinarily consist in adding one part of "chloride of lime" to about 500,000 parts of water, allowing the water to stand at least one-half hour before use. (Pages 80 and 81.)

(b) (1) Drinking water for the men, (2) water for cooking purposes, (3) drinking water for the animals, (4) water for bathing and (5) water for washing clothing. (Pages 80 to 86 incl.)

(c) See sketch.

Latrines should be placed as far as possible from the water supply. They should not drain toward the water supply. (Pages 93-99.)

2. (a) Flies transmit the germs of cholera, dysentery and typhoid (pages 238 and 239). Kitchens should be screened

to keep them out (page 52). Flies breed in human feces, etc. To prevent this latrines should be screened (page 239).

(b) A typhoid carrier is a person who passes the living and virulent bacilli from his body, usually in his feces or urine, in such a condition that they may infect other persons (page 228).

3. Infectious diseases are those which are generally caused from the ingestion of the causative organisms by way of the alimentary canal, but may be produced by the injection of the living organisms beneath the skin (page 222). Example —typhoid fever (page 222).

Contagious diseases are those which are more readily transmissible through contact or association: sometimes called "air-borne" diseases (page 255). Example—small-pox (page 255).

4. Pork is often infected with Trichinae, small worms about a sixteenth of an inch in length. If consumption of pork by men is preceded by thorough cooking no harm will result. If not, larvae may be scattered through his muscular system, and he suffers from pains and fever, which may cause his death (page 174).

5. Malaria is transmitted only by Anopheles mosquitoes (page 178). The success in combating malaria depends on the anti-mosquito measures taken (page 283). Of these the destruction of breeding places near habitations is the most important. The filling of pools, puddles, etc., drainage by means of ditches, the reclamation of swamps and the use of crude petroleum or larvacides in the breeding places are some of the measures that can be taken to combat the spread of malaria (pages 286 to 295).

Does the Present Automatic Rifle Meet the Needs of the Rifleman?

By W. A. Blain
Major, Infantry, Field Officers' Class, The Infantry School

The cause which led up to the invention of the automatic rifle was a desire for increased rapidity of fire.

The first step to increase the rapidity of fire was the making of a case to contain both the powder and the bullet, but this had to be forced into the rifle from the muzzle with a ramrod, and the primer then placed on the priming vent. The second step was the invention of the rifle which was loaded from the breech, both the powder and the bullet being held in a case called a cartridge, which also contained the primer. This was a great step forward and soon led to other improvements. One of these improvements was the breech-loading magazine rifle. In this rifle a magazine contains several cartridges which are loaded into the rifle by hand operated mechanism. The result of this was a great increase in the rapidity of fire, and it is the type of rifle with which the bulk of the infantry is now armed.

But still the clamor continued for a faster firing weapon. This culminated in the invention of the automatic firing weapons, which, for the rifleman, brought forth the automatic rifle. This is automatically loaded as soon as fired, that is, it is ready to fire again without any effort on the part of the firer. There are two general principles employed to cause this automatic action, that of using the force of recoil to reload the piece, and that of using the gas generated on discharge to perform these functions. The most familiar example of the former is the Colt's Automatic Pistol. The Light Browning, or Browning Automatic, which is the automatic rifle adopted for use in the United States Army, is of the latter type.

In order to determine whether or not this rifle meets the needs of the rifleman, it will be necessary to investigate what kind of a rifle it is, its characteristics and its employment.

Data regarding the Browning Automatic Rifle:*

Weight of rifle—15 lbs. 8 ounces
Weight of magazine, empty—7 ounces
Weight of magazine, filled—1 lb. 7 ounces
Length of barrel—24 inches.
Sights graduated up to 1600 yards.
Caliber of bore—.30 inches
Rate of fire—500 shots per minute
Weight of bullet—150 grains
Weight of powder—47 grains.
Weight of shell—198.5 grains
Weight of cartridge (total)—395.5 grains
Chamber pressure—47,000 to 50,000 lbs. per square inch
Muzzle velocity—2682 feet per second
Habitual type of fire—semi-automatic.

The weight of the rifle with one filled magazine is 16 lbs. 15 ounces, and the belt with 10 extra magazines, and the tool box, will bring the load of the automatic rifleman to about 35 lbs. This is a considerable load for one man to addition to his other equipment, and is one reason why our soldiers in France threw away the automatic and secured a rifle and belt from some casualty when the opportunity presented itself.

The present automatic rifle has several defects, but most of them admit of easy correction. Among these are the following:

1. The front sight is not protected, therefore liable to become bent or damaged.
2. The sights are not graduated for settings less than 100 yards.
3. The sight has no windage guage, which oftimes requires the user to aim off his target in order to hit it.
4. The present stock is too short, which makes aiming difficult. (I believe this correction has already been made.)
5. It requires both hands to take out an empty magazine, as the release cannot be pressed and the magazine withdrawn with one hand. This makes it very awkward and time is lost in reloading.
6. The hand guard is much too large and not of a shape to fit into the hand. It is made large to protect the hand against the excessive heat of the rifle. It is believed this difficulty could be overcome by having a smaller hand guard, lined with asbestos or some similar material.

Characteristics of the automatic rifle: *

1. It is capable of the rapid production of a large volume of accurate fire.
2. It is capable of delivering fire from any of the positions used by riflemen, and from the march.
3. It has substantially the mobility, visibility, and vulnerability of one service rifle, together with the fire power of several.
4. Its cone of fire is deep and narrow, and its dispersion much less than that of the number of rifles it would be necessary to employ to produce the same fire power.
5. Its fire is easily controlled and can be shifted in any direction at will.
6. It is not suitable for overhead fire, nor generally speaking, indirect fire.
7. It is not capable of sustained fire.
8. It is liable to accidental cessation of fire.
9. It can act only by means of fire power and mobility.

From these characteristics we may make the following deductions:

Its fire power is as great as that of several rifles, for all ordinary firing.

It is especially suited for putting a large volume of fire on a special target.

Its use allows a much greater volume of fire to be delivered for the same frontage of firing line.

It should be ready for action at all times, therefore all members of the squad should be trained in its use, so that, in case the automatic rifleman becomes a casualty, some other member of the squad can continue it in action.

It can be used any place the ordinary service rifle can be used.

It can change positions quickly in case its location is determined.

It can be used effectively for marching fire.

The automatic rifleman makes a very indistinct target, hard to locate if semi-automatic fire is used, and as difficult to hit as any other rifleman.

By the nature of its cone of fire it is more effective in a flanking direction than when used frontally. It is nearly as mobile as the service rifle, and more mobile than the machine gun.

Its fire can be quickly shifted from one target to another, as it is entirely controlled by one man. To produce the same effect with service riflemen would necessitate a change of position.

It is not fitted for overhead fire, so cannot take the place of machine guns, nor is it capable of sustained fire.

*W. D. Doc. No. 853. Par. 21. Page 13.

*Lecture "Training the Automatic Rifleman." Infantry School, Camp Benning, page 14.

Digitized by Google

Frequent stoppages occur so men should be well trained in its use in order that it may be kept in action as much as possible.

It is not suited for hand to hand combat as it is not fitted with a bayonet, and is too heavy and clumsy to be used in that kind of fighting even it fitted with a bayonet.

Due to its weight the man using it is subjected to much more fatigue than those armed with the service rifle.

Due to the rapidity with which it can be fired it consumes a large amount of ammunition.

Employment of the Automatic Rifle.

In our service there is one man in each squad armed with the automatic rifle, so that it is an integral part of the squad armament and should be kept with the squad at all times.

Its place in the firing line will necessarily vary according to the situation to be met. If the entire squad rushes from one position to another, the automatic rifle necessarily advances with the squad. If a line is advancing, preceded by scouts, when the scouts are stopped and it is necessary to infiltrate to build up a line on the scouts, the automatic rifleman should be the first man sent forward, so as to bring the great fire power of his weapon to bear on the enemy at the earliest practicable moment.

It is especially valuable for delivering flanking fire and whenever a force is sent on a flanking movement it should be accompanied by the full quota of automatic riflemen.

While a very powerful weapon, it uses ammunition rapidly, so that it should not be used more than is absolutely necessary. If the rifles of the party are sufficient to execute the task, the automatics should remain silent, holding their fire for a time when more needed, and not be without ammunition at a critical time.

Unless firing on a specially designated target the fire of the automatic rifle should be distributed over the entire squad target.

The automatic rifle is particularly valuable where a large volume of fire is necessary and there is not room to deploy a sufficient number of rifles, for example, when fighting in narrow streets, etc.

It is a valuable weapon for delivering marching fire. This class of fire is extremely desirable in combat in the woods, or to keep down the fire of the enemy while our line is advancing.

It is valuable in advance and rear guard, and of great value with patrols. Every combat patrol of four men or over should have an automatic rifleman as one of their number.

It is valuable in covering the return of patrols, especially in night raids, as two or three automatic rifles posted on the flanks can do great execution if the patrol is pursued.

It is also valuable in detached posts as it adds considerable strength to the fire power and morale of the occupants.

It is particularly valuable in an outpost line which is thinly held, as a great amount of fire power can be developed and the line held by only a few men, giving great economy of man power.

It is good weapon to cover ground which is defiladed from the fire of machine guns, or narrow approaches and defiles, with a minimum of man power.

It is quite mobile, so is not tied to any fixed position, but can be changed as quickly as a man can, and accordingly can bring fire quickly to bear on a surprise target no matter from which direction the target is approaching.

It is easily pushed forward to a flank, under cover, so as to deliver flanking fire when necessary, and is particularly effective when so used, as its cone of fire is long and narrow.

Its use with automatic fire is exceptional and only against very close and well defined targets. In fact it is so exceptional that the automatic fire could be dispensed with without materially decreasing the value of the rifle.

Its normal fire is semi-automatic, that is, fire in which the trigger must be pressed separately for each shot. This fire can be delivered very rapidly and permits of the aim being corrected between shots, making this class of fire much more accurate.

As it is not on a fixed mount, it must not be used for overhead fire, except in cases where the service rifle could be safely used in this manner, such as tiers of fire, etc.

It can be used for night firing, to cover or keep open gaps in the wire, or to cover a ravine or defile. It should be sighted by daytime and stakes driven in the ground so the proper position can be taken at night.

It is not capable of delivering sustained fire on account of the lack of an efficient cooling device. It is necessarily air cooled to keep down its weight, and gets very hot after a short period of continuous firing.

Its liability to accidental cessation of fire makes it absolutely necessary that all the men in the squad be thoroughly trained in its use and the correction of defects, so it can be ready for use at any time its fire is called for.

To recapitulate, the automatic rifle finds its greatest usefulness in:

The assault, with the assaulting waves.
Engaging enemy machine guns or automatic rifles.
Dealing with counter attacks from the flanks.
In quickly building up a strong firing line.
Being pushed forward to deliver flanking fire or to deal with menacing enemy agents.
In covering the advance of the rest of the squad.
In narrow defiles, or from any narrow frontage, from which it is necessary to deliver a large volume of fire.
In advance and rear guards.
With combat patrols.
In the outpost line or with detached posts.
In defense, in the front lines.
In delivering marching fire.
To cover dead spaces in the machine gun belt.
In the defense of a salient.
In advancing through woods.
In following a smoke screen, or barrage.

We have thus seen its characteristics, and the different ways in which it can be employed. In any special situation with which the infantry is confronted these are only to be used as a guide, because the automatic rifle must be used as the circumstances dictate so as best to take advantage of its great fire power. It should never be employed according to some fixed rule, but meet each situation as it presents itself. This is where a thorough knowledge of its characteristics, its power and its limitations, will stand the automatic rifleman in good stead.

Having taken note of its defects, its characteristics, and its means of employment, let us now consider if this weapon meets all the needs of the rifleman as a combat weapon. It is believed that anyone who has seen a demonstration of the fire effect of a squad with and without the automatic rifle, will agree as to its material addition to the fighting strength of the squad. By actual firing, under service conditions, which is the only true test, the number of hits on the target were almost doubled when the automatic rifle was used as a part of the squad armament, as against the number of hits when only the service rifle was used. The old saying that it is the infantry which wins battles is as true today as it was at any time in history. It therefore follows that the army with the best infantry is one that will win out in the end, and as men are very nearly equal, it can further be deduced that the infantry which has the superior weapon will be the winner. Now the chief weapons of the infantry are fire and movement, and since the automatic rifle does not impede the movement to any great extent, and also since its use, even as

Digitized by Google

few as one per squad, almost doubles the fire power of that squad, thereby increasing its chances of winning, it seems to be clear that some form of automatic rifle is essential for arming modern infantry.

Following out this theory, if one automatic rifle per squad so increases the fighting strength of the squad, why would not the fighting power be correspondingly increased if every man in the squad was armed with an automatic rifle? I believe it would be. The solution would then seem to be easy—issue each man an automatic rifle in place of the present service rifle. There are several reasons why the presnt Light Browning is not fittd for this. Let us enumerate some of them:

1. It is too heavy. As before stated, our soldiers in France threw away the automatic with which they were armed, and secured service rifles from some casualty. Why was this done? I have heard the reason put forth that it was because they were armed with the French Chauchat, and that it was no good. But that answer is not sufficient. It is true that the majority of our men overseas were armed with the French automatic rifle, but, if I am reliably informed, at least one of our divisions was armed with the Light Browning, and an officer told me that he was over the ground over which that division had advanced and that the ground was strewn with these automatics. Inefficiency then could not be the correct reason, for the Light Browning is the best automatic rifle that has been issued to any army.

I believe there were two main reasons. First: The men did not appreciate what a valuable weapon they were carrying, were not familiar with it, and were very much more familiar with the service rifle. Second: The automatic rifleman had a much heavier load to carry and was required to keep up with his neighbor who had a much lighter load. The 8 to 9 pounds more that he had to carry made a big difference in a day's march and when he had a good chance to lighten it he did so.

2. The present automatic rifle does not have a bayonet. While the rifleman's chief weapons are fire and movement, yet, even in this day of long range weapons, hand to hand combat must sometimes be indulged in. It is an old saying that "you cannot shoot the enemy out of a position." What recourse then does the rifleman have? His other weapon is the bayonet. It is his only weapon for hand to hand fighting, and if he does not have it, it is impossible to make him close with the enemy. Also the moral effect of having a bayonet is too great to be estimated. The present automatic rifle is too heavy to add the weight of a bayonet, and it is too clumsy to use one effectively were it added.

3. It requires one of the other riflemen in the squad to help him carry enough ammunition. The extra ammunition is carried in extra magazines, each weighing within an ounce of half a pound apiece, which very materially adds to the load to be carried.

From the above it can be seen that the present automatic rifle is not a satisfactory weapon for issue to each rifleman. I believe that the needs of the future demand that each rifleman be armed with an *automatic loading rifle*. It is not necessary, nor even desirable, that it be an automatic firing rifle, as the present rifle is not accurate when automatic fire is used, and the rifle can be fired fast enough when the trigger is pressed separately for each shot.

The objection may be raised at this point that we will never be able to supply sufficient ammunition if each man is armed with an automatic. While on its face this does seem to be a serious objection, yet our experience in the World War would not seem to bear this out, as I have never heard, nor seen recorded, a single instance where our troops suffered from a shortage of small arms ammunition. The fact that the rifle advocated would be only an automatic loader would serve to keep a better check on the expenditure of ammunition.

Let us consider some of the specifications for an *automatic loading rifle* that will be suitable for arming all riflemen:

1. It should be as simple as possible in operation.

2. It should weight not to exceed one pound more than the weight of the present Springfield rifle, Model 1903.

3. It should have powers equal to the present automatic rifle and be capable of the same employment.

4. The defects of the present automatic rifle should, as far as practicable, be eliminated.

5. It should be equipped with a bayonet.

6. It should be capable of being loaded, by clip if possible, directly into a fixed magazine, doing away with the necessity of carrying extra magazinees, thus lightening the load to be carried.

7. With all men armed with an automatic loading rifle it will not be necessary for the magazine to carry over ten rounds. This will decrease the weight of the weapon.

It seems to be the natural tendency of the American to be able to shoot well, and as we devote much more time to rifle practice than any other nation, it is easily seen what a tremendous fighting machine one of our rifle companies would become if each man was armed with an automatic loading rifle.

Conclusions—

1. That it is desirable to have each rifleman armed with an automatic loading rifle.

2. This being true, that the present Light Browning is not a satisfactory weapon for this purpose and therefore does not meet the needs of the rifleman as a combat weapon.

3. That every endeavor should be made to develop an automatic rifle along the lines suggested, and that every encouragement be given to those now working along these lines, so that before we are compelled to take part in another war we will have an efficient automatic loading rifle to place in the hands of our riflemen, and by so doing have an infantry that will be invincible.

To show that inventors are already working along these lines the following is quoted from an article published in the *Infantry Journal* for October, 1920. The article is entitled "The Sub-machine Gun" and is written by Major A. B. Richeson, Reserve Corps:

"A sergeant-gunner with a submachine gun, firing from the standing position without rest, at a range of 500 yards, discharged 600 rounds in 70 seconds, and made 100 hits on the target. This record was made in a recent test of a new weapon with which its inventors expect to revolutionize automatic arms. The submachine gun is nothing more nor less than a machine gun in the form of a pistol which can be carried in a case under the coat if desired, and yet is able to deliver a stream of several hundred shots in a minute. It is the simplest of all automatic weapons, one type having but 11 parts, and in less than a minute can be readily dismounted by hand without the use of a tool.

"Magazines are of the disk type, having a capacity of 50 and 100 cartridges. The inventors say it can be produced at a price hitherto unknown in automatic arms. The military uses which such a weapon would have will instantly suggest themselves to the army. The submachine gun has a range up to one mile. The extreme lightness and simplicity of this weapon are made possible by the new application of an old scientific principle in the construction of the breechblock.

The Colt Patent Firearms Co. is manufacturing the submachine gun, which is soon to appear on European battlefields. Several South American governments have adopted the new gun. The submachine gun was developed by one who has also successfully applied its operating principle to semi-automatic shotguns. For the autorifle it is claimed that it is the first and only gun firing from the shoulder semi-automatically and weighing less than ten pounds that has ever been through the Springfield endurance test without breakage or repair."

ADAPTABILITY FOR ANY KIND OF WORK

WILLIAMS BUCKETS

Whether it be in loading or unloading and handling all kinds of bulk materials, for dredging and excavating work, or for any of the many heavy capacities in which buckets are commonly employed, WILLIAMS BUCKETS may be relied upon thoroughly.

Williams Buckets

"Built to Dig and Last While Digging"

They live up to their name. They are built to give constant service. Built with large bearings and with well-guarded cables. They hold their alignment and stand the gaff in all kinds of digging and handling.

Send for our complete catalog, showing the full line of WILLIAMS BUCKETS.

The Gift Ideal

Among the many pleasant surprises Christmas morning, none will be more acceptable than an emblem of your Society, fashioned by the leading silversmiths in the country.

They may be had in buttons, pins, or charms, in bronze or gold, at prices which are surprisingly low.

Please make reservations *now* to insure delivery before Christmas.

Secretary, SOCIETY OF AMERICAN MILITARY ENGINEERS,
423-425 G Street, N.W.,
Washington, D. C.

Please reserve for me the following emblems which I have checked. I will make payment on or before December 15th.

Material	*Button or charm*	*Brooch-pin*
Bronze	$0.75 each	$1.00 each
10k solid gold	5.00 each	5.50 each
14k solid gold	6.00 each	6.50 each

Never a dollar lost
Never a day's delay in paying interest
Never a sale below par
—15 years of perfect safety to investors

That is the record on which we offer you our Guaranteed First Mortgage Investments.

You can put as little as $100 or any multiple thereof in them at 6 per cent per annum —with guaranteed safety—from 6 months to 5 years.

Your investment is secured by improved real estate worth twice the amount of the mortgage.

In addition to this ample security, payment of both interest and principal is unconditionally guaranteed by every dollar of our resources.

Title to the property mortgaged is guaranteed by the Title Guarantee and Trust Company.

Tell us where to send you a copy of our latest folder, "All Bother and Worry Lifted."

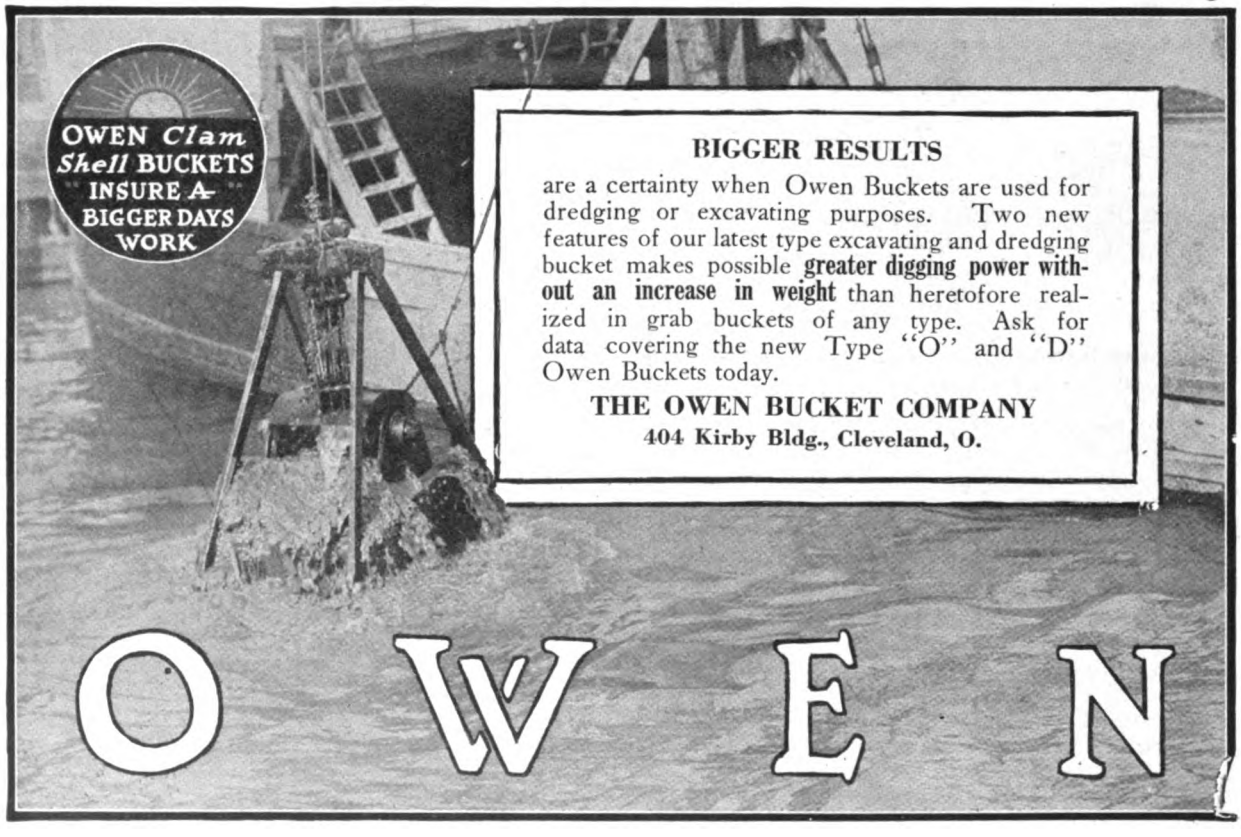
The Obligation of Supremacy

A reputation of "par excellence" in any trade is both an asset and a liability. It attracts business but at the same time obligates its holder to a most intense degree of concern to maintain his supremacy. This obligation operates as a guarantee as effectively as any written bond.

In laying pavements, WARREN BROTHERS COMPANY are compelled to give in their supervision and attention to detail that no engineer, regardless of his individual ability, can afford to give. The greater his skill and experience, the more the engineer realizes this and welcomes the technical supervision of detail by the specialist. Proven under every condition and climate.

Warrenite-Bitulithic



plus our expert supervision and inspection, has demonstrated its supremacy throughout the United States and Canada.

LOCOMOTIVE CRANES
CLAM SHELL BUCKETS - SHIPBUILDING CRANES
CAR DUMPERS PILE DRIVERS
THE McMYLER INTERSTATE CO.
CLEVELAND OHIO

THE LARGEST CRANE AND THE LARGEST STIFF-LEG DERRICK

The crane shown, which lifted 505 tons at one time, is in operation in the Philadelphia Navy Yard, where it was erected by the aid of the largest stiff-leg derrick ever constructed.
The height of the crane is 235 feet, while the derrick is equipped with a boom 252 feet long.
Both the crane and the derrick were designed and built by THE McMYLER INTERSTATE CO.
By those who are uninformed, this crane installation may be accepted as an index to our possibilities.

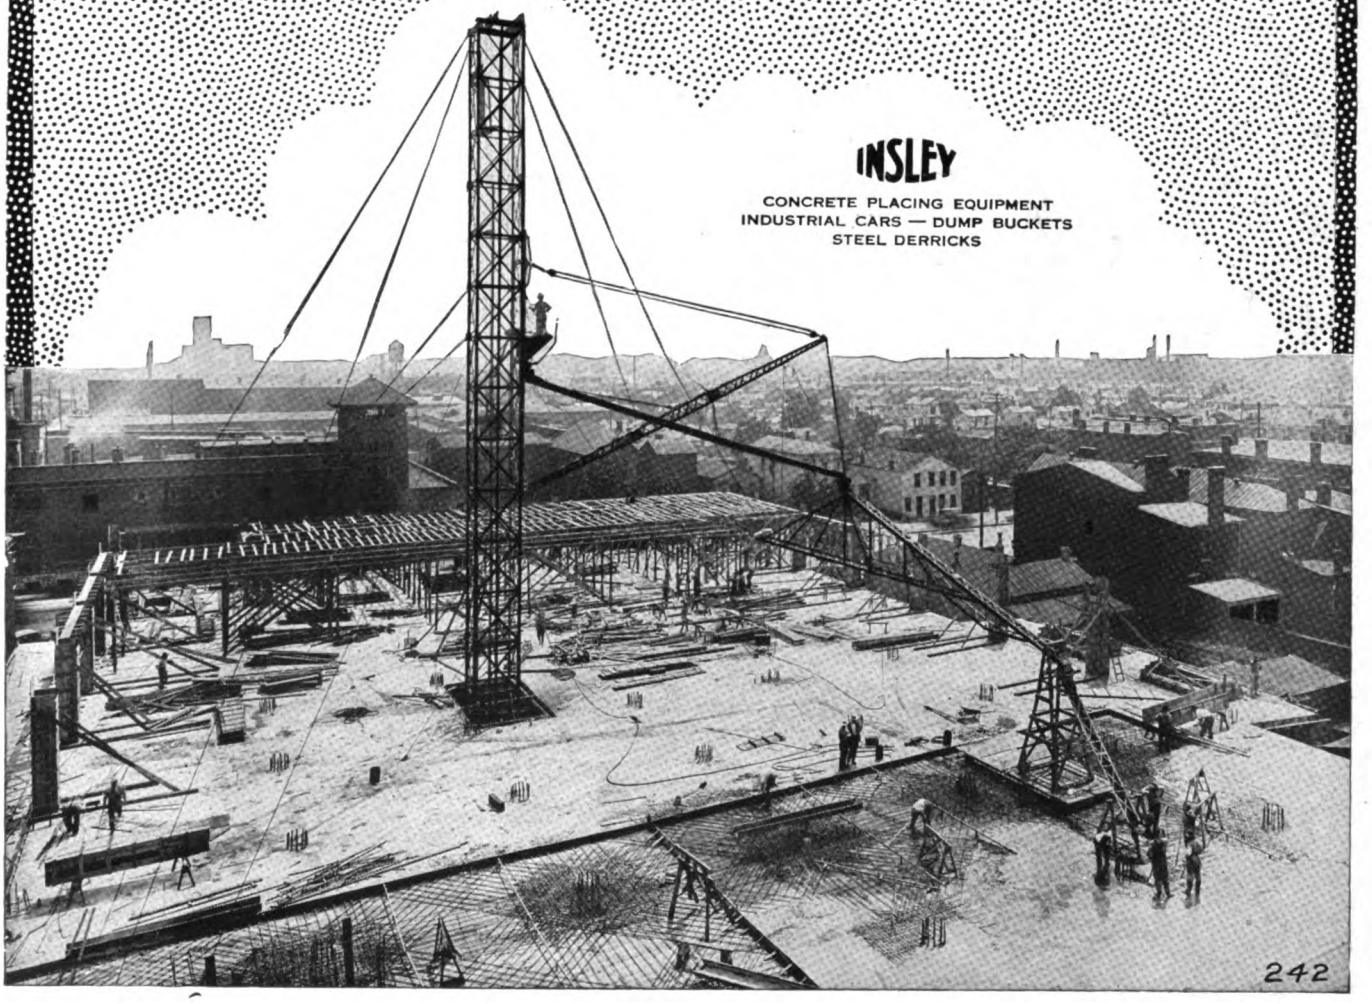
Insley Concrete Distributing Equipment

FOR the reinforced concrete building which involves the placement of five thousand or more cubic yards of concrete there is no equipment which offers the Money and Time saving possibilities that are to be found in the INSLEY STEEL TOWER, QUICK SHIFT, COUNTERWEIGHT CHUTE PLANT.

THE STEEL TOWER is permanent equipment which should form a part of every contractor's permanent construction plant because of its money saving qualities as compared with wood towers.

THE QUICK SHIFT feature saves a day's time and labor every time a move has to be made from one floor to another.



THE COUNTERWEIGHT CHUTE eliminates the time and labor which would otherwise be required for moving chutes on the job.

There is a reason for finding this equipment on the best organized jobs. Let us go into details with you when figuring your next contract.

Reasons!

It is evident to users of Clyde equipment that there exists definite reasons why they become so perfectly satisfied with the operation and maintenance of their machinery. The steady, uninterrupted movements of the Clyde Hoist and the accurate control over the Clyde Derrick means the complete understanding on the part of Clyde construction engineers of the problems to be solved.

Perfect construction, carefully selected materials and absolute accuracy of detail combine to create a syncronized operation rarely found in big out door equipment.

Shown below is a Clyde Stiff Leg Derrick, operated by O'Conner & Gilkison of Cleburne, Texas, tackling a big job. Motive power is furnished by a Clyde 45 H. P. three drum gasoline hoist.

Specific details on any portion of the Clyde line may be obtained at any time by addressing the main office or our nearest branch.
